The older adult should exercise a minimum of 30 minutes on most days of the week as able. Teach the patient to avoid physical activity in temperature extremes and maintain a moderate pace. Heat intolerance results from a decreased ability to sweat efficiently. When planning a physical activity program, recommend (1) longer warm-up periods, (2) longer periods of low-level activity, and/or (3) longer rest periods between sessions.

TABLE 37.7 Select Conditions Influencing Myocardial O_2 Needs

Decreased O_2 Supply	Increased O_2 Demand or Consumption
Cardiac	
• Coronary artery atherosclerosis	• Aortic stenosis
• Coronary artery spasm	• Cardiomyopathy
• Coronary artery thrombosis	• Dysrhythmias
• Dysrhythmias	• Left ventricular hypertrophy
• Heart failure	• Tachycardia
• Valve disorders	
Noncardiac	
• Anemia	• Anxiety
• Asthma	• Hypertension
• Chronic obstructive pulmonary disease	• Hyperthermia
• Hypovolemia	• Hyperthyroidism
• Hypoxemia	• Physical exertion
• Pneumonia	• Substance (stimulant) use (e.g., cocaine, amphetamines)
• Substance (stimulant) use (e.g., cocaine, amphetamines)	

TABLE 37.8 PQRST Assessment of Angina

Use the following memory aid to obtain information from the patient who has chest pain:

	Factor	Questions to Ask Patient
P	Precipitating events	What events or activities precipitated the pain or discomfort (e.g., argument, exercise, resting)?
Q	Quality of pain	What does the pain or discomfort feel like (e.g., pressure, dull, aching, tight, squeezing, heaviness)?
R	Region (location) and radiation of pain	Can you point to where the pain or discomfort is located? Does the pain or discomfort radiate to other areas (e.g., back, neck, arms, jaw, shoulder, elbow)?
S	Severity of pain	On a scale of 0 to 10, with 0 indicating no pain and 10 being the most severe pain you could imagine, what number would you give the pain or discomfort?
T	Timing	When did the pain or discomfort begin? Has it changed since this time? Have you had pain/discomfort like this before?

Encouraging the older patient to adopt a healthy lifestyle may increase the quality of life and reduce the risk for CAD and fatal heart events. Older adults face many of the same challenges as younger persons related to making lifestyle changes. Older adults are more likely to consider change either (1) when hospitalized or (2) when symptoms (e.g., chest pain) are the result of CAD and not normal aging (see Table 35.1). First, assess for health literacy and the readiness to change. Then, help the patient select the lifestyle changes most likely to produce the greatest reduction in risk for CAD.

CHRONIC STABLE ANGINA

CAD is a chronic and progressive disease. Patients who are asymptomatic for many years may eventually develop chronic stable chest pain. When the demand for myocardial O_2 exceeds the ability of the coronary arteries to supply the heart with O_2, *myocardial ischemia* occurs. **Angina**, or chest pain, is the clinical manifestation of myocardial ischemia. It is caused by either an increased demand for O_2 or a decreased supply of O_2 (Table 37.7). The most common reason for angina to develop is significant narrowing of 1 or more coronary arteries by atherosclerosis. This leads to insufficient blood flow to the heart muscle. When ischemia occurs from an atherosclerotic plaque, the artery is usually blocked (stenosed) 70% or more (50% or more for the left main coronary artery).[15]

Chronic stable angina refers to chest pain that occurs intermittently over a long period of time with a similar pattern of onset, duration, and intensity of symptoms. It is often provoked by physical exertion, stress, or emotional upset. It is important to get an accurate assessment of angina symptoms (Table 37.8). Some patients deny feeling pain. They may describe a pressure, heaviness, or discomfort in the chest as a squeezing, heavy, tight, or suffocating sensation. Other symptoms, such as dyspnea or fatigue, may occur. Chronic angina pain usually does not change with position or breathing.

Most angina pain is substernal. It may radiate to the jaw, neck, shoulders, and/or arms. Many people with angina describe a feeling of indigestion or a burning sensation in the epigastric region. The sensation may be felt between the shoulder blades (Fig. 37.3). Often, people who describe pain between the shoulder blades or indigestion type pain dismiss it as not being heart related. Some patients, especially women and older adults, report atypical symptoms of angina, including dyspnea, nausea, mid-epigastric discomfort, and/or fatigue.[4,9] We refer to this as an *angina equivalent*.

The pain of chronic stable angina usually lasts for only a few minutes. It often subsides when the precipitating factor is resolved (e.g., by resting, calming down, using sublingual nitroglycerin [SL NTG]) (Table 37.9). Pain at rest is unusual. It may indicate UA. With ischemia, the 12-lead ECG often shows ST segment depression and/or T wave inversion. These changes represent an inadequate supply of blood and O_2 to the heart muscle. In the normal ECG, the ST segments should be isoelectric or flat (on the isoelectric line) (Fig. 37.4A). ST depression is significant if it is at least 1 mm (1 small box) below the isoelectric line in at least 2 contiguous leads (2 leads that look at the same wall of the heart). The ECG changes return to baseline when adequate blood flow is restored, and pain is relieved.

We treat patients with chronic stable angina with drug therapy. Because chronic stable angina is often predictable, drugs are timed to provide peak effects during the time of day when angina is likely to occur. For example, if angina occurs when rising, the patient can take medication as soon as awakening and wait 30 minutes to 1 hour before engaging in activity. A comparison of the major types of angina is shown in Table 37.10.

Silent ischemia refers to ischemia that occurs in the absence of any subjective symptoms. Patients with diabetes have an increased prevalence of silent ischemia. This is likely due to

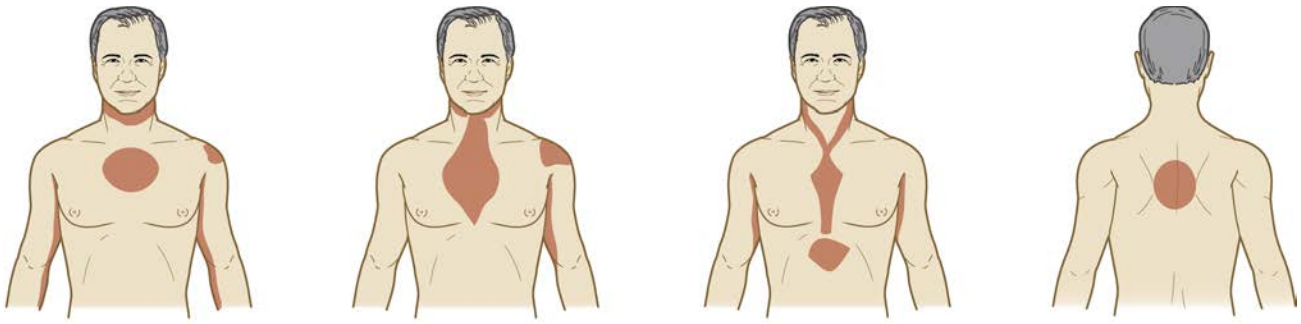

Fig. 37.3 Common locations and patterns of pain during angina or MI.

TABLE 37.9 Precipitating Factors of Angina

Circadian Rhythm Patterns
- Manifestations of CAD tend to occur in the early morning and within the first few hours after awakening

Consumption of Heavy Meal (e.g., holiday meals)
- Can increase the workload of the heart
- During the digestive process, blood is diverted to the GI system, reducing blood flow in the coronary arteries

Physical Exertion
- Increases HR, reducing the time the heart spends in diastole (the time of greatest coronary blood flow), resulting in an increase in myocardial O_2 demand
- Isometric exercise of the arms (e.g., raking, lifting heavy objects, snow shoveling) can cause exertional angina

Sexual Activity
- Increases the cardiac workload and sympathetic stimulation
- In a person with CAD, the extra cardiac workload may precipitate angina

Stimulants (e.g., cocaine, amphetamines)
- Increase HR and BP and increases myocardial O_2 demand
- Stimulate vasoconstriction and decreases myocardial O_2 supply
- May precipitate dysrhythmias

Strong Emotions
- Stimulate the sympathetic nervous system, activating the stress response
- Increase the workload of the heart

Temperature Extremes
- Increase the workload of the heart
- Blood vessels constrict in response to a cold stimulus
- Blood vessels dilate and blood pools in the skin in response to a hot stimulus

Tobacco Use and Environmental Tobacco Smoke
- Decrease available O_2 by increasing the level of carbon monoxide
- Nicotine stimulates catecholamine release, causing vasoconstriction and an increased HR

diabetic neuropathy affecting the nerves that innervate the cardiovascular system. When silent ischemia occurs in a monitored patient, we can see ECG changes (e.g., ST depression and/or T wave inversion) (Fig. 37.4A). Ischemia with pain or without pain has the same prognosis.

Prinzmetal's Angina

Prinzmetal's angina *(variant angina, vasospastic angina)* is a rare form of angina that often occurs at rest without increased physical demand. Risk factors include a history of migraine headaches, Raynaud's phenomenon, and heavy smoking. It is usually due to hyperreactivity of the smooth muscle of a major coronary artery resulting in strong contraction (spasm) of the vessel. Coronary spasm is more common in Asians than whites.[16] The spasm may occur in the presence or absence of CAD.

Factors contributing to coronary artery spasm include increased levels of certain substances (e.g., alcohol, cocaine), exposure to medications that narrow blood vessels (e.g., sumatriptan), or cold weather exposure. When spasm occurs, the patient has angina and transient ST segment elevation (not usually from an MI) (Fig. 37.4B). The pain may occur during rapid-eye-movement (REM) sleep when myocardial O_2 consumption increases between midnight and early morning or at rest. The pain may be relieved by moderate exercise, with SL NTG, or it may disappear spontaneously. Cyclic, short bursts of pain at the same time each day may occur with this type of angina. Treatment includes calcium channel blockers and/or nitrates. The patient should stop the use of any offending substances.

Microvascular Angina

In *microvascular angina,* chest pain occurs in the absence of significant CAD or coronary spasm of a major coronary artery. In these patients, chest pain is related to myocardial ischemia from atherosclerosis or spasm of the small distal branch vessels of the coronary microcirculation. This is known as *coronary microvascular disease or dysfunction* (MVD). It is more common in women.[9,16] Often the angina is prolonged and brought on by physical exertion. These patients usually have a positive stress test. With cardiac catheterization, no obstructive coronary disease is present in the major coronary arteries. Prevention and treatment of coronary MVD follow the same recommendations as for CAD.

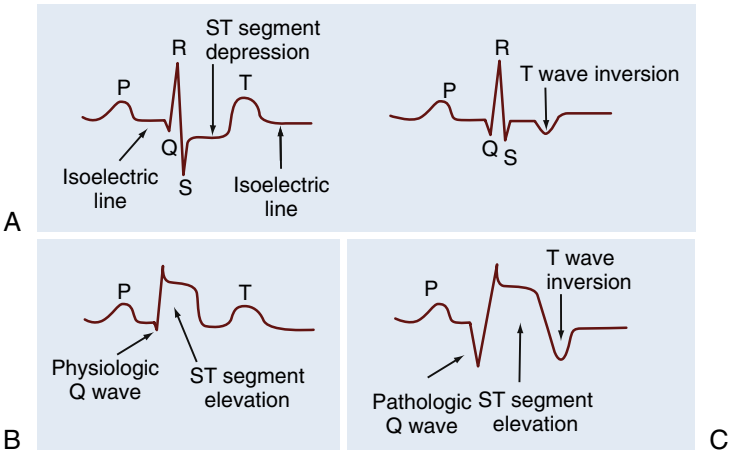

Fig. 37.4 ST segment, T wave, and Q wave changes associated with myocardial ischemia (A), injury coronary spasm (B), and infarction (C). (From Bucher L, Melander S: *Critical care nursing,* Philadelphia, 1999, Saunders.)

TABLE 37.10 Comparison of Major Types of Angina

Type	Etiology	Characteristics
Chronic stable angina	Myocardial ischemia (usually from CAD) caused by an O_2 supply/demand mismatch	• Episodic pain lasting a few minutes • Provoked by exertion or stress • Relieved by rest or nitroglycerin
Microvascular angina	Myocardial ischemia from microvascular disease affecting the small, distal branches of coronary arteries	• More common in women • Triggered by activities of daily living (e.g., shopping, work) vs. physical exercise (exertion) • Treatment may include nitroglycerin (long- and short-acting forms)
Prinzmetal's angina	Coronary vasospasm	• Occurs primarily at rest • Triggered by smoking and increased levels of some substances (e.g., histamine, epinephrine, cocaine) • May occur in presence or absence of CAD • Treatment may include long-acting nitrates and/or calcium channel blockers
Unstable angina	Rupture of unstable plaque, exposing thrombogenic surface	• New-onset angina • Chronic stable angina that increases in frequency, duration, or severity • Occurs at rest or with minimal exertion • Lasts more than 10 min

INTERPROFESSIONAL AND NURSING CARE: CHRONIC STABLE ANGINA

Chronic stable angina can progress or develop into ACS (UA or MI). Therefore, any change in the usual pattern of angina should be evaluated. A patient with chronic stable angina may be admitted with a change in the angina pattern. Until an assessment and diagnostic studies are completed, it may be unclear if the patient is having typical chronic stable angina, UA, or an MI.

The goal of treatment for a patient admitted with angina is to decrease O_2 demand and/or increase O_2 supply. Nursing care focuses on the priority problems of managing acute pain and anxiety while increasing O_2 delivery to the myocardium. The overall goals for a patient who presents with angina include (1) pain relief, (2) immediate and appropriate treatment, (3) preservation of heart muscle if an MI is suspected, (4) effective coping with illness-associated anxiety, (5) participation in a rehabilitation plan, and (6) reduction of risk factors.

Acute Care

If your patient has chest pain, but you are unsure if the pain is from chronic stable angina, UA, or an MI, plan to perform the following measures: (1) position patient upright unless contraindicated and apply supplemental O_2, (2) assess vital signs, (3) apply a continuous ECG monitor, (4) obtain a 12-lead ECG, (5) provide prompt pain relief, first with SL or IV NTG, followed by an IV opioid analgesic, if needed, (6) obtain cardiac biomarkers, (7) assess heart and breath sounds, and (8) obtain a chest x-ray. The patient may be anxious and may have pale, cool, clammy skin. The BP and HR may be high. There may be an atrial (S_4) or a ventricular (S_3) gallop. A new systolic murmur heard during an angina attack may indicate ischemia of a papillary muscle of the mitral valve, causing mitral regurgitation (the mitral valve does not close properly, and blood leaks back into the left atrium). The murmur may be transient and disappear when symptoms resolve.

Ask the patient to describe the pain and rate it on a scale of 0 to 10 before and after treatment to evaluate the effectiveness

TABLE 37.11 Treatment of Chronic Stable Angina and Acute Coronary Syndrome

Strategies for the patient with chronic stable angina should address all the treatment elements and related patient teaching in the following mnemonic:

Element	Treatment
A	Antiplatelet/anticoagulant therapy
	Antianginal therapy
	ACE inhibitor/angiotensin receptor blocker
B	β-Blocker
	BP control
C	Cigarette smoking cessation
	Cholesterol (lipid) management
	Calcium channel blockers
	Cardiac rehabilitation
D	Diet (weight management)
	Diabetes management
	Depression screening
E	Education
	Exercise
F	Flu vaccination

Modified from Smith SC, Benjamin EJ, Bonow RO, et al.: AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update, *J Am Coll Cardiol* 58:2432, 2011.

of the interventions. Use the same words the patient used to describe the symptoms (e.g., tightness, pressure). Assess for other signs of pain, such as restlessness; ECG changes; high HR, respiratory rate, or BP; clutching the chest or bed linens; or other nonverbal cues. Support and reassure the patient. Use a calm approach to help reduce the patient's anxiety during an angina attack. If the chest pain is not related to an ACS, the patient may be discharged within 1 or 2 days. Further testing may be done during the hospitalization or as an outpatient.

CHECK YOUR PRACTICE

A visitor finds you in the hallway and tells you that her parent is having chest pain. The patient is not assigned to you.

- How would you proceed?

Patient Teaching

Reassure the patient with a history of angina that a long, active life is possible. Preventing or at least reducing the frequency of angina is key, so teaching is essential. Emphasize risk factor modification to slow the progression of CAD. Help the patient to identify their risk factors for CAD and ways to reduce modifiable risk factors (Tables 37.1 and 37.2). Give the patient information about CAD, angina, precipitating factors for angina (Table 37.9), and medications to treat angina (Tables 37.11 and 37.12 and Fig.37.5).

Teach the patient and caregiver about diets low in salt and saturated fats (Tables 37.4 and 37.5). Maintaining ideal body weight is important in controlling angina because excess weight increases the heart's workload. Give the patient a regular, individualized program of physical activity that conditions rather than stresses the heart. An example includes brisk walking on a flat surface at least 30 minutes a day on most days of the week.[10]

You can provide patient teaching in a variety of ways. One-on-one contact between you and the patient is often the most effective approach. Time during daily care (e.g., assessment, giving drugs) offers many teachable moments. Teaching aids, such as videos, heart models, and printed information, are important resources for patients and caregivers (see Chapter 4).

Help the patient to identify and avoid factors that precipitate angina (Table 37.9). For example, teach the patient to avoid exposure to extremes of weather and eating large, heavy meals. Tell the patient to rest for 1 to 2 hours after a heavy meal because blood shifts to the GI tract.

If needed, arrange for counseling to assess the psychologic adjustment of the patient and caregiver to the diagnosis of CAD and the resulting angina. Many patients feel a threat to identity, self-esteem, and their usual roles in society.

Drug Therapy

Drug therapy for chronic stable angina aims to reduce angina symptoms and the risk for MI and death. The most common medications to optimize myocardial perfusion in chronic stable angina include nitrates, angiotensin-converting enzyme (ACE) inhibitors, β-blockers, and calcium channel blockers (Tables 37.11 and 37.12 and Fig. 37.5). Aspirin is given for secondary prevention (for patients with diagnosed CAD) in the absence of contraindications (e.g., a true aspirin allergy) (Table 37.12).

Nitrates

Short-acting nitrates are first-line therapy for an acute episode of angina. Nitrates produce their principal effects by the following mechanisms:

Dilating peripheral blood vessels: This results in decreased systemic vascular resistance (SVR), venous pooling, and decreased venous blood return to the heart (preload). Myocardial O_2 demand then decreases because of the reduced cardiac workload.

Dilating coronary arteries and collateral vessels: This may increase blood flow to the ischemic areas of the heart. However, when the coronary arteries are severely atherosclerotic, coronary dilation is hard to achieve.

Orthostatic hypotension is common with all nitrates. Monitor BP after the first dose, since venous dilation may cause a drop in BP, especially in volume-depleted patients.

Short-acting nitroglycerin preparations. SL NTG tablets or translingual spray (Nitrolingual) usually relieve pain in about 5 minutes and last about 30 to 40 minutes. The recommended dose of SL NTG is 1 tablet sublingually (SL) or 1 to 2 metered sprays of translingual NTG on or under the tongue. If symptoms are unchanged or worse after 5 minutes, the patient should contact the emergency response system (e.g., 911).

Teach the patient and caregiver the proper storage and use of NTG. It should always be easily accessible to the patient. Store the tablets away from light and heat sources, including body heat, to protect them from degradation. Keep tablets in their

TABLE 37.12 Drug Therapy

Chronic Stable Angina and Acute Coronary Syndrome

Drug	Mechanism of Action and Considerations
Angiotensin-Converting Enzyme (ACE) Inhibitors (see Table 36.6)	
benazepril (Lotensin) captopril enalapril (Vasotec) fosinopril (Monopril) lisinopril (Zestril) quinapril (Accupril) ramipril (Altace)	• Prevents conversion of angiotensin I to angiotensin II, resulting in vasodilation • May prevent or limit ventricular remodeling • Decreases endothelial dysfunction • Useful with HF, decreased LV function, tachycardia, MI, hypertension, diabetes, and chronic kidney disease
Angiotensin II Receptor Blockers (see Table 36.6)	
candesartan (Atacand) irbesartan (Avapro) losartan (Cozaar) olmesartan (Benicar) telmisartan (Micardis) valsartan (Diovan)	• Inhibits binding of angiotensin II to angiotensin I receptors, resulting in vasodilation • Used for patients intolerant of ACE inhibitors
Anticoagulant Agents (see Table 41.10)	
Direct Thrombin Inhibitors	
bivalirudin (Angiomax) argatroban	• Direct inhibition of the clotting factor thrombin • Both drugs can be used during PCI • Argatroban is used mainly for patients with or at risk for heparin-induced thrombocytopenia
Low-Molecular-Weight Heparin[a]	
dalteparin (Fragmin) enoxaparin (Lovenox)	• Binds to antithrombin III, enhancing its effect • Heparin–antithrombin III complex inactivates activated factor X and thrombin • Prevents conversion of fibrinogen to fibrin
Unfractionated Heparin[a]	
heparin	• Prevents conversion of fibrinogen to fibrin and prothrombin to thrombin
Vitamin K Antagonist[a]	
warfarin (Coumadin)	• Interferes with hepatic synthesis of vitamin K–dependent clotting factors • Used for patients with atrial fibrillation or those at risk for thromboembolism (large anterior wall infarctions or ventricular aneurysms) • Closely monitor for bleeding when taking with antiplatelet drugs
Factor Xa Inhibitors	
apixaban (Eliquis) fondaparinux (Arixtra) rivorixaban (Xarelto)	• Block the clotting activity of Factor Xa to prevent clot formation • Apixaban and rivorixaban are used to prevent stroke in patients with non-valvular atrial fibrillation but are not FDA approved to prevent thromboembolism (large anterior wall infarctions or ventricular aneurysms) or for use in patients with mechanical heart valves • Fondaparinux may be used for patients with UA or NSTEMI

Drug	Mechanism of Action and Considerations
Antiplatelet Agents	
aspirin	• Inhibits cyclooxygenase, which in turn produces thromboxane A_2, a potent platelet activator • Given as soon as ACS is suspected, unless truly allergic
cangrelor (Kengreal)	• Inhibits platelet aggregation • Given IV • Approved for use in patients during a PCI procedure
clopidogrel (Plavix)	• Inhibits platelet aggregation • Used in combination with low-dose aspirin to treat ACS with or without PCI and after elective PCI for CAD • An alternative for patients who cannot take aspirin
prasugrel (Effient)	• Inhibits platelet aggregation • Used as an alternative to clopidogrel in combination with aspirin for patients with ACS who had PCI • Not indicated to treat patients with ACS not undergoing PCI • Not for use after elective PCI
ticagrelor (Brilinta)	• Inhibits platelet aggregation • Used in combination with low-dose aspirin to treat ACS with or without PCI • Effectiveness may be decreased by aspirin dosages >100 mg/day
vorapaxar (Zontivity)	• Inhibits platelet aggregation • Increases risk for bleeding, including life-threatening and fatal bleeding (boxed warning) • Must not be used in people who have had a stroke, transient ischemic attack (TIA), or bleeding in the head, because the risk for bleeding in the head is too great
Glycoprotein IIb/IIIa Inhibitors	
abciximab (ReoPro) eptifibatide (Integrilin) tirofiban (Aggrastat)	• Prevents the binding of fibrinogen to platelets, thereby blocking platelet aggregation • May be used in combination with aspirin for patients with ACS or during PCI
β-Adrenergic Blockers (see Table 36.6)	
atenolol (Tenormin) carvedilol (Coreg) metoprolol (Lopressor) nadolol (Corgard)	• Inhibits sympathetic nervous stimulation of the heart • Reduces heart rate, contractility, and BP • Reduces ischemia • Decreases afterload • Cardioselective β-blockers include atenolol, bisoprolol, and metoprolol

TABLE 37.12 Drug Therapy—cont'd

Chronic Stable Angina and Acute Coronary Syndrome

Drug	Mechanism of Action and Considerations
Calcium Channel Blockers (see Table 36.6)	
amlodipine (Norvasc) diltiazem (Cardizem) felodipine nicardipine (Cardene) verapamil (Calan) nifedipine (Procardia)	• Prevents calcium entry into vascular smooth muscle cells and myocytes (cardiac cells) • May prevent or control coronary vasospasm • Promotes coronary and peripheral vasodilation • Reduces HR, contractility, and BP • Dihydropyridines (e.g., nifedipine, amlodipine) are more potent vasodilators • Non-dihydropyridines (e.g., diltiazem, verapamil) have greater effect on reducing heart rate and contractility
Nitrates (see Table 36.6)	
isosorbide dinitrate (Isordil) isosorbide mononitrate (Imdur) Sublingual nitroglycerin (Nitrostat) Translingual spray nitroglycerin (Nitrolingual) Nitroglycerin ointment Transdermal nitroglycerin IV nitroglycerin	• Promotes peripheral vasodilation, decreasing preload and afterload • Promotes coronary artery vasodilation • May prevent or control coronary vasospasm

Drug	Mechanism of Action and Considerations
Opioid	
morphine	• Functions as an analgesic and sedative • Acts as a vasodilator to reduce preload and myocardial O_2 consumption
Sodium Current Inhibitor	
ranolazine (Ranexa)	• Treats chronic angina in patients who have not had an adequate response with other antianginal medications • Does not affect the BP or HR
Thrombolytic Agents	
reteplase (Retavase) alteplase (Activase) tenecteplase (TNKase)	• Breaks up fibrin meshwork in clots • Used only in STEMI when access to a hospital with PCI capability is not available or too far away

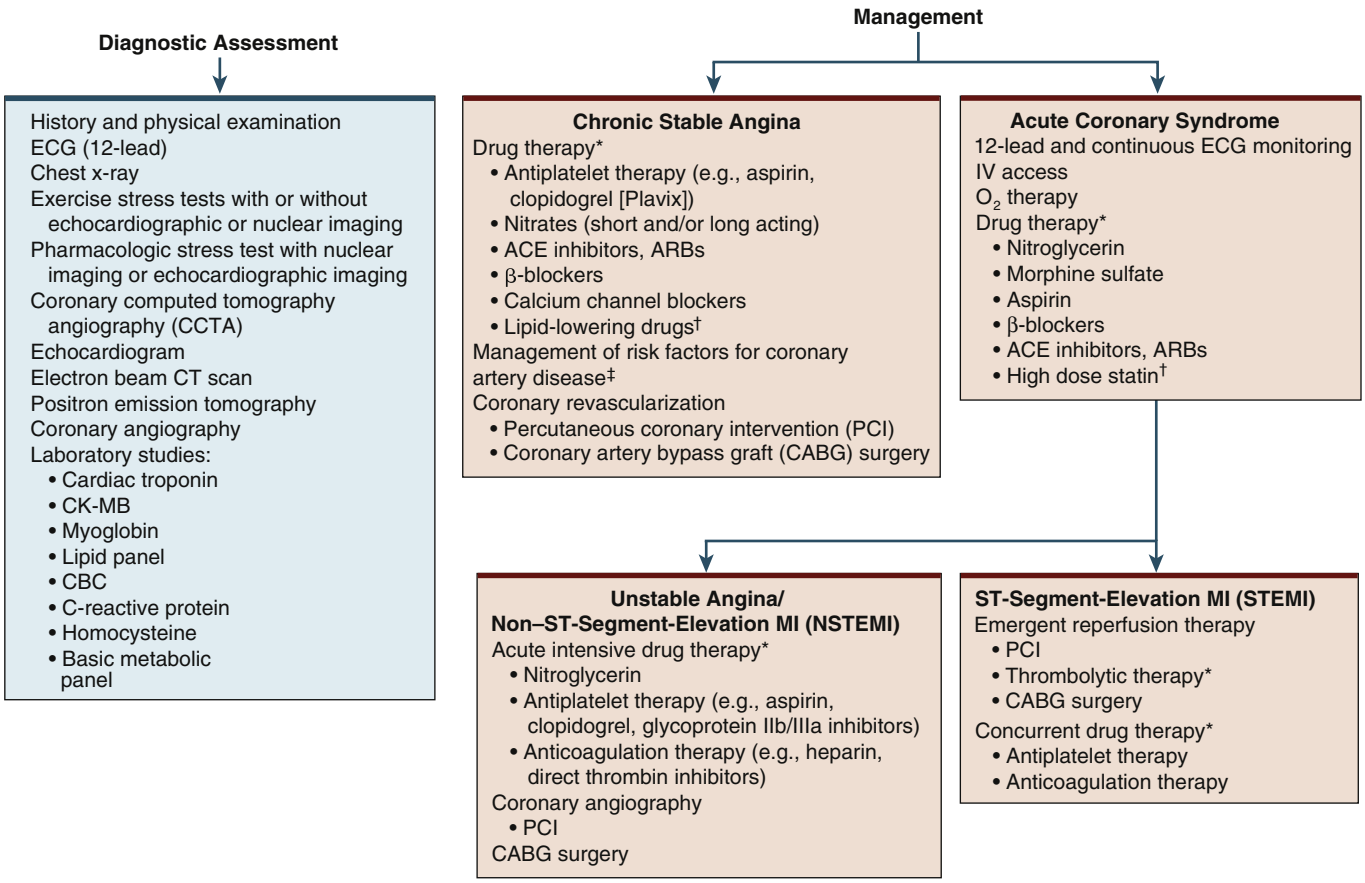

Fig. 37.5 Interprofessional care: chronic stable angina and acute coronary syndrome. *Table 37.12. †Table 37.6. ‡Tables 37.2, 37.4, and 37.5.

original bottles. Once opened, the tablets lose potency. They should be replaced every 6 months.

Tell the patient to sit down and place the NTG tablet under the tongue and allow it to dissolve. If using the spray, the patient should direct it on or under the tongue, not inhale it. SL NTG tablets should cause a tingling sensation when taken; if not, they may be outdated. Warn the patient that a headache, dizziness, or flushing may occur. Caution the patient to change positions slowly after NTG use because orthostatic hypotension may occur.

Patients can use NTG prophylactically before starting an activity that is known to cause angina (e.g., emotionally stressful situation, sexual intercourse). In these cases, the patient can take a tablet or spray 5 to 10 minutes before beginning the activity. Tell the patient to report any changes in the usual pattern of pain, such as increasing frequency, nighttime angina, or angina at rest.

Long-Acting Nitrates

Tolerance to long-acting NTG can develop. To limit this, schedule your patients for a 10- to 14-hour nitrate-free period every day. Remind patients that taking a long-acting NTG preparation should not keep them from using translingual or SL NTG if chest pain develops.

Oral nitrates, such as isosorbide dinitrate (e.g., Isordil) and isosorbide mononitrate (e.g., Imdur), are longer acting than SL or translingual NTG. They can reduce the frequency of angina attacks and treat Prinzmetal's angina. The main side effect is headache from the dilation of cerebral blood vessels. Tell patients to take acetaminophen to relieve the headache. Over time, headaches may decrease.

Nitropaste is a 2% NTG topical ointment dosed by the inch. It is placed on the upper body or arm, over a flat muscular area that is free of hair and scars. Once absorbed, it prevents or reduces angina frequency for 3 to 6 hours. The ointment should be wiped off each evening to allow for a 10- to 14-hour nitrate-free interval to prevent nitrate tolerance.

Transdermal NTG is a single patch applied once a day to the upper body or upper arms for timed release of NTG over a 24-hour period. Patches should be worn for 12 to 14 hours. They should be removed in the evening to allow for a 10- to 14-hour nitrate-free interval to prevent nitrate tolerance.

DRUG ALERT

Nitrates

- Keep SL NTG tablets in a dark, airtight container to maintain potency.
- Tell patients to sit down before using short-acting nitrates.
- SL NTG must be placed under the tongue.
- Spray translingual NTG onto or under the tongue.
- Tell patient not to combine NTG with drugs used for erectile dysfunction (e.g., sildenafil) as severe hypotension can occur.
- Monitor for orthostatic hypotension after administration.
- Headaches are common after taking any NTG preparation.
- Caregivers should use gloves to apply and remove NTG ointment or transdermal patches to avoid contact with drug.
- Never cardiovert or defibrillate over NTG ointment or a transdermal patch.
- When using long-acting nitrates, provide a 10- to 14-hr nitrate-free period.
- Remind patient using long-acting nitrates that short acting nitrates can still be used when needed.

Angiotensin-Converting Enzyme (ACE) Inhibitors and Angiotensin Receptor Blockers (ARBs)

Patients with chronic stable angina who have an ejection fraction (EF) of 40% or less, diabetes, hypertension, or CKD should take an ACE inhibitor (e.g., lisinopril) indefinitely, unless contraindicated. Patients with chronic stable angina and a normal EF, diabetes, and one other CAD risk factor also should take an ACE inhibitor to decrease the risk for MI, stroke, and death.[17]

These drugs result in vasodilation and reduced blood volume. Most important, they can prevent or reverse ventricular remodeling in patients who have had an MI. For patients who are intolerant of ACE inhibitors (e.g., cough, angioedema), angiotensin receptor blockers (ARBs) (e.g., losartan) are used. ACE inhibitors and ARBs are discussed in Chapter 36 and Table 36.6.

β-Adrenergic Blockers

Beta (β)-Blockers are used to relieve angina symptoms in patients with chronic stable angina. Patients who have LV dysfunction, an elevated BP, or had an MI should start and continue β-blockers indefinitely, unless contraindicated due to asthma or severe bradycardia. These drugs decrease myocardial contractility, HR, SVR, and BP, to reduce the myocardial O_2 demand and relieve angina symptoms. β-Blockers that reduce the risk for death in patients with LV dysfunction, HF, or MI include carvedilol (Coreg), metoprolol succinate (Toprol XL), and bisoprolol (Zebeta).[9]

β-Blockers have many side effects. These include bradycardia, hypotension, wheezing from bronchospasm, and GI effects. Many patients report weight gain, depression, fatigue, and sexual problems. Absolute contraindications to using β-blockers include severe bradycardia and acute decompensated HF. Patients with asthma should avoid β-blockers, especially nonselective ones. They are used cautiously in patients with diabetes since they mask signs of hypoglycemia. β-Blockers should not be stopped abruptly without medical supervision. This may result in an increase in the number and intensity of angina attacks (rebound effect).

Calcium Channel Blockers

If β-blockers are contraindicated, poorly tolerated, or do not control angina symptoms, calcium channel blockers are used. Their main effects are (1) systemic vasodilation with decreased SVR, (2) decreased myocardial contractility, (3) coronary vasodilation, and (4) decreased HR. They also are used to treat Prinzmetal's angina.

There are 2 groups of calcium channel blockers. The dihydropyridines (e.g., amlodipine, nifedipine) cause more vasodilation. The nondihydropyridines (e.g., verapamil, diltiazem) have a greater effect on decreasing HR and contractility.

Side effects include fatigue, headache, dizziness, flushing, hypotension, and peripheral edema. The nondihydropyridines enhance the action of digoxin by increasing serum digoxin levels. We closely monitor digoxin levels after starting these agents. Teach the patient the signs and symptoms of digoxin toxicity. Verapamil can cause severe constipation by relaxing GI smooth muscle and slowing peristalsis, especially in older adults.

Lipid-Lowering Drugs

A moderate or high dose of a lipid-lowering drug is given, unless contraindicated (Table 37.6). Patients with chronic stable angina should follow a diet low in saturated fat and cholesterol.

Sodium Current Inhibitor

Ranolazine (Ranexa), a sodium current inhibitor, is used to treat chronic angina in patients who have not had an adequate response with other antianginal medications. Although it is not a first-line agent, it is usually added only when the angina is not well controlled. Ranolazine does not affect the BP or HR. It can prolong the QT interval. Use it very cautiously in patients with a long QT interval or who are taking other QT-prolonging drugs (e.g., fluoxetine [Prozac]). Common side effects include dizziness, nausea, constipation, and headache.

Diagnostic and Intervention Studies

When a patient describes new-onset chest pain, and we suspect CAD or when a patient with chronic stable angina has a change in the angina pattern, a variety of studies are done (Fig. 37.5). After a detailed health history and physical assessment, we compare a 12-lead ECG with a previous ECG for changes that may indicate an ACS. Laboratory tests (e.g., cardiac biomarkers) can determine if the patient has an ACS. Other laboratory tests (e.g., lipid profile, CRP) can identify risk factors for CAD. A chest x-ray may show heart enlargement, aortic calcifications, and pulmonary congestion. An echocardiogram can detect resting LV wall motion abnormalities, which may suggest CAD.

If the ECG and cardiac biomarkers are negative, the patient may have an exercise stress test with or without imaging (echocardiography to look for wall motion abnormalities or nuclear imaging to look for perfusion abnormalities). This may occur during the hospitalization or as an outpatient. For those with physical limitations in walking, a pharmacologic (e.g., adenosine) or dipyridamole stress test with nuclear imaging or a pharmacologic (dobutamine) stress echocardiogram are options. Stress testing with imaging will be abnormal if coronary blockages are greater than 50% in the left main coronary artery or 70% in other vessels. Electron beam computed tomography (EBCT) or coronary computed tomography angiography (CCTA, CTA) testing may be done if there is no evidence of ACS and the patient remains free of chest pain. See Table 35.10 for more about these studies.

Cardiac Catheterization

For patients with increasing angina symptoms, cardiac catheterization is the gold standard test. It can identify and localize CAD, especially when the ECG shows ST depression and/or T wave inversion or cardiac biomarkers are positive. It may be done for a patient with chest discomfort who has a normal ECG and biomarkers but has an abnormal stress test. This procedure should be done only if the patient is a candidate for percutaneous or surgical coronary revascularization.

If a coronary blockage is amenable to treatment, **coronary revascularization** with **percutaneous coronary intervention (PCI)** may be recommended. PCI may be done at the same time as the cardiac catheterization. During PCI, a catheter with a deflated balloon tip is inserted into the blocked coronary artery. The deflated balloon is positioned inside the blockage and inflated. This compresses the plaque against the artery wall, resulting in vessel dilation and a larger vessel diameter. This procedure is called *balloon angioplasty.*

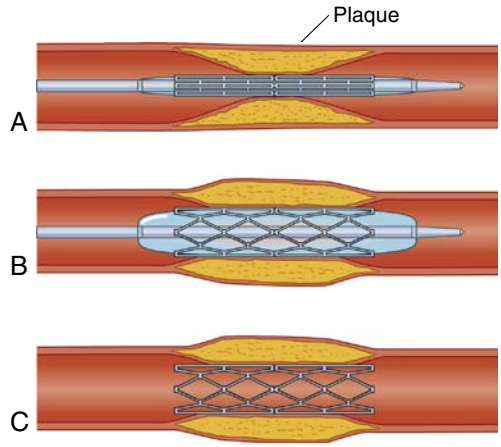

Fig. 37.6 Placement of a coronary artery stent. (A) The stent is placed at the site of the lesion. (B) The balloon is inflated, expanding the stent. The balloon is then deflated and removed. (C) The implanted stent is left in place.

Intracoronary stents are usually placed after a balloon angioplasty. A **stent** is an expandable mesh-like structure designed to keep the vessel open by supporting the arterial wall (Figs. 37.6 and 37.7). There are 2 types of stents: bare metal (BMS) and drug-eluting (DES). A DES is coated with a drug (e.g., everolimus, zotarolimus) to reduce the risk for overgrowth of the intimal lining *(neointimal hyperplasia)* within the stent. This overgrowth, called in-stent restenosis (ISR), is the build-up of scar tissue inside the stent. ISR may occur within a few months to a year after stent placement. The risk of ISR is lower with the use of a DES.

Because stents are thrombogenic, drugs are used to prevent platelet aggregation and thrombosis within the stent. Drugs commonly used during PCI are unfractionated heparin (UH) or low-molecular-weight heparin (LMWH), a direct thrombin inhibitor (e.g., bivalirudin [Angiomax]), and/or a GP IIb/IIIa inhibitor (e.g., eptifibatide [Integrilin]) (Table 37.12). After PCI for stable coronary disease, the patient receives dual antiplatelet therapy (DAPT) (e.g., aspirin plus clopidogrel [Plavix]) until the intimal lining grows over the metal stent and provides a smooth vascular surface.

After DES placement, DAPT is used for a minimum of 12 months to prevent thrombosis inside the stent. With the newer generation DESs, 3 to 6 months of DAPT is enough to prevent stent thrombosis. The duration of DAPT for patients with a BMS is a minimum of 1 month after PCI. Aspirin continues forever with either type of stent.[18]

Potential complications from cardiac catheterization with PCI include (1) abrupt closure from coronary artery dissection or rupture, (2) vascular injury at the artery access site (e.g., femoral, radial), (3) acute MI from acute stent thrombosis or from plaque dislodging and blocking the vessel distal to the original blockage, (4) stent embolization, (5) failure to cross the

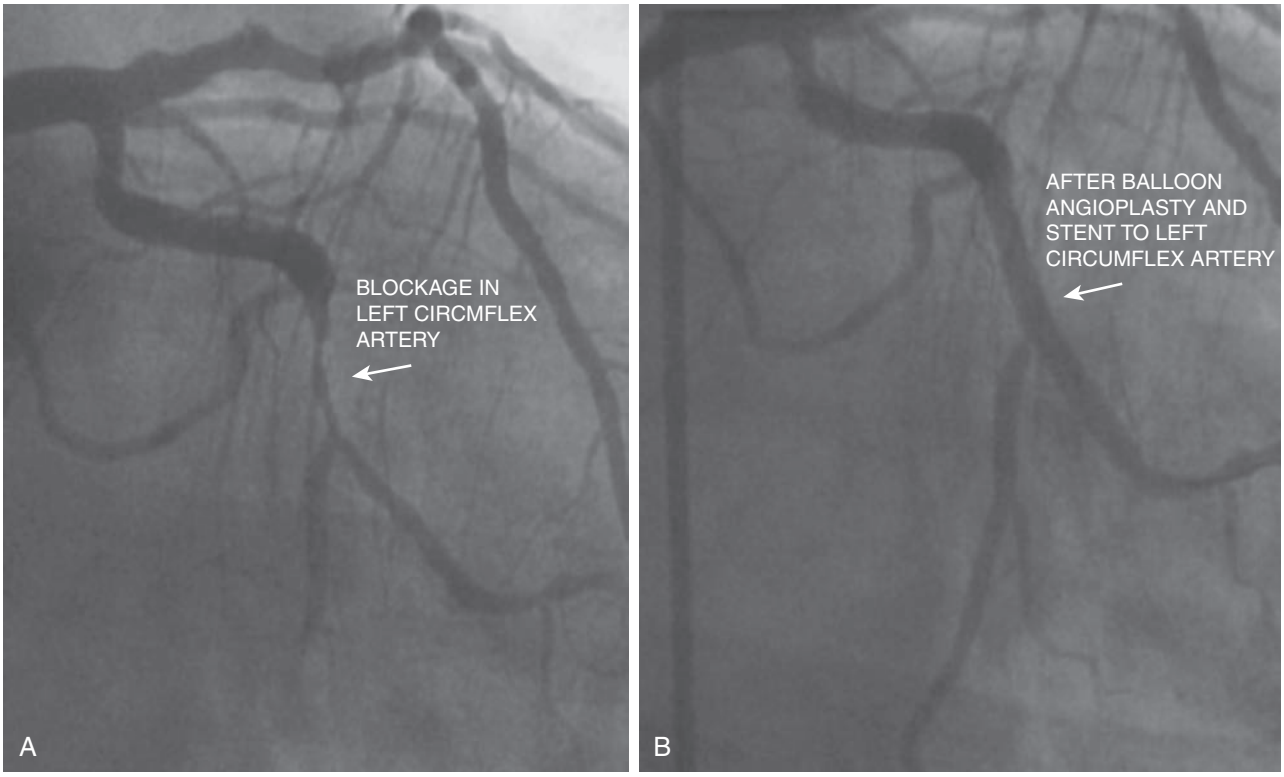

Fig. 37.7 (A) 90% occlusion of the left circumflex artery *(arrow)*. (B) Left circumflex artery is opened following balloon angioplasty and DES placement.

blockage with a balloon or stent, (6) coronary spasm, (7) dye allergy, (8) renal problems, (9) bleeding (e.g., retroperitoneal bleeding when the femoral artery is used or vascular access-site bleeding), (10) infection, (11) stroke, and (12) need for emergent coronary artery bypass graft (CABG) surgery. The risk for dysrhythmias during and after PCI is high, so monitor the ECG afterwards. Before and after catheterization and PCI, patients need frequent interventions (Table 35.12 and Table 37.13).

More PCIs than CABGs are done in the United States.[1] PCI may not be feasible for all patients (e.g., patients with 3-vessel CAD [3 different coronary arteries] and/or significant left main CAD).[19] Coronary revascularization with CABG surgery may be recommended after cardiac catheterization.

Surgical Coronary Revascularization

In patients with chronic stable angina, coronary revascularization with CABG surgery is recommended for patients who (1) do not respond well to medical management, (2) have left main coronary artery or 3-vessel disease, (3) are not candidates for PCI (e.g., blockages are long or difficult to access), or (4) continue to have chest pain after PCI. CABG may be an option for patients with diabetes, LV dysfunction, and/or CKD.[19] CABG surgery and PCI are palliative treatment for CAD and not a cure. Lifestyle changes and medications may help slow the progression of CAD and reduce the risk for recurrent events. Even after CABG, the bypass grafts are subject to the same progressive disease process as native coronary arteries.

CABG surgery consists of placing 1 or more arterial or venous graft(s) to provide blood to the heart muscle distal to the blocked coronary artery. Vessels used as grafts include the (1) saphenous vein from the leg, (2) radial artery from the forearm, and (3) internal mammary artery (IMA), also known as the internal thoracic artery (ITA). It is a branch of the subclavian artery (Fig. 37.8). The gastroepiploic artery is a rarely used option due to the time and difficulty in harvesting it.

Conventional Coronary Artery Bypass Graft Surgery

Traditional CABG surgery requires a sternotomy (opening of the chest cavity) and *cardiopulmonary bypass* (CPB). During CPB, blood is diverted from the patient's heart to a machine. There it is oxygenated and returned (via a pump) to the patient. This allows the HCP to operate on a quiet, non-beating, bloodless heart while vital organs are perfused. CPB can cause postoperative neurologic problems, renal problems, dysrhythmias (especially atrial fibrillation.), and systemic inflammatory response syndrome (SIRS).[19]

The left IMA (LIMA) is the most common artery used for a bypass graft. The proximal part remains attached to its origin (the left subclavian artery). The distal end of the LIMA is dissected from the chest wall. Next, it is sutured to the coronary artery distal to the blockage. It usually is used to bypass the left anterior descending (LAD) artery because the LAD supplies blood to the largest part of the heart muscle (anterior wall). IMAs also tend to have longer patency rates than saphenous veins (Fig. 37.8). Using the right IMA and LIMA carries an increased risk of sternal wound infection, especially in patients with diabetes or obesity.[19,20]

Saphenous veins can be used for bypass grafts. The HCP endoscopically removes the saphenous vein from 1 or both legs. A section is sutured into the ascending aorta near the opening

TABLE 37.13 NURSING MANAGEMENT

Percutaneous Coronary Intervention

Preprocedure

- Assess for allergies, especially to contrast dye.
- Perform baseline assessment, including vital signs, pulse oximetry, heart and breath sounds, neurovascular assessment of extremities (e.g., distal pulses, skin temperature, skin color, sensation).
- Withhold food and fluids for 6–12 hr before planned procedures.
- Assess baseline laboratory values (e.g., cardiac biomarkers, creatinine).
- Give ordered drugs before the procedure and stop drugs not needed for the procedure.
- Teach patient and caregiver about procedure and postprocedure care.

Postprocedure

- Perform assessment and compare to baseline: vital signs, pulse oximetry, heart and breath sounds, neurovascular assessment of extremity used for procedure, assessment of catheter insertion site for hematoma, bleeding, and bruit.
- Assess neurovascular status of involved extremity every 15 min for the first hour, then according to agency policy.
- Place compression device over arterial site to achieve hemostasis, per agency policy.
- Check for bleeding or hematoma at catheter insertion site every 15 min for the first hour, then according to agency policy.
- Report changes in neurovascular status of involved extremity or any bleeding.
- Monitor ECG for dysrhythmias or other changes (e.g., ST segment elevation or depression).
- Monitor patient for chest pain and other sources of pain or discomfort (e.g., back, vascular access site).
- Monitor IV infusions of antianginals (e.g., nitroglycerin) and antiplatelet medications (e.g., eptifibatide).
- Maintain bedrest as prescribed after femoral artery access.
- Teach patient and caregiver about discharge drugs (e.g., aspirin, clopidogrel, lipid lowering drugs).
- Teach patient and caregiver about discharge care, including signs and symptoms to report to HCP (e.g., access site complications, return of chest pain).

Assistive Personnel (AP)

- Supervise AP:
  - Take vital signs and report increases or decreases in HR or BP to RN.
  - Report patient descriptions of chest pain, shortness of breath, and/or any other discomfort or distress to RN.
  - Report changes in neurovascular status of the involved extremity or any bleeding to the RN.
  - Help with oral hygiene and hydration, meals, and toileting.
  - Record oral intake and urine output as ordered.

of the native coronary artery and then anastomosed to the coronary artery distal to the blockage (Fig. 37.8). Saphenous vein grafts are more prone to develop diffuse intimal hyperplasia, future stenosis, and graft occlusion.

The radial artery, another potential graft, is a thick muscular artery prone to spasm. Perioperative calcium channel blockers and long-acting nitrates are used to control the spasms.[20] Patency rates are not as good as the IMA but are better than saphenous veins. Serious extremity complications (e.g., hand ischemia, wound infection) are rare after removal of the radial artery. Patients may have paresthesias and impaired sensation after radial artery harvest.

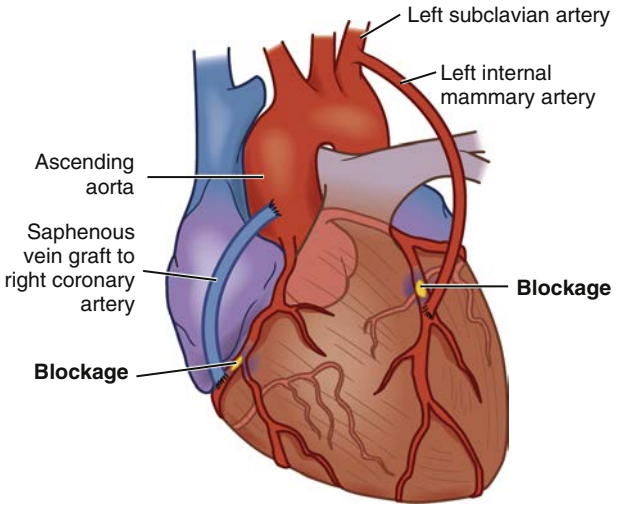

Fig. 37.8 Proximal end of the left internal mammary artery (LIMA) is left attached to the subclavian artery, and the distal end of the LIMA is sutured into the LAD artery below the blockage. Proximal end of the saphenous vein is sutured to the aorta. The distal end is sutured into the right coronary artery below the area of blockage.

All bypass grafts are subject to the fat and cholesterol build-up that occurs in the native coronary arteries. Controlling risk factors as well as antiplatelet and statin therapy after CABG surgery helps maintain vein graft patency.

Women have higher periprocedural mortality and morbidity rates than men. We attribute this to the late treatment of CAD. Women first present with CAD at an older age and have more co-morbidities at the time of surgery. Other factors include smaller diameter coronary vessels, smaller body surface area, and the fact that women are less likely to be referred for catheterization.[19]

Minimally Invasive Direct Coronary Artery Bypass

Minimally invasive direct coronary artery bypass (MIDCAB) offers patients an approach to surgical treatment that does not involve a sternotomy and CPB. The technique requires several small incisions between the ribs or a mini-thoracotomy. The LIMA is dissected away from the chest wall by direct visualization.[20] The right IMA is more difficult to access with the thoracotomy approach.[20] A mechanical stabilizer immobilizes the operative site.

In the early days of MIDCAB, we only used the IMA as a graft to the LAD or right coronary artery. Today, MIDCAB can be used for multivessel revascularization in select patients. Some patients have hybrid procedures in which they have a MIDCAB for the LAD artery and undergo a PCI of a second or third artery later.

Off-Pump Coronary Artery Bypass

The *off-pump coronary artery bypass* (OPCAB) procedure uses a median sternotomy to access all coronary vessels. OPCAB is performed on a beating heart (no CPB) using mechanical stabilizers. OPCAB is associated with less blood loss, less renal

dysfunction, less postoperative atrial fibrillation, and fewer neurologic complications.[19]

Totally Endoscopic Coronary Artery Bypass

Totally endoscopic coronary artery bypass (TECAB) uses robotic technology to perform CABG surgery. It requires several instrument ports in the chest cavity. This procedure is done without the use of CPB or with the use of CPB using femoral access. Benefits include potentially less blood loss, less pain, less risk of sternal wound infection, and shorter recovery times.[20]

Transmyocardial Laser Revascularization

Transmyocardial laser revascularization is an indirect revascularization procedure. It is used for patients with advanced CAD who are not candidates for conventional CABG surgery and who have persistent angina despite maximum medical therapy. Using a left thoracotomy approach, a high-energy laser creates channels in the heart muscle to allow blood flow to ischemic areas. It is an adjunctive therapy when bypass grafts cannot be placed or in combination with CABG surgery.[20]

Postoperative Care After CABG Surgery

Care after CABG surgery is provided in the intensive care unit (ICU) for the first 24 to 48 hours. Ongoing intensive monitoring of the patient's hemodynamic status is critical. The patient will have many invasive lines for monitoring heart status and other vital functions (see Chapter 35). These include (1) hemodynamic monitoring (e.g., CO), (2) an arterial line for continuous BP monitoring, (3) pleural and mediastinal chest tubes for chest drainage, (4) continuous ECG monitoring, (5) an endotracheal tube connected to mechanical ventilation, (6) epicardial pacing wires for emergency pacing of the heart, (7) a urinary catheter to monitor urine output, and (8) a nasogastric tube for gastric decompression. Most patients are extubated within 6 hours and transferred to a step-down unit within 24 to 48 hours for continued monitoring.

Many of the complications that develop after CABG surgery relate to the use of CPB. Major complications of CPB are systemic inflammation, bleeding and anemia from damage to red blood cells and platelets, fluid and electrolyte imbalances, infections, and hypothermia from CPB. Focus your care on assessing the patient for bleeding (e.g., chest tube drainage, incision sites), monitoring hemodynamics, checking fluid status, replacing blood and electrolytes as needed, and restoring temperature (e.g., warming blankets).

Postoperative dysrhythmias, especially atrial fibrillation (e.g., AF), are common. The incidence of AF after CABG surgery is 20% to 50%.[19] β-Blockers should be started at least 24 hours before CABG surgery and restarted as soon as possible after surgery (unless contraindicated) to reduce the incidence of AF.[19] Discharge may be delayed in patients who develop AF so we can control the HR and start anticoagulation therapy. See Chapter 39 for information on treating AF.

You must also provide wound care for the patient's surgical sites (e.g., leg, chest, arm). Chest incisions often do not need dressings after 24 hours. Management of the chest wound is like that of other chest surgeries (see Chapter 28). Care of the leg incision is minimal since endoscopy is used to harvest the vein.

Care of a radial artery harvest site includes monitoring sensory and motor function of the hand. The patient with radial artery harvest should take a calcium channel blocker and/or a long-acting nitrate after surgery to reduce the incidence of arterial spasm at the arm or anastomosis site.[20]

Other nursing interventions include strategies to manage pain and prevent venous thromboembolism (e.g., early ambulation, sequential compression device) and respiratory complications (e.g., incentive spirometry, splinting during coughing and deep-breathing exercises). Chapter 20 details care of the postoperative patient.

Postoperative cognitive dysfunction (POCD) can manifest days to weeks after surgery. It usually improves within a few months after surgery. For some, POCD becomes a chronic problem. This includes impairment of memory, concentration, language comprehension, and social integration. Depression and anxiety are common. Patients may cry or become teary. POCD is discussed in Chapter 20.

The older patient (> age 80) can often undergo elective CABG with good results. Many have multiple preoperative co-morbidities, so the incidence of postoperative complications (e.g., dysrhythmias, stroke, POCD, infection) is higher. Although the treatment benefits may outweigh risks in this group, morbidity and mortality are higher than in younger persons.[19]

Postoperative nursing care of the patient with a MIDCAB, OPCAB, or TECAB procedure is similar to that for conventional CABG surgery patients. The recovery time usually is shorter. Patients often resume routine activities sooner than patients who have conventional CABG surgery. Pain control is important regardless of the procedure. Patients often report higher levels of pain with a thoracotomy incision than a sternotomy incision.

Alternative Therapies for Refractory Chronic Stable Angina

For patients with refractory angina, *enhanced external counterpulsation* (EECP) may be used. EECP consists of placing inflatable BP cuffs around the legs. The cuffs sequentially inflate during diastole and deflate during systole from the calves to the thighs. This action increases venous return and augments diastolic BP. This increases coronary perfusion, improves LV diastolic filling, and helps with collateral circulation. Patients get treatments 5 days a week for a total of 35 treatments. EECP is contraindicated in patients with decompensated HF, severe peripheral arterial disease, and severe aortic insufficiency.[9]

ACUTE CORONARY SYNDROME

When chest pain from ischemia is prolonged and not immediately reversible, **acute coronary syndrome (ACS)** may develop. ACS includes the spectrum of non-ST elevation ACS (*UA and non–ST-segment-elevation myocardial infarction* (NSTEMI)) and *ST-segment-elevation myocardial infarction* (STEMI) (Fig. 37.9). When patients first present with chest pain, compare the ECG to a previous ECG whenever possible. ST-elevations on the

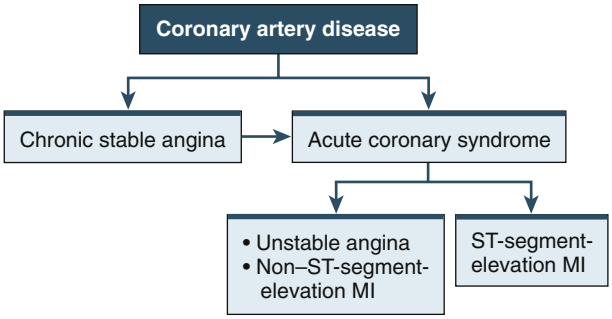

Fig. 37.9 Relationships among coronary artery disease, chronic stable angina, and acute coronary syndrome.

12-lead ECG likely indicate a STEMI (Fig. 37.4B). ST elevation represents myocardial injury that is potentially reversible, but, if not treated, will likely evolve to permanent necrosis (tissue death) of the myocardium. Patients with UA or NSTEMI may or may not have ST segment depression and/or T wave inversion on the ECG. For these patients, it is difficult to tell between UA and NSTEMI until we evaluate serum cardiac biomarkers.[12]

Heart muscle cells become hypoxic within the first 10 seconds of a total coronary occlusion as they are deprived of O_2 and glucose needed for aerobic metabolism and contractility. Anaerobic metabolism begins, and lactic acid accumulates. In ischemic conditions, heart cells are viable for about 20 minutes. Irreversible heart damage starts after 20 minutes if there is no collateral circulation (Fig. 37.2).[21] With restoration of blood flow (reperfusion), aerobic metabolism resumes, contractility is restored. Cellular repair begins.

ACS occurs when a previously stable atherosclerotic plaque ruptures, releasing the lipid core into the vessel. This causes platelet aggregation and thrombus formation. The vessel may be partially blocked by a thrombus (manifesting as UA or NSTEMI) or totally blocked by a thrombus (manifesting as STEMI). It is unclear what causes the plaque to suddenly become unstable. Systemic inflammation (described earlier) may play a role. Patients with suspected ACS need immediate hospitalization.

UNSTABLE ANGINA

Unstable angina (UA) is chest pain that is new in onset, occurs at rest, or occurs with increasing frequency, duration, or less effort than the patient's chronic stable angina pattern. The pain usually lasts 10 minutes or more.

The patient with chronic stable angina may develop UA, or UA may be the first clinical sign of CAD. Unlike chronic stable angina, UA is unpredictable. It must be treated immediately. The patient with previously diagnosed chronic stable angina describes a significant change in the pattern of angina. It occurs with increasing frequency and with less exertion than previously. It may occur during sleep or even at rest. The patient without previously diagnosed angina describes chest pain that has progressed rapidly in the past few hours, days, or weeks, often ending in pain at rest. ECG changes that may occur with UA include ST depression and/or T wave inversion (Fig. 37.4A). We refer to these changes as ischemic changes.

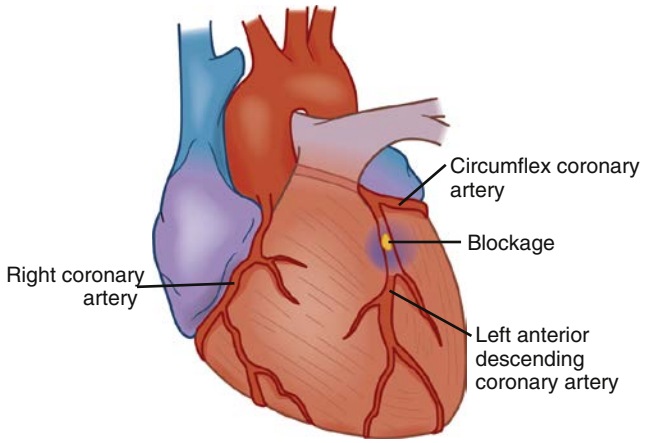

Fig. 37.10 Occlusion of the LAD coronary artery, resulting in acute MI.

Fig. 37.11 Acute MI in the posterolateral wall of the left ventricle. Note the absence of staining in the areas of necrosis *(white arrow)*. Note the scarring from a previous anterior wall MI *(black arrow)*. (From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

ST-ELEVATION AND NON–ST-ELEVATION MYOCARDIAL INFARCTION

A **myocardial infarction (MI)** occurs because of an abrupt stoppage of blood flow through a coronary artery with a thrombus caused by platelet aggregation. This causes irreversible myocardial cell death (necrosis) in the heart muscle beyond the blockage (Figs. 37.10 and 37.11). Serum cardiac biomarkers are released into the blood. Most MIs occur in the person with preexisting CAD.

A STEMI, caused by an occlusive thrombus, results in ST-elevation in the ECG leads facing the area of infarction (Figs. 37.4B; 37.12 and 37.13). ST segment elevation is significant if it is 1 mm (1 small block) or more above the isoelectric line in at least 2 contiguous leads (2 leads that look at the same wall of the heart) except in V_2 and V_3. There the ST elevation must be 2 mm (2 small blocks) or more.[22]

A STEMI is an emergency. To limit the infarct size, the artery must be opened within 90 minutes of presentation to restore blood and O_2 to the heart muscle and limit the infarct size. This can be done either by PCI or with thrombolytic (fibrinolytic) therapy. PCI is the first-line treatment, if available (Fig. 37.6). Thrombolytic therapy is done in hospitals that do not have a catheterization laboratory for PCI. If the patient does not seek

treatment quickly, the STEMI will evolve to cause potentially significant heart muscle damage. A pathologic Q wave will be seen on the ECG if the patient does not seek immediate treatment. A pathologic Q wave is just a deep Q wave or a Q wave that is greater than or equal to one-third the height of the R wave in the same lead (Figs. 37.4C and 37.13).

NSTEMI, caused by a nonocclusive thrombus, does not cause ST segment elevation on the 12-lead ECG. The ECG may or may not show ST depression and/or T wave inversion in the leads facing the area of infarction (Fig. 37.12). NSTEMI patients do not need an emergent catheterization but usually undergo catheterization within 12 to 72 hours. Thrombolytic therapy is not a treatment option.

With either NSTEMI or STEMI, an echocardiogram may show *hypokinesis* (worsening myocardial contractility) or *akinesis* (absent myocardial contractility) in the infarcted area(s). The degree of LV dysfunction depends on the area of the heart involved and size of the infarction.

The acute MI process evolves over hours to a few days. The earliest tissue to become ischemic is the subendocardium (the innermost layer of tissue in the heart muscle). If ischemia persists, it takes around 4 to 6 hours for the entire thickness of the heart muscle to necrose. If the thrombus is not completely blocking the artery, the time to complete necrosis may be as long as 12 hours.

Most MIs affect the LV and are described based on the location of damage (e.g., anterior, inferior, lateral, septal, or posterior wall infarction). The location of the MI and ECG changes correlate with the involved coronary artery (Table 37.14). For example, in most people, the right coronary artery supplies blood to the inferior and posterior LV walls. Blockage of the right coronary artery results in an inferior wall and/or posterior wall MI. Anterior wall infarctions result from blockages in the LAD artery. Blockages in the left circumflex artery usually cause lateral wall MIs. Damage can occur in more than 1 location, especially if more than 1 coronary artery is involved (e.g., anterolateral MI). Right ventricular MIs are much less common and treated differently from LV MIs. Suspect a right ventricular MI in patients who have a left inferior wall STEMI.[23]

The degree of collateral circulation influences the severity of the MI (Fig. 37.2). Not everyone develops collateral circulation. A person with a long history of CAD may develop good collateral circulation to provide the tissue around the evolving infarction with an adequate blood supply. This is one reason a younger person may have a more serious first MI than an older person with the same degree of blockage.

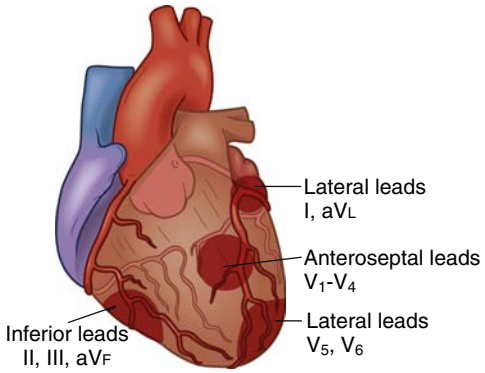

Fig. 37.12 Definitive ECG changes occur in leads that face the area of ischemia, injury, or infarction. Reciprocal changes may occur in leads facing opposite the area of ischemia, injury, or infarction.

Clinical Manifestations

Pain

Chest pain with an MI is often worse than with previous episodes of angina. Persistent and unlike any other pain, it is usually described as a heavy, pressure, tight, burning, constricted, or crushing feeling. Common locations are the substernal or epigastric area. The pain may radiate to the neck, lower jaw, and arms or to the back (Fig. 37.3). When epigastric pain is present, the patient may relate it to indigestion, take antacids without relief, and therefore delay seeking treatment. It may occur while the patient is active or at rest, asleep, or awake. Pain often occurs in the early morning hours. It usually lasts for 20 minutes or longer.

Not everyone who has an MI has classic symptoms. Some patients may not have pain but may have "discomfort," weakness, nausea, indigestion, or shortness of breath. Some women may have atypical discomfort, shortness of breath, or fatigue. Patients with diabetes may have silent (asymptomatic) MIs because of cardiac neuropathy or have atypical symptoms (e.g., shortness of breath). An older patient may have a change in mental status (e.g., confusion), shortness of breath, pulmonary edema, dizziness, or a dysrhythmia.

Sympathetic Nervous System Stimulation

During the initial phase of MI, the ischemic heart cells release catecholamines (norepinephrine and epinephrine). This results in diaphoresis, increased HR and BP, and vasoconstriction

TABLE 37.14 ECG Evidence in Acute Coronary Syndrome

	ECG EVIDENCE		
Left Ventricle Involvement	Leads Facing Area	Leads Opposite Area (Reciprocal Changes)	Associated Coronary Artery
Septal wall	V_1, V_2	II, III, aV_F	Left anterior descending (LAD)
Anterior wall	V_3, V_4	II, III, aV_F	LAD
Lateral wall, low	V_5, V_6	II, III, aV_F	LAD or circumflex
Lateral wall, high	I, aV_L	II, III, aV_F	Circumflex
Inferior wall	II, III, aV_F	I, aV_L, V_5, V_6	Right coronary artery, posterior descending coronary artery

of peripheral blood vessels. The patient's skin may be ashen, clammy, and cool to touch.

Cardiovascular Manifestations

In response to the release of catecholamines, BP and HR may be high initially. Later, the BP may drop because of decreased CO. If severe enough, this may result in decreased renal perfusion and urine output. Crackles, if present, may persist for several hours to several days, suggesting LV dysfunction. Jugular venous distention (JVD), hepatic engorgement, and peripheral edema may mean right ventricular dysfunction.

Your patient may have abnormally distant heart sounds. Other abnormal sounds suggesting LV dysfunction are S_3 and S_4. A loud holosystolic murmur may occur with a ventricular septal defect or papillary muscle rupture resulting in mitral regurgitation (the valve does not close properly allowing blood to leak back into the left atrium).

Nausea and Vomiting

Your patient may have nausea and vomiting. These symptoms can result from reflex stimulation of the vomiting center by the severe pain. They can also result from vasovagal reflexes initiated in the area of the infarcted heart muscle, especially with inferior wall MIs.

Fever

The temperature may increase to 100.4°F (38°C) within 24 to 48 hours. Fever may last 4 to 5 days. This increase is due to a systemic inflammatory process caused by the death of myocardial cells.

Healing Process

The body's response to cell death is the inflammatory process (see Chapter 12). Within 24 hours, leukocytes infiltrate the area. The dead heart cells release enzymes that are important diagnostic indicators of MI. The proteolytic enzymes of the neutrophils and macrophages begin to remove necrotic tissue by the fourth day. During this time, the necrotic muscle wall is thin.

Once infarction takes place, catecholamine-mediated lipolysis and glycogenolysis occur. These processes allow the increased plasma glucose and free fatty acids to be used by the O_2-depleted myocardium for anaerobic metabolism. This is why glucose levels are often high after MI.

The necrotic zone of a STEMI is identified by ECG changes (e.g., lowering of the initially elevated ST segments, T wave inversion and/or a pathologic Q wave) within 1 or 2 days. At this point, the neutrophils and monocytes have cleared the necrotic debris from the injured area. The collagen matrix that will eventually form scar tissue is laid down.

At 10 to 14 days after MI, the new scar tissue is still weak. The heart muscle is vulnerable to increased stress during this time. At the same time, the patient's activity level may be increasing, so special caution and assessment are necessary. By 6 weeks after MI, scar tissue has replaced necrotic tissue and the injured area is considered healed. Often the scarred area is less compliant than the surrounding area. This may be manifested by abnormal wall motion on an echocardiogram or nuclear imaging (e.g., hypokinesis, akinesis), LV dysfunction, altered conduction patterns, dysrhythmias, or HF. Years later, the scarred area may become an irritable focus for life-threatening dysrhythmias causing sudden cardiac death (SCD).

These changes in the infarcted heart muscle also cause changes in the unaffected areas. To try to compensate for the damaged muscle, the normal myocardium hypertrophies and dilates. This process is called *ventricular remodeling*. Remodeling of normal myocardium can lead to the development of late HF, especially in the person with atherosclerosis of other coronary arteries and/or an anterior MI. ACE inhibitor drugs are given to limit ventricular remodeling.

Complications of Myocardial Infarction

Dysrhythmias

Any condition that affects the heart cells' sensitivity to nerve impulses (e.g., ischemia, electrolyte imbalances, SNS stimulation) can cause dysrhythmias. Dysrhythmias are the most common complication after an MI. They occur in 80% to 90% of patients. Ventricular tachycardia (VT) and ventricular fibrillation (VF) are the most common cause of death in patients in the prehospital period. VT or VF most often occur within the first 4 hours after the onset of pain. Premature ventricular contractions (PVCs) may precede VT and VF.

Bradycardias (e.g., complete heart block) can develop when key areas of the conduction system are destroyed (e.g., infarction involves the sinus or atrioventricular node). A patient who is symptomatic with bradycardia may require an external pacemaker or a temporary transvenous pacemaker.

With reperfusion (thrombolytic therapy or PCI), it is common to see PVCs, asymptomatic nonsustained VT, and idioventricular rhythms. These rhythms are not associated with an increased risk for SCD. They are not treated unless the patient is symptomatic.[23] See Chapter 39 for information about dysrhythmias and their management.

Heart Failure

Heart failure (HF) is a complication that occurs when the right or left ventricle's pumping action is reduced. Depending on the severity and extent of the injury, left-sided HF occurs initially with subtle signs, such as mild dyspnea, restlessness, agitation, or slight tachycardia. Other signs indicating the onset of left-sided HF include pulmonary congestion on chest x-ray, an S_3 heart sound, crackles on auscultation of the lungs, paroxysmal nocturnal dyspnea (PND), and orthopnea. Signs of right-sided HF include JVD, hepatic congestion, abdominal distention, or lower extremity edema. See Chapter 38 for information about the treatment of acute decompensated HF.

Cardiogenic Shock

Cardiogenic shock occurs when O_2 and nutrients supplied to the tissues are inadequate because of severe LV failure, papillary muscle rupture, ventricular septal rupture, LV free wall rupture, or right ventricular infarction.[23] This occurs less often when STEMI is treated early and rapidly with PCI or thrombolytic therapy. Cardiogenic shock, which has a high death rate, requires aggressive management. This includes control of dysrhythmias,

mechanical circulatory devices (e.g., intraaortic balloon pump [IABP], extracorporeal membrane oxygenation [ECMO]), and support of contractility with vasoactive drugs (e.g., dobutamine). Goals of therapy are to maximize O_2 delivery, reduce O_2 demand, and prevent complications (e.g., acute kidney injury). See more about cardiogenic shock in Chapter 42.

Papillary Muscle Dysfunction or Rupture

Papillary muscle dysfunction may occur if the infarcted area includes or is near the papillary muscle that attaches to the mitral valve (see Fig. 35.2). Suspect papillary muscle dysfunction if you hear a new systolic murmur suggestive of mitral regurgitation at the heart apex. An echocardiogram confirms the diagnosis.

Papillary muscle rupture is a rare and life-threatening complication. It causes acute and massive mitral valve regurgitation with no time for the heart to compensate. Dyspnea, pulmonary edema, and decreased CO result from the backup of blood in the left atrium. This condition aggravates an already damaged LV by reducing CO even further. The patient undergoes rapid clinical decline. Treatment includes afterload reduction with nitroprusside (Nipride) and/or IABP therapy and immediate surgery with mitral valve repair or replacement. See Chapter 40 for information on valve disorders.

Left Ventricular Aneurysm

Left ventricular aneurysm results when the infarcted heart wall thins and bulges out during contraction. This can develop within a few days, weeks, or months. It is more common with anterior MIs.[23] The patient with a ventricular aneurysm may develop HF, dysrhythmias, and angina. Besides ventricular rupture, which is usually fatal, ventricular aneurysms can hide thrombi that can lead to an embolic stroke. Anticoagulation therapy is recommended unless contraindicated.

Ventricular Septal Wall Rupture and Left Ventricular Free Wall Rupture

A new loud systolic murmur heard in patients with acute MI may signal ventricular septal wall rupture. Depending on the size of the defect and degree of right and LV dysfunction, HF and cardiogenic shock may occur. The patient must undergo emergency repair, either surgically or percutaneously. The defect can quickly expand and lead to hemodynamic compromise.[23]

LV free wall rupture is an emergent clinical situation. Rapid hemodynamic compromise and death ensues if not treated immediately. Although this is a rare complication, death rates are high. Free wall rupture occurs more often in patients after their first MI, patients with anterior MIs, older adults, and women.[23]

Pericarditis

Acute pericarditis, an inflammation of the visceral and/or parietal pericardium, may occur 2 or 3 days after an acute MI. The key sign is mild to severe chest pain that increases with inspiration, coughing, and movement of the upper body. Sitting in a forward position often relieves the pain. The pain is usually different from pain due to an MI.

If you suspect pericarditis, assess for the presence of a friction rub over the pericardium. You can hear the sound best with the diaphragm of the stethoscope at the mid to lower left sternal border. It may be persistent or intermittent. Fever may be present. The patient may have hypotension and/or a narrow pulse pressure if there is significant pericardial effusion or cardiac tamponade. Asymptomatic pericardial effusions are common after STEMI.[23]

Besides physical findings, a 12-lead ECG is helpful in making a diagnosis. Typical ECG changes include diffuse ST segment elevations in many unrelated leads (with STEMI, ST elevation occurs in the leads facing the infarcted wall). This reflects the inflammation of the pericardium. Treatment includes pain relief with high doses of aspirin (e.g., 650 mg every 4 to 6 hours). Nonsteroidal antiinflammatory drugs (NSAIDs) and corticosteroids are avoided in the first 4 weeks after MI because they can interfere with myocardial scar formation.[21,23] Pericarditis is discussed in Chapter 40.

Dressler Syndrome

Dressler syndrome is pericarditis and fever that develop 1 to 8 weeks after MI. Although the cause is unclear, it may be an autoimmune reaction to the necrotic heart muscle. The patient has chest pain, fever, malaise, and arthralgia. A pericardial friction rub may be heard. A pericardial effusion may be present on echocardiogram. Laboratory findings include a high white blood cell count and sedimentation rate. High-dose aspirin is the treatment of choice.

Diagnostic Studies

In addition to the patient's history of pain, risk factors, and health history, the primary diagnostic studies used to determine whether a person has UA or MI (STEMI or NSTEMI) include a 12-lead ECG and serum cardiac biomarkers.

Electrocardiogram Findings

The ECG is one of the primary tools to diagnose UA or an MI (STEMI or NSTEMI). Whenever possible, we should compare a new ECG to a previous ECG. Changes in the QRS complex, ST segment, and T wave caused by injury, ischemia, and infarction can develop slowly or quickly with UA and MI. The pattern of ECG changes among the 12 leads provides information on the coronary artery involved in ACS (Table 37.14).

The ECG must be read carefully since changes can be absent or subtle at first. For this reason, we do serial 12-lead ECGs. For diagnostic and treatment purposes, it is important to distinguish between STEMI and NSTEMI/UA. STEMI patients usually have a complete coronary occlusion and must go to the catheterization laboratory emergently. You will see ST elevation in the leads facing the infarcted wall on the 12-lead ECG (Figs. 37.4B, 37.12, and 37.13 and Table 37.14). ST segment elevation is significant if it is 1 mm or more above the isoelectric line (2 mm or more in V2 and V3) in at least 2 contiguous leads.[22] Within a few hours to days, the ST segments begin to lower, with T wave inversion and pathologic Q waves developing in the same leads if reperfusion is delayed or not done (Fig. 37.4C; Fig. 37.13).[37] The pathologic Q wave will remain

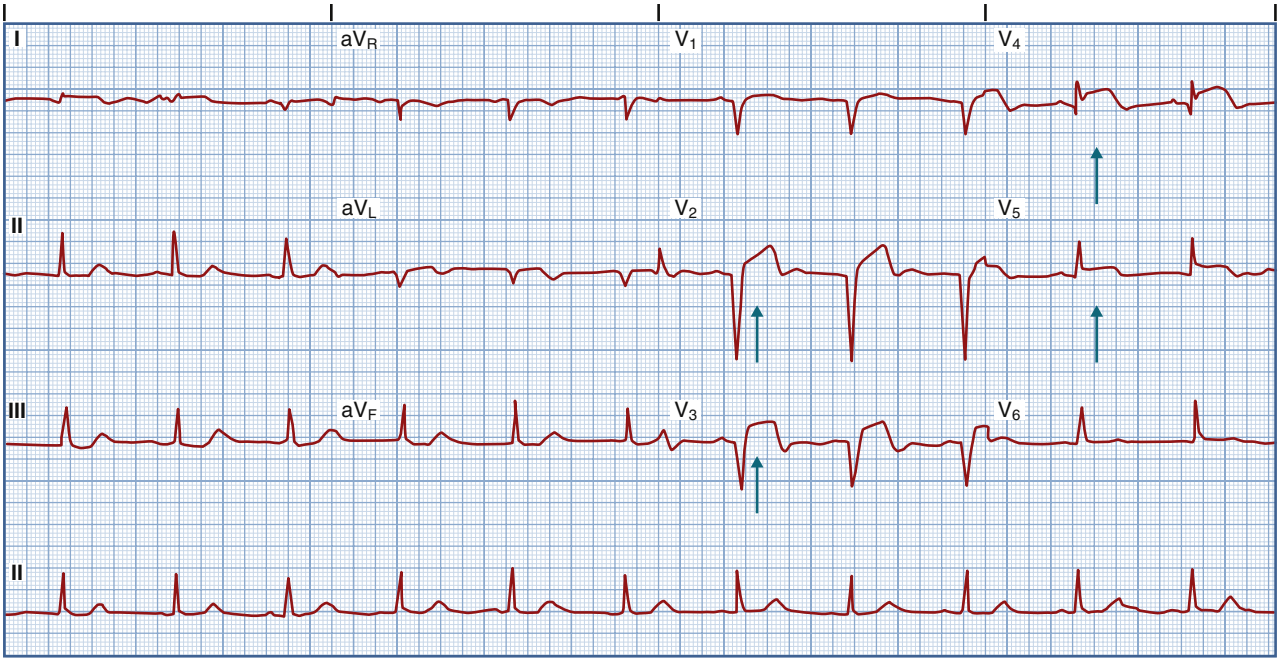

Fig. 37.13 ECG findings with anteroseptal lateral wall MI. Normally, leads I, aVL, and V_1 to V_3 have a positive R wave. Note the pathologic Q waves in these leads and the ST segment elevation in leads V_2 to V_6 *(arrows)*.

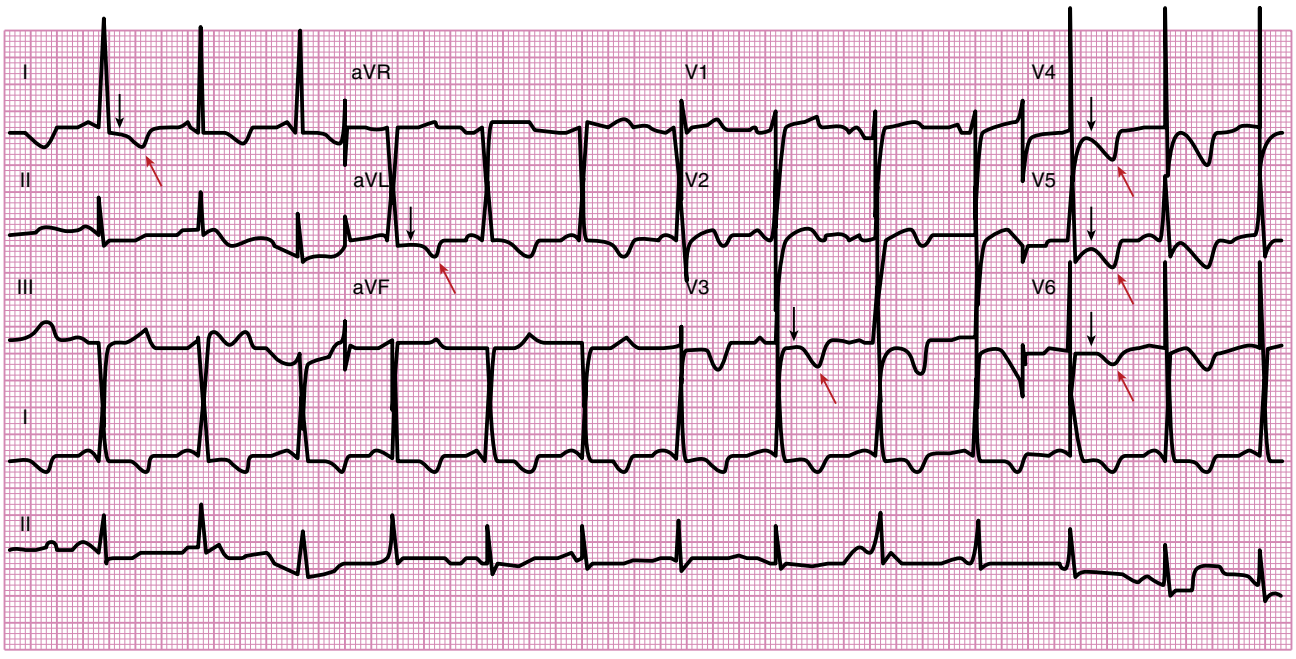

Fig. 37.14 ECG findings with anterior and lateral ischemia or an NSTEMI. Note the ST depression in the lateral leads (lead I, aVL, V5 and V6 *[black arrows]*) and the T wave inversion in I, aVL, V5 and V6 (*red arrows*). These leads face the lateral wall. Note the ST depression in 2 anterior leads (V3 and V4 *[black arrows]*) and the T wave inversion in V3 and V4 (*red arrows*). These leads face the anterior wall.

on the ECG forever. With early reperfusion, Q waves may not develop. T wave inversion may persist for months after a STEMI.

Patients with NSTEMI or UA usually have transient thrombosis or incomplete coronary occlusion. ECG changes with UA or an NSTEMI include ST depression and/or T wave inversion in the leads facing the area of ischemia or infarction (Figs. 37.4 A,37.12, 37.14, and Table 37.14). Both groups may present with angina and have the same ECG changes. The only way to tell if the patient is having an NSTEMI or UA is by drawing cardiac biomarkers. The biomarkers will be high in the NSTEMI patient but normal in the patient with UA. NSTEMI patients do not develop pathologic Q waves on the ECG.

Because MI is a dynamic process that evolves over time, serial ECGs are done to show the evolution of ischemia, injury, infarction, and resolution of the infarction.

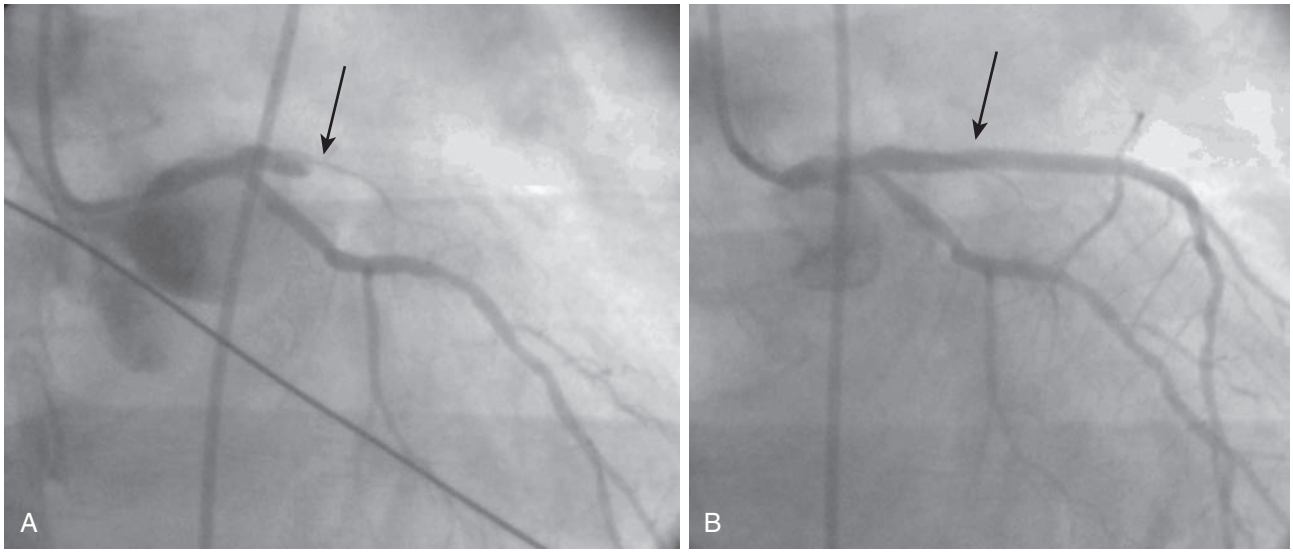

Fig. 37.15 (A) 100% thrombotic occlusion of the left anterior descending artery *(arrow)* causing a STEMI. (B), After PCI with a drug-coated stent to the left anterior descending artery *(arrow)*. Blood flow is restored to the entire left anterior descending artery.

Serum Cardiac Biomarkers

Serum cardiac biomarkers are proteins released into the blood from necrotic heart muscle after an MI (see Table 35.9). These biomarkers are important in the diagnosis of MI. The presence of biomarkers helps distinguish between UA (negative biomarkers) and NSTEMI (positive biomarkers).

Cardiac-specific troponin biomarkers are highly specific indicators of MI. There are 2 subtypes: cardiac-specific troponin T (cTnT) and cardiac-specific troponin I (cTnI). Serum levels of cTnI and cTnT increase 4 to 6 hours after the onset of MI, peak at 10 to 24 hours, and return to baseline over 10 to 14 days. Serial sets of conventional cardiac-specific troponins are drawn over 24 hours (e.g., every 6 hours × 3). These tests are the standard cardiac biomarker to identify MI.

A high-sensitivity cardiac troponin test (hs-cTn) provides more rapid detection of MI compared to the conventional cardiac-specific troponin assays, allowing for a quicker diagnosis. Serum levels of hs-cTn rise within 1 hour of cardiac injury and stay high for 7 to14 days. A second hs-cTn is drawn 2 to 3 hours after the first one if STEMI is ruled out.

CK levels begin to rise about 6 hours after an MI, peak at about 18 hours, and return to normal within 24 to 36 hours. The CK enzymes are fractionated into bands. The CK-MB band is specific to heart muscle cells and helps to quantify myocardial damage. CK-MB is a less sensitive marker for myocardial injury compared to troponin.[12]

Cardiac Catheterization

The patient with a STEMI must undergo cardiac catheterization within 90 minutes of presentation to the emergency department (ED) or receive thrombolytic therapy within 30 minutes in agencies without PCI capability. The goal is to open the totally occluded artery and limit the infarction size (Fig. 37.15). The patient with UA or NSTEMI usually undergoes cardiac catheterization during the hospitalization to diagnose and evaluate the extent of the disease. They do not need an emergent catheterization. Guidelines suggest that it is reasonable for them to undergo cardiac catheterization within 12 to 72 hours after presentation.[12] If appropriate, a PCI is done at this time. Depending on the findings and patient factors, some patients are treated with medical therapy. Others are referred for CABG surgery.

INTERPROFESSIONAL CARE: ACUTE CORONARY SYNDROME

It is very important to quickly diagnose and treat a patient with ACS to preserve heart muscle. Initial management of the patient with chest pain most often occurs in the ED. Table 37.15 presents the emergency care of the patient with chest pain. Obtain vital signs, a 12-lead ECG, and start continuous ECG monitoring. Position the patient in an upright position unless contraindicated and start O_2 by nasal cannula to keep O_2 saturation above 93%. Obtain IV access for drug administration. Give SL NTG and 162 to 325 mg of chewable aspirin if not given before arrival at the ED. Give morphine for pain unrelieved by NTG. Give a high-dose statin (e.g., atorvastatin 80 mg). Obtain baseline labs including cardiac biomarkers.

If the ECG shows ST elevation, the patient is taken directly for cardiac catheterization in PCI-capable hospitals. Thrombolytic therapy is started if the patient is unable to be quickly transported to a PCI-capable hospital. If the ECG shows ST depression and/or T wave inversion, we admit the patient to an ICU or telemetry unit for ongoing care. Dysrhythmias are treated according to agency protocols. Serial cardiac biomarkers are drawn until the peak level drops off. UA and NSTEMI patients start on heparin or GP IIb/IIIa inhibitors (e.g., eptifibatide [Integrilin]) either before catheterization or at the time of PCI. GP IIb/IIIa inhibitors may be used during PCI for STEMI patients. Fig. 37.5 shows the interprofessional care of ACS.

TABLE 37.15 EMERGENCY MANAGEMENT

Chest Pain

Etiology	Assessment Findings	Interventions
Cardiovascular • Aortic aneurysm • Aortic valve disease • Dysrhythmia • MI • Myocardial ischemia • Pericarditis ***Respiratory*** • Costochondritis • Pleurisy • Pneumonia • Pneumothorax, hemothorax • Pulmonary edema • Pulmonary embolus ***Chest Trauma*** • Cardiac tamponade • Flail chest • Great vessel injury • Hemothorax • Pulmonary contusion • Rib/sternal fracture ***Gastrointestinal*** • Cholecystitis • Esophagitis • GERD • Hiatal hernia • Peptic ulcer ***Others*** • Acute anxiety • Drugs (e.g., cocaine) • Strenuous exercise • Stress	• Angina, pain in chest, neck, jaw, arm, or shoulder • Anxiety • Decreased or increased BP • Cold, clammy skin • Decreased O_2 saturation • Diaphoresis • Dyspnea, tachypnea • Dysrhythmias • Epigastric pain • Feeling of impending doom • Indigestion, heartburn • Irregular HR, murmurs • Narrowed pulse pressure • Nausea and vomiting • Palpitations • Pericardial friction rub • Syncope, loss of consciousness • Tachycardia, bradycardia • Unequal BP readings in upper extremities • Weakness	***Initial*** • If unresponsive, assess circulation, airway, and breathing. • If responsive, monitor airway, breathing, and circulation (ABC). • Position patient upright unless contraindicated. • Give O_2 by nasal cannula or nonrebreather mask. • Obtain baseline vital signs, including O_2 saturation. • Auscultate heart and breath sounds. • Obtain 12-lead ECG. • Insert 2 IV catheters. • Assess pain using PQRST mnemonic (Table 37.8). • Medicate for pain as ordered (e.g., nitroglycerin, morphine). • Start continuous ECG monitoring and identify underlying rhythm. • Obtain baseline blood work (e.g., cardiac biomarkers, CBC, basic metabolic panel, coagulation studies). • Obtain portable chest x-ray. • Assess for contraindications for antiplatelet, anticoagulant, or thrombolytic therapy, or percutaneous coronary intervention as appropriate. • Give aspirin for heart-related chest pain unless contraindicated. • Give a high-dose statin. • Give antidysrhythmic drugs for life-threatening dysrhythmias. ***Ongoing Monitoring*** • Monitor ABCs, vital signs, level of consciousness, heart and breath sounds, heart rhythm, and O_2 saturation. • Assess and record response to drugs (e.g., decrease in chest pain) and remedicate or titrate drugs (e.g., nitroglycerin) as needed. • Provide reassurance and emotional support to patient and caregiver. • Explain all interventions and procedures to patient and caregiver in simple terms. • Anticipate need for intubation if respiratory distress is evident. • Prepare for CPR and defibrillation if cardiac arrest is evident. • Anticipate need for transcutaneous pacing for symptomatic bradycardia or heart block.

Emergent Percutaneous Coronary Intervention

Emergent PCI is the first line of treatment for patients with confirmed STEMI (i.e., ST-elevation and positive cardiac biomarkers). The goal is to open the blocked artery within 90 minutes of arrival to an agency that has interventional cardiac catheterization to limit the infarction size. In this case, the patient undergoes a cardiac catheterization to locate and assess the severity of the blockage(s), determine the presence of collateral circulation, and evaluate LV function. During the procedure, BMS or DES is inserted into the blocked coronary artery (Figs. 37.6 and 37.15). If other coronary arteries are found to have significant blockage during the emergent catheterization, PCI may be done at the same time on the noninfarct arteries if the patient is hemodynamically stable.[15] Often STEMI patients with other coronary artery blockages are discharged and brought back later for an elective PCI unless they have ongoing symptoms. After PCI for ACS, DAPT (low-dose aspirin plus ticagrelor [Brilinta] or prasugrel [Effient]) is continued for 1 year. Aspirin is continued forever. Patients with severe LV dysfunction may require VAD therapy and/or inotropes (e.g., dobutamine). A few patients need emergent CABG surgery.

The advantages of PCI (compared to CABG surgery) include (1) faster reperfusion to limit infarction size; (2) it is performed with IV sedation and local anesthesia; (3) the patient is ambulatory shortly after the procedure; (4) the length of stay is about 3 to 4 days after an uncomplicated MI with PCI compared with the 4 to 6 days with CABG surgery, thus reducing hospital costs; and (5) the patient can return to work several weeks sooner after PCI, compared with a 6- to 8-week convalescence after CABG.

Complications of PCI that may lead to emergent CABG include dissection or rupture of the coronary artery, abrupt artery closure, acute stent thrombosis, and failure to cross the blockage with a balloon or stent. There is a risk that the infarction could be extended if a part of the plaque dislodges and blocks the vessel distal to the catheter.

Thrombolytic Therapy

Thrombolytic (fibrinolytic) therapy is indicated only for patients with a STEMI in agencies that do not have an interventional

CHECK YOUR PRACTICE

Your patient had an emergent PCI 2 days ago for a STEMI. You are about to give him his morning medications, which include clopidogrel and aspirin. The patient asks you if he will need to take these medications forever.

- What would you tell the patient?

cardiac catheterization laboratory or when one is too far away to transfer the patient quickly. Patients admitted to non–PCI-capable hospitals can be moved to a PCI-capable hospital if the first medical contact to balloon inflation (PCI) time can be done within 120 minutes.[23] Treatment of STEMI with thrombolytic therapy aims to limit the infarction size by dissolving the thrombus in the coronary artery to reperfuse the heart muscle. The goal is to give the thrombolytic within 30 minutes of the patient's arrival to the ED.

Indications and Contraindications

All thrombolytics (e.g., tenecteplase, alteplase) are given IV (Table 37.12). The cost, efficacy, and ease of administration guide the choice of a thrombolytic agent. Although they have different pharmacokinetics, they all open the blocked artery by lysis of the thrombus. Because thrombolytics lyse the pathologic clot, they may also lyse other clots (e.g., a postoperative site). Patient selection is important because minor or major bleeding can be a complication of therapy.

Inclusion criteria for thrombolytic therapy are (1) chest pain less than 12 hours with 12-lead ECG findings consistent with a STEMI and (2) no absolute contraindications (Table 37.16). Patients with chest pain lasting 12 to 24 hours with ECG changes supporting STEMI may be considered for thrombolytic therapy.[23]

Procedure

Each hospital has a protocol for giving thrombolytic therapy. We complete 2 common steps before starting thrombolytic therapy: (1) draw blood to obtain baseline laboratory values and (2) start 2 or 3 lines for IV therapy. Perform all other invasive procedures before giving the thrombolytic agent to reduce the risk of bleeding.

Depending on the drug selected, therapy is given either by an IV bolus or via an infusion over up to 3 hours. Note the time when therapy begins. Monitor the patient during and after the thrombolytic. Assess heart rhythm, vital signs, and pulse oximetry. Assess the heart and lungs often to evaluate the patient's response to therapy. Regularly assess for changes in neurologic status that may indicate cerebral bleeding.

When reperfusion occurs (e.g., a blocked coronary artery is opened and blood flow is restored to the heart muscle), several clinical signs can be seen. The most reliable sign is the return of the ST segment to baseline on the ECG. Other signs include resolution of chest pain and an early, rapid rise of the serum cardiac biomarkers. These levels increase as the necrotic heart cells release proteins into the circulation after perfusion is restored to the area. The presence of *reperfusion dysrhythmias* (e.g., accelerated idioventricular rhythm) is a less reliable sign of reperfusion. These dysrhythmias are generally self-limiting and do not require aggressive treatment.

A major concern with thrombolytic therapy is reocclusion of the artery. The site of the thrombus is unstable, and another clot may form. Therefore, IV heparin therapy is started. If another clot forms, the patient will describe similar chest pain symptoms, and ECG changes will return. Patients receiving thrombolytic therapy should be moved to an agency with PCI capabilities as soon as possible so PCI can be done if thrombolytic therapy fails.

The main complication with thrombolytic therapy is bleeding. Ongoing nursing assessment is essential. Minor bleeding (e.g., surface bleeding from IV sites or gingival bleeding) is expected. Control bleeding by applying manual pressure followed by a pressure dressing or ice packs.

TABLE 37.16 Contraindications for Thrombolytic Therapy

Absolute Contraindications

- Active internal bleeding
- History of intracranial hemorrhage
- Intracranial or intraspinal surgery within 2 months
- Known structural or vascular abnormality (e.g., arteriovenous malformation)
- Known intracranial cancer (primary or metastatic)
- Recent (within past 3 months) ischemic stroke
- Severe uncontrolled hypertension
- Significant closed-head or facial trauma within past 3 months
- Suspected aortic dissection
- For streptokinase, prior treatment within the past 6 months

Relative Contraindications

- Active peptic ulcer disease
- Current use of oral anticoagulants
- Dementia
- History of chronic, severe, poorly controlled hypertension
- Known intracranial pathology not covered in absolute contraindications
- Major surgery (<3 weeks)
- Noncompressible vascular punctures
- Pregnancy
- Prior ischemic stroke (>3 months ago)
- Recent (within 2–4 weeks) internal bleeding
- Significant hypertension on presentation (SBP >180 mm Hg or DBP >110 mm Hg)
- Traumatic or prolonged (>10 min) cardiopulmonary resuscitation

Source: O'Gara PT, Kushner FG, Ascheim DD, et al: 2013 ACCF/AHA guideline for the management of ST-elevation myocardial infarction: a report of the ACC/AHA Task Force on Practice Guidelines, *Circ* 127:e362, 2013.

SAFETY ALERT

Thrombolytic Therapy

- Minor or major bleeding can occur with thrombolytic drugs.
- Place 2 or 3 IV lines before starting thrombolytic therapy.
- If signs and symptoms of major bleeding occur (e.g., drop in BP, increase in HR, sudden change in the patient's mental status, blood in the urine or stool), stop the drug and notify the HCP.

Drug Therapy

See Table 37.12 and Fig. 37.5 present drug therapy for patients with chronic stable angina and ACS. When a patient presents with suspected ACS, antiplatelet therapy (e.g., chewable aspirin for UA patients plus ticagrelor for STEMI and NSTEMI patients), IV NTG, and high-dose atorvastatin (80 mg) are drug treatments of choice. Since STEMI patients go directly to cardiac catheterization, systemic anticoagulation with either subcutaneous LMWH or IV UH is used only for UA and NSTEMI patients. GP IIb/IIIa inhibitors may be used for NSTEMI patients or during PCI for STEMI patients. DAPT should continue for 1 year after a STEMI or NSTEMI whether the patient receives a stent or not. Aspirin should never be stopped. Oral β-blockers are started within the first 24 hours if there are no contraindications (e.g., HF, heart block, hypotension). Calcium channel blockers are used if the patient cannot tolerate β-blockers. They are used cautiously after MI because they can decrease contractility. ACE inhibitors are added after an MI if there are no contraindications. Nitrates may be used for persistent chest pain.

IV Nitroglycerin

IV NTG is used in the initial treatment of the patient with ACS. SL NTG can be used until the IV NTG is prepared. The goal of therapy is to reduce angina pain and improve coronary blood flow. IV NTG decreases preload and afterload while increasing the myocardial O_2 supply. The onset of action is immediate. Titrate NTG to eliminate chest pain. Because hypotension is a common side effect, closely monitor BP. Patients who become hypotensive may be volume depleted and may benefit from an IV fluid bolus. Closely assess for volume overload after the bolus (e.g., crackles on lung auscultation).

Morphine

Morphine is the drug of choice for chest pain that is unrelieved by NTG. As a vasodilator, it decreases cardiac workload by lowering myocardial O_2 consumption, reducing contractility, and decreasing BP and HR. Morphine can help reduce anxiety and fear. In rare situations, morphine can depress respirations. Monitor patients for signs of bradypnea or hypotension, which are conditions to avoid in myocardial ischemia and infarction.

β-Adrenergic Blockers

β-blockers decrease myocardial O_2 demand by reducing HR, BP, and contractility. They are given to patients who are not at risk for complications of MI (e.g., cardiogenic shock, bradycardia, hypotension). They reduce the risk for reinfarction and HF. Therapy continues indefinitely.

Angiotensin-Converting Enzyme Inhibitors and Angiotensin Receptor Blockers

ACE inhibitors should be started within the first 24 hours if the BP is stable and there are no contraindications. They are taken indefinitely in patients after STEMI or NSTEMI, with HF, or an EF of 40% or less. ACE inhibitors can help prevent ventricular remodeling and prevent or slow the progression of HF. ARBs are an option if patients cannot tolerate ACE inhibitors (e.g., angioedema, cough).

Antidysrhythmic Drugs

Dysrhythmias are the most common complications after an MI. In general, they are self-limiting and not treated aggressively unless they are life threatening (e.g., sustained VT). Chapter 39 discusses the drugs used in the treatment of dysrhythmias.

Lipid-Lowering Drugs

All patients with ACS need a lipid panel. Patients with ACS or CAD should receive lipid-lowering drugs indefinitely, unless contraindicated (Table 37.6). Patients on a lipid lowering drug at the time of the MI should have the dose maximized or switched to a more potent statin.

Aldosterone Antagonists

Aldosterone antagonists (e.g., spironolactone, eplerenone) can decrease mortality after a STEMI regardless of the LV function.[24] One of these drugs should be added if there are no contraindications (e.g., hyperkalemia, increased creatinine).

Stool Softeners

After an MI, the patient may be predisposed to constipation because of bed rest and opioid drugs. Stool softeners (e.g., docusate sodium) prevent straining and the resultant vagal stimulation from the *Valsalva maneuver*. Vagal stimulation produces bradycardia and can provoke dysrhythmias. A laxative may be used, if needed.

Nutrition Therapy

Initially, patients may be NPO (nothing by mouth) except for water until stable (e.g., pain free, nausea resolved). Advance the diet as tolerated to a low-salt, low-saturated-fat, and low-cholesterol diet (Tables 37.4 and 37.5).

❖ NURSING MANAGEMENT: ACUTE CORONARY SYNDROME

◆ Assessment

Table 37.17 presents the subjective and objective data to obtain from a patient with ACS.

◆ Clinical Problems

Clinical problems for the patient with ACS may include

- Impaired cardiac function
- Pain
- Anxiety
- Activity intolerance

More information on clinical problems of patients with ACS is in eNursing Care Plan 37.1 available on the website for this chapter.

◆ Planning

Nursing care focuses on the priority problems of pain and impaired cardiac function. The immediate goals for a patient

TABLE 37.17 NURSING ASSESSMENT

Acute Coronary Syndrome

Subjective Data

Important Health Information

Health history: Previous history of CAD, chest pain/angina, MI, valve disease (e.g., aortic stenosis), heart failure, or cardiomyopathy. History of hypertension, diabetes, anemia, lung disease, hyperlipidemia. History of premature CAD in a family member

Medications: Use of antiplatelets, anticoagulants, nitrates, ACE inhibitors, β-blockers, calcium channel blockers, antihypertensive drugs, lipid-lowering drugs, over-the-counter drugs (e.g., vitamin and herbal supplements)

History of present illness: Description of events related to current illness (Table 37.9), including any self-treatments and response

Functional Health Patterns

Health perception–health management: Sedentary lifestyle, tobacco use, exposure to environmental smoke, drug use

Nutritional-metabolic: Indigestion, heartburn, nausea, belching, vomiting

Elimination: Urinary urgency or frequency, straining at stool

Activity-exercise: Palpitations, dyspnea, dizziness, weakness

Cognitive-perceptual: Substernal chest pain or pressure (squeezing, constricting, aching, sharp, tingling), radiation to jaw, neck, shoulders, back, or arms (Table 37.8)

Coping–stress tolerance: Stressful lifestyle, depression, anger, anxiety, feeling of impending doom

Objective Data

General

Anxious, fearful, restless, distressed

Cardiovascular

Tachycardia or bradycardia, pulsus alternans (alternating weak and strong heartbeats), pulse deficit, dysrhythmias (especially ventricular), murmur, S_3, S_4, ↑ or ↓ BP

Skin

Cool, clammy, pale skin

Possible Diagnostic Findings

Positive serum cardiac biomarkers, ↑ serum lipids; ↑ WBC count. Pathologic Q wave, ST segment elevation, and/or ST-T wave abnormalities on ECG. Heart enlargement, calcifications, or pulmonary congestion on chest x-ray. Abnormal wall motion with stress echocardiogram or resting echocardiogram. Positive findings on cardiac catheterization.

with ACS include (1) pain relief, (2) quick and appropriate treatment, and (3) preservation of heart muscle. During the hospitalization, the overall goals include (1) effective coping with illness-associated anxiety, (2) participation in a rehabilitation plan, and (3) reduce risk factors.

Implementation

Acute Care

Monitor vital signs and pulse oximetry frequently (e.g., every hour) during the first few hours after admission to the ICU or telemetry unit and closely thereafter, according to agency protocol. Start continuous ECG monitoring. Obtain serial 12-lead ECGs and draw serial cardiac biomarkers. Maintain bed rest according to agency policy and gradually increase activity unless contraindicated.

For patients with UA and NSTEMI, heparin (UH or LMWH) is used to prevent microemboli from forming and causing further chest pain. DAPT (e.g., aspirin and ticagrelor) is recommended for STEMI and NSTEMI patients (with or without a stent) (Table 37.12). UA patients receive aspirin. If they have a stent placed, they receive DAPT. Cardiac catheterization is an option for patients with UA and NSTEMI after being stabilized or if angina returns or increases in severity. Depending on the results, options include risk factor reduction with medical management, PCI, or CABG surgery.

For patients with STEMI, reperfusion therapy begins as soon as possible. *Reperfusion therapy* includes emergent PCI (preferred, for PCI-capable hospitals) or thrombolytic therapy (in hospitals not capable of performing PCI). The goal in the treatment of STEMI is to save as much heart muscle as possible. Technical advances in PCI technology have almost eliminated CABG surgery as the primary treatment for patients with STEMI unless there is another reason to perform surgery (e.g., ventricular septal rupture, papillary muscle rupture).

Pain

Provide NTG, morphine, and supplemental O_2 as needed to eliminate or reduce chest pain. Ongoing evaluation and documentation of the effectiveness of the interventions is important. Once pain is relieved, some patients interpret the absence of pain as an absence of heart disease. Provide information about the importance of continued therapy to limit myocardial damage.

Monitoring

Maintain continuous ECG monitoring. Treat life-threatening dysrhythmias quickly. During the initial period after MI, sustained VT and VF are the most common lethal dysrhythmias.[23] In many patients, PVCs precede these dysrhythmias. We usually do not treat isolated PVCs. VT is treated if it is sustained VT. Treatment of nonsustained VT depends on the patient's hemodynamic status.

Using the bedside ST segment monitor, assess the patient's ST segments for shifts above or below the baseline of the ECG (signals reinfarction or ischemia). Silent ischemia, noted only by ST segment depression and/or T wave inversion, occurs without subjective symptoms (e.g., chest pain). Notify the HCP if you see ST segment changes with or without clinical symptoms.

Perform a physical assessment to detect changes from the patient's baseline findings. Assess for signs and symptoms of early HF (e.g., dyspnea, tachycardia, crackles, distended neck veins, an S3 heart sound). Monitor intake and output. If a nasal cannula is being used, check the nares for irritation or dryness, which can cause considerable discomfort.

Rest and Comfort

Promoting rest and comfort for the patient with any degree of heart damage is important. There is no evidence for prolonged bed rest for the patient with an uncomplicated MI (e.g., angina resolved, no signs of complications). Their activity should slowly increase. A patient with an uncomplicated STEMI may sit in a chair within a few hours after the event, especially if the radial

TABLE 37.18 Phases of Rehabilitation After Acute Coronary Syndrome

Phase I: Hospital
- Occurs while the patient is still hospitalized
- Activity level depends on severity of angina or MI
- Patient may first sit up in bed or chair, perform range-of-motion exercises and self-care (e.g., washing, shaving), and progress to walking in hallway and limited stair climbing
- Attention focuses on management of chest pain, anxiety, dysrhythmias, and complications

Phase II: Early Recovery
- Begins after the patient is discharged
- Usually lasts from 2 to 12 weeks and is held in an outpatient facility but may be done in the home
- Activity level is gradually increased under the supervision of the cardiac rehabilitation team and with ECG monitoring
- Team may suggest that physical activity (e.g., walking program) be started at home
- Information about risk factor reduction is provided at this time

Phase III: Late Recovery
- Long-term maintenance program
- Individual physical activity programs are designed and implemented at home, a local gym, or the rehabilitation center
- Patient and caregiver restructure lifestyles and roles
- Therapeutic lifestyle changes should become lifelong habits
- Medical supervision recommended

artery was used for the PCI. A period of bed rest may be ordered after a large STEMI. The use of the bathroom, a commode, or a bedpan is based on patient preference and hemodynamic status. UA and NSTEMI patients may sit in a chair when angina is resolved if there are no complications.

When sleeping or resting, the body requires less work from the heart than it does when active. It is important to plan nursing and other interventions to ensure adequate rest periods free from interruption. Comfort measures that can promote rest include a quiet environment, use of relaxation techniques (e.g., music therapy, guided imagery), and assurance that staff is nearby and responsive to the patient's needs.

The patient must understand the reasons why activity is limited. Gradually increase the patient's heart workload through more demanding physical tasks. Before discharge, it is important that the patient achieve an activity level adequate for home care. Discuss and encourage outpatient cardiac rehabilitation. Table 37.18 outlines the phases of cardiac rehabilitation.

Anxiety

A degree of anxiety is present in all patients with ACS. Your role is to identify the source of anxiety and assist the patient in reducing it. If the patient is afraid of being alone, allow a caregiver to sit by quietly and check the patient frequently. If a source of anxiety is the unknown, explore these concerns with the patient. For anxiety caused by lack of information, provide teaching based on the patient's stated need and level of understanding. Answer the patient's questions with clear, simple explanations.

CHECK YOUR PRACTICE

You are walking in the hallway with a 64-year-old woman who had an MI 3 days ago. She is being discharged tomorrow. She is visibly anxious and irritable, wringing her hands, and talking very fast. She tells you, "My heart is pounding." You do not know if she is anxious or about to have another MI.
- What should you do?

Begin teaching at the patient's level. For example, many patients are not ready to learn about the pathology of CAD. The earliest questions usually relate to how the disease affects perceived control and independence. Examples include
- When will I leave the ICU?
- When can I be out of bed?
- When will I be discharged?
- When can I return to work?
- How many changes will I have to make in my life?
- Will this happen again?

Tell the patient that more complete teaching will begin once they are feeling stronger. Often the patient may not be able to ask the most serious concern of ACS patients: Am I going to die? Even if a patient denies this concern, it is helpful for you to start a conversation by remarking that fear of dying is a common concern among most patients who have had ACS. This gives the patient "permission" to talk about an uncomfortable and fearful topic.

Emotional and Behavioral Reactions

Patients' emotional and behavioral reactions vary, but often follow a predictable pattern (Table 37.19). Your role is to understand what the patient is currently experiencing and to support the use of constructive coping styles.

Assess the support structure of the patient and caregiver. Determine how you can help maximize the support system. Often the patient is separated from their support system at the time of hospitalization. With patient permission, you can talk with the caregiver(s) about the patient's progress and support the caregivers who will provide the necessary assistance to the patient. Open visitation is helpful in decreasing anxiety and increasing support for the patient with ACS.[25] Help the patient identify additional support systems (e.g., spiritual care, Mended Hearts) that can assist during the hospital stay and/or after discharge.

Patient Teaching

Patient teaching is needed at every stage of the patient's hospitalization and recovery (e.g., ED, telemetry unit, home). Give patients and caregivers the tools they need to make informed decisions about their health. For teaching to be meaningful, the patient must be aware of the need to learn. Careful assessment of the patient's health literacy and learning needs helps you set realistic goals (see Chapter 4).

The timing of the teaching is important. When patients and caregivers are in crisis, they may not be ready to learn new information. Answer the patient's questions in simple, brief terms. The answers often need repetition. When the shock accompanying a crisis subsides, the patient and caregiver are better able to focus on new and more detailed information.

TABLE 37.19 Psychosocial Responses to Acute Coronary Syndrome

Anger and Hostility
- Often expressed as, "Why did this happen to me?"
- May be directed at family, staff, or medical regimen

Anxiety and Fear
- Fears long-term disability and death
- Overtly displays apprehension, restlessness, insomnia, tachycardia
- Less overtly displays increased verbalization, projection of feelings to others, hypochondriasis
- Fears activity
- Fears recurrent chest pain, heart attacks, and sudden death

Denial
- May have history of ignoring signs and symptoms related to heart disease
- Minimizes severity of health condition
- Ignores activity restrictions
- Avoids discussing illness or its significance

Dependency
- Totally reliant on staff
- Unwilling to perform tasks or activities unless approved by HCP
- Wants ECG monitoring to continue
- Hesitant to leave the ICU, telemetry unit, or hospital

Depression
- Mourns loss of health, altered body function, and changes in lifestyle
- Realizes seriousness of situation
- Begins to worry about future implications of health problem
- Shows manifestations of withdrawal, crying, apathy
- May be more evident after discharge

Realistic Acceptance
- Focuses on optimum rehabilitation
- Plans changes compatible with altered cardiac function
- Actively engages in lifestyle changes to address modifiable risk factors

Limit your use of medical terms. For example, you are caring for a patient with UA who asks you why he has chest tightness when he climbs stairs. Begin by explaining that the heart is a muscle that works as a pump. Like all muscles, it needs O_2 to work (or pump) properly. When fat and cholesterol block the blood vessels supplying the heart muscle with O_2, less O_2 is available to the muscle. As a result, the pump cannot work well. Tell the patient that the chest tightness (angina) is the heart's message that it is having trouble doing its work. Use a model of the heart to support what you are explaining.

Anticipatory guidance involves preparing the patient and caregiver for what to expect during recovery and rehabilitation. By learning what to expect, the patient gains a sense of control.

The idea of perceived control is operationalized as the process by which the patient makes decisions by cutting back. Cutting back is one way of reducing the psychologic and physiologic losses after ACS (or any other life-changing event). For example, a middle-aged man who smokes 2 packs of cigarettes a day, is 20 lb. overweight, and gets no physical exercise may feel overwhelmed. He may decide that he can live with a weight reduction plan and will get more exercise (though not daily) but that it is not possible for him to quit smoking. He believes that because he is changing 2 of his 3 risk factors, he will be healthier. Ideally, the tobacco risk factor should be a priority for this patient. If the patient does not accept information about risks and effects of tobacco use, you must respect their choices.

In addition to teaching the patient and caregiver what they wish to know, several types of information are essential in achieving optimal health. Table 37.20 presents a teaching guide for the patient with ACS and the caregiver.

TABLE 37.20 PATIENT & CAREGIVER TEACHING

Acute Coronary Syndrome

Include the following information in the teaching plan for the patient with acute coronary syndrome and the caregiver:
- Signs and symptoms of angina and MI and what to do should they occur (e.g., how to take nitroglycerin)*
- When and how to seek help (e.g., contact 911)[a]
- Anatomy and physiology of the heart and coronary arteries
- Cause and effect of CAD
- Definition of terms (e.g., CAD, angina, MI, heart failure)
- Identification of and plan to decrease risk factors[a] (Tables 37.1, 37.2, 37.3, 37.4, and 37.5)
- Reasons for tests and treatments (e.g., ECG monitoring, blood work, cardiac catheterization), activity limitations and rest, diet, and drugs[a]
- Appropriate expectations about recovery (anticipatory guidance)
- Resumption of work, physical activity, sexual activity
- Measures to promote recovery and health (e.g., cardiac rehabilitation)
- Importance of the gradual, progressive resumption of activity[a]

[a] Identified by patients as important to learn before discharge.

Physical Activity

Physical activity, an integral part of rehabilitation, is necessary for optimal physiologic functioning and psychologic well-being. It has a direct, positive effect on maximal O_2 uptake, increasing CO, decreasing blood lipids, decreasing BP, increasing blood flow through the coronary arteries, increasing muscle mass and flexibility, improving the psychologic state, and assisting in weight loss and control. A regular schedule of physical activity, even after many years of sedentary living, is beneficial.

One method of identifying levels of physical activity is by using **metabolic equivalent (MET)** units: 1 MET is the amount of O_2 needed by the body at rest—3.5 mL of O_2 per kilogram per minute, or 1.4 cal/kg of body weight per minute. The MET determines the energy costs of various exercises (Table 37.21).

In the hospital, we gradually increase the activity level so that by the time of discharge the patient can tolerate moderate-energy activities of 3 to 6 METs. Many patients with UA or an uncomplicated MI are in the hospital for 3 or 4 days. By day 2, the patient can walk in the hallway and begin climbing a few steps. Because of the short hospital stay, it is critical to give the patient specific guidelines for physical activity so that overexertion will not occur. Tell the patient to always "listen to what your body is saying"—the most important aspect of recovery.

Teach patients that the AHA recommends 30 minutes of moderate-intensity aerobic activity (e.g., brisk walking) at least 5 days a week.[10] For patients who have been hospitalized for

TABLE 37.21 Energy Expenditure in Metabolic Equivalents (METs)

Low-Energy Activities (<3 METs or <3 cal/min)

Activities in Hospital

- Eating
- Resting supine
- Washing hands, face

Activities Outside Hospital

- Driving a car
- Painting, seated
- Sewing by machine
- Sweeping floor

Moderate-Energy Activities (3–6 METs or 3–5 cal/min)

Activities in Hospital

- Showering
- Sitting on bedside commode
- Using bedpan
- Walking at 3–4 mph

Activities Outside Hospital

- Cycling at 5.5 mph on level ground
- Going up a flight of stairs
- Golfing
- General gardening
- Ironing, standing
- Painting, standing

High Energy Activities (6–8 METs or 6–8 cal/min)

- Mowing lawn using walking mower
- Performing carpentry
- Walking 5 mph

Very-High-Energy Activities (>9 METs or >9 cal/min)

- Cross-country skiing
- Cycling at >13 mph
- Running at >6 mph
- Shoveling heavy snow (not recommended for any patient with CAD)

a coronary event (e.g., PCI, UA, NSTEMI, STEMI), they must "work up" to 30 minutes of exercise per day. An exercise stress test may be done after hospitalization to assess for chest pain with activity and help guide physical activity. The patient who has been physically inactive and just starting an exercise program should do so under supervision whenever possible. Cardiac rehabilitation, either in a group or home setting, is recommended.[10,12,23,26]

Teach patients to check their HR. Some patients may use technology (e.g., cell phone applications, fitness trackers) to check their HR. The patient should know the limits within which to exercise. Tell the patient that the HR should return to the resting HR within a few minutes of stopping the exercise. Tell the patient to stop exercising and rest if chest pain or shortness of breath occurs. The key factor is the patient's response to physical activity in terms of symptoms rather than absolute HR, especially since many patients are taking β-blockers and may not be able to reach a target HR. You cannot overstress this point. Basic physical activity guidelines for patients after ACS follow the FITT formula (Table 37.3).

The basic categories of physical activity are isometric (static) and isotonic (dynamic). Most daily activities are a mixture of the two. *Isometric activities* involve the development of tension during muscular contraction but produce little or no change in muscle length or joint movement. Lifting, carrying, and pushing heavy objects are isometric activities. These activities are associated with the Valsalva maneuver and may cause a vasovagal response. Because the HR and BP change rapidly during isometric work, they should limit isometric exercises.

Isotonic activities involve changes in muscle length and joint movement with rhythmic contractions at relatively low muscular tension. Walking, jogging, swimming, bicycling, and jumping rope are examples of activities that are mostly isotonic. Isotonic exercise can put a safe, steady load on the heart and lungs and improve the circulation to other organs.

Women who have an MI often have poor adherence to a regular physical activity program.[4] Women often are caregivers for everyone but themselves. They may prioritize a physical activity program as less important than caring for others. Often women describe continued fatigue.

Another factor linked to poor adherence to a physical activity program after MI is depression. Depression is common among patients with CAD, especially in women.[4] Routinely screen for depression and recommend referral for treatment as appropriate. Many patients recover physically from ACS or CABG surgery but do not attain psychologic well-being.

Cardiac Rehabilitation

Cardiac rehabilitation is the restoration of a person to an optimal state of function in 6 areas: (1) physiologic, (2) psychologic, (3) mental, (4) spiritual, (5) economic, and (6) vocational. All patients who have had UA, an MI, a PCI, or CABG surgery should receive a referral for outpatient or home-based cardiac rehabilitation (Table 37.18). Exercise-based cardiac rehabilitation is a Class I recommendation from the AHA for any patient with HF or a cardiac event.[9,12,15]

Unfortunately, cardiac rehabilitation is often not recommended, and participation is less than optimal. Outpatient programs are helpful, but not all patients are able to take part in them due to cost, location, and travel limitations (Box 37.4). Home-based cardiac rehabilitation programs then provide an alternative.[26] Maintaining contact (e.g., telehealth, exercise logs, Internet) with the patient is a key to the success of these programs.

In considering rehabilitation, the patient must recognize that CAD is a chronic disease. It is not curable. Therefore, they may need basic lifestyle changes to promote recovery and future health. Tell patients that recovery takes time, and resuming physical activity after ACS or heart surgery is slow and gradual. However, with appropriate and adequate supportive care, recovery is more likely.

Resuming Sexual Activity

It is important to include sexual counseling for heart patients and their partners. This often-neglected area of discussion may be difficult for both the patient and HCP to approach. However, the patient's concern about resumption of sexual activity after

BOX 37.4 EVIDENCE-BASED PRACTICE

Participating in Cardiac Rehabilitation

You are caring for M.M., a 79-year-old male who had a NSTEMI and PCI with stent placement 3 days ago. The HCP prescribed cardiac rehabilitation 3 times per week for 12 weeks, to begin in 4 weeks. M.M. and his wife live in a rural area and express concern that it will be hard for M.M. to travel to attend the nearest center-based program 40 min from their home. They ask you if M.M. needs to take part in the rehabilitation program or if there are other options they can pursue.

Making Clinical Decisions

Synthesis of Best Available Evidence

Cardiac rehabilitation programs help to aid in recovery and prevent further cardiac events. They typically include exercise, healthy lifestyle education, and/or psychologic interventions, such as stress reduction counseling. Programs are available in supervised centers or in the home. Home-based programs are an option to increase access and participation in cardiac rehabilitation. The programs are similar in terms of outcomes of mortality, exercise capacity, and health-related quality of life.

Clinician Expertise

You know that taking part in a home-based or center-based cardiac rehabilitation program will help to aid in recovery and prevent further cardiac events after a NSTEMI.

Patient Preferences and Values

M.M. and his wife want him to take part in cardiac rehabilitation but express concern about attending a hospital-based program.

Implications for Nursing Practice

1. What strategies may be useful in encouraging M.M. to take part in a program?
2. Why is it important to reinforce the benefits of adhering to a recommended exercise program?
3. What would you suggest since they are concerned about not being able to travel to a center-based program?

Reference for Evidence

Thomas RJ, Beatty AL, Beckie TM, et al.: Home-based cardiac rehabilitation: a scientific statement from the American association of cardiovascular and pulmonary rehabilitation, the AHA, and the ACC, *Circulation* 140:e69, 2019.

hospitalization for ACS often produces more stress than the physiologic act. Most patients change their sexual behavior because they are concerned about sexual inadequacy, death during intercourse, and impotence. A concerned and knowledgeable HCP can clarify any misconceptions with specific counseling.

Before providing guidelines on resumption of sexual activity, it is important to know the patient's physiologic status, physiologic effects of sexual activity, and psychologic effects of having an MI. Sexual activity for most middle-aged men and women with their usual partners is a moderate-energy activity equivalent to climbing 2 flights of steps or walking briskly.[27]

You may be uncertain of how and when to begin counseling about resumption of sex. It is helpful to consider sex as a physical activity and to discuss or explore feelings in this area when discussing other physical activities. One helpful approach is, "Many people who have had a heart attack wonder when they will be able to resume sexual activity. Has this been of concern to you?" You may also state, "Sexual activity, like other forms of activity, should be gradually resumed after MI. If your ability to perform sexually is concerning you, the energy you use is likely no more than climbing 2 flights of steps or walking briskly." Facilitate discussion by providing the patient with reading material on resumption of sexual activity. Say something such as, "If resuming sexual activity has been of concern to you, this information should be helpful." This type of nonthreatening statement brings up the topic, allows the patient to explore personal feelings, and gives the patient an opportunity to raise questions with you or another HCP. Table 37.22 outlines common guidelines.

TABLE 37.22 PATIENT & CAREGIVER TEACHING

Sexual Activity After Acute Coronary Syndrome

Include the following information in the teaching plan for the patient and their partner after acute coronary syndrome:

- Resume sexual activity at a level that relates to sexual activity before experiencing ACS.
- Physical training may improve the physiologic response to intercourse. Encourage daily physical activity during recovery.
- Reduce the consumption of food and alcohol before intercourse is anticipated (e.g., waiting 3–4 hr after eating a large meal before engaging in sexual activity).
- Familiar surroundings and a familiar partner reduce anxiety.
- Masturbation may be a useful sexual outlet and may reassure the patient that sexual activity is still possible.
- Avoid hot or cold showers just before and after intercourse.
- Foreplay is desirable because it allows a gradual increase in HR before orgasm.
- Positions during intercourse are a matter of personal choice.
- Orogenital sex places no undue strain on the heart.
- A relaxed atmosphere free of fatigue and stress is optimal.
- Prophylactic use of nitrates to decrease chest pain during sexual activity may be needed.
- Use of erectile agents (e.g., sildenafil) within 48 hr is contraindicated if taking nitrates in any form.
- Avoid anal intercourse because of the chance of inducing a vasovagal response.

Tell the patient that the inability to perform sexually after MI is common and that sexual problems usually disappear after several attempts. Reinforce the idea that patience and understanding usually solve the problem. However, many male patients may be interested in using drugs to correct erectile dysfunction. Warn the patient not to use these drugs with nitrates because severe hypotension, and even death, has been reported. Tell patients to discuss the use of these drugs with their HCP.

It is common for a patient who has chest pain on physical exertion to have some angina during sexual stimulation or intercourse. The patient may take NTG prophylactically if he is not using erectile dysfunction medications. Tell the patient to delay sex after a heavy meal or excess alcohol intake, when extremely tired or stressed, or with unfamiliar partners. Patients should avoid anal intercourse because of the chance of eliciting a vasovagal response.

Tell the patient that resumption of sex depends on the patient and partner's emotional readiness and on the HCP's assessment of the extent of recovery. It is generally safe to resume sexual activity when patients can exercise ≥3 to 5 METS (e.g., walking up a flight of steps) without chest pain or excessive shortness of breath.[27]

◆ Evaluation

The expected outcomes are that the patient with ACS will

- Maintain stable signs of adequate cardiac output
- Have relief of pain and/or shortness of breath
- Report decreased anxiety and increased sense of self-control
- Achieve a realistic program of activity that balances physical activity with energy-conserving activities
- Describe the disease process, measures to reduce risk factors, and rehabilitation activities necessary to manage the therapeutic regimen

SUDDEN CARDIAC DEATH

Sudden cardiac death (SCD) is an abrupt, unexpected death resulting from a variety of cardiac causes. Over 350,000 adults have an out-of-hospital cardiac arrest every year.[1]

Etiology and Pathophysiology

SCD is the sudden unexpected death occurring within 1 hour of symptom onset. In SCD, a sudden disruption in heart function from a life-threatening dysrhythmia causes an abrupt loss of CO and cerebral blood flow. The affected person may or may not have a known history of heart disease. SCD is the first manifestation of CAD or structural heart disease in up to 50% of people. However, SCD can occur without evidence of CAD.[28] CAD is the main cause of SCD in the United States, especially in adults over 35 years of age.[29]

Acute ventricular dysrhythmias (e.g., VT or VF) cause most cases of SCD and may or may not be associated with an acute MI. Many SCD survivors have a history of a prior (old) MI that caused LV dysfunction and a reduced LVEF. These dysrhythmias have a high rate of recurrence. It is difficult to know who is at high risk for SCD. However, LV dysfunction (EF <30%) is the most common criterion to help guide decisions about implantable cardioverter-defibrillators (ICD) implantation. The use of ICDs for primary and secondary prevention has significantly reduced the incidence of SCD from VT and VF.[28,29]

Structural heart disease (e.g., hypertrophic cardiomyopathy) is a risk factor for SCD, especially in young, athletic people. Some cases of SCD (especially in people less than age 45) involve changes in the conduction system. These include prolonged QT syndrome, Wolff-Parkinson-White syndrome complicated by atrial fibrillation, and Brugada syndrome.

Clinical Manifestations

Some people have symptoms within 1 hour of an SCD event, such as angina, palpitations, dizziness, or lightheadedness. People who experience SCD because of CAD fall into 2 groups: (1) those who had a prior (old) MI and (2) those who had an acute MI. SCD is more common in people who had a prior (old) MI. Those who had a prior MI and survive SCD are at risk for another SCD event because of the continued electrical instability from the scarred heart muscle. They are usually referred for an ICD for secondary prevention. Patients who have SCD from an acute MI should undergo at least 40 days of maximal medical therapy to see if there is recovery in the EF before an ICD is implanted.[29]

Interprofessional and Nursing Care

People who survive an SCD event need a diagnostic workup to determine whether they also had an acute MI. Serial analysis of cardiac biomarkers and ECGs are done to rule out ACS. Because some people with SCD have undiagnosed CAD, cardiac catheterization can identify if significant CAD (e.g., greater than 70% stenosis in multiple coronary arteries) was the cause of the SCD event. PCI or CABG surgery may be needed because significant CAD may be a reversible cause of SCD.

If no reversible cause is identified and the EF is low normal, it is useful to know if these patients are likely to have a recurrence. Assessment of dysrhythmias in these patients may include obtaining an electrophysiology study (EPS).[29] EPS is done under fluoroscopy. Pacing electrodes are placed in various intracardiac areas and stimuli are selectively used to reproduce life-threatening dysrhythmias. See Chapters 35 and 39 for a discussion of EPS.

For patients with syncope suspected to be caused by ventricular dysrhythmias, an outpatient wearable cardiac monitor (e.g., Holter monitor) can be used for up to 48 hours or a Mobile Cardiac Outpatient Telemetry (MCOT) (e.g., CardioNet) may be worn up to 30 days. An implantable cardiac loop recorder (e.g., LINQ) may be implanted and left in place up to 3 years.

The most common approach to preventing a recurrence of SCD and improving survival is the use of an ICD.[28,29] See Chapter 39 for a discussion of ICDs. Drug therapy with an antiarrhythmic such as amiodarone may be used with an ICD to decrease episodes of ventricular dysrhythmias if the patient is receiving multiple ICD shocks due to the dysrhythmias.

Some patients at risk for SCD (e.g., during the time when a patient with an MI and low EF must wait at least 40 days on maximum medical therapy to see if there is improvement in LV function) may use a wearable cardioverter-defibrillator (e.g., LifeVest) as a bridge to ICD or heart transplantation.[30] The wearable cardioverter-defibrillator is a personal external defibrillator that has 2 main parts: a garment and monitor. The garment is worn under clothing. It has electrodes that continuously record the patient's ECG and deliver a shock, if needed. If the patient has VT or VF, the device sounds an alarm to confirm that the patient is unresponsive. If the patient is conscious, the patient can press a button to stop the shock. If the patient does not respond, the device sounds an alarm to notify bystanders that a shock is about to be delivered. If the dysrhythmia continues and the patient still does not respond, a treatment shock is delivered through the electrodes.[30] The patient wears the device except when bathing or showering.

Teach people about the care of SCD victims and the needed actions to save lives. Rapid CPR and defibrillation with an automatic external defibrillator (AED), combined with early

advanced cardiac life support, has improved long-term survival rates for a witnessed arrest due to ventricular dysrhythmias.

Be alert to the patient's psychosocial adaptation to this sudden "brush with death." Many patients develop a "time bomb" mentality. They and their caregivers fear the recurrence of cardiac arrest. They may become anxious, angry, and depressed. The grief response varies. Patients and caregivers may need to deal with other issues, such as driving restrictions, role reversal, and change in occupation. Be attuned to the specific needs of the patient and caregiver. Provide information and emotional support.

Case Study

Myocardial Infarction

(© iStockphoto/Thinkstock.)

Patient Profile

D.M., a 51-year-old, white, small business owner, is rushed to the ED by ambulance with crushing, substernal chest pain that radiates down his left arm. He reports dizziness and nausea.

Subjective Data

- Short of breath, nauseous
- History of chronic stable angina and hypertension
- States he is "borderline diabetic"
- Overweight, but recently lost 10 lb.
- Does not exercise
- Has 3 teenage children who are causing "problems"
- Recently lost his best friend and business partner, who died from cancer

Objective Data

Physical Assessment

- Diaphoretic
- BP 165/100 mm Hg, pulse rate 120/min, respiratory rate 26/min

Diagnostic Studies

- 12-lead ECG shows sinus tachycardia with occasional PVCs and ST elevation in leads II, III, aV_F, V_5, V_6 consistent with an inferolateral wall MI
- High troponin level
- Total cholesterol 350 mg/dL (9.1 mmol/L)
- Hb A1C 9.0%

Interprofessional Care

- ED: Notify the cardiac catheterization laboratory of patient with STEMI
- O_2 2 L/min via nasal cannula, titrate to keep O_2 saturation above 93%
- Continuous ECG monitoring
- 2 IV access sites
- Aspirin 325 mg (chewable) now
- Atorvastatin 80 mg PO
- Eptifibatide IV (this should *not* delay the patient getting to the cardiac catheterization laboratory)
- Weight-based heparin IV (only used if the patient does not go directly to cardiac catheterization)
- SL NTG until an IV line is placed, then titrate nitroglycerin IV to relieve chest pain; hold for systolic BP below 100 mm Hg
- Morphine 2 mg IV q5–15 min as needed for chest pain unrelieved by NTG
- Vital signs (including pulse oximetry) every 10 min
- Prepare patient for cardiac catheterization with possible PCI

Discussion Questions

1. ***Recognize:*** Explain the pathogenesis of CAD. What risk factors contribute to its development? What risk factors were present in D.M.'s life?
2. ***Analyze***: Which coronary artery(ies) is (are) most likely occluded in D.M.'s coronary circulation?
3. ***Analyze***: Explain the significance of the results of the laboratory tests and the 12-lead ECG finding.
4. ***Plan***: Give a rationale for each treatment measure ordered for D.M.
5. ***Prioritize:*** What are the priority nursing interventions for D.M. before PCI? Immediately after PCI?
6. ***Act***: Identify activities you can delegate to assistive personnel (AP).
7. ***Evaluate***: What outcomes would show that interprofessional care was successful?

Answers and a corresponding conceptual care map available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which information would the nurse include in teaching a patient about CAD? *(select all that apply)*
   - **a.** Diffuse involvement of plaque formation in coronary veins
   - **b.** Abnormal levels of cholesterol, especially low-density lipoproteins
   - **c.** Accumulation of lipid and fibrous tissue within the coronary arteries
   - **d.** Development of angina due to a decreased blood supply to the heart muscle
   - **e.** Chronic vasoconstriction of coronary arteries leading to permanent vasospasm
2. After teaching a patient about ways to decrease risk factors for CAD, which patient statement indicates to the nurse that further instruction is needed?
   - **a.** "I can keep my blood pressure normal with medication."
   - **b.** "I would like to add weightlifting to my exercise program."
   - **c.** "I can change my diet to decrease my intake of saturated fats."
   - **d.** "I will change my lifestyle to reduce activities that increase my stress."
3. A hospitalized patient with a history of chronic stable angina tells the nurse they are having chest pain. Which information about ischemia would the nurse use as a basis for planning care?
   - **a.** It will always progress to myocardial infarction.
   - **b.** It can be relieved by rest, nitroglycerin, or both.

c. It is often associated with vomiting and extreme fatigue.
d. It indicates that irreversible myocardial damage is occurring.

4. The nurse is caring for a patient who is 2 days post MI. The patient reports that chest pain when taking a deep breath. Which action would be a *priority*?
a. Notify the provider STAT and obtain a 12-lead ECG.
b. Obtain vital signs and auscultate for a pericardial friction rub.
c. Apply high-flow O_2 by face mask and auscultate breath sounds.
d. Medicate the patient with an opiate analgesic and reevaluate in 30 minutes.

5. A patient is in the ICU with a diagnosis of NSTEMI. Which drugs would the nurse expect the patient to receive? *(select all that apply)*
a. Oral statin therapy
b. Antiplatelet therapy
c. Thrombolytic therapy
d. Prophylactic antibiotics
e. Intravenous nitroglycerin

6. A patient is recovering from an uncomplicated MI. Which rehabilitation guideline is a *priority* to include in the teaching plan?
a. Refrain from sexual activity for a minimum of 3 weeks.
b. Plan a diet program that aims for a 1- to 2-lb. weight loss per week.
c. Begin an exercise program that aims for at least 5 30-minute sessions per week.
d. Consider the use of erectile agents and prophylactic NTG before sexual activity.

7. Which finding is the strongest predictor of risk for sudden cardiac death?
a. Aortic valve disease
b. Mitral valve disease
c. Left ventricular dysfunction
d. Atherosclerotic heart disease

1. b, c, d; 2. b; 3. b; 4. b; 5. a, b, e; 6. c; 7. c.

CONCEPTUAL FOCUS

Fatigue
Fluids and Electrolytes
Functional Ability
Gas Exchange
Perfusion
Self-Management

LEARNING OUTCOMES

1. Compare the pathophysiology of heart failure with reduced ejection fraction (HFrEF) and heart failure with preserved ejection fraction (HFpEF).
2. Relate the compensatory mechanisms involved in heart failure (HF) to the development of acute decompensated heart failure (ADHF) and chronic HF.
3. Describe appropriate nursing and interprofessional care to manage the patient with ADHF.
4. Describe appropriate nursing and interprofessional care to manage the patient with chronic HF.
5. Discuss advanced therapeutic options for patients with stage D HF.
6. Discuss the nursing and interprofessional care of a patient with a circulatory assist device.
7. Describe the indications for heart transplantation and the nursing care of heart transplant recipients.

KEY TERMS

acute decompensated heart failure
cardiac resynchronization therapy
heart failure (HF)
heart failure with preserved ejection fraction (HFpEF)
heart failure with reduced ejection fraction (HFrEF)
heart transplantation
intraaortic balloon pump (IABP)
orthopnea
paroxysmal nocturnal dyspnea (PND)
pulmonary edema
ventricular assist device (VAD)

HEART FAILURE

Heart failure (HF) is a complex clinical syndrome that develops in response to myocardial insult. It results in the inability of the heart to provide sufficient blood to meet the oxygen (O_2) needs of tissues and organs. The decreased cardiac output (CO) leads to decreased tissue perfusion, impaired gas exchange, fluid volume imbalance, and decreased functional ability. This chapter describes the nursing and interprofessional care of patients with HF.

The *percentage* of the total blood volume in the left ventricle (LV) at the end of diastole that is pumped out of the LV with the next systole is the left ventricular ejection fraction (LVEF). HF involves a defect in either ventricular systolic function/LV contraction (**heart failure with reduced ejection fraction [HFrEF]**) and/or a defect in ventricular diastolic function/filling (**heart failure with preserved ejection fraction [HFpEF]**).[1]

HF is associated with many cardiovascular diseases (CVDs). These include hypertension (HTN), coronary artery disease (CAD), and myocardial infarction (MI). HF is increasing in incidence and prevalence. This is partially due to better survival after cardiac events and the aging population. HF is mainly a disease of older adults. The incidence is similar in men and women.[2]

HF is a major health problem in the United States. The number of people with HF has increased from 5.7 million (2009–2012) to 6.2 million (2013–2016). That number is projected to rise to over 8 million adults with HF by 2030.[2] HF is the most common reason for hospital admission in adults over the age of 65. This places a significant economic burden on the health care system.[1] The complex, progressive nature of HF often results in poor outcomes, such as hospital readmissions. Around 25% of patients discharged with a primary diagnosis of HF are readmitted within 30 days. Overall survival after the onset of HF has improved. This is likely due to evidence-based risk and management

BOX 38.1 PROMOTING HEALTH EQUITY

Heart Failure

- Blacks and Hispanics develop HF at an earlier age, are admitted to the hospital more often, and have higher mortality rates related to HF as compared to Whites.
- Hispanics have more CVD risk factors but are 25% less likely to die of heart disease than Whites.[4]

TABLE 38.1 Primary Causes of Heart Failure

- Cardiomyopathy (e.g., viral, postpartum, substance use)
- Congenital heart defects (e.g., ventricular septal defect)
- CAD, including MI
- HTN, including hypertensive crisis
- Hyperthyroidism
- Myocarditis
- Pulmonary HTN
- Rheumatic heart disease
- Valve disorders (e.g., mitral stenosis)

approaches.[2] Still, 1 in 8 US adult deaths is associated with an HF diagnosis. The total cost of HF care exceeds $30 billion annually, with over half of these costs spent on hospitalizations.[2]

TABLE 38.2 Common Precipitating Causes of Heart Failure

Cause	Mechanism
Anemia	↓ O_2-carrying capacity of the blood stimulating ↑ in CO to meet tissue demands, leading to increase in cardiac workload and increase in size of LV
Bacterial endocarditis	*Infection:* ↑ metabolic demands and O_2 requirements *Valve dysfunction:* causes stenosis or regurgitation
Dysrhythmias	May ↓ CO and ↑ workload and O_2 requirements of myocardial tissue
Fluid overload	↑ Preload causing volume overload on the RV
Hypothyroidism	Indirectly predisposes to ↑ atherosclerosis. Severe hypothyroidism decreases myocardial contractility
Infection	↑ O_2 demand of tissues, stimulating ↑ CO
Nutrition deficiencies	May ↓ cardiac function by ↑ myocardial muscle mass and myocardial contractility
Obstructive sleep apnea	Frequent nighttime apnea results in ↑ afterload, intermittent hypoxia, and ↑ sympathetic nervous system activity.
Paget's disease	↑ Workload of the heart by ↑ vascular bed in the skeletal muscle
Pulmonary embolism	↑ Pulmonary pressure resulting from obstruction leads to pulmonary HTN, ↓ CO
Thyrotoxicosis	Changes the tissue metabolic rate, ↑ HR and workload of the heart

Etiology

HTN and CAD are the primary risk factors for HF. HTN is a modifiable risk factor that should be aggressively treated and managed (Box 38.1). Long-term treatment of HTN reduces the incidence of HF by 50%.[1] Co-morbidities, such as diabetes, metabolic syndrome, advanced age, tobacco use, and vascular disease, contribute to the development of HF. Other causes include congenital abnormalities (e.g., septal defects), infiltrative cardiomyopathies (e.g., sarcoidosis), infections and inflammatory processes (e.g., viral myocarditis), persistent dysrhythmias, and toxins (e.g., alcohol, drug use, chemotherapy).[3]

Any interference with the normal mechanisms regulating CO may cause HF. CO depends on (1) preload, (2) afterload, (3) myocardial contractility, and (4) HR. These factors affect stroke volume (SV), which is the amount of blood pumped per heartbeat. Thus, the equation: CO = SV × HR. Any changes in these factors can lead to decreased ventricular function and HF. Preload and afterload are discussed in Chapter 31.

The major causes of HF are divided into primary causes (Table 38.1) and precipitating causes (Table 38.2). Precipitating causes increase the workload of the heart, causing acutely decreased heart function.

Genetic Link

Cardiomyopathies, diseases that weaken the heart muscle and cause HF, can be acquired or inherited. The inherited forms involve autosomal dominant traits with variable genetic expression. Such mutations are typically found in genes encoding sarcomeric proteins.[5] The body's largest known protein, *titin,* responds to such a mutated gene. Titin mutations impair sarcomere function and disrupt chemical signaling, which weakens ventricular structure and stability.[6]

Identifying pathogenic genetic variants has important value for disease prediction and therapy. Post-viral myocarditis, which can cause HF, is thought to be caused by an interaction between a virus and a genetic predisposition.[5] Specific genes and gene mutations are linked to the development of HTN and CAD, known risk factors for HF (see Chapters 36 and 37).

Pathophysiology

HF develops in response to myocardial injury and results in decreased heart function. Manifestations of HF are the result of neurohormonal compensatory mechanisms activated in response to myocardial dysfunction, leading to *remodeling* of myocardial structure and changes in function (Fig. 38.1).

Left-Sided Heart Failure

The most common form of HF, left-sided HF, results from the inability of the LV to either (1) empty adequately during systole or (2) fill adequately during diastole. We can further classify left-sided HF as HFrEF (systolic HF), HFpEF (diastolic HF), or a combination of the two.

Heart failure with reduced EF (systolic failure). HFrEF results from an inability of the heart to pump blood effectively (e.g., MI), increased afterload (e.g., HTN), cardiomyopathy, and mechanical problems (e.g., heart valve disease).[3] The hallmark of HFrEF is a decrease in the LVEF. Normal LVEF is 55% to 65%. Patients with HFrEF generally have an LVEF less than 40%. It can be as low as 5% to 10%.

The LV in HFrEF does not generate enough pressure to eject blood forward through the aorta. Over time, the LV dilates and hypertrophies. The weakened heart muscle cannot generate adequate SV, which impairs CO. Because the LV cannot effectively

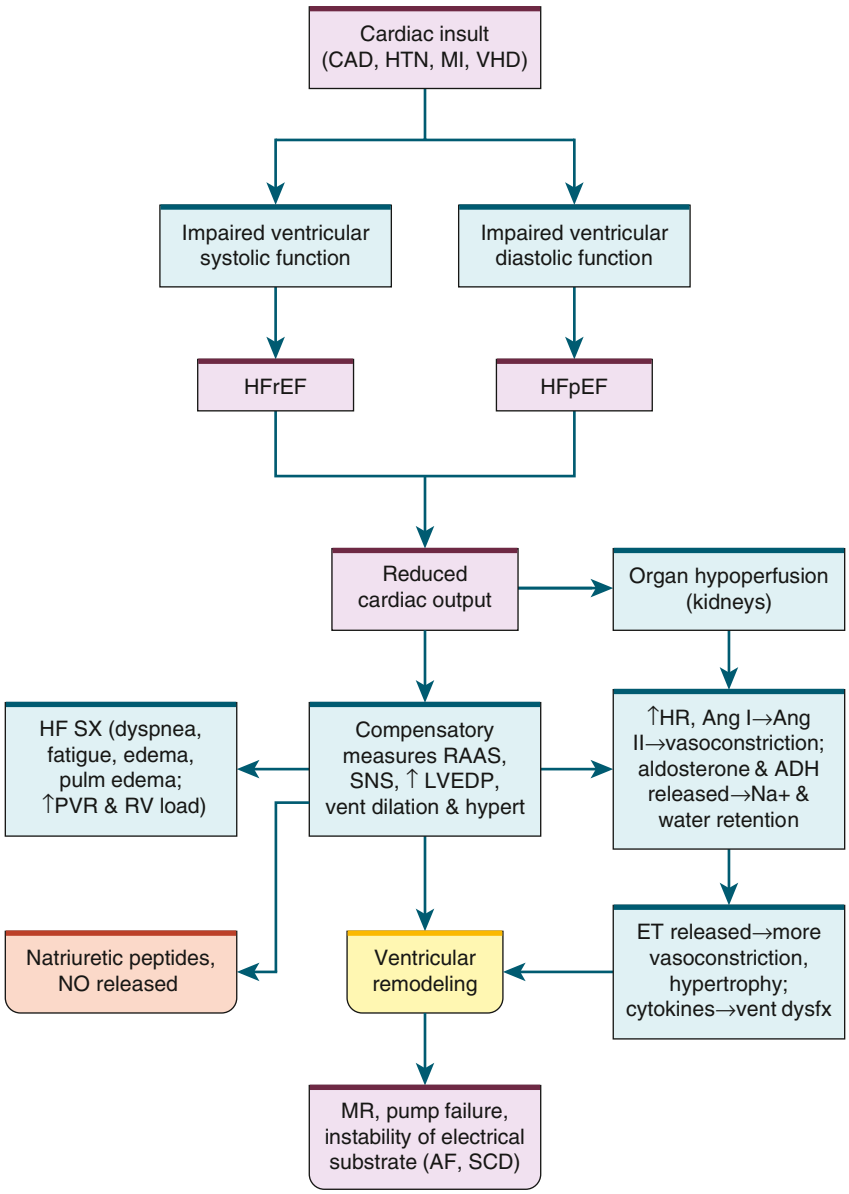

Fig. 38.1 Pathophysiology of HF. *Ang I,* Angiotensin I; *Ang II,* angiotensin II; *ADH,* Antidiuretic hormone; *ET,* endothelin; *HFpEF,* HF with preserved ejection fraction; *HFrEF,* HF with reduced ejection fraction; *LVEDP,* left ventricular end-diastolic pressure; *MR,* mitral regurgitation; *NO,* nitric oxide; *PVR,* pulmonary vascular resistance; *RAAS,* renin-angiotensin-aldosterone system; *SCD,* sudden cardiac death; *SNS,* sympathetic nervous system; *VHD,* valvular heart disease.

push blood forward, end diastolic volumes and pressures in the LV increase. When the LV fails, blood backs up into the left atrium (LA). This causes fluid accumulation in the lungs. The increased pulmonary hydrostatic pressure causes fluid leakage from the pulmonary capillary bed into the interstitium and then the alveoli. This results in pulmonary congestion and edema (Fig. 38.2A–D). Fortunately, therapies can reduce morbidity and mortality in HFrEF.

Heart failure with preserved EF (diastolic failure). HFpEF results from the inability of the ventricles to relax and fill during diastole. About 50% of patients with HF have HFpEF. HTN is the primary cause of HFpEF.[1] Other risk factors include older age, female gender, diabetes, and obesity (Box 38.2). In HFpEF, the LV is generally stiff and noncompliant, causing high filling pressures. Decreased filling volume in the ventricles results in decreased SV. The eventual result of HFpEF is the same as that of HFrEF, a reduced CO leading to fluid congestion. The diagnosis of HFpEF is based on (1) signs and symptoms of HF, (2) normal LVEF, and (3) evidence of LV diastolic dysfunction by echocardiography or cardiac catheterization. Therapies are aimed at reducing underlying risk factors, treating co-morbidities, and reducing symptoms.[7]

Patients with borderline HFpEF (LVEF 41% to 49%) have similar characteristics and receive similar therapies to those for patients with HFpEF.[1] The patient with ventricular failure of any type may have low BP, low CO, and poor renal perfusion. Poor exercise tolerance and dysrhythmias are common. The patient may present acutely from an MI or chronically from worsening cardiomyopathy or HTN. In both acute and chronic causes of HF, the body's response is to use compensatory mechanisms to try to maintain CO and BP.[3]

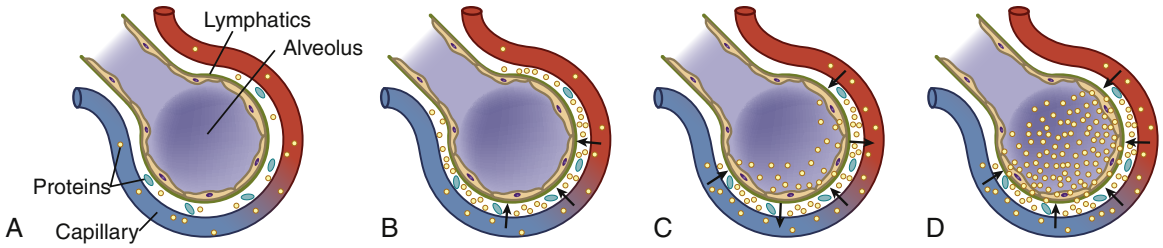

Fig. 38.2 As pulmonary edema progresses, it inhibits O_2 and CO_2 exchange at the alveolar-capillary interface. (A) Normal relationship. (B) Increased pulmonary capillary hydrostatic pressure causes fluid to move from the vascular space into the pulmonary interstitial space. (C) Lymphatic flow increases to try to pull fluid back into the vascular or lymphatic space. (D) Failure of lymphatic flow and worsening of left-sided HF result in further movement of fluid into the interstitial space and into the alveoli. (Modified from Urden LD, Stacy KM, Lough ME: *Critical care nursing: diagnosis and management,* ed 6, St Louis, 2010, Mosby.)

BOX 38.2 BIOLOGIC SEX CONSIDERATIONS

Heart Failure

Men

- Have HFrEF more often
- Ischemic heart disease (MI, CAD) is the most common cause of HF in men
- ACE inhibitor therapy reduces mortality more in asymptomatic HFrEF

Women

- Make up 50% of people living with HF
- Are often misdiagnosed due to perceptions of HF as a male condition
- Underrepresented in major HF trials
- Have HFpEF more often
- With HFrEF, more often have non-ischemic cardiomyopathy
- Often present with greater symptom burden
- HTN is the most common cause of HF
- Women with HF tend to be older compared to men[4]

Right-Sided Heart Failure

Right-sided HF occurs when the right ventricle (RV) does not pump effectively. When the RV fails, fluid backs up into the venous system. This causes movement of fluid into the tissues and organs (e.g., peripheral edema, abdominal ascites, hepatomegaly, jugular venous distention [JVD]).

The most common cause of right-sided HF is left-sided HF. As the LV fails, fluid backs up into the pulmonary system, increasing pressures in the lungs. The RV works harder to push blood to the pulmonary system. Over time, this increased workload weakens the RV, and gradually it fails. Other causes of right-sided HF (independent of the function of the LV) include RV infarction, pulmonary embolism, and *cor pulmonale* (RV dilation and hypertrophy caused by pulmonary disease) (see Chapter 31).

Biventricular Failure

Biventricular failure includes both LV and RV dysfunction. There is an inability of both ventricles to pump effectively. Because of decreased contractility, fluid build-up and systemic venous engorgement occur. Inadequate CO results in decreased perfusion to vital organs.[3]

Compensatory Mechanisms

HF can have an abrupt onset as with acute MI, or it can be a subtle process resulting from slow, progressive changes. The overloaded heart uses compensatory mechanisms to try to maintain adequate CO. The main compensatory mechanisms include (1) neurohormonal responses: renin-angiotensin-aldosterone system (RAAS) and the sympathetic nervous system (SNS); (2) ventricular dilation; and (3) ventricular hypertrophy.

Neurohormonal response

Renin-angiotensin-aldosterone system. The renin-angiotensin-aldosterone system (RAAS) works to maintain homeostasis. The goal of RAAS activation is increased preload and ventricular contractility to maintain CO. RAAS activation promotes retention of fluid and sodium. The juxtaglomerular apparatus in the kidneys senses decreased renal perfusion from a falling CO. In response, the kidneys release renin, which converts angiotensinogen to angiotensin I (see Chapter 49 and Fig. 49.1). Angiotensin I is next converted to angiotensin II by a converting enzyme made in the lungs. Angiotensin II, a potent vasoconstrictor, stimulates renal water and sodium retention and the release of aldosterone from the adrenal gland. Aldosterone acts in the nephron to stimulate sodium retention and potassium excretion and promotes myocardial fibrosis in the failing heart.

Continuous activation of the RAAS and SNS in HF leads to increased levels of antidiuretic hormone (ADH). ADH regulates water retention by stimulating renal tubular reabsorption. It is released via baroreceptor signals in response to arterial low pressure/under filling. ADH causes vasoconstriction and increases BP and central venous pressure (CVP). The consequences are fluid congestion and hyponatremia.[8] Chronic activation of the RAAS can cause harmful effects, such as cardiac myocyte apoptosis (programmed cell death), hypertrophy, and fibrosis. These cause the burdensome signs and symptoms that develop with HF.[9]

Sympathetic nervous system. Baroreceptors sense low arterial pressure, stimulating the sympathetic nervous system (SNS) to try to maintain CO. Catecholamines (epinephrine and norepinephrine) are released. Stimulation of β-adrenergic receptors increases HR *(chronotropy)* and ventricular contractility *(inotropy)*. Chronic SNS stimulation increases myocardial O_2 demand on the already weakened heart.

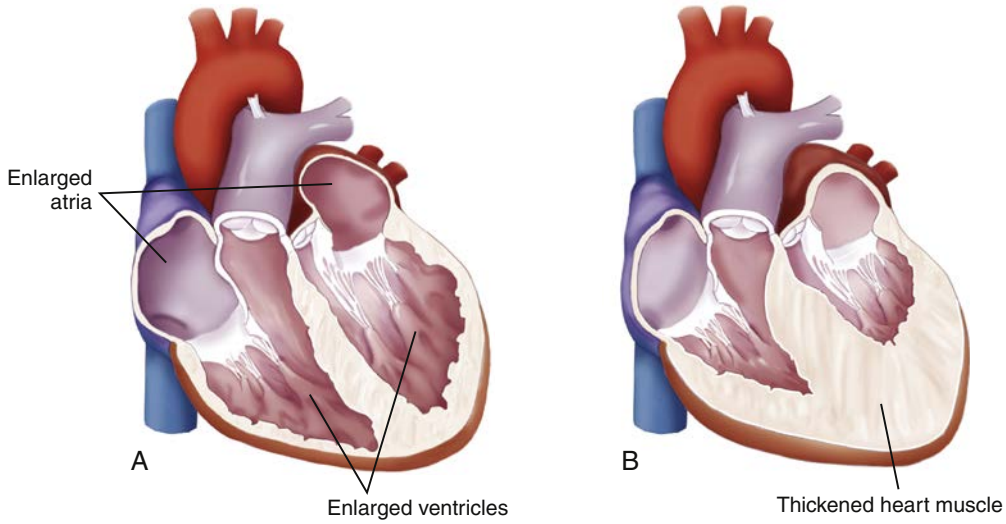

Fig. 38.3 (A) Dilated heart chambers. (B) Hypertrophied heart chambers.

Continuous activation of the neurohormonal responses (RAAS and SNS) in HF leads to high levels of ADH, endothelin, and proinflammatory cytokines. Together, these factors further increase the heart's workload, intensify ventricular dysfunction, and force ventricular remodeling.[8]

Peptides and cytokines. Endothelin, a vasoconstrictor peptide made by the vascular endothelial cells, is stimulated by hypoxia, ischemia, neurohormones, and inflammatory cytokines. Although endothelin stimulates contraction in most smooth muscles, it has the opposite effect on the heart, acting as a negative inotrope. This decreases ventricular contractility in the failing heart.

Myocytes release proinflammatory cytokines in response to heart injury (e.g., MI, HF). Two cytokines, tumor necrosis factor (TNF) and interleukin-1 (IL-1), further depress heart function through a negative inotropic effect, causing myocyte hypertrophy and apoptosis. Over time, a systemic inflammatory response occurs.[10] High levels of endothelin and proinflammatory cytokines increase the heart's workload, progressive LV dysfunction, myocyte hypertrophy, and ventricular remodeling.[9]

Ventricular adaptations

Dilation. *Dilation* is an enlargement of the heart chambers (Fig. 38.3A). It occurs when pressure in the heart chambers (usually the LV) is elevated over time. The heart muscle fibers stretch in response to the volume of blood in the heart at the end of diastole. According to the *Frank-Starling Law,* the strength of the heart's contraction is directly proportional to its diastolic stretch. The implication is that increased preload (a greater influx of blood into the ventricle during diastole) will cause a more forceful contraction. This increased contraction initially leads to increased CO and maintains BP and perfusion. Dilation starts as an adaptive mechanism to cope with increasing blood volume. However, excessive preload exhausts the Frank-Starling mechanism, and overstretched cardiac muscle fibers no longer increase CO.

Hypertrophy. *Hypertrophy* is an adaptive increase in the heart muscle thickness as a slow response to overwork and strain (Fig. 38.3B). It takes time for this increased muscle tissue to develop. Initially, the increased contractile power of the muscle fibers leads to increased CO and maintains tissue perfusion. Over time, hypertrophic heart muscle has poor contractility, needs more O_2 to perform work, has poor coronary artery circulation, becomes ischemic more easily, and is prone to dysrhythmias.

Remodeling. Pathologic *ventricular remodeling* is a change in the structure (dimensions, mass, shape) of the heart. Ventricular remodeling in HF occurs over time in response to pressure or volume overload and/or cardiac injury and compensatory mechanisms. These include neurohormonal, ET, cytokine activation, and ventricular adaptations, including dilation and hypertrophy. This altered shape of the ventricles eventually leads to increased ventricular mass, increased wall tension, increased O_2 consumption, and impaired contractility. The shape of the heart becomes less elliptical and more spherical. The ventricles become larger but less effective pumps. The LVEF further declines due to loss of mechanical advantage from all these changes in the ventricle. Increases in angiotensin II, aldosterone, and cytokines stimulate collagen synthesis leading to fibrosis and further impaired pumping ability.[11] Ventricular remodeling is associated with sudden cardiac death and a worse prognosis in HF. Therapies that reverse remodeling can improve symptoms and quality of life while decreasing hospitalizations and mortality.[11] Evidence-based therapies to prevent or reverse remodeling include ACE inhibitors, angiotensin receptor neprilysin inhibitors, β-adrenergic blockers, aldosterone antagonists, and cardiac resynchronization therapy.

Beneficial Counterregulatory Mechanisms

The body tries to maintain balance through several counterregulatory processes. Natriuretic peptides (atrial natriuretic peptide [ANP] and brain [b-type] natriuretic peptide [BNP]) are hormones made by the heart muscle. ANP is released from the atria and BNP is released from the ventricles in response to increased blood volume and cardiac wall stretching.[12]

The natriuretic peptides have beneficial renal, cardiovascular, and hormonal effects. Renal effects include (1) increased glomerular filtration rate and diuresis and (2) excretion of sodium (natriuresis). Cardiovascular effects include (1) vasodilation and (2) decreased BP. Hormonal effects include (1) inhibition of aldosterone and renin secretion and (2) interference with ADH release. The combined effects of ANP and BNP help to counter the adverse effects of the SNS and RAAS.[12] We can measure serum BNP levels. High serum BNP corresponds with fluid retention and is a predictor of mortality in HF.

Nitric oxide (NO) and prostaglandin are counterregulatory substances released from the vascular endothelium in response to the compensatory mechanisms activated in HF. NO and prostaglandin work to relax the arterial smooth muscle. This results in vasodilation and decreased afterload.[11]

Compensated HF occurs when compensatory mechanisms succeed in maintaining an adequate CO for tissue perfusion. *Decompensated HF* occurs when these mechanisms can no longer maintain adequate CO and inadequate tissue perfusion results.

Classifications of Heart Failure

New York Heart Association Classes of Heart Failure

The New York Heart Association (NYHA) Functional Classification places patients in 1 of 4 categories (I–IV) based on physical activity limitation due to symptom burden.[1] NYHA class designation changes based on worsening or improving symptoms.

The Stages of Heart Failure

The American College of Cardiology Foundation and the American Heart Association (ACCF/AHA) developed a staging system (A–D) that emphasizes the evolution and progression of HF as well as treatment strategies.[1] This system identifies people at risk for developing HF who do not currently have heart disease (stage A). This classification encourages addressing the patient's risk factors and treating existing conditions to prevent disease progression. This staging system is progressive and unidirectional. Patients advance to a higher (worse) stage as the disease progresses. Table 38.3 compares the NYHA classification and ACC/AHA staging system.

TABLE 38.3 Comparison of ACCF/AHA Stage of Heart Failure and NYHA Functional Classification

ACCF/AHA Stages		NYHA Functional Classification	
A	At high risk for HF, but no heart disease or symptoms	**None**	
B	Heart disease is present but there are no signs or symptoms	**I**	No limitation of physical activity. Ordinary physical activity does not cause symptoms of HF.
C	Heart disease is present with prior or current symptoms	**I**	No limitation of physical activity. Ordinary physical activity does not cause symptoms of HF.
		II	Slight limitation of physical activity. Comfortable at rest, but ordinary physical activity results in symptoms of HF.
		III	Marked limitation of physical activity. Comfortable at rest, but less than ordinary activity causes symptoms of HF.
		IV	Inability to carry out any physical activity without discomfort. Symptoms may be present at rest.
D	Advanced heart disease with continued HF requiring specialized therapy	**IV**	Inability to carry out any physical activity without discomfort. Symptoms may be present at rest.

ACCF, American College of Cardiology Foundation; *AHA,* American Heart Association; *NYHA,* New York Heart Association.

Clinical Manifestations: Acute Decompensated Heart Failure

Acute decompensated heart failure (ADHF) is an increase (usually sudden) in symptoms of HF with a decrease in functional status, often requiring rapid escalation of therapy and hospital admission. ADHF is the most common cause of hospitalization for older Americans.[13] The presentation of ADHF typically includes symptoms and signs related to pulmonary congestion and volume overload. Neurohormonal activation leads to impaired regulation of sodium excretion through the kidneys that results in sodium and fluid accumulation. To help compensate, the lymphatic system increases its flow to help maintain a constant volume of the pulmonary extravascular fluid (Fig. 38.2A and B). The lungs become less compliant. There is increased resistance in the small airways. This early stage is associated with a mild increase in the respiratory rate (RR) and a decrease in partial pressure of O_2 in arterial blood (PaO_2).

If pulmonary venous pressure continues to increase, more fluid moves into the interstitial space than the lymphatics can remove, causing *interstitial edema* (Fig. 38.2C). Tachypnea develops, and the patient becomes symptomatic (e.g., short of breath). If the pulmonary venous pressure increases further, the alveolar lining is disrupted. Fluid moves into the alveoli *(alveolar edema).* This is accompanied by a worsening of the arterial blood gas values (lower PaO_2, increased $PaCO_2$, progressive respiratory acidosis).

ADHF can manifest as **pulmonary edema**. This is an acute, life-threatening situation, in which the lung alveoli become filled with serosanguineous fluid (Fig. 38.2D). The most common cause of pulmonary edema is left-sided HF. Other causes of pulmonary edema are listed in Table 30.19.

Clinical findings of pulmonary edema include acute manifestations of left HF, such as dyspnea, *orthopnea*, and *paroxysmal nocturnal dyspnea*. JVD is often present as the most sensitive and specific sign for elevated LV filling pressures. Coughing provides an early clue to developing pulmonary edema in patients with chronic HF. The patient is usually anxious and pale and may be cyanotic. The RR is often over 30 breaths per minute. You may see use of accessory respiratory muscles. Pink, frothy sputum may be present in patients with severe disease. Auscultation of the lungs may reveal crackles and wheezes throughout. However, the absence of crackles does not rule out ADHF, as many patients with a history of chronic HF develop increased lymphatic drainage of the alveolar edema. The patient's HR is

TABLE 38.4 Clinical Profile in Acute Decompensated Heart Failure

		CONGESTION (WET)	
		No	**Yes**
LOW PERFUSION (COLD)	**No**	**Dry-Warm** • PAWP normal • CO normal • Signs and symptoms: none	**Wet-Warm** • PAWP ↑ • CO normal • Signs and symptoms: dyspnea, edema, orthopnea
	Yes	**Dry-Cold** • PAWP ↓ or normal • CO ↓ • Signs and symptoms: edema, hypotension, cool extremities	**Wet-Cold** • PAWP ↑ • CO ↓ • Signs and symptoms: altered mental status, decreased O_2 saturation, reduced urine output, shock

PAWP, Pulmonary artery wedge pressure.

often rapid with an abnormal S_3 or S_4 heart sound (Table 35.4). BP may be high or decreased depending on the severity of the HF. Hypotension indicates severe LV systolic dysfunction and possible cardiogenic shock. Cool extremities occur with low CO and poor perfusion. Skin pallor, ashy color, or mottling may be present from peripheral vasoconstriction. Sometimes, hoarseness may be present because of compression of the recurrent laryngeal nerve from an enlarged LA (Ortner sign).

We categorize patients with ADHF into 1 of 4 groups based on hemodynamic and clinical status: dry-warm, dry-cold, wet-warm, and wet-cold (Table 38.4).[1] The most common presentation in patients with ADHF is the wet and warm patient. A patient is "wet" due to volume overload (e.g., congestion, dyspnea) but "warm" due to maintaining adequate perfusion (warm skin, positive pulses).

CHECK YOUR PRACTICE

You are assigned to a patient with ADHF who was admitted to the HF unit. The patient has bilateral crackles in the mid-lower lung fields and dyspnea on exertion (e.g., moving from the bed to the commode). Their skin is warm, and pulses are present in all extremities. Your preceptor asks you to categorize your patient based on the classification systems in Tables 38.3 and 38.4.

- In what NYHA class would you place your patient?
- In what ACCF/AHA stage would you place your patient?
- What ADHF clinical profile does your patient best fit?

Clinical Manifestations: Chronic Heart Failure

Chronic HF is a progressive syndrome of reduced CO and increased venous pressure associated with the death of cardiac muscle cells. Neurohormonal and hemodynamic mechanisms to compensate for reduced CO include vasoconstriction and SNS stimulation, an inflammatory response involving cytokines, and ventricular remodeling. These physiologic responses are responsible for the manifestations of chronic HF. Many therapies for chronic HF work by counteracting these mechanisms. Table 38.5 lists the manifestations of right-sided and left-sided chronic HF.

Right-Sided Heart Failure	Left-Sided Heart Failure
Signs	
• Right ventricular heaves • ↑ HR • Anasarca (massive generalized edema) • Ascites • Edema (e.g., pedal, scrotum) • Hepatomegaly • JVD • Murmurs • Weight gain	• Left ventricular heaves • ↑ HR • S_3 and S_4 heart sounds • ABGs: ↓ PaO_2, slight ↑ $PaCO_2$ • Confusion, restlessness • Dry, hacking cough • Crackles (pulmonary edema) • Pleural effusion • PMI displaced inferiorly and left of the midclavicular line (LV hypertrophy) • Pulsus alternans (alternating pulses: strong, weak) • Shallow respirations up to 32–40/min • Frothy, pink-tinged sputum (advanced pulmonary edema)
Symptoms	
• Anorexia and GI bloating • Anxiety, depression • Fatigue • Nausea • RUQ pain	• Anxiety, depression • Dyspnea • Fatigue, weakness • Nocturia • Orthopnea • Paroxysmal nocturnal dyspnea

Fatigue

Fatigue from usual daily activities can be an early symptom of chronic HF. As CO decreases, fatigue eventually limits activities. Anemia is another potential cause of fatigue in HF.

Dyspnea

Dyspnea is the most common manifestation of chronic HF. It is caused by increased pulmonary pressures from interstitial and alveolar edema. Dyspnea can occur early in the HF disease process with mild exertion. As HF progresses, dyspnea develops with less exertion or at rest.

Orthopnea, or dyspnea in the recumbent position, suggests HF. Orthopnea occurs due to redistribution of fluid from the legs into the lungs while lying down. The dyspnea is usually relieved with sitting up. Ask the patient about the number of pillows used under the head while sleeping or about sleeping in a recliner to aid breathing.

Paroxysmal nocturnal dyspnea (PND) is episodic, sudden dyspnea that wakes a patient at night. PND is caused by fluid accumulation in the pulmonary vessels entering the alveoli while the patient is supine. The patient awakens in a panic with feelings of suffocation and a strong desire to sit or stand to aid breathing.

Cough

A chronic, nonproductive cough that is worse when lying down is often from pulmonary congestion and can be a sign of HF. Other potential causes of cough include gastric conditions, medications (e.g., ACE inhibitors due to increased bradykinin levels), and pulmonary conditions.

Tachycardia

Tachycardia is an early sign of HF. One of the body's first responses to compensate for a reduced CO is to increase the HR via activation of the SNS. Over time, persistent tachycardia is harmful and may worsen HF symptoms. Adequate HR control in patients with chronic HF has been associated with better clinical outcomes, including decreased hospitalizations and mortality.[1]

Palpitations

Palpitations, or an irregular heartbeat, can occur due to dysrhythmias with chronic HF. Atrial fibrillation (AF) is the most common of these dysrhythmias. Patients may report a fast or irregular heartbeat, a fluttering sensation, or "skipped beats" that may be intermittent. Palpitations may be accompanied by dyspnea, lightheadedness, or near syncope if the dysrhythmia further decreases CO.

Edema

Edema is a common sign of HF. Common sites include dependent body areas (peripheral edema), liver (hepatomegaly), abdominal cavity (ascites), and lungs (pulmonary edema, pleural effusion). If the patient is in bed, dependent sacral and scrotal edema may develop. Pressing the edematous skin with the finger may leave a depression *(pitting edema).* Edema can indicate volume overload and be a sign of ADHF. It is important to note that not all lower extremity edema is a result of HF. Hypoproteinemia, renal insufficiency, cellulitis, venous stasis, cirrhosis, and certain drugs can cause peripheral edema.

Changes in Urine Output

Urine output may be decreased because of decreased renal perfusion. HF patients often develop resistance to diuretics, which can result in a drop in urinary output. *Nocturia* is the tendency to urinate excessively during the night. It is due to increased renal perfusion in the supine position.

Skin Changes

A low CO can result in decreased perfusion to the extremities, causing *mottling,* a blue or gray skin coloring. The skin may appear dusky because tissue capillary O_2 extraction is increased with chronic HF. Chronic edema can result in pigment changes. A coolness or clammy feeling to touch can occur with poor perfusion. The skin can become dry from over diuresis. It is important to recognize skin signs of other conditions, such as venous stasis, peripheral arterial disease, and cellulitis.

Neurologic Manifestations

Dizziness, lightheadedness, near syncope, or syncope from hypoperfusion to the brain can occur due to reduced CO and/or dysrhythmias. Hypotension from HF medications and hypovolemia are also common causes of neurologic symptoms in chronic HF.

Mental Status and Behavior Changes

Cerebral hypoperfusion may occur because of hypoxia to the brain from decreased CO. The patient or caregiver may report confusion, forgetfulness, inattentiveness, and restlessness. Assess for possible confounding conditions, including neurologic problems, such as stroke or transient ischemic attack (TIA) and psychologic disorders (especially depression and anxiety). About 1 in 5 patients with HF have clinical depression. This doubles the risk of mortality and readmissions.[14] Patients with psychologic disorders have poorer adherence to treatment plans. Screen all HF patients for depression or coexisting mental health conditions.

Sleep Problems

Snoring and daytime sleepiness can indicate sleep apnea, a common condition with chronic HF. Sleep apnea screening questions include those about daytime sleepiness and falling asleep, feeling rested in the morning, frequent nighttime awakenings, and results of a sleep study. Alternatively, insomnia could be due to psychologic issues, including anxiety or depression, or excessive daytime napping. Nocturia may disturb the patient's rest.

Chest Pain

Chest pain or angina can be the result of the reduced CO associated with HF compounded with CAD. Chest pain in HF can also occur due to myocardial stretch from volume overload. Careful questioning and assessment will help distinguish among potential causes for chest pain in the patient with chronic HF.

Weight Changes

Many factors contribute to weight changes. Progressive weight gain in the patient with chronic HF may indicate fluid retention. Renal failure may contribute to fluid retention. Abdominal fullness from ascites and hepatomegaly often causes anorexia and nausea. As HF advances, cardiac *cachexia* with muscle wasting and fat loss can be masked by edema.

Complications of Heart Failure

Pleural Effusion

Pleural effusion, fluid between the 2 tissue layers (pleura) that cover the lung and line the chest wall, is a common complication in HF. Increased capillary hydrostatic pressure in the circulation causes fluid leakage into the pleural space. Pleural effusions may cause dyspnea, cough, and chest pain. Pleural effusion is discussed in Chapter 30.

Dysrhythmias and Dyssynchronous Contraction

Both atrial and ventricular dysrhythmias are common in HF. Structural changes, including myocardial stretch, fibrosis, and chamber dilation, alter the electrical paths of the heart. Early or delayed depolarizations common in HF can trigger dysrhythmias. AF is quite common in patients with HF. The prevalence increases as the severity of HF increases. AF occurs when numerous sites in the atria fire spontaneously and rapidly, and organized atrial depolarization with contraction no longer occurs. Loss of "atrial kick" during systole may contribute to decreased CO and worsening HF symptoms.

AF promotes thrombus formation within the atria. Thrombi can break loose and form emboli, placing patients at significant risk for stroke. Treatment with anticoagulation is a priority if there are no significant contraindications. Treatment with drugs to achieve HR control is important. Other options include cardioversion and ablation. Atrial fibrillation is discussed in Chapter 39.

An enlarged LV and very low LVEF increase the risk for thrombus formation in the LV. Anticoagulant therapy may be considered.

Patients with HF are at risk for dangerous ventricular dysrhythmias (e.g., ventricular tachycardia [VT], ventricular fibrillation [VF]). SCD (sudden loss of cardiac function due to a fatal ventricular tachyarrhythmia) is a major cause of death in those with HF. Patients with HFrEF are at greatest risk for SCD. Guidelines recommend implanting a prophylactic implantable cardioverter-defibrillator (ICD) for patients with an LVEF less than 35%, who are NYHA Class II or III.[1] SCD is discussed in Chapter 37. Dysrhythmias are discussed in Chapter 39.

Ventricular remodeling can lead to dyssynchrony in ventricular contractions. One ventricle may contract before the other ventricle, leading to poor ventricular filling (preload), reduced force of ventricular contraction (systole), and severe mitral regurgitation (MR). This worsens HF symptoms. **Cardiac resynchronization therapy (CRT),** with implantable cardiac devices, can significantly improve patient morbidity and mortality. Many HF patients receive a combination ICD and CRT device, discussed later in the chapter.

Hepatomegaly

HF can lead to severe hepatomegaly as the liver becomes congested with venous blood. The hepatic congestion can lead to impaired liver function. Eventually liver cells die, fibrosis occurs, and cirrhosis can develop (see Chapter 48).

Cardiorenal Syndrome

Reduction in CO results in decreased renal perfusion, decreased glomerular filtration rate, and increased serum creatinine. Neurohormonal activation causes sodium and water retention, worsening HF symptoms and renal function. Impaired renal function with HF is an independent risk factor for HF morbidity and mortality. [1]

Anemia

The primary cause of anemia in chronic HF is chronic kidney insufficiency. Renal vasoconstriction results in the kidney producing less erythropoietin, leading to anemia. Excessive cytokine production also can reduce erythropoietin secretion. The anemia itself can worsen cardiac function due to increased cardiac workload through tachycardia, fluid retention, and increased SV. Because anemia further reduces renal blood flow, it adds stress to the heart and worsens fatigue and other manifestations of chronic HF.

Diagnostic Studies

Diagnosing HF can be challenging. Signs and symptoms may mimic many other medical conditions (e.g., anemia, lung disease). Diagnostic tests for ADHF and chronic HF are outlined in Table 38.6. A primary goal in diagnosis is to find the underlying cause of HF.

An echocardiogram is a valuable, noninvasive diagnostic tool used in patients with HF. The echocardiogram gives information about chamber size and function, LVEF, heart valve function, wall thickness and motion, presence of effusion or thrombus, and intracardiac and pulmonary pressures. This test helps to distinguish between HFrEF and HFpEF. Other useful tests include 12-lead ECG, ambulatory heart monitors, chest x-ray, 6-minute walk test, multigated acquisition (MUGA) scan, cardiopulmonary exercise stress test, cardiac MRI, and cardiac catheterization/angiogram. Polysomnography studies may help

TABLE 38.6 Interprofessional Care

Heart Failure

Both ADHF and Chronic HF	ADHF	Chronic HF
Diagnostic Assessment		
• History and physical assessment • Determine underlying cause • Serum chemistries, cardiac biomarkers, BNP or NT-proBNP level (see Table 35.9), liver function tests, thyroid function tests, CBC, lipid profile, kidney function tests, urinalysis • Chest x-ray • 12-lead ECG • 2-Dimensional echocardiogram (see Table 35.10) • Nuclear imaging studies (see Table 35.10) • Cardiac catheterization (see Table 35.11)	• Measure LV function • Hemodynamic monitoring • Endomyocardial biopsy in select patients	• Cardiopulmonary exercise stress test • 6-min walk test • Sleep studies in select patients
Management		
• Treatment of underlying cause • Drug therapy (Table 38.7) • Circulatory assist devices (e.g., ventricular assist device) • Daily weights • Sodium- and possibly fluid-restricted diet • O_2 by mask or nasal cannula if indicated	• High-Fowler's position • Noninvasive positive pressure ventilation • Circulatory assist device: IABP, ECMO, LVAD • Endotracheal intubation and mechanical ventilation • Vital signs, urine output at least q1hr until stable • Continuous ECG and pulse oximetry monitoring • Hemodynamic monitoring (e.g., intraarterial BP, PAWP, CO) • Cardioversion (e.g., atrial fibrillation) • Ultrafiltration	• Cardiac resynchronization therapy with biventricular pacing and internal cardioverter-defibrillator • Heart transplantation • Rest-activity periods • Dietitian consult • Physical/occupational therapy consult • Cardiac rehabilitation • Home health nursing care (e.g., telehealth monitoring) • Palliative and end-of-life care

identify obstructive sleep apnea. An endomyocardial biopsy may be done during heart catheterization to evaluate for infective or infiltrative disease in patients who develop unexplained, new-onset HF.

Laboratory studies aid in the diagnosis of HF. In general, BNP and N-terminal prohormone of BNP (NT-proBNP) levels correlate positively with the degree of LV failure.[12] Levels are temporarily higher in patients receiving nesiritide (Natrecor) and may remain high in patients with chronic, stable HF. So, it is important to know baseline levels. Increases in BNP or NT-proBNP levels can be caused by conditions other than HF, including pulmonary embolism, renal failure, and acute coronary syndrome.

Interprofessional Care: Acute Decompensated Heart Failure

Mortality and readmission rates for ADHF remain unacceptably high. Professional HF organizations have developed quality improvement initiatives, such as "Get with the Guidelines" and the Acute Decompensated HF Registry (ADHERE), to help HCPs and agencies improve HF outcomes.[1]

Goals of therapy for the patient hospitalized with ADHF include (1) relieving symptoms; (2) optimizing volume status; (3) supporting oxygenation, ventilation, CO, and end organ perfusion; (4) identifying and addressing the cause of the ADHF; (5) avoiding complications; (6) providing patient teaching addressing factors that precipitated HF exacerbation; and (7) planning discharge.

Patients with ADHF need ongoing monitoring and assessment of vital signs, O_2 saturation, weight, mentation, ECGs, and indicators of volume overload and decreased organ perfusion. Findings indicating fluid volume overload include edema, ascites, JVD, a positive hepatojugular reflux test, an S_3 heart sound, crackles, hypoxia, and worsening renal function.

Stable patients with ADHF may be treated in the emergency department (ED) or admitted to a telemetry unit. Assess these patients at least every 4 hours (e.g., vital signs, pulse oximetry) for adequate oxygenation. Record intake, output, and daily weights to evaluate fluid status. If the patient has dyspnea, place in a high-Fowler's position with the feet horizontal in the bed or dangling at the bedside. This position helps decrease venous return by pooling the blood in the extremities and increases the thoracic capacity for breathing.

If unstable, patients are managed in an intensive care unit (ICU). In addition to continual ECG and O_2 saturation monitoring, we assess vital signs and urine output at least hourly. Signs of decreased perfusion include hypotension, decreased urine output, cool extremities, altered mentation, heart murmur, dysrhythmias, and worsening renal and liver function tests. The patient may have hemodynamic monitoring, including arterial BP and pulmonary artery pressures. If a pulmonary artery (PA) catheter is placed, we monitor CO and pulmonary artery wedge pressure (PAWP). PAWP is an indirect measurement of LA filling pressure. A normal PAWP is 6 to 15 mm Hg. Patients with ADHF may have a PAWP as high as 30 mm Hg. Therapies are adjusted to maximize CO and reduce PAWP. Hemodynamic monitoring is discussed in Chapter 35.

Supplemental O_2 helps increase the PaO_2. In severe pulmonary edema, the patient may need noninvasive positive pressure ventilation (e.g., bilevel positive airway pressure [BiPAP]) or intubation and mechanical ventilation. BiPAP also decreases preload. O_2 therapy and ventilatory support is discussed in Chapter 28.

Nonpharmacologic Therapies

Ultrafiltration, or *aquapheresis,* is an option for the patient with volume overload when diuretics have not been effective.[1] It can rapidly remove intravascular fluid volume and excess sodium from the patient's blood while maintaining hemodynamic stability. Hemodialysis can be used for volume overload with renal failure. These treatments are discussed in Chapter 51.

Implantation of CRT, a biventricular pacemaker, may be done in patients with ADHF who meet specific criteria and do not respond to more traditional therapies.

In the ICU, *mechanical cardiac assist devices* are used temporarily to manage worsening HF. An intraaortic balloon pump (IABP) can increase coronary blood flow to the heart muscle and decrease the heart's workload through *counterpulsation*. The IABP is useful in hemodynamically unstable patients because it can decrease PA pressures and systemic vascular resistance (SVR), leading to improved CO. Ventricular assist devices (VADs) can help maintain the pumping action of a weakened heart.

Extracorporeal membrane oxygenation (ECMO) can offer short-term mechanical circulatory support for refractory HF and cardiogenic shock or as a bridge to heart transplant.[15] ECMO requires an ICU setting and an interprofessional team.

Drug Therapy

Drug therapy is essential in treating ADHF (Table 38.7).

Diuretics. Diuretics are the first line for treating patients with volume overload. They decrease sodium reabsorption at various sites within the kidneys, enhancing sodium and water loss. Decreasing intravascular volume with diuretics reduces fluid returning to the LV (preload). This allows for more efficient LV pumping, decreased pulmonary vascular pressures, and improved alveolar gas exchange. IV loop diuretics (e.g., furosemide) by bolus or infusion is preferred. Increased urine output, decreased symptoms, and fluid weight loss indicate effective diuretic therapy. Serum potassium and magnesium levels are continually monitored.

Vasodilators. Patient with ADHF who are not hypotensive receive vasodilators. IV nitroglycerin (NTG) is a primary venodilator that reduces blood return to the right side of the heart. It also improves coronary artery blood flow by dilating the coronary arteries. So, NTG reduces preload, slightly reduces afterload (in high doses), and increases myocardial O_2 supply. Tolerance often develops with continued IV use, requiring higher doses. When titrating IV NTG, monitor BP often (every 5 to 10 minutes) to avoid hypotension. Patients on IV vasodilators may have an indwelling arterial line or continuous noninvasive blood pressure monitoring.

Sodium nitroprusside (Nitropress) is a potent IV arterial vasodilator that reduces both preload and afterload, thus improving myocardial contraction, increasing CO, and reducing pulmonary congestion. Complications of therapy include hypotension and, at high doses, thiocyanate (cyanide) toxicity. It is given in an ICU.

TABLE 38.7 Drug Therapy

Heart Failure

Drug	Mechanism of Action
Anticoagulants (see Table 37.10)	• Prevent thromboembolism • Recommended for patients with an ejection fraction <20% and/or atrial fibrillation
Antidysrhythmic Drugs (see Table 39.9)	• Prevent or treat dysrhythmias
β-Adrenergic Blockers (see Table 36.6)	
bisoprolol carvedilol (Coreg) metoprolol succinate (Toprol-XL)	• Promote reverse remodeling • ↓ Afterload • Inhibit SNS • Reverse cardiac remodeling • Reduce mortality in patients with chronic HF
Diuretics (see Table 36.7)	
Loop Diuretics bumetanide (Bumex) furosemide (Lasix)	• Block absorption of sodium and chloride in the kidneys at the loop of Henle • ↑ Urine output • ↓ Fluid volume • ↓ Preload • ↓ Pulmonary venous pressure • Relieve symptoms of fluid congestion
Thiazide Diuretics hydrochlorothiazide metolazone (Zaroxolyn)	• Affect electrolyte reabsorption at the distal renal tubule causing sodium and chloride excretion • ↑ Urine output (milder diuretic effect than loop diuretics) • ↓ BP
Aldosterone Antagonists (Potassium-Sparing Diuretics) eplerenone (Inspra) spironolactone (Aldactone)	• Inhibit aldosterone that causes sodium and water retention and antiinflammatory responses in HF • Prevent potassium loss by inhibiting sodium and potassium exchange in the distal tubule • Mild diuretic effect • Reduce mortality and hospitalizations in patients with chronic HF
Osmotic Diuretics dapagliflozin (Farxiga)	• Inhibit SGLT2 activity and modulate reabsorption of glucose in the kidneys, causing glucose excretion in the urine • Osmotic diuretic in HF • Reduces risk of CV death and hospitalization in those with HFrEF
Morphine	
morphine (MS Contin, Duramorph)	• Bind to opioid receptors • May decrease the chemoreceptor response to hypoxia, and/or cause vasodilation reducing pulmonary congestion • Reduce anxiety

Drug	Mechanism of Action
Neprilysin-Angiotensin Receptor Inhibitors	
sacubitril/valsartan (Entresto)	• Sacubitril inhibits neprilysin, decreasing natriuretic degradation which promotes diuresis, natriuresis • Valsartan selectively blocks angiotensin II receptors • ↓ BP • Dilate venules and arterioles • ↑ Renal blood flow • May decrease mortality and hospitalizations in patients with chronic HF
Positive Inotropes	
β-Adrenergic Agonists[a] dobutamine dopamine	• ↑ Contractility (positive inotropic effect) • ↑ CO • May reduce PAWP • May cause dysrhythmias • ↑ Myocardial O_2 demand
Digitalis Glycoside digoxin	• Weak positive inotrope mostly at higher doses • Reduce effects of RAAS and SNS • May reduce HF symptoms and hospitalization if added to standard therapy for chronic HF
Phosphodiesterase Inhibitor[a] milrinone	• Produce mild vasodilation • ↑ SV and CO • Promote vasodilation
Renin-Angiotensin-Aldosterone System Inhibitors (see Table 36.6)	
ACE Inhibitors benazepril (Lotensin) captopril enalapril (Vasotec)	• Dilate venules and arterioles • ↓ Afterload and SVR • ↑ Renal blood flow • May relieve HF symptoms • Promote reverse remodeling • May reduce mortality and hospitalizations in patients with chronic HF
Angiotensin II Receptor Blockers losartan (Cozaar) valsartan (Diovan)	
Selective SA Node Inhibitor	
ivabradine (Corlanor)	• Selectively inhibits the I *f*-current in the SA node • ↓ HR • May reduce CVD death and hospitalizations in patients with HFrEF in sinus rhythm with a HR ≥70 bpm • Used only for patients with chronic HF
Vasodilators	
isosorbide dinitrate/hydralazine (BiDil) nitrates (e.g., nitroglycerin, isosorbide dinitrate [Isordil]) nitroprusside (Nitropress)[a]	• ↓ Afterload • Dilate the arterioles of the kidneys, leading to increased renal perfusion and fluid loss • ↓ BP • ↓ Preload • Nesiritide may reduce PAWP • May relieve HF symptoms (e.g., dyspnea) • Isosorbide dinitrate/hydralazine, fixed dose, may reduce morbidity and mortality in Blacks with HFrEF and NYHA Class III–IV symptoms

[a]Used for ADHF only.

DRUG ALERT

Sodium Nitroprusside (Nitropress)

- Record baseline BP and continuously monitor during administration.
- Arterial BP monitoring is recommended during drug infusion.
- Too rapid rate of IV infusion can reduce BP too quickly and cause hypotension.
- Headache, dizziness, nausea, agitation, and restlessness can occur.
- Monitor for toxic thiocyanate (drug by-product) levels if infusion is greater than 3 mcg/kg/min.

IV nesiritide is a recombinant form of BNP used for short-term treatment of ADHF after a failed response to IV diuretics.[1] As a venous and arterial vasodilator, its main effects include a reduction in PAWP and decrease in dyspnea. The primary adverse effect is symptomatic hypotension, so we carefully monitor BP.

Morphine. Morphine dilates pulmonary and systemic blood vessels, reducing preload and afterload. It is often given in small IV boluses to relieve the dyspnea associated with ADHF. Monitor the patient closely. Morphine has serious adverse effects, including respiratory depression requiring mechanical ventilation.

Positive inotropes. Inotropic drugs increase myocardial contractility and are used for patients with low CO despite adequate or high fluid volume. Drugs include β-agonists (e.g., dopamine, dobutamine, norepinephrine [Levophed]) and phosphodiesterase inhibitors (milrinone). β-Agonists are used as a short-term treatment of ADHF. In addition to increasing myocardial contractility and SVR, dopamine dilates the renal blood vessels and enhances urine output. Unlike dopamine, dobutamine is a selective β-agonist that works mainly on the β_1-receptors in the heart. It does not increase SVR. Effectiveness of inotropes is evaluated by assessing for improved CO, BP, urine output, and reduced filling pressures.

DRUG ALERT

Dopamine and Dobutamine

- Monitor IV site. Tissue necrosis and sloughing can occur with drug extravasation.
- High doses may cause ventricular dysrhythmias.

Milrinone has both inotropic and vasodilator properties. Milrinone improves myocardial contractility, increases CO, decreases afterload, and reduces BP. Like dopamine and dobutamine, this drug is available only for IV use. Adverse effects include dysrhythmias, thrombocytopenia, and liver toxicity.

Digitalis is a weaker positive inotrope that can be added if symptoms persist after other medications have been started. Digoxin can mildly increase contractility but also increases myocardial O_2 consumption. It can reduce heart rate, especially in those with atrial fibrillation. We monitor digoxin levels if toxicity is suspected and make dose adjustments based on renal function. Serum potassium and magnesium levels must be maintained.

Current evidence recommends the use of inotropic therapy only for the short-term management of patients with ADHF who have not responded to conventional drug therapy (e.g., diuretics, vasodilators, morphine).[1] Use continuous cardiac monitoring with all positive inotropic drugs as they can cause life-threatening dysrhythmias.

! SAFETY ALERT

Infusion Pumps

- To control the rate and assist with titration, use an infusion pump whenever you are giving IV vasodilators and inotropes.
- Ideally, pumps with drug libraries can help to avoid rates and doses that are out of the safe range for the drug.

Interprofessional Care: Chronic Heart Failure

The evolution of evidence-based medication and device therapies has dramatically improved the potential for better patient outcomes with chronic HF. The Heart Failure Society of America (HFSA) and the AHA have regularly published and updated guidelines on therapies for HF. Specialized inpatient, transitional, and ambulatory HF units are staffed with interprofessional HF teams (Table 38.6).

Chronic HF therapies are tailored to the patient based on co-morbid conditions. The goals of chronic HF therapies include (1) optimal symptom management, (2) decreased mortality and morbidity, and (3) minimizing side effects. Specifically, these therapies treat the underlying cause and contributing factors, maximize CO, improve ventricular function, improve quality of life (QOL), and preserve target organ function.

In a person with HF, the blood may not be adequately oxygenated, reducing O_2 saturation. The use of supplemental O_2 improves saturation and helps meet tissue O_2 needs. This helps to relieve patient dyspnea and fatigue. Ongoing pulse oximetry monitors the need for and effectiveness of O_2 therapy.

Physical and emotional rest allows the patient to conserve energy and decreases the need for more O_2. The degree of rest recommended depends on the severity of HF. A patient with severe HF may be on bed rest. A patient with mild to moderate HF can be ambulatory with restricted activity. Urge the patient to take part in prescribed activities with adequate recovery periods. Consider a structured exercise program, such as cardiac rehabilitation, for all patients with chronic HF. These programs are associated with decreased hospitalizations, reduced mortality, improved QOL, and less depression.[16]

Drug Therapy

The cornerstone of drug therapy in chronic HF is neurohormonal blockade. The results of neurohormonal blockade include decreased plasma aldosterone levels, decreased SNS activity, vasodilation, and sodium and water excretion. Drug therapy for chronic HF is outlined in Table 38.7.

Evidence-based drug therapy for HFrEF

ACE inhibitors. ACE inhibitors are first-line drugs to decrease mortality, hospitalizations, and symptoms in patients with HFrEF.[1] ACE inhibitors block the RAAS by inhibiting

the conversion of angiotensin I to angiotensin II. They reduce afterload and SVR and slow ventricular remodeling by inhibiting ventricular hypertrophy.

Major side effects include symptomatic hypotension, persistent dry cough, hyperkalemia, angioedema (allergic reaction involving edema of the face and airways), and renal insufficiency (in high doses). Aging and renal insufficiency slow the metabolism of ACE inhibitors and may lead to increased serum drug levels. We monitor renal function and serum potassium levels. Examples of ACE inhibitors are shown in Table 38.7. More information about ACE inhibitors is found in Chapter 36.

DRUG ALERT

Captopril

- May cause severe hypotension and hyperkalemia.
- Monitor patient for first-dose hypotension (first-dose syncope).
- Skipping doses or stopping the drug can result in rebound HTN.
- Angioedema, a rare adverse effect, can be sudden and life-threatening.

Angiotensin II receptor blockers. For patients who are unable to tolerate ACE inhibitors, angiotensin II receptor blockers (ARBs) are recommended.[1] They prevent the vasoconstrictor and aldosterone-secreting effects of angiotensin II by binding to the angiotensin II receptor sites. ARBs promote afterload reduction and vasodilation. The side effects are similar to those of ACE inhibitors except that ARBs do not typically cause a cough. Angioedema is less common. Monitoring is similar to that for ACE inhibitors.

Neprilysin-angiotensin receptor inhibitors. Sacubitril/valsartan (Entresto) is a combination of a neprilysin inhibitor (sacubitril) and an ARB (valsartan). This drug provides dual blockade of the RAAS and the natriuretic peptide system. Sacubitril, a recombinant form of BNP, inhibits neprilysin, an enzyme that degrades natriuretic peptides. Sacubitril inhibition allows for more available circulating BNP. This results in decreased SVR, afterload, and CVP and increased natriuresis and diuresis. This drug is an alternative to ACE inhibitors and ARBs in patients meeting criteria with symptomatic HFrEF. It reduces death and hospitalization. Monitor patients for hypotension, renal insufficiency, and angioedema.[17]

Aldosterone antagonists. Spironolactone (Aldactone) and eplerenone (Inspra) are potassium-sparing diuretics that inhibit aldosterone activation. They work by binding to receptors at the aldosterone-dependent sodium-potassium exchange site in the distal renal tubule, where they have a mild diuretic effect. They may prolong survival in patients with HFrEF.[1] Carefully monitor serum potassium levels and renal function.

DRUG ALERT

Spironolactone (Aldactone)

- Monitor potassium levels during treatment.
- Use with caution in patients taking digoxin, since hyperkalemia may reduce the effects of digoxin.
- Teach patient to avoid foods high in potassium (e.g., bananas, oranges).
- Assess male patients for gynecomastia, a common side effect of long-term use.

β-Adrenergic blockers. β-Blockers directly block the negative effects of the SNS (e.g., increased HR) on the failing heart. Three β-blockers decrease mortality in patients with HFrEF: metoprolol succinate (Toprol-XL), bisoprolol, and carvedilol (Coreg). They may also increase LVEF. The improvement in LVEF is dose-related, so we give the highest tolerated dose.[1] However, because β-blockers can reduce myocardial contractility, care must be taken in patients with volume overload. After a low starting dose, the dose is increased every 2 weeks as tolerated. Major side effects include worsening of HF symptoms, hypotension, fatigue, and bradycardia.

DRUG ALERT

Carvedilol (Coreg)

- Obtain standing BP 1 hr after dosing to assess tolerance.
- Overdose can cause profound bradycardia, hypotension, bronchospasm, and cardiogenic shock.
- Abrupt withdrawal may result in sweating, palpitations, and headaches.

Ivabradine (Corlanor). Ivabradine selectively inhibits a particular sodium/potassium current in the SA node, causing a decreased HR. Patients with HFrEF who are in sinus rhythm with an HR greater than 70 bpm and have symptoms despite optimal doses of other medications may have fewer hospitalizations when taking Ivabradine. Monitor patients for bradycardia and lightheadedness.[17]

Hydralazine/isosorbide dinitrate combination (Bidil). This drug is a combination of 2 vasodilators: hydralazine and isosorbide dinitrate. It can significantly reduce mortality and improve LVEF and exercise tolerance by reducing afterload through vasodilation. The drug is specifically effective in Black persons with HFrEF already receiving optimal doses of other evidence-based medications.[1] Major side effects include hypotension and headache. Like other nitrates, it should not be used with phosphodiesterase inhibitors, such as sildenafil (Viagra).

Digitalis. Digitalis (digoxin), a weak positive inotrope, acts mainly as a neurohormonal modulator that reduces the effects of the SNS and suppresses renin secretion from the kidneys. Low-dose digitalis decreases HF hospitalizations and symptoms in patients who are still symptomatic despite standard HF therapies.[1,13] There is no mortality benefit. Better outcomes occur with digoxin serum levels under 0.9 ng/mL. Higher serum levels are associated with increased mortality and digoxin toxicity. Dose should be based on body mass, renal function, and concomitant medications. The usual daily dose in HF is 0.125 mg. Monitor renal function and serum potassium levels.

Dapagliflozin (Farxiga). Dapagliflozin, a sodium-glucose cotransporter-2 (SGLT-2) inhibitor, reduces the risk of CV death and hospitalization for patients with HFrEF. This medication was developed to treat type 2 diabetes by stopping absorption of extra glucose from the urine. The drug's effects in HF appear to be related to the unique osmotic diuretic properties. Side effects include dehydration and serious urinary tract and yeast infections. Use with caution in older adults and those with

kidney disease, low BP, or taking diuretics. Monitor volume status and kidney function.

Medications for symptom management

Diuretics. Diuretics reduce symptoms of fluid overload in both HFrEF and HFpEF. They reduce edema, pulmonary venous pressure, and preload by promoting renal excretion of sodium and water (see Table 36.7). Loop diuretics (e.g., furosemide [Lasix], bumetanide [Bumex]) act on the ascending loop of Henle to promote sodium, chloride, and water excretion. Potential problems include low serum potassium levels, ototoxicity, and possible allergic reaction in patients sensitive to sulfa-type drugs. Thiazide diuretics inhibit sodium reabsorption in the distal tubule, promoting excretion of sodium and water. They can severely lower potassium levels.

In chronic HF, the patient receives the lowest effective dose of diuretic. Side effects of diuretics include dehydration, hypotension, orthostasis, renal problems, and electrolyte imbalances. Diuretic resistance in HF patients may require increasing doses and adding different types of diuretics.

Device Therapy

Patients with HFrEF may benefit from implantable cardiac devices. HF patients must be on appropriate therapies before becoming a candidate for device therapy. In patients with an LVEF less than 35%, neurohormonal effects and cardiac remodeling can result in dyssynchronous contraction of the LV and RV, contributing to poor ventricular filling and reduced CO. CRT (biventricular pacing) is recommended for these patients.[1] With CRT, an extra pacing lead is placed through the coronary sinus to a coronary vein of the LV to coordinate right and left ventricular contractions (Fig. 38.4). They are also at significant risk for SCD. An ICD is recommended for primary prevention of SCD.[1] Patients with symptomatic HFrEF often need both CRT and an ICD. Combination implantable devices are available. Pacemakers and defibrillators are discussed in Chapter 39. Mechanical assist devices available to sustain HF patients with deteriorating function and those awaiting cardiac transplant are discussed later in the chapter.

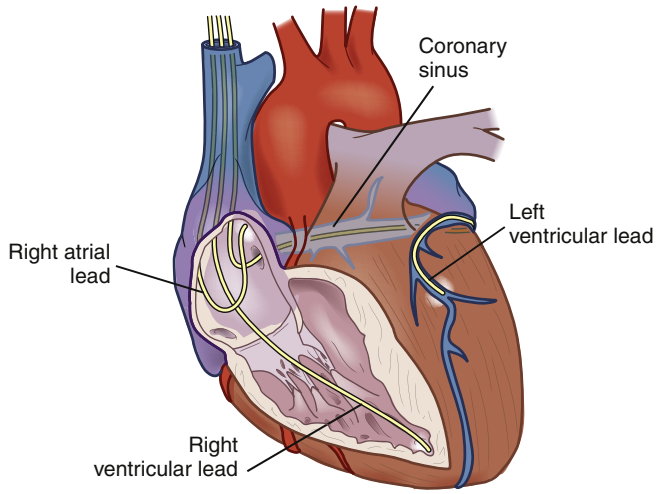

Fig. 38.4 Placement of pacing leads in cardiac resynchronization therapy.

CHECK YOUR PRACTICE

Your patient is scheduled for a biventricular pacemaker for worsening HF. She currently has a demand pacemaker and asks you why she needs this new one.

- How would you respond to her question?

Remote Monitoring of Physiologic Data

Implanted ICD and CRT devices can be used to remotely monitor patients. Information from these devices can predict HF decompensation and help with clinical decision making. Parameters monitored remotely include BP, weight, HR trends (can evaluate adequacy of beta blockade, increasing HR can indicate worsening HF), HR variability (HRV, a reduction is associated with higher risk for exacerbation and hospitalization), patient activity level, dysrhythmias, and intrathoracic impedance (an indicator of intrathoracic fluid level providing early detection of impending ADHF).[18] Implantable remote hemodynamic monitoring is also possible. A PA sensor can be implanted during a right heart catheterization. It can provide information about HR, systolic, diastolic, and mean pulmonary artery pressures (PAP). Early detection of increases in intracardiac pressures, PAP, and fluid status in patients with both HFrEF and HFpEF allows for proactive management and decreased hospitalizations.[19]

Nutrition Therapy

A high-sodium diet and not taking prescribed medications as directed are common reasons HF patients are readmitted to the hospital. Take a detailed diet history. Review what foods the patient eats, and when, where, and how often the patient dines out. Assess the cultural value of food. Use this information to help the patient and caregiver in making diet choices within an individualized and culturally sensitive diet plan. The AHA website has helpful diet guidelines for patients with HF.

HF guidelines vary on sodium restriction. There is agreement that excess sodium may worsen HF symptoms and lead to an exacerbation. A low sodium intake may lead to adverse events in later stages of HFrEF. The degree of sodium restriction depends on the severity of the HF and the effectiveness of diuretic therapy. Generally, sodium intake is restricted to 2 grams per day (Table 38.8). Teach the patient what foods are low and high in sodium content and how to read labels. Review how to find sodium content per serving and the number of servings per package (Fig. 38.5). Teach ways to enhance food flavors without the use of salt (e.g., adding lemon juice, spices). Discuss the high sodium content of most restaurant foods.

The patient with mild to moderate HF usually does not need fluid restrictions. Fluid restrictions may be needed for stage D HF patients with persistent fluid retention despite appropriate sodium restriction.

To monitor fluid status, tell patients to weigh themselves at the same time each day. To ensure valid trending, this should be before breakfast, using the same scale, and wearing the same type of clothing. For patients with visual limitations, suggest scales with large numbers or an audible response. Tell patients to call the HCP about a weight gain of 3 lb (1.4 kg) over 2 days or a 3- to 5-lb (2.3-kg) gain over a week.[13]

TABLE 38.8 Nutrition Therapy

Low-Sodium Diets

General Principles

- Do not add salt or seasonings containing sodium when preparing food.[a]
- Do not use salt at the table.[a]
- 1 tsp of salt equals 2.3 g of sodium.
- Avoid high-sodium foods (e.g., canned soups, processed meats, cheese, frozen meals).
- Limit milk products to 2 cups daily.

Sample Menu Plans for 2400-mg Sodium Diet

Breakfast	Sodium (mg)
⅔ cup bran cereal	161
(⅔ cup Shredded Wheat cereal)[b]	3
1 slice whole-wheat bread	149
1 medium banana	1
6 oz fruit yogurt, fat free	85
1 cup fat-free milk	126
2 Tbsp jelly	5
Coffee, 8 oz	5
Lunch	
Chicken breast sandwich	
2 slices (3 oz) chicken breast, skinless	65
2 slices whole wheat bread	299
1 slice (¾ oz) American cheese	328
(1 slice [¾ oz] Swiss cheese, natural)[b]	54
Large-leaf romaine lettuce	1
2 slices tomato	90
1 Tbsp mayonnaise, low fat	90
1 medium peach	7
Dinner	
¾ cup vegetarian spaghetti sauce	459
(6 oz no-salt-added tomato paste)[b]	260
1 cup spaghetti	1
3 Tbsp parmesan cheese	389
Spinach salad	
1 cup fresh spinach leaves	24
¼ cup fresh carrots (grated)	10
¼ cup fresh mushrooms (sliced)	1
2 Tbsp vinaigrette dressing	0
½ cup canned pears, juice pack	4
½ cup corn, cooked from frozen	4
Snack	
⅓ cup almonds	4
¼ cup dried apricots	3
6 oz fruit yogurt, fat free	85

[a]1 tsp of salt equals 2.3 g of sodium.
[b]Substitutes to reduce to 1500-mg sodium diet.

Chicken Noodle Soup

❖ NURSING MANAGEMENT: HEART FAILURE

◆ Assessment

Subjective and objective data that you should obtain from a patient with HF are shown in Table 38.9. Carefully review the patient's current prescription and over-the-counter (OTC) drugs. Patients with chronic HF often take multiple other medications for coexisting conditions and underlying CVD. OTC medications known to pose significant risk to people with HF include nonsteroidal antiinflammatory drugs (NSAIDs), high-dose aspirin, ephedrine, pseudoephedrine, and diet pills. NSAIDs can increase sodium retention and worsen HF.

Review the patient's diet to assess issues related to HF. Explore the patient's chronic health problems as they may exacerbate HF, affecting the plan of care and the timing and choice of therapies. For example, a patient with sleep apnea may minimize some HF symptoms by using a continuous positive airway pressure device at night.

◆ Clinical Problems

Clinical problems for the patient with HF include:

- Activity intolerance
- Fatigue
- Fluid imbalance
- Health maintenance alteration
- Impaired cardiac function
- Impaired respiratory function
- Inadequate tissue perfusion

More information on clinical problems and interventions for the patient with HF is presented in eNursing Care Plan 38.1 on the website for this chapter.

◆ Planning

Nursing care focuses on the priority problems of decreased CO, impaired oxygenation, fluid overload, intolerance of physical activity, and managing a complex medication regimen.

TABLE 38.9 NURSING ASSESSMENT

Heart Failure

Subjective Data

Important Health Information

Health history: CAD (including recent MI), HTN, cardiomyopathy, valve or congenital heart disease, diabetes, hyperlipidemia, renal disease, thyroid or lung disease, rapid or irregular heart rate

Medications: Use of and adherence with any heart drugs. Use of diuretics, estrogens, corticosteroids, NSAIDs, OTC drugs, herbal supplements

Functional Health Patterns

Health perception–health management: Fatigue, depression, anxiety

Nutritional-metabolic: Usual sodium intake. Nausea, vomiting, anorexia, stomach bloating. Weight gain, ankle swelling

Elimination: Nocturia, decreased daytime urine output, constipation

Activity-exercise: Dyspnea, orthopnea, cough (e.g., dry, productive). Palpitations, dizziness, fainting

Sleep-rest: Number of pillows used for sleeping. Paroxysmal nocturnal dyspnea, insomnia, sleep apnea

Cognitive-perceptual: Chest pain or heaviness. RUQ pain, abdominal discomfort. Behavior changes, visual changes

Objective Data

Cardiovascular

Tachycardia, S_3, S_4, murmurs. Pulsus alternans. PMI displaced inferiorly and posteriorly, lifts and heaves, jugular venous distention

Gastrointestinal

Abdominal distention, hepatosplenomegaly, ascites

Neurologic

Restlessness, confusion, decreased attention or memory

Respiratory

Tachypnea, crackles, wheezes. Frothy, blood-tinged sputum

Skin

Cool, diaphoretic skin. Cyanosis or pallor. Peripheral edema (right-sided HF)

Possible Diagnostic Findings

Altered serum electrolytes (especially Na^+ and K^+), ↑ BUN, creatinine, or liver function tests. ↑ NT-proBNP or BNP. Chest x-ray showing cardiomegaly, pulmonary congestion, and interstitial pulmonary edema. Echocardiogram showing increased chamber size, decreased wall motion, decreased LVEF or normal LVEF with evidence of diastolic dysfunction (abnormal relaxation/filling). Atrial and ventricular enlargement on ECG. ↓ O_2 saturation

The overall goals for the patient with HF include (1) decrease in symptoms (e.g., shortness of breath, fatigue); (2) decrease in peripheral edema; (3) increase in exercise tolerance; (4) adherence with the treatment plan, including appropriate evidence-based medication and device therapies; and (5) no complications related to HF.

Implementation

Health Promotion

Communication and joint decision making that includes the patient, caregiver, and interprofessional team promotes high-quality, patient-centered care. Aggressively identify and treat risk factors in the patient with stage A HF in order to prevent or slow the progression to symptomatic HF.[20] Patients with obesity, metabolic syndrome, diabetes, HTN, and hyperlipidemia are already at stage A HF. Recommended lifestyle modifications begin with weight management, diet, and regular exercise. Often, medications are needed. Encourage patients to get recommended vaccinations. Patients with valve disease contributing to HF should be evaluated for valve repair or replacement. Coronary revascularization should be considered in patients with CAD. Antidysrhythmic drugs or pacing therapy may be indicated for patients with serious dysrhythmias or conduction disturbances.

Acute Care

Many persons with HF have 1 or more episodes of ADHF. Common precipitating factors include respiratory infections, dysrhythmias, acute coronary syndrome, uncontrolled HTN, and nonadherence to medications and/or diet. Patients with ADHF are usually stabilized in the ED, then admitted to an ICU, intermediate care unit, or specialized HF unit with continuous ECG monitoring.

Successful HF care depends on several important principles: (1) HF is a progressive disease; (2) treatment plans are established with QOL goals; (3) symptom management depends heavily on adherence to self-management protocols (e.g., daily weights, diet, exercise, recognizing signs and symptoms of decompensation) and drug and device therapies; (4) precipitating factors, etiologies, and contributing conditions must be addressed; (5) complex care needs often require care across settings, increasing risk for fragmented care; and (6) support systems are essential to the success of the treatment plan.

Ambulatory Care

Transitional care programs and protocols help to ensure coordination and continuity of health care as patients transfer between settings. Intensive disease management programs that include extensive patient education on self-management and exercise and close home surveillance follow-up by nurses can reduce short-term readmission rates in the highest risk patients.[21]

Goals of ambulatory HF care include symptom management, QOL maintenance, identifying and mitigating factors precipitating ADHF and hospitalization, and closely monitoring responses to and potential side effects of therapies. HF is a chronic and progressive condition that requires lifelong therapies. Include the patient and caregivers in the overall care plan (Boxes 38.3 and 38.4). Help them develop a clear action plan for response to signs and symptoms of impending exacerbation. A patient and caregiver guide for the patient with HF is shown in Table 38.10.

Home health (HH) professionals can be a vital part of the ambulatory and transitional care HF team. HH nurses often use individualized care protocols coordinated with the patient and HCP to identify worsening HF (e.g., weight gain, increased dyspnea). Many HH agencies offer specialized HF programs. Telehealth and device remote monitoring technology (e.g., electronic scale, BP cuff, pulse oximeter) can collect physiologic and

BOX 38.3 ETHICAL/LEGAL DILEMMAS

Competence

Situation

M.T., a 60-year-old man, has been waiting for a heart transplant for 6 months. He has been in the intensive care unit (ICU) for 1 month with a ventricular assist device (VAD). He recently had a stroke, which is a complication of the device. It left him paralyzed on his right side. He is only able to answer yes/no questions by shaking his head. He has needed mechanical ventilation since his stroke. For the past 2 weeks, he has needed hemodialysis because of renal failure. Recently, when you suction him, he turns his head away from you and bites down on the endotracheal tube. Although he does not have an advance directive, his wife and daughter tell you that, on many occasions before these events, he expressed that he would not want to live if he lost his independence. His wife and daughter request to have the mechanical ventilator withdrawn.

Ethical/Legal Points for Consideration

- Decisional capacity for informed consent related to treatment decisions involves 4 elements: (1) information provided about possible treatment options must be understood by patients, (2) patients must have the capacity to deliberate about the treatment choices and their consequences, (3) patients' treatment decisions must be freely chosen and made without coercion, and (4) patients must be able to communicate their decisions.
- Legal competence, as determined by the courts, has a low threshold. The ability to respond to questions by signaling a yes or no may be enough to prove understanding of the questions, ability to discriminate between choices, and ability to communicate choices, providing that the answers make sense and are appropriate. Review how your state defines legal competence.
- Next of kin are the legal decision makers in the absence of advance directives if the patient is unable to make decisions for himself. Decisional capacity should be tested without assuming it is absent.
- Some courts have accepted past assertions of preferences, past behavior, and assertions of their parties as evidence to support end-of-life preferences in the absence of advance directives.
- Know your agency's policies and local laws and regulations about informed consent and end-of-life decision making.

Discussion Questions

1. What would you do next given M.T.'s behavior and the information from his wife?
2. What are your feelings and concerns about caring for a patient for whom withdrawal of treatment will result in death?

BOX 38.4 EVIDENCE-BASED PRACTICE

Decreasing Readmissions for Heart Failure

N.C. is an 82-year-old female admitted to the cardiac unit with acute HF. Her medical record shows she had an MI 2 years ago. She has been admitted to the hospital 6 times in the last 18 months. N.C. is slightly short of breath when she speaks but has no dyspnea at rest. Her ankles have 1+ edema. Per report of the ED nurse, she received IV furosemide and had an output of 1200 mL before her transfer to the cardiac unit. Her current prescribed daily medications include metoprolol and lisinopril. N.C. is unable to confirm this information but tells you she takes 2 white pills when she remembers. She says she lives alone but her daughter sometimes stops by, but she cannot recall when her daughter last visited. The daughter arrives after she gets off work and tells you she sees her mother several times a week.

Making Clinical Decisions

Synthesis of Best Available Evidence

Readmission for HF is a quality measure. Health care agencies devote extensive resources to trying to minimize the need for patient readmission. Patients with HF who have unrecognized cognitive impairment have higher readmission rates and mortality than persons with intact cognition.

Clinician Expertise

As part of your unit's admission protocol for patients over 70, you complete a Mini-Cog screening for cognitive impairment. N.C. recalls only 1 of the 3 words; she draws the clock face but cannot place the hands for 11:10. You report these findings to the HCP during admission rounds. The patient's daughter, who was present for this screening, asks the HCP about the meaning of the results. The HCP says the findings suggest cognitive impairment and tells her additional measures may be needed to address N.C.'s living situation and her ability to manage her HF. After the HCP leaves, her daughter asks you what can be done to keep her mother out of the hospital. After determining the daughter's understanding of the effects of HF, you suggest including her in all education provided to her mother. You explain that caregiver engagement in education has shown to support better outcomes for patients like N.C. with HF. You confirm with the HF nurse navigator the daughter's interest in being involved in disease management education.

Patient Preferences and Values

N.C.'s daughter tells you, "I thought the heart attack was going to be the end of her. I want to learn everything I can to help her manage the heart failure."

Implications for Nursing Practice

1. What are important topics related to HF management that should be discussed with N.C.'s daughter?
2. How can you continue to involve N.C. in HF self-management despite her cognitive impairment?
3. What other resources can you offer to N.C. and her daughter?

Reference for Evidence

Agarwal KS, Bhimaraj A, Xu J, et al.: Decreasing heart failure readmissions among older patients with cognitive impairment by engaging caregivers, *J Cardiovasc Nurs* 35:253–261, 2020.

symptom data (Fig. 38.6).[17,18] Results can be sent to the HCP via telephone or secure website. In response to collected data, therapeutic interventions, such as a temporary increase in diuretic therapy, can be implemented to improve function and prevent hospitalization.

Teach the patient the basic mechanism of action of medications and signs of drug toxicity in easily understood terms. Effective self-care includes proper technique in taking a pulse (for a full minute) and use of home monitoring equipment. The patient should understand when to hold heart rate–lowering medications, such as β-blockers and digoxin. If patients are taking diuretic and/or potassium supplement medications, teach them the signs and symptoms of hypokalemia and hyperkalemia. These include weakness, fatigue, constipation, and muscle cramping.

Exercise training (e.g., CR) can improve symptoms of chronic HF. Exercise for patients with HF is safe and improves overall sense of well-being. It has been associated with reduced mortality.[16] Tailor exercise programs based on what the patient most enjoys doing. Teach the patient about the importance of rest periods, especially after exertion, and energy-conserving behaviors. Changes may be needed if the environment involves

TABLE 38.10 PATIENT & CAREGIVER TEACHING

Heart Failure

Include the following instructions when teaching the patient and caregiver about the management of heart failure:

Diet Therapy
- Consult the diet plan and list of permitted and restricted foods.
- Adhere to specific sodium restriction guidelines outlined by your HCP.
- Read labels to assess sodium content. Check the labels of over-the-counter drugs, such as laxatives, cough medicines, and antacids for sodium content.
- Avoid using salt when preparing foods or adding salt to foods.
- Weigh yourself at the same time each day, preferably in the morning, using the same scale and wearing similar clothes.
- Eat small, frequent meals.

Activity Program
- Increase walking and other activities gradually, provided they do not cause fatigue or dyspnea.
- Consider a cardiac rehabilitation program.
- Avoid extremes of heat and cold.

Ongoing Monitoring
- Know the signs and symptoms of worsening HF. These include increasing dyspnea, cough, orthopnea, PND, weight gain, edema, fluid retention, fatigue, and tiredness with physical activity.
- Recall the symptoms when illness began. Reappearance of previous symptoms may indicate a recurrence.
- Report at once any of the following to the HCP:
  - Weight gain of 3 lb (1.4 kg) in 2 days, or 3–5 lb (2.3 kg) in a week
  - Difficulty breathing, especially with activity or when lying flat
  - Waking up breathless at night
  - Frequent dry, hacking cough, especially when lying down
  - Fatigue, weakness
  - Swelling of ankles, feet, or abdomen. Swelling of face or difficulty breathing (if taking ACE inhibitors)
  - Nausea with abdominal swelling, pain, and tenderness
  - Dizziness or fainting
- Follow up with HCP on regular basis.
- Consider joining a local support group with your family members and/or caregiver(s).

Health Promotion
- Obtain annual influenza vaccination.
- Obtain pneumococcal and COVID-19 vaccines.
- Develop plan to reduce risk factors (e.g., BP control, tobacco cessation, blood glucose/Hb A1C control, weight reduction).

Rest
- Plan a regular daily rest and activity program.
- After exertion, such as exercise and ADLs, plan a rest period.
- Consider shorter working hours or schedule rest period during working hours.
- Avoid emotional upsets. Share any concerns, fears, feelings of depression, with HCP.

Drug Therapy
- Take each drug as prescribed.
- Develop a system (e.g., daily chart, weekly pillbox) to ensure drugs are taken.
- Count pulse rate each day before taking drugs (if appropriate). Know the limits that your HCP wants for your pulse rate.
- Take BP at determined intervals (if appropriate). Know your target BP limits.
- Know signs and symptoms of orthostatic hypotension and how to prevent them.
- If taking anticoagulants, know signs and symptoms of internal bleeding (bleeding gums, increased bruises, blood in stool or urine) and what to do.
- Know your INR and target range if taking warfarin (Coumadin) and how often to have blood checked.

Fig. 38.6 Home-based telehealth monitoring unit. (Used with permission from Honeywell HomMed.)

an increased cardiac workload (e.g., frequent climbing of stairs). Consult with a physical therapist or occupational therapist as needed.

End-Stage Heart Failure Therapy

Therapeutic options for stage D HF patients include (1) chronic inotropic therapy, (2) mechanical circulatory support (MCS) devices, (3) palliative care and hospice (with or without ICD deactivation), and (4) heart transplant. Patients who are not eligible for heart transplant may be candidates for lifelong MCS. MCS devices have significantly improved outcomes and QOL for patients with end-stage HF. MCS started before onset of severe right HF and systemic organ failure reduces mortality.[13]

Palliative and End-of-Life Care

HF mortality rates remain high. One in 5 persons with HF dies within a year of diagnosis. The estimated 5-year survival rate is worse than for most types of cancer. Repeated hospitalizations and ED visits for ADHF predict end-stage HF.[1,17]

The ACCF and AHA provide guidelines for patients with end-stage HF (stage D).[1] End-of-life discussions and management include advanced directives and information about advanced HF therapies (e.g., VADs, heart transplants), palliative care, and hospice.

Palliative care may be appropriate early in the course of HF in conjunction with other therapies intended to prolong life. Palliative nursing care emphasizes (1) unifying the patient, family, and health care team in formulating a plan of care; (2) aggressive symptom management; (3) avoiding therapies that are not effective and may prolong suffering; (4) integrating emotional and spiritual support for patient and family; and (5) determining when a patient may be ready to consider hospice care.

Patients with advanced CVD are eligible for hospice when (1) an HCP certifies that a life expectancy of 6 months or less is expected assuming the disease takes its normal course, (2) the patient has received optimal medical treatment and is not a candidate for further invasive procedures, and (3) the patient is assessed at NYHA Class IV. End-stage HF patients who meet hospice criteria are often referred late or not at all. Challenges in referring these patients to hospice include (1) difficulties with accurate life expectancy prediction, (2) reluctance to accept a DNR order due to multiple resuscitation survivals and implantable devices, and (3) a lack of patient and family understanding as to the chronic and terminal nature of HF. [22]

End-of-life nursing care of HF patients includes ongoing assessment and evaluation of interventions for effectiveness. Strategies include patient and caregiver support, drug therapies, and nondrug therapies. Palliative and end-of-life care are discussed in Chapter 10.

◆ Evaluation

The expected outcomes are that the patient with HF will:

- Maintain adequate O_2/CO_2 exchange at the alveolar-capillary membrane to meet O_2 needs of the body
- Maintain adequate blood pumped by the heart to meet metabolic demands of the body
- Have a reduction or absence of edema and stable baseline weight
- Achieve a realistic program of activity that balances physical activity with energy-conserving activities

MECHANICAL CIRCULATORY SUPPORT DEVICES

MCS devices decrease cardiac work and improve organ perfusion in patients with HF when conventional drug therapy is no longer adequate. MCS devices can help carefully selected patients for short-term management, long-term and bridge-to-transplant management, or as destination therapy.[13] Short-term MCS include IABPs, extracorporeal membrane oxygenation (ECMO), and continual flow pumps. The limitations of bed rest and the risk for infection and vascular complications prevent long-term use of these devices. Long-term MCS ventricular assist devices (VADs) include percutaneous devices (PVADs) and transplanted devices (LVADs, BiVADs). VADs provide highly effective long-term support as standard care in many heart transplant centers.

The type of device used depends on the extent and nature of the heart problem. They provide support in 3 situations: (1) the left, right, or both ventricles require support while recovering from acute injury (e.g., postcardiotomy); (2) the patient must be stabilized before heart surgery (e.g., a ruptured septum); and (3) the heart has failed, and the patient is awaiting heart transplantation. All MCS devices decrease cardiac workload, increase myocardial perfusion, and augment circulation.

Intraaortic Balloon Pump

The **intraaortic balloon pump (IABP)** provides temporary circulatory assistance by reducing afterload (through reducing systolic pressure) and augmenting the aortic diastolic pressure. This improves coronary blood flow. Table 38.11 lists common indications for an IABP.

The IABP consists of a sausage-shaped balloon, a pump that inflates and deflates the balloon, a control panel for synchronizing the balloon inflation to the cardiac cycle, and fail-safe features. The balloon is inserted percutaneously or surgically into the femoral artery. It is moved toward the heart and placed in the descending thoracic aorta just below the left subclavian artery and above the renal arteries (Fig. 38.7). After placement, an x-ray confirms the position.

A pneumatic device fills the balloon with helium at the start of diastole (immediately after aortic valve closure) and deflates it just before the next systole. The ECG is the trigger used to start the deflation on the upstroke of the R wave (of the QRS) and inflation on the T wave. The dicrotic notch of the arterial pressure tracing is used to refine timing (Fig. 38.8).

IABP therapy is known as *counterpulsation* because the timing of balloon inflation is opposite the ventricular contraction. The

TABLE 38.11 Common Indications and Contraindications for IABP Therapy

Indications

- Acute MI with any of the following[a]:
  - Ventricular aneurysm accompanied by ventricular dysrhythmias
  - Acute ventricular septal defect
  - Acute mitral valve dysfunction
  - Cardiogenic shock
  - Refractory chest pain with or without ventricular dysrhythmias
  - Short-term bridge to heart transplantation
  - Unstable angina unresponsive to drug therapy
  - High-risk interventional cardiology procedures
  - Cardiac surgery (e.g., prophylaxis before surgery, failure to wean from cardiopulmonary bypass [CPB], left ventricular failure after CPB)

Contraindications

- Irreversible brain damage
- Moderate to severe aortic insufficiency
- Abdominal aortic and thoracic aneurysms
- Terminal or untreatable diseases of any major organ system
- Generalized peripheral vascular disease (e.g., aortoiliac disease)[b]
- Major coagulopathy (e.g., disseminated intravascular coagulation [DIC])

[a]Allows time for emergent angiography and corrective heart surgery to be done.
[b]May inhibit balloon placement and is a relative contraindication; sheathless insertion may be used.

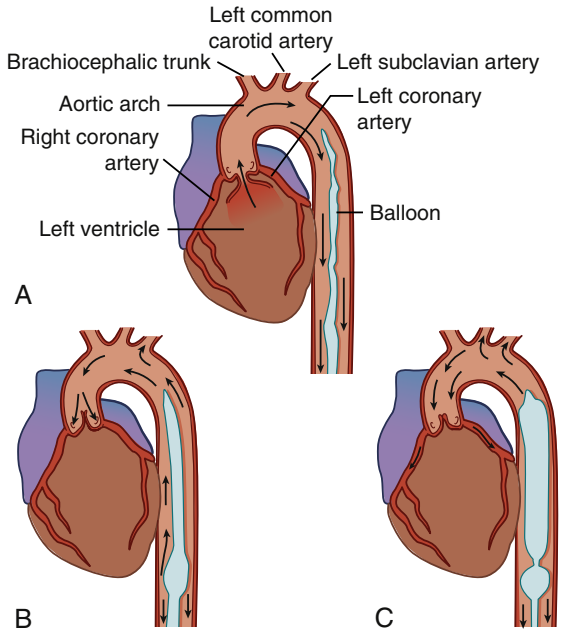

Fig. 38.7 IABP. (A) During systole the balloon is deflated, which helps with ejection of blood into the periphery. (B) In early diastole, the balloon begins to inflate. (C) In late diastole, the balloon is totally inflated, which augments aortic pressure and increases the coronary perfusion pressure. This increases coronary and cerebral blood flow.

Fig. 38.8 Monitoring on an IABP machine. (© beerkoff/iStock.com.)

IABP assist ratio is 1:1 in the acute phase of treatment, meaning that 1 IABP cycle of inflation and deflation occurs for every heartbeat.

Effects of Counterpulsation

In late diastole when the balloon is totally inflated, blood is forcibly displaced distal to the extremities and proximal to the coronary arteries and main branches of the aortic arch. Diastolic arterial pressure rises (diastolic augmentation). This increases coronary artery perfusion pressure and perfusion of vital organs. The rise in coronary artery perfusion pressure increases blood flow to the myocardium. The balloon is rapidly deflated just before systole. This creates a vacuum that causes aortic pressure to drop. When aortic resistance to left ventricular ejection is reduced (reduced afterload), the left ventricle empties more easily and completely. SV increases while myocardial O_2 consumption decreases. Table 38.12 describes the hemodynamic effects of IABP therapy.

TABLE 38.12 Hemodynamic Effects of Counterpulsation

Effects of Inflation During Diastole

- ↑ Diastolic pressure (may exceed systolic pressure)
- ↑ Pressure in the aortic root during diastole
- ↑ Coronary artery perfusion pressure
- Improved O_2 delivery to the myocardium
- ↓ Angina
- ↓ ECG evidence of ischemia
- ↓ Ventricular ectopy

Effects of Deflation During Systole

- ↓ Afterload
- ↓ Peak systolic pressure
- ↓ Myocardial O_2 consumption
- ↑ Stroke volume, possibly associated with:
- Improved mentation
- Warm skin
- ↑ Urine output
- ↓ HR
- ↑ Forward flow of blood, ↓ preload
- ↓ Pulmonary artery pressures
- ↓ Crackles

Complications of IABP Therapy

Vascular injuries, such as aortic dissection and compromised distal circulation, are common with IABP therapy. Thrombus and embolus formation add to the risk for circulatory compromise to the extremity. The action of the IABP can destroy platelets and cause thrombocytopenia. Movement of the balloon can block the left subclavian, renal, or mesenteric arteries. This can result in a weak or absent radial pulse, decreased urine output, and reduced or absent bowel sounds. Patients receiving IABP therapy are prone to infection. Local or systemic signs of infection require catheter removal. To reduce these complications, perform cardiovascular, neurovascular, and hemodynamic assessments every 15 to 60 minutes, depending on the patient's status (Table 38.13).

Mechanical complications from IABP are rare but can occur. Improper timing of balloon inflation may cause increased afterload, decreased CO, myocardial ischemia, and increased myocardial O_2 demand. If the balloon develops a leak, the pump will automatically stop. The catheter must be promptly removed to avoid an embolus. Signs of a leak include less effective augmentation, repeated alarms for gas loss, and blood backing up into the catheter. A malfunction of the balloon or console triggers fail-safe alarms and automatically shuts down the unit. You must be able to recognize complications immediately and report them to the HCP.

TABLE 38.13 NURSING MANAGEMENT

Complications of IABP Therapy

Potential Complication	Nursing Interventions
Arterial trauma caused by insertion or displacement of balloon	• Assess and mark peripheral pulses before inserting balloon to use as baseline for assessing pulses after insertion. • Assess perfusion to both upper and lower extremities at least every hour. • Measure urine output at least every hour (occlusion of renal arteries causes severe ↓ in urine output). • Observe arterial waveforms for sudden changes. • Keep head of bed no higher than 45 degrees. • Do not flex cannulated leg at the hip. • Immobilize cannulated leg to prevent flexion using a draw sheet tucked under the mattress, soft ankle restraint, or knee immobilizer.
Balloon leak or rupture	• Prepare for emergent removal and possible reinsertion.
Hematologic problems due to platelet aggregation along the balloon (e.g., thrombocytopenia)	• Monitor coagulation profiles, hematocrit, and platelet count.
Hemorrhage from insertion site	• Check site for bleeding at least every hour. • Monitor vital signs for signs of hypovolemia with each check.
Infection at site	• Use strict aseptic technique for insertion and dressing changes for all lines. • Cover all insertion sites with occlusive dressings. • Give prescribed prophylactic antibiotic for entire course of therapy.
Issues related to immobilization (e.g., pressure injuries)	• Reposition patient at least q2hr, being careful to maintain proper positioning. • Use appropriate pressure-relieving devices.
VTE caused by trauma, balloon obstruction of blood flow distal to catheter	• Give prophylactic heparin therapy (if ordered). • Assess pulses, urine output, and level of consciousness at least every hour. • Check circulation, sensation, and movement in both legs at least every hour.

The patient with an IABP is relatively immobile. They are limited to side-lying or supine positions with the head of bed elevated less than 45 degrees. The patient may be receiving mechanical ventilation and often has multiple invasive lines. All of this increases the risk for pressure injury and makes it hard to find a comfortable position. The patient may have sleep problems and anxiety. Adequate sedation, pain relief, skin care, and comfort measures are essential.

As the patient improves, circulatory support provided by the IABP is gradually reduced. Weaning involves reducing the IABP assist ratio from 1:1 to 1:2 and assessing the patient's response. If the patient stays stable, the ratio is changed from 1:2 to 1:3 until the IABP catheter is removed. Pumping must continue until the line is removed even if the patient is stable. This reduces the risk for clot formation around the catheter.

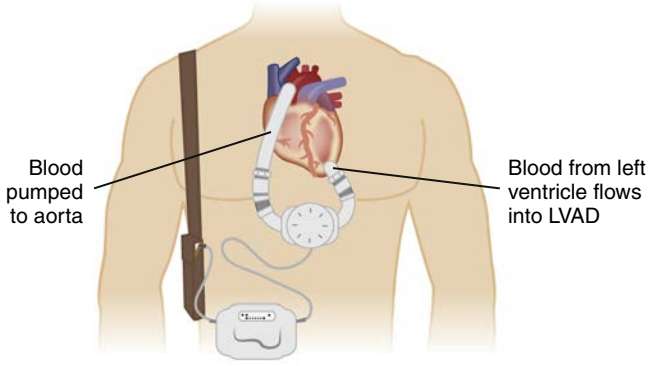

Fig. 38.9 Schematic diagram of a biventricular assist device (BVAD). (From Urden LD, Stacy KM, Lough ME: *Critical care nursing: diagnosis and management,* ed 8, St Louis, 2018, Mosby.)

Ventricular Assist Devices

A **ventricular assist device (VAD)** provides short- and long-term support for the failing heart. VADs are inserted into the path of flowing blood to augment or replace the action of the ventricle. Some VADs are implanted internally (e.g., peritoneum). Others are placed externally. A typical VAD shunts blood from the left atrium or ventricle to the device and then to the aorta. Some VADs provide right or biventricular support (Fig. 38.9). VADs operate on AC current or batteries. They allow for more mobility than the IABP.

Appropriate patient selection for VAD therapy is critical. Failure to wean from cardiopulmonary bypass (CPB) after surgery is a key indicator for VAD support. Other indications include (1) postcardiotomy cardiogenic shock, (2) a bridge to recovery or heart transplantation, and (3) patients with New York Heart Association Class IV heart disease who have failed medical therapy. Relative contraindications for VAD therapy include (1) BSA less than manufacturer's limit (e.g., 1.2 m^2), (2) irreversible end-stage organ damage, and (3) co-morbidities that would limit life expectancy to less than 3 years.

Implantable Artificial Heart

A fully implantable artificial heart can sustain the body's circulatory system. This device can provide a bridge to transplantation or replace the hearts of patients who are not eligible for a transplant and have no other treatment options. A major advantage of the artificial heart is that patients do not need immunosuppression therapy and thus avoid its inevitable, long-term effects. Risks include infection, thrombus, and stroke. Patients need lifelong anticoagulation and ongoing care from the interprofessional team.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: MECHANICAL CIRCULATORY SUPPORT

The patient with an IABP needs highly skilled care. Perform frequent and thorough cardiovascular assessments. These include measuring hemodynamic parameters (e.g., arterial BP, CO, SVR),

auscultating the heart and lungs, and evaluating the ECG (e.g., rate, rhythm). Assess for adequate tissue perfusion (e.g., skin color and temperature, mental status, capillary refill, peripheral pulses, urine output, bowel sounds) at regular intervals. IABP therapy should improve these findings.

Nursing care of the patient with a VAD is like that of the patient with an IABP. Observe the patient for bleeding, cardiac tamponade, ventricular failure, infection, dysrhythmias, renal failure, hemolysis, and VTE. The patient with VAD may be mobile and need an activity plan. In some cases, patients with VADs may go home. Preparation for discharge is complex and needs in-depth teaching about the device and support equipment (e.g., battery chargers). A competent caregiver must always be present.

Ideally, patients with MCS will recover, receive an artificial heart, or undergo heart transplantation. However, many patients die, or make the decision to no longer seek treatment, and death follows. Both the patient and caregiver need emotional support. Consult other team members, such as social workers or clergy, as needed.

HEART TRANSPLANTATION

Heart transplantation is the transfer of a healthy donor heart to a patient with a diseased heart. It is done to treat a variety of terminal or end-stage heart conditions (Table 38.14). In the United States, more than 3500 patients are awaiting heart transplants. Although the number of end-stage HF patients in need of a transplant has increased, the number of donors has remained about the same. The 1-year heart transplant survival rate is close to 90%. Despite an increasingly complex patient population, half of the recipients are alive 13 years after transplant.[23]

TABLE 38.14 Common Indications and Contraindications for Heart Transplantation

Indications

- End-stage HF refractory to medical care
- Severe, decompensated, inoperable, heart valve disease
- Recurrent life-threatening dysrhythmias not responsive to maximal interventions, including defibrillators
- Any other heart problems that severely limit normal function and/or have a mortality risk of more than 50% within 2 years

Absolute Contraindications

- Active infection, including HIV infection
- Chronologic age over 70 years or physiologic age over 65 years
- Advanced cerebral or peripheral vascular disease not amenable to correction
- Life-threatening illness (e.g., cancer) that will limit survival to <5 years despite therapy
- Severe lung disease that will likely result in the patient being ventilator-dependent after transplant

Relative Contraindications

- Severe obesity
- Psychologic impairment
- Evidence of noncompliance with medical therapy
- Active substance use (e.g., alcohol, drugs, tobacco)
- Irreversible liver or kidney failure not explained by HF
- Uncontrolled diabetes with vascular and neurologic complications
- Lack of social support network that can make long-term commitment for patient's welfare
- Unrealistic expectations by the patient or caregiver about transplant, its risks, and its benefits

Criteria for Selection

A careful selection process ensures that hearts are distributed fairly and to those who will benefit most. The United Network for Organ Sharing (UNOS) manages a system to assign donor organs. UNOS and transplantation are discussed in Chapter 14.

Indications and contraindications for a heart transplant are outlined in Table 38.14. Once a person meets the criteria for a transplant, an exhaustive physical examination and diagnostic workup are done. We assess heart function and vascular and immune systems. The patient and caregiver undergo a comprehensive psychologic evaluation of coping skills, support systems, and commitment to follow a rigorous life-long regimen. The complexity of the transplant process may be overwhelming to a patient without an adequate support system and understanding of the needed lifestyle changes.

Donor and recipient matching is based on body and heart size and an immunologic assessment. That assessment includes ABO blood type, antibody screen, panel of reactive antibody (PRA) level, and human leukocyte antigen typing.

A person accepted as a transplant candidate is placed on a transplant list. This may happen quickly during an acute illness or after a longer period. Stable patients may wait at home and receive ongoing medical care. If unstable, a patient may be hospitalized for more intensive therapy. Unfortunately, the overall waiting period for a new heart is long. Many patients die while waiting for a transplant.

Surgical Procedure

The transplant donor is someone who has irreversible brain injury. A surgical team goes to the hospital of the donor to remove donated organs after the declaration of brain death. The retrieved organs are transported on ice until they can be implanted. For the heart, this is optimally less than 4 hours. Often the donor heart is flown to the recipient's hospital. The donor heart is then implanted into the recipient using 1 of 2 approaches. In the biatrial approach, the recipient's damaged heart is removed at the midatrial level, and the donor heart connected at the LA, PA, aorta, and RA. In the bicaval approach, the RA of the recipient's heart (with the SA node and atrial conduction intact) is preserved and then the donor heart is connected. CPB during the surgery maintains oxygenation and perfusion to vital organs.

Post-Transplantation

After cardiac transplant, a variety of complications can occur. In the first year after transplantation, the major causes of death are infection and acute rejection. There is a risk for SCD.

Immunosuppressive therapy is the key in posttransplant management. Most immunosuppressive regimens include corticosteroids, calcineurin inhibitors (tacrolimus), and antiproliferative drugs (mycophenolate mofetil). The mechanisms of

action and side effects of these and other immunosuppressants are discussed in Chapter 14. Because of the use of immunosuppressive therapy, infection is a primary concern after transplant surgery. Long-term immunosuppressive therapy increases the risk for cancers, especially lymphomas, and cardiac vasculopathy (accelerated CAD).

To detect rejection, an endomyocardial biopsy is done weekly for the first month, monthly for the next 6 months, and yearly thereafter. In this procedure, the HCP inserts a catheter into the jugular vein and moves it into the RV. The catheter uses a bioptome, a device with 2 small cups that can be closed, to remove small samples of heart muscle for analysis.

Nursing care throughout the posttransplant period focuses on promoting patient adaptation to the transplant process, monitoring heart function, managing lifestyle changes, and ongoing teaching and support of the patient and caregiver.

Case Study

Heart Failure

(© iStockphoto/Thinkstock.)

Patient Profile

J.E. is a 70-year-old Hispanic woman who was admitted to the intermediate care unit with increasing shortness of breath, fatigue, and weight gain.

Subjective Data

- HTN for 20 years
- MI at 58 years of age
- Has increasing shortness of breath, fatigue, and an unexplained 11-lb weight gain during the past 2 weeks
- Had a respiratory tract infection 2 weeks ago; has persistent cough and edema in legs
- Cannot climb a flight of stairs without getting short of breath
- Sleeps with head elevated on 3 pillows
- Lives alone, does not always remember to take medication

Objective Data

Physical Assessment

- Moderate respiratory distress, use of accessory muscles, respiratory rate 36 breaths/min
- Systolic heart murmur
- Bilateral crackles in all lung fields
- Cyanotic lips and extremities
- Skin cool and diaphoretic

Diagnostic Studies

- Chest x-ray results: cardiomegaly with right and left ventricular hypertrophy; fluid in lower lung fields
- Echocardiogram results: ejection fraction 20%

Interprofessional Care

- Furosemide 40 mg IV twice daily
- Potassium 40 mEq PO twice daily
- Sacubitril/valsartan (Entresto) 97 mg/103 mg PO twice daily
- Nitroglycerine IV drip starting at 5 mcg/min
- Continuous ECG monitoring
- Diet: 2-gram sodium diet
- Titrate O_2 to keep O_2 saturation >93%
- Monitor intake and output, and daily weights
- Serum electrolytes; cardiac biomarkers q8h × 3

Discussion Questions

1. ***Recognize:*** What clinical manifestations of ADHF did J.E. exhibit?
2. ***Analyze:*** How would a serum NT-proBNP be beneficial in the diagnosis of ADHF?
3. ***Plan:*** Give the rationale for each of the HCP's orders prescribed for J.E.
4. ***Prioritize:*** What are your priority nursing interventions for J.E.?
5. ***Act:*** Which interventions can you delegate to AP or other members of the interprofessional team?
6. ***Evaluate:*** What outcomes would indicate nursing interventions were successful?

Answers and a corresponding concept map available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which statements accurately describe heart failure with preserved ejection fraction (HFpEF)? *(select all that apply)*
   - **a.** Uncontrolled hypertension is a primary cause.
   - **b.** Left ventricular ejection fraction may be within normal limits.
   - **c.** The pathophysiology involves ventricular relaxation and filling.
   - **d.** Multiple evidence-based therapies have been shown to decrease mortality.
   - **e.** Therapies focus on symptom control and treatment of underlying conditions.
2. Which compensatory mechanism involved in both chronic heart failure and acute decompensated heart failure leads to fluid retention and edema?
   - **a.** Ventricular dilation
   - **b.** Ventricular hypertrophy
   - **c.** Increased systemic blood pressure
   - **d.** Renin-angiotensin-aldosterone activation
3. The nurse is caring for a patient with acute decompensated heart failure who is receiving IV dobutamine. Which drug action is expected? *(select all that apply)*
   - **a.** Raises the heart rate
   - **b.** Dilates renal blood vessels
   - **c.** Increases heart contractility
   - **d.** Acts as a selective β-agonist
   - **e.** Increases systemic vascular resistance

4. A patient with chronic heart failure and atrial fibrillation is treated with low-dose digitalis and a loop diuretic. Which actions would the nurse take to prevent complications of this drug combination? *(select all that apply)*
   - **a.** Monitor serum potassium levels.
   - **b.** Teach the patient how to take a pulse rate.
   - **c.** Keep an accurate measure of intake and output.
   - **d.** Withhold digitalis if the pulse rhythm is irregular.
   - **e.** Teach the patient about diet potassium restrictions.
5. Which factor is a significant barrier to hospice referrals for patients with stage D heart failure?
   - **a.** Family member refusal
   - **b.** Scarcity of hospice care
   - **c.** History of pacemaker placement
   - **d.** Difficulty in estimating prognosis
6. The hemodynamic changes the nurse expects to find after successful initiation of intraaortic balloon pump therapy include *(select all that apply)*
   - **a.** decreased SV.
   - **b.** decreased SVR.
   - **c.** decreased PAWP.
   - **d.** increased diastolic BP.
   - **e.** decreased myocardial O_2 consumption.
7. Which are the greatest risks for patients in the **first** year after heart transplantation? *(select all that apply)*
   - **a.** Cancer
   - **b.** Infection
   - **c.** Rejection
   - **d.** Vasculopathy
   - **e.** Sudden cardiac death

1. a, b, c, e; 2. d; 3. c, d; 4. a, b; 5. d; 6. b, c, d, e; 7. b, c, e.

Dysrhythmias

Kimberly Day

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Fluids and Electrolytes

Perfusion

LEARNING OUTCOMES

1. Examine the nursing care of patients needing continuous electrocardiographic monitoring.
2. Distinguish the clinical characteristics and ECG patterns of normal sinus rhythm, common dysrhythmias, and pacemaker rhythms.
3. Describe the nursing and interprofessional management of patients with common dysrhythmias.
4. Compare and contrast defibrillation and cardioversion.
5. Describe the nursing and interprofessional management of patients with pacemakers and implantable cardioverter-defibrillators.
6. Select appropriate interventions for patients undergoing electrophysiologic testing and radiofrequency catheter ablation therapy.

KEY TERMS

asystole
atrial fibrillation
atrial flutter
automatic external defibrillator (AED)
cardiac pacemaker
complete heart block
dysrhythmias
premature atrial contraction (PAC)
premature ventricular contraction (PVC)
telemetry monitoring
ventricular fibrillation (VF)
ventricular tachycardia (VT)

This chapter describes basic principles of electrocardiographic monitoring and the recognition and treatment of common dysrhythmias. Adequate perfusion requires the heart to generate sufficient cardiac output (CO) to distribute blood to the body tissues. Abnormal heart rhythms, called **dysrhythmias**, can directly decrease CO by changing stroke volume and heart rate (HR). For example, tachycardia from a fever may decrease CO and cause hypotension. Your ability to recognize normal heart rhythms and dysrhythmias is an essential nursing skill.[1] Prompt recognition of a dysrhythmia and assessing the patient's response to the rhythm is critical to maintaining adequate perfusion.

RHYTHM IDENTIFICATION AND TREATMENT

Conduction System

Four properties of heart cells allow the conduction system to start an electrical impulse, send it through the heart tissue, and stimulate muscle contraction (Table 39.1). The heart's conduction system consists of specialized neuromuscular tissue found throughout the heart (see Fig. 35.4A). A normal impulse starts in the sinoatrial (SA) node in the upper right atrium near the entrance of the vena cava. It spreads over the atrial myocardium via interatrial and internodal pathways, causing atrial contraction. The impulse then travels to the atrioventricular (AV) node, through the bundle of His, and down the left and right bundle branches to the Purkinje fibers in the ventricles, causing ventricular contraction.[2]

Nervous Control of the Heart

The autonomic nervous system plays a vital role in the rate of impulse formation, speed of conduction, and strength of cardiac contraction. The parts of the autonomic nervous system that affect the heart are the vagus nerve fibers of the parasympathetic nervous system and the nerve fibers of the sympathetic nervous system.

Stimulation of the vagus nerve slows firing of the SA node and slows impulse conduction of the AV node. This decreases HR. Stimulation of the sympathetic nerves increases SA node firing, AV node impulse conduction, and cardiac contractility. This increases HR.[2]

Electrocardiographic Monitoring

The *electrocardiogram* (ECG) is a graphic tracing of the electrical impulses in the heart. The waveforms on the ECG represent the electrical activity of depolarization and repolarization produced by the movement of ions across the membranes of heart cells (see Fig. 35.4B).

The membrane of a heart cell is semipermeable. This allows it to maintain a high concentration of potassium and a low concentration of sodium inside the cell. Outside the cell, a high concentration of sodium and a low concentration of potassium exist. The inside of the cell, when at rest or in the polarized state, is negatively charged compared with the outside. When a cell or groups of cells are stimulated, the cell membrane changes its permeability. This change allows sodium to move rapidly into the cell. The inside of the cell is then positively charged compared with the outside *(depolarization)*. A slower movement of ions across the membrane restores the cell to the polarized state, called *repolarization*. Fig. 39.1 describes the phases of the cardiac action potential.[2]

A 12-lead ECG view of the heart is helpful in assessing dysrhythmias. Six of the leads measure electrical forces in the frontal plane. These are bipolar (positive and negative) leads I, II, and III and unipolar (positive) leads aVR, aVL, and aVF (Fig. 39.2A and B). The 6 unipolar leads (V_1 through V_6) measure the electrical forces in the horizontal plane (precordial leads) (Fig. 39.2C). The 12-lead ECG may show changes suggesting structural changes, conduction changes, damage (e.g., ischemia, infarction), electrolyte imbalance, or drug toxicity. Fig. 39.3 is an example of a normal 12-lead ECG.

We can use 1 or more ECG leads to continuously monitor a patient. The most common leads used are leads II and V_1 (Fig. 39.4). We use a modified chest lead (MCL_1) when only 3 leads are available for monitoring. MCL_1 is similar to V_1. Accurate ECG interpretation depends on the correct placement of the leads on the patient. The monitoring leads used are determined by the patient's clinical status.[3]

The ECG monitor continuously displays the heart rhythm. Paper attached to the monitor records the ECG (rhythm strip)

TABLE 39.1 Properties of Heart Cells

Property	Definition
Automaticity	Ability to initiate an impulse spontaneously and continuously
Excitability	Ability to be electrically stimulated
Conductivity	Ability to transmit an impulse along a membrane in an orderly manner
Contractility	Ability to respond mechanically to an impulse

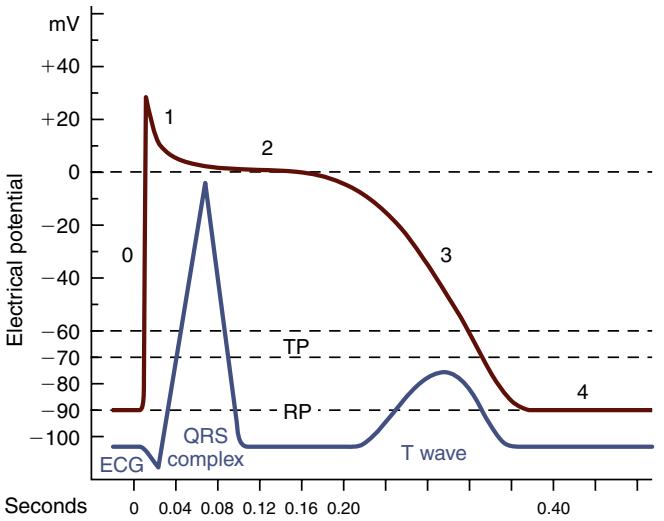

Fig. 39.1 Phases of the cardiac action potential. The electrical potential, measured in millivolts *(mV)*, is indicated along the vertical axis of the graph. Time, measured in seconds (sec), is indicated along the horizontal axis. The action potential has 5 phases, labeled *0* through *4*. Each phase represents a specific electrical event or combination of electrical events. Phase 0 is the upstroke of rapid depolarization and corresponds with ventricular contraction. Phases 1, 2, and 3 represent repolarization. Phase 4 is known as complete repolarization (or the polarized state) and corresponds to diastole. *RP,* Resting membrane potential; *TP,* threshold membrane potential.

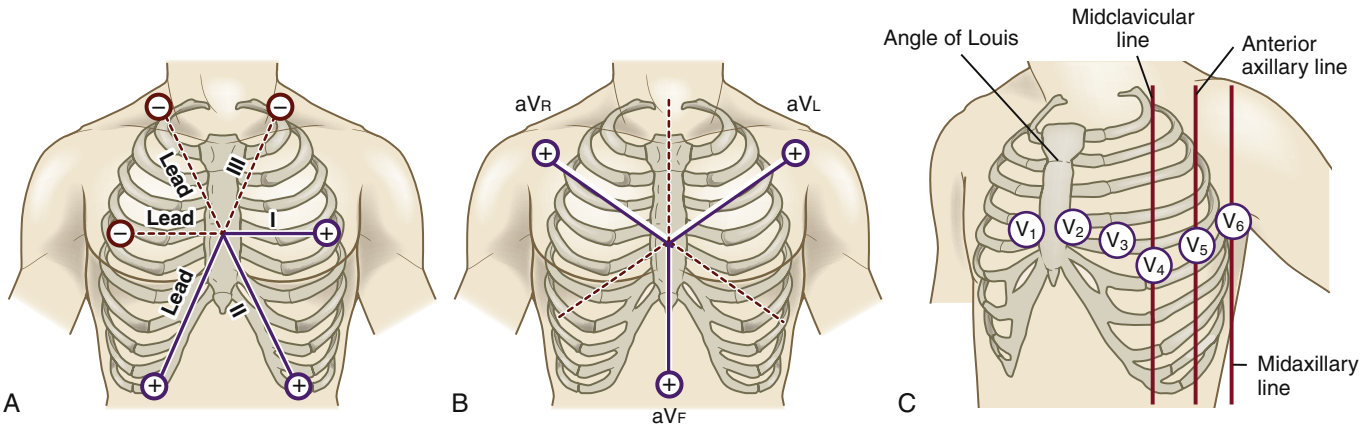

Fig. 39.2 (A) Limb leads I, II, and III. These bipolar leads are placed on the extremities. Shown are the angles from which these leads view the heart. (B) Limb leads aVR, aVL, and aVF. These unipolar leads use the center of the heart as their negative electrode. (C) Placement for the unipolar chest leads: V_1, 4th intercostal space at the right sternal border; V_2, 4th intercostal space at the left sternal border; V_3, halfway between V_2 and V_4; V_4, 5th intercostal space at the left midclavicular line; V_5, 5th intercostal space at the left anterior axillary line; V_6, 5th intercostal space at the left midaxillary line.

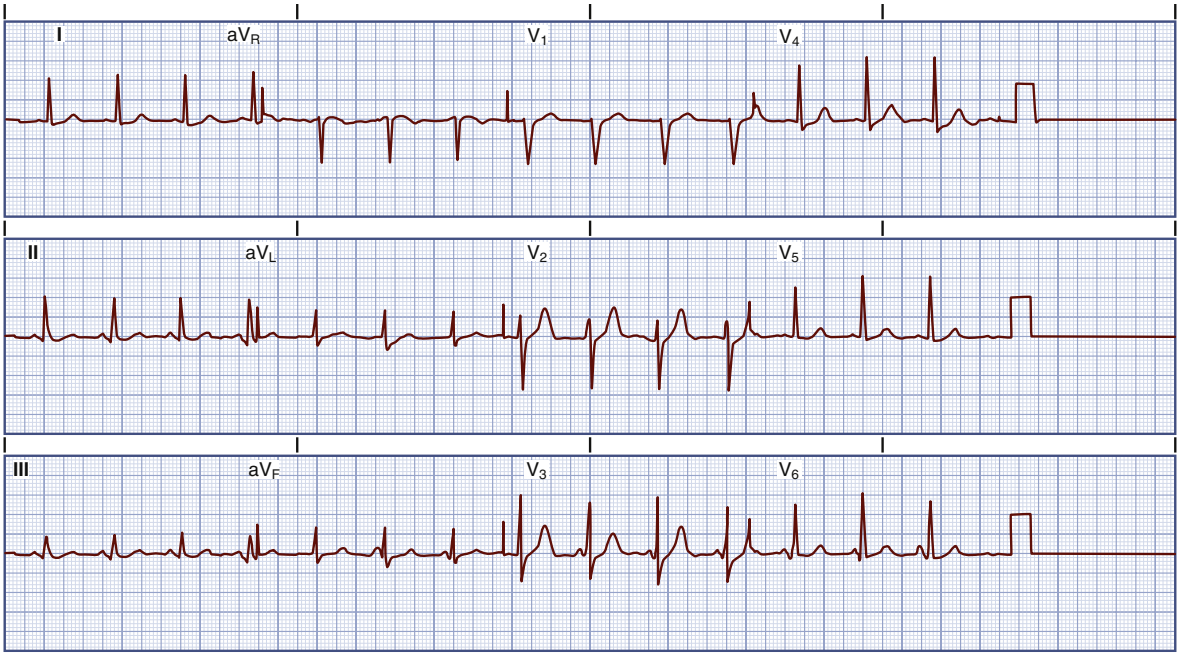

Fig. 39.3 12-lead ECG showing a normal sinus rhythm.

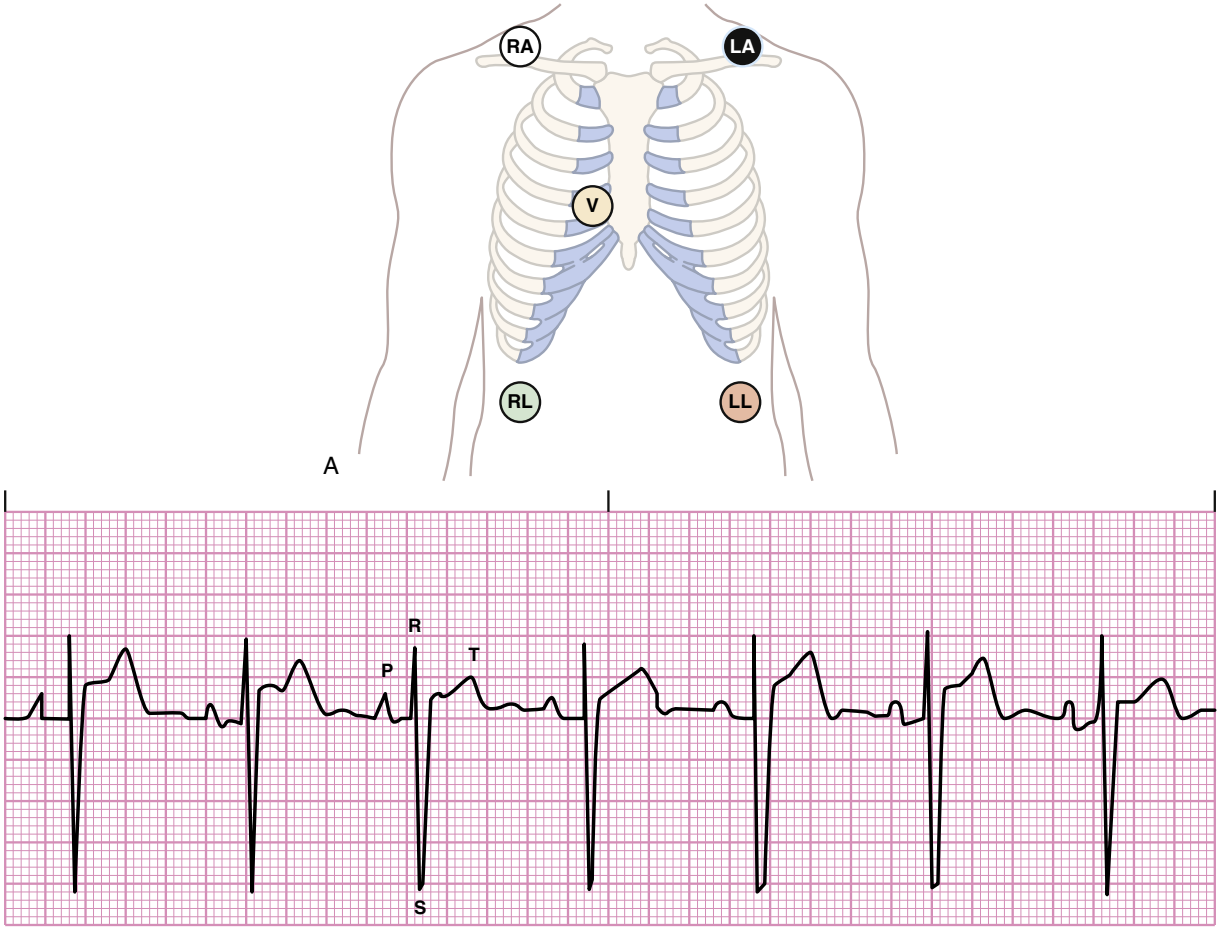

Fig. 39.4 (A) Lead placement for V_1 using a 5-lead system. (B) Typical ECG tracing in lead V_1. *LA,* Left arm; *LL,* left leg; *RA,* right arm; *RL,* right leg; *V,* chest lead.

to provide a record of the patient's rhythm. It allows for measurement of complexes and intervals and assessment of dysrhythmias.

To correctly interpret an ECG, measure time and voltage on the ECG paper. ECG paper consists of large (heavy lines) and small (light lines) squares (Fig. 39.5). Each large square consists of 25 smaller squares (5 horizontal and 5 vertical). Horizontally, each small square (1 mm) represents 0.04 second. This means that 1 large square equals 0.20 second and that 300 large squares equal 1 minute. Vertically, each small square (1 mm) represents 0.1 millivolt (mV). This means that 1 large square equals 0.5 mV. Use these squares to calculate the HR and measure time intervals for the different ECG complexes.

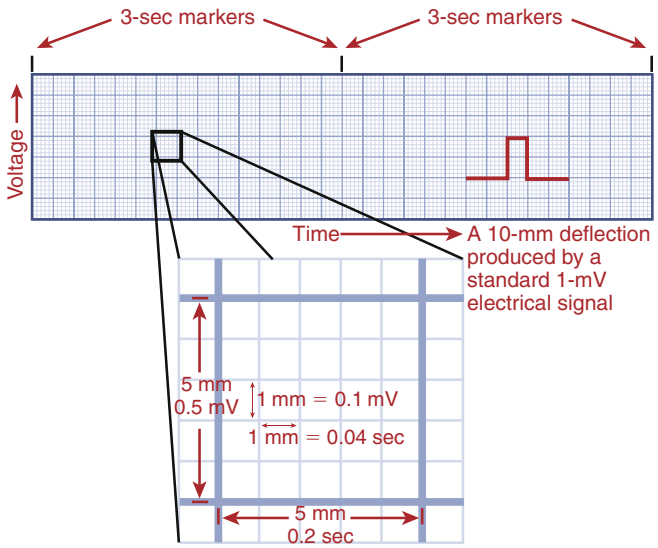

Fig. 39.5 Time and voltage on the ECG; 6-sec strip. (Modified from Wesley K: *Basic dysrhythmias and acute coronary syndromes,* ed 4, St Louis, 2011, Mosby JEMS.)

You can use a variety of methods to calculate the HR from an ECG. The most accurate way is to count the number of QRS complexes in 1 minute. A simpler way is to note that every 3 seconds, a marker appears on the ECG paper (Fig. 39.5). Count the number of QRS complexes in 6 seconds and multiply that number by 10. This is the estimated number of beats per minute (Fig. 39.6).

Another method to calculate the HR is to count the number of small squares between 1 R-R interval. Divide this number into 1500 to get the HR. Last, you can count the number of large squares between 1 R-R interval and divide this number into 300 to get the HR (Fig. 39.6). All these methods are more accurate when the rhythm is regular.

Another way to measure distances on the ECG strip is to use calipers. Often a P or R wave will not fall directly on a light or heavy line. Place the fine points of the calipers exactly on the parts you need to measure and then move to another part of the strip for a more precise time measurement.

Fig. 39.7 shows the components of a normal ECG tracing. Table 39.2 describes ECG waveforms and intervals, normal durations, and possible sources of changes. Table 39.3 presents a systematic approach to assessing a heart rhythm.

ECG leads consist of an electrode pad fixed with electrical conductive gel. Before placing these on the patient, properly prepare the skin. Clip excess hair on the chest wall with scissors. Gently rub the skin with dry gauze until slightly pink. If the skin is oily, wipe with alcohol first. If the patient is diaphoretic, apply a skin protectant before placing the electrode.

Artifact is a distortion of the baseline and waveforms seen on the ECG (Fig. 39.8). It is hard to accurately interpret an ECG when artifact is present. You may see artifact on the monitor when leads

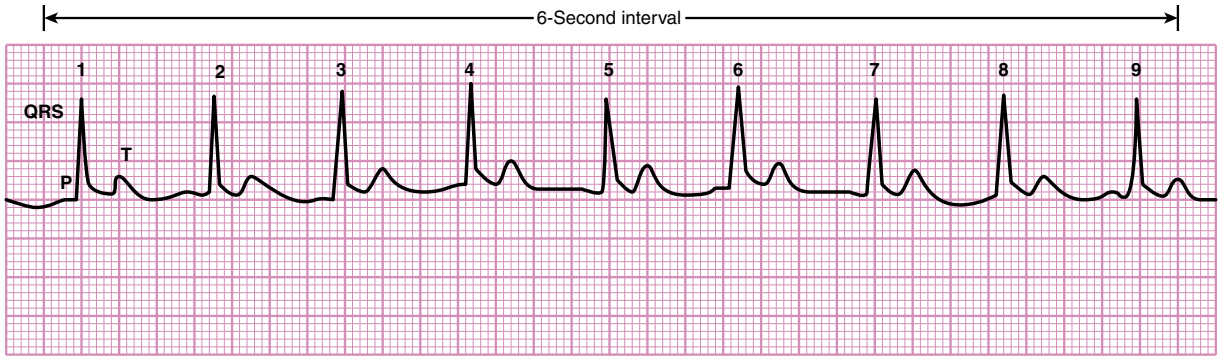

Fig. 39.6 When the rhythm is regular, heart rate can be easily determined by counting the number of "R" waves. The estimated heart rate is 90 beats/min. NOTE: Recorded from lead II.

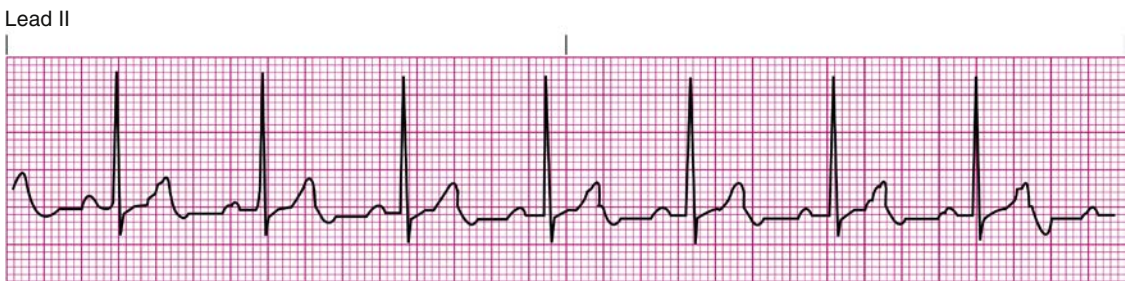

Fig. 39.7 Normal sinus rhythm. NOTE: Recorded from lead II.

TABLE 39.2 ECG Waveforms and Intervals[a]

Description	Normal Duration (sec)	Source of Possible Variation
P Wave		
Represents time for the passage of the electrical impulse through the atrium causing atrial depolarization (contraction). Should be upright	0.06–0.12	Problem in conduction within atria
PR Interval		
Measured from beginning of P wave to beginning of QRS complex. Represents time taken for impulse to spread through the atria, AV node and bundle of His, bundle branches, and Purkinje fibers to a point immediately before ventricular contraction	0.12–0.20	Problem in conduction usually in AV node, bundle of His, or bundle branches but can be in atria as well
QRS Complex		
Q wave: First negative (downward) deflection after the P wave, short and narrow, not present in several leads	<0.03	MI may result in development of a pathologic Q wave that is wide (≥0.03 sec) and deep (≥25% of the height of the R wave)
R wave: First positive (upward) deflection in the QRS complex	Not usually measured	
S wave: First negative (downward) deflection after the R wave	Not usually measured	
QRS Interval		
Measured from beginning to end of QRS complex. Represents time taken for depolarization (contraction) of both ventricles (systole)	<0.12	Problem in conduction in bundle branches or in ventricles
ST Segment		
Measured from the S wave of the QRS complex to the beginning of the T wave. Represents the time between ventricular depolarization and repolarization (diastole). Should be isoelectric (flat)	0.12	Changes (e.g., elevation, depression) usually caused by ischemia, injury, or infarction
T Wave		
Represents time for ventricular repolarization. Should be upright	0.16	Changes (e.g., tall, peaked; inverted) usually caused by electrolyte imbalances, ischemia, infarction
QT Interval[b]		
Measured from beginning of QRS complex to end of T wave. Represents time taken for entire electrical depolarization and repolarization of the ventricles. Normal adult women have slightly longer QT intervals than men.	0.34–0.43	Problems usually affecting repolarization more than depolarization and caused by drugs, electrolyte imbalances, and changes in heart rate

[a]HR influences the duration of these intervals, especially the PR and QT intervals (e.g., QT interval shortens in duration as heart rate increases).
[b]A corrected QT interval (QTc) is calculated to account for the influence of heart rate.

and electrodes are not secure, the conductive gel is becoming dry, there is muscle activity (e.g., shivering, ambulating), or electrical interference. If artifact occurs, check the connections in the equipment. Replace the electrodes if the conductive gel has dried out.

Telemetry Monitoring

Telemetry monitoring is the observation of a patient's HR and rhythm at a site distant from the patient. This technology can help rapidly identify dysrhythmias, ischemia, or infarction. There are 2 types of systems for telemetry monitoring. The first type is a centralized monitoring system. It requires you or a telemetry technician to continuously observe a group of patients' ECGs at a central location. The second system of telemetry monitoring does not require constant surveillance. These systems have the capability of detecting and storing data. Advanced alarm systems provide different levels of detection of dysrhythmias, ischemia, or infarction.

Electrophysiologic Mechanisms of Dysrhythmias

Dysrhythmias result from disorders of impulse formation, impulse conductions, or both. The heart has specialized cells in the SA node, atria, AV node, bundle of His, and Purkinje fibers (His-Purkinje system), which can fire (discharge) spontaneously. This is termed *automaticity.* Normally, the SA node is the natural pacemaker of the heart. It spontaneously fires 60 to 100 times per minute (Table 39.4). A secondary pacemaker from another site may fire in 2 ways. If the SA node fires more slowly than a secondary pacemaker, the electrical signals from the secondary pacemaker may "escape." The secondary pacemaker will then fire automatically at its intrinsic rate. These secondary pacemakers may start from the AV node at a rate of 40 to 60 times per minute or the His-Purkinje system at a rate of 20 to 40 times per minute.

Another way that secondary pacemakers can start is when they fire more rapidly than the normal pacemaker of the SA node. *Triggered beats* (early or late) may come from an *ectopic focus* or *accessory pathway* (area outside the normal conduction pathway) in the atria, AV node, or ventricles. This results in a dysrhythmia, which replaces the normal sinus rhythm.

The impulse started by the SA node, or an ectopic focus, is conducted to the heart cells. The property of myocardial tissue that allows it to be depolarized by a stimulus is called *excitability.*

TABLE 39.3 Approach to Assessing Heart Rhythm

When assessing a heart rhythm, use a consistent and systematic approach. One such approach includes the following:

1. Look for the P wave. Is it upright or inverted? Is there 1 for every QRS complex or more than 1? Are atrial fibrillatory or flutter waves present?
2. Evaluate the atrial rhythm. Is it regular or irregular?
3. Calculate the atrial rate.
4. Measure the duration of the PR interval. Is it normal duration or prolonged? Is the duration consistent before each QRS?
5. Evaluate the ventricular rhythm. Is it regular or irregular?
6. Calculate the ventricular rate.
7. Measure the duration of the QRS complex. Is it normal duration or prolonged?
8. Assess the ST segment. Is it isoelectric (flat), elevated, or depressed?
9. Measure the duration of the QT interval. Correct for heart rate (cQT) to determine if it is normal or prolonged.*
10. Note the T wave. Is it upright or inverted?

Other questions to consider include:

1. What is the dominant or underlying rhythm and/or dysrhythmia?
2. What is the clinical significance of your findings?
3. What is the treatment for the particular rhythm?

*A website for calculating the cQT interval for heart rate can be found at www.mdcalc.com/corrected-qt-interval-qtc.

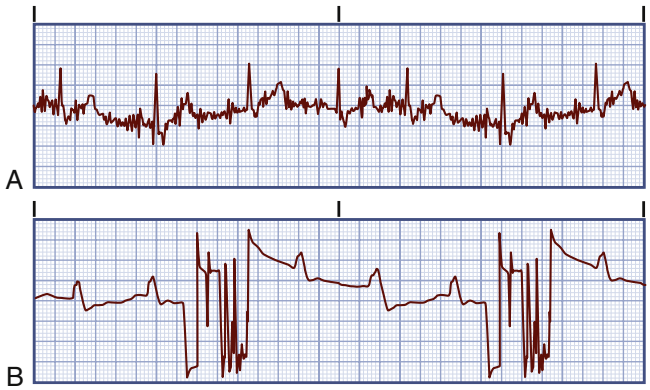

Fig. 39.8 Artifact. (A) Muscle tremor. (B) Loose electrodes.

TABLE 39.4 Intrinsic Rates of the Conduction System

Part of Conduction System	Rate
SA node and atria	60–100 times/min
AV node and bundle of His	40–60 times/min
Bundle branches and Purkinje fibers	20–40 times/min

The level of excitability is determined by the length of time after depolarization before the tissues can be restimulated. The recovery period after stimulation is the *refractory phase* or period. The *absolute refractory phase* or period occurs when excitability is zero, and the heart cannot be stimulated. The *relative refractory period* occurs slightly later in the cycle, and excitability is more likely. In states of *full excitability,* the heart is completely recovered. Fig. 39.9 shows the relationship between the refractory period and ECG.

If conduction is depressed and some areas of the heart are blocked (e.g., by infarction), the unblocked areas are activated earlier than the blocked areas. When the block is unidirectional, this uneven conduction may allow the initial impulse to reenter areas that were previously not excitable but have recovered. The reentering impulse may be able to depolarize the atria and ventricles, causing a premature beat or rapid rhythm.

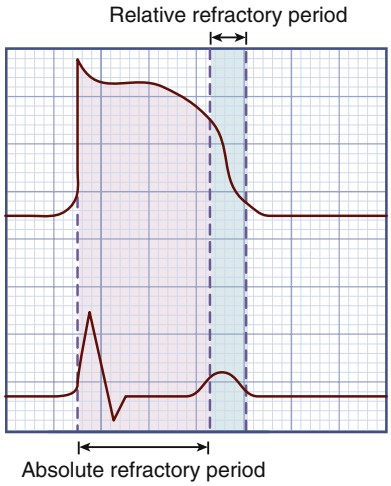

Fig. 39.9 Absolute and relative refractory periods correlated with the heart muscle's action potential and with an ECG tracing. (Modified from Urden LD, Stacy KM, Lough ME: *Critical care nursing: diagnosis and management,* ed 6, St Louis, 2010, Mosby.)

Evaluating Dysrhythmias

Dysrhythmias occur as the result of various abnormalities and disease states. Assess the heart rhythm, any changes in rhythm, and the patient's clinical status. Determining the cause of dysrhythmias is a priority. The cause influences the patient's treatment. Table 39.5 presents common causes of dysrhythmias.

Dysrhythmias occurring in nonmonitored settings present management challenges. If the patient becomes symptomatic (e.g., chest pain, syncope), determining the rhythm by heart monitoring is a high priority. Activate the emergency response system (ERS). Table 39.6 outlines the emergency care of the patient with a dysrhythmia.

In addition to continuous ECG monitoring during hospitalization, several other tests can assess dysrhythmias and the effectiveness of antidysrhythmic drug therapy. These include an electrophysiologic study (EPS), Holter monitoring, event monitoring (or loop recorder), exercise treadmill testing, and signal-averaged ECG. They can be done on an inpatient or outpatient basis. See Tables 35.10 and 35.11 for nursing care related to these tests.

An *electrophysiologic study* can identify the causes of heart blocks, tachydysrhythmias (dysrhythmias with rates greater than 100 beats/min), bradydysrhythmias (dysrhythmias with rates less than 60 beats/min), and syncope. An EPS study can locate accessory pathways and determine the effectiveness of antidysrhythmic drugs.

The Holter monitor continuously records the ECG while the patient is ambulatory and performing daily activities. The patient keeps a diary and records activities and any symptoms. Events in the diary are correlated with any dysrhythmias seen on the ECG. Use of event monitors has improved

TABLE 39.5 Common Causes of Dysrhythmias

Heart Conditions

- Accessory pathways
- Cardiomyopathy
- Conduction defects
- Heart failure
- Myocardial ischemia, infarction
- Valve disease

Other Conditions

- Acid-base imbalances
- Alcohol
- Caffeine, tobacco
- Connective tissue disorders
- Drowning
- Drug effects (e.g., antidysrhythmic drugs, stimulants, β-blockers) or toxicity
- Electric shock
- Electrolyte imbalances (e.g., hyperkalemia, hypocalcemia)
- Emotional crisis
- Herbal supplements (e.g., areca nut, wahoo root bark, yerba maté)
- Hypoxia
- Metabolic conditions (e.g., thyroid problems)
- Sepsis, shock
- Toxins

TABLE 39.6 EMERGENCY MANAGEMENT

Dysrhythmias

Assessment Findings	Interventions
• Irregular rate and rhythm; ↑ HR, bradycardia • Chest, neck, shoulder, back, jaw, or arm pain • Cold, clammy skin • ↓ Level of consciousness, confusion • ↓ or ↑ BP • ↓ O_2 saturation • ↓ Peripheral pulses • Diaphoresis • Dizziness, syncope • Dyspnea • Extreme restlessness, anxiety • Feeling of impending doom • Nausea and vomiting • Numbness, tingling of arms • Pallor • Palpitations • Weakness and fatigue	**Initial** • If unresponsive, assess circulation, airway, and breathing (CAB). • If responsive, monitor airway, breathing, and circulation (ABC). • Apply O_2 via nasal cannula or nonrebreather mask. • Take baseline vital signs with O_2 saturation. • Obtain 12-lead ECG. • Begin continuous ECG monitoring. • Identify underlying rate and rhythm. • Identify dysrhythmia. • Establish IV access. • Obtain baseline laboratory studies (e.g., CBC, electrolytes). **Ongoing Monitoring** • Monitor ABCs, vital signs, level of consciousness, O_2 saturation, and heart rhythm. • Anticipate need for antidysrhythmic drugs and analgesics. • Anticipate need for intubation if respiratory distress occurs. • Anticipate need to begin advanced cardiovascular life support (e.g., CPR, defibrillation, transcutaneous pacing).

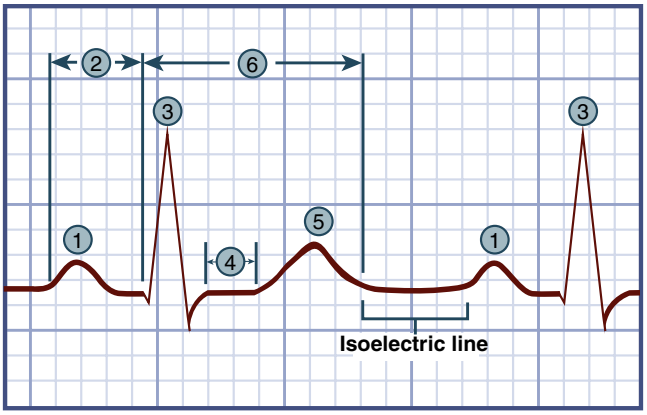

Fig. 39.10 The ECG tracing as seen in normal sinus rhythm. *1,* P wave; *2,* PR interval; *3,* QRS complex: Q wave, R wave, S wave; *4,* ST segment; *5,* T wave; *6,* QT interval. Isoelectric (flat) line or baseline represents the absence of electrical activity in the heart cells. (See Table 35.2 for timing of intervals.)

the evaluation of dysrhythmias in outpatients. Event monitors are recorders that the patient activates only when they have symptoms. New technology using smartphone apps can obtain and save ECG recordings and even detect some dysrhythmias. See an example of KardiaMobile at https://www.alivecor.com/kardiamobile.

Exercise treadmill testing evaluates the patient's heart rhythm during exercise. Any exercise-induced dysrhythmias or ECG changes that occur can be evaluated for treatment. The signal-averaged ECG identifies *late potentials*. Their presence suggests the patient may be at risk for developing serious ventricular dysrhythmias.

Overview of Cardiac Rhythms

Figs. 39.10 through 39.21 give examples of the ECG tracings of common normal rhythms and dysrhythmias. Table 39.7 presents the characteristics of each.

Normal Cardiac Rhythms

Normal sinus rhythm. *Normal sinus rhythm* refers to a rhythm that starts in the SA node at a rate of 60 to 100 beats/min and follows the normal conduction pathway (Fig. 39.10). The P wave is normal, precedes each QRS complex, and has a normal shape and duration. The PR interval is normal. The QRS complex has a normal shape and duration. Normal sinus rhythm implies that cardiac electrical activity is normal.

Sinus arrhythmia. In *sinus arrhythmia,* the conduction pathway is the same as that in sinus rhythm, but the SA node fires irregularly. This often results from changes in intrathoracic pressure during breathing. The HR increases slightly during inspiration and decreases slightly during exhalation. It remains 60 to 100 beats/min. It is common in healthy adults.

Types of Dysrhythmias

Sinus Bradycardia

In *sinus bradycardia,* the conduction pathway is the same as that in sinus rhythm, but the SA node fires at a rate less than 60 beats/min (Fig. 39.11A). *Symptomatic bradycardia* refers to a HR that is less

TABLE 39.7 Characteristics of Common Dysrhythmias

Pattern	Rate and Rhythm	P Wave	PR Interval	QRS Complex
Normal sinus rhythm (NSR)	60–100 beats/min and regular	Normal	Normal	Normal
Sinus bradycardia	<60 beats/min and regular	Normal	Normal	Normal
Sinus tachycardia	101–180 beats/min and regular	Normal	Normal	Normal
Premature atrial contraction (PAC)		Abnormal shape	Normal	Normal (usually)
Paroxysmal supraventricular tachycardia (PSVT)	151–220 beats/min and regular	Abnormal shape, may be hidden in the preceding T wave	Normal or shortened	Normal (usually)
Atrial flutter	*Atrial:* 200–350 beats/min and regular *Ventricular:* > or <100 beats/min and may be regular or irregular	Flutter (F) waves (saw-toothed pattern); more flutter waves than QRS complexes. May occur in a 2:1, 3:1, 4:1, etc., pattern	Not measurable	Normal (usually)
Atrial fibrillation	*Atrial:* 350–600 beats/min and irregular *Ventricular:* > or <100 beats/min and irregular	Fibrillatory (f) waves	Not measurable	Normal (usually)
Junctional dysrhythmias	40–180 beats/min and regular	Inverted, may be hidden in QRS complex or behind the S wave	Shortened, if present	Normal (usually)
First-degree AV block	Normal and regular	Normal	>0.20 sec	Normal
Second-degree AV block				
• **Type I** (Mobitz I, Wenckebach heart block)	*Atrial:* Normal and regular *Ventricular:* Slower and irregular	Normal	Progressive lengthening (longer, longer, longer, drop, now you have a Wenckebach)	Normal QRS width, with pattern of 1 non-conducted (blocked) QRS complex
• **Type II** (Mobitz II heart block)	*Atrial:* Usually normal and regular *Ventricular:* Slower and regular or irregular	More P waves than QRS complexes (e.g., 2:1, 3:1)	Normal or prolonged but consistent for every QRS	Widened QRS, preceded by ≥2 P waves, with non-conducted (blocked) QRS complex
Third-degree AV block (complete heart block)	*Atrial:* Regular but may appear irregular due to P waves hidden in QRS complexes *Ventricular:* 20–60 beats/min and regular	Normal, but no connection with QRS complex	Inconsistent	Normal or widened, no relationship with P waves
Premature ventricular contraction (PVC)	Underlying rhythm can be any rate, regular or irregular rhythm, PVCs occur at variable rates	Not usually visible, hidden in the PVC	Not measurable	Wide and distorted
Ventricular tachycardia (VT)	150–250 beats/min and regular or irregular	Not usually visible	Not measurable	Wide and distorted
Accelerated idioventricular rhythm	40–100 beats/min and regular	Not usually visible	Not measurable	Wide and distorted
Ventricular fibrillation (VF)	Not measurable and irregular	Absent	Not measurable	Not measurable

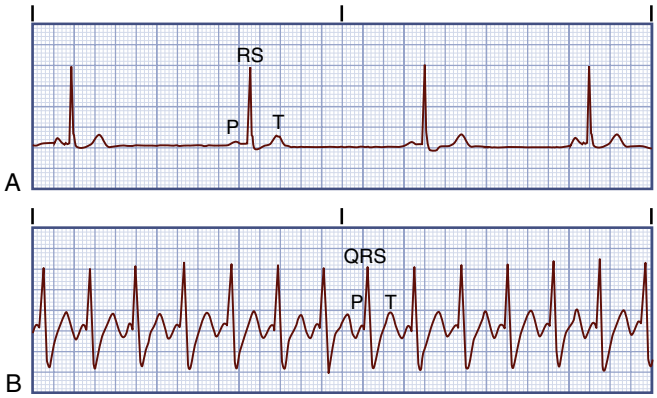

Fig. 39.11 (A) Sinus bradycardia. (B) Sinus tachycardia.

than 60 beats/min and causes the patient to have symptoms of inadequate perfusion (e.g., fatigue, dizziness, chest pain, syncope).[4,5]

Clinical associations. Sinus bradycardia may be a normal sinus rhythm in aerobically trained athletes and in some people during sleep. It also occurs in response to a Valsalva maneuver, hypothermia, increased intraocular pressure, vagal stimulation, and certain drugs (e.g., β-blockers, calcium channel blockers). Common disease states associated with sinus bradycardia are hypothyroidism, increased intracranial pressure, and inferior myocardial infarction (MI).

ECG characteristics. In sinus bradycardia, the HR is less than 60 beats/min, and rhythm is regular. The P wave precedes each QRS complex and has a normal shape and duration. The

PR interval is normal. The QRS complex has a normal shape and duration.

Clinical significance. The significance of sinus bradycardia depends on how the patient tolerates it. Manifestations of symptomatic bradycardia include pale, cool skin, hypotension, weakness, angina, dizziness, confusion, and shortness of breath.

Treatment. If bradycardia is due to drugs, these may have to be held, stopped, or reduced. For the patient with symptoms, treatment consists of giving IV atropine (anticholinergic drug).[6] If atropine is ineffective, transcutaneous pacing or a dopamine or epinephrine infusion are options. The patient may need a permanent pacemaker.

Sinus Tachycardia

The conduction pathway is the same in *sinus tachycardia* as in normal sinus rhythm. The discharge rate from the sinus node increases because of vagal inhibition or sympathetic stimulation. The sinus rate is 101 to 180 beats/min (Fig. 39.11B).[7]

Clinical associations. Sinus tachycardia is associated with many physiologic and psychologic stressors. Stressors include exercise, fever, pain, hypotension, hypovolemia, anemia, hypoxia, hypoglycemia, myocardial ischemia, heart failure (HF), hyperthyroidism, anxiety, and fear. It can be an effect of drugs, such as epinephrine, norepinephrine (Levophed), atropine, caffeine, theophylline, or hydralazine. Many over-the-counter cold remedies have active ingredients (e.g., pseudoephedrine) that can cause tachycardia.

ECG characteristics. In sinus tachycardia, the HR is 101 to 180 beats/min, and rhythm is regular. The P wave is normal and precedes each QRS complex. The PR interval is normal. The QRS complex has a normal shape and duration.

Clinical significance. The clinical significance of sinus tachycardia depends on the patient's tolerance of the increased HR. The patient may have dizziness, dyspnea, and hypotension because of decreased CO. An increased HR increases myocardial oxygen (O_2) consumption. Angina or an increase in infarction size may occur with sinus tachycardia in those with coronary artery disease (CAD) or an acute MI.

Treatment. The underlying cause guides the treatment. For example, if the patient has tachycardia from pain, effective pain management is important to treat the tachycardia. In clinically stable patients, we may try vagal maneuvers. IV β-blockers (e.g., metoprolol), adenosine (Adenocard), or calcium channel blockers (e.g., diltiazem) can reduce HR and decrease myocardial O_2 consumption.[5] Clinically unstable patients may need synchronized cardioversion.

Premature Atrial Contraction

A **premature atrial contraction (PAC)** is a contraction starting from an ectopic focus in the atrium (a location other than the SA node) sooner than the next expected sinus beat. The ectopic signal starts in the left or right atrium and travels across the atria by an abnormal pathway. This creates a distorted P wave (Fig. 39.12). At the AV node, the ectopic signal may be stopped (non-conducted PAC), delayed (lengthened PR interval), or conducted normally. If the signal moves through the AV node, in most cases, it is conducted normally through the ventricles.

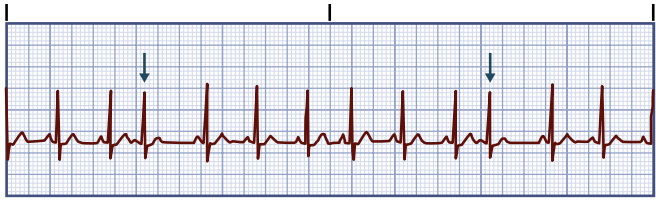

Fig. 39.12 Premature atrial contractions *(arrows)*.

Clinical associations. In a normal heart, a PAC can result from emotional stress, fatigue, or from caffeine, tobacco, or alcohol use. A PAC can also result from hypoxia, electrolyte imbalances, hyperthyroidism, chronic obstructive pulmonary disease (COPD), and heart disease, including CAD and valvular disease.

ECG characteristics. HR varies with the underlying rate and frequency of the PAC. The rhythm is irregular. The P wave has a different shape from that of a P wave originating in the SA node. It may be hidden in the preceding T wave. The PR interval may be shorter or longer than the PR interval coming from the SA node but is within normal limits. The QRS complex is usually normal. If the QRS interval is 0.12 second or more, abnormal conduction through the ventricles is occurring.

Clinical significance. In a person with a healthy heart, isolated PACs are not significant. Patients may report palpitations or a sense that the heart "skipped a beat." In a person with heart disease, frequent PACs may indicate enhanced automaticity of the atria or a reentry mechanism. Such PACs may warn of or start more serious dysrhythmias (e.g., supraventricular tachycardia [SVT]).

Treatment. Treatment depends on the patient's symptoms. Sources of stimulation, such as caffeine or sympathomimetic drugs (e.g., epinephrine, dopamine), may be withdrawn. β-Blockers may be used to decrease PACs.

Paroxysmal Supraventricular Tachycardia

Paroxysmal supraventricular tachycardia (PSVT), also known as supraventricular tachycardia or atrial tachycardia, is a dysrhythmia starting in an ectopic focus anywhere above the bifurcation of the bundle of His (Fig. 39.13).[6] Identifying the ectopic focus is often hard even with a 12-lead ECG since it requires recording the dysrhythmia as it starts.

PSVT occurs because of a reentrant phenomenon (reexcitation of the atria when there is a 1-way block). Usually, a PAC triggers a run of repeated premature beats. *Paroxysmal* refers to an abrupt onset and ending. A brief period of *asystole* (absence of all cardiac electrical activity) may follow the termination. AV block may prevent some of the impulses from being conducted to the ventricles. PSVT can occur with Wolff-Parkinson-White (WPW) syndrome or "preexcitation" with extra conduction or accessory pathways.

Clinical associations. In the normal heart, PSVT may occur with overexertion, emotional stress, deep inspiration, and stimulants, such as caffeine and tobacco. PSVT is associated

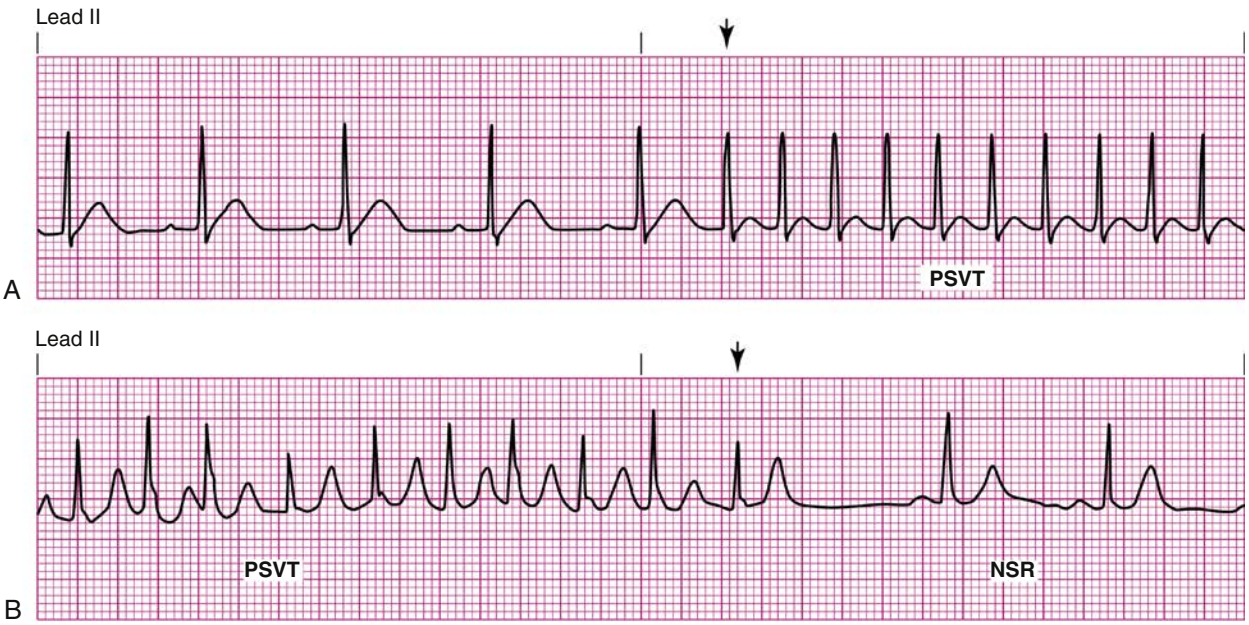

Fig. 39.13 Paroxysmal supraventricular tachycardia (PSVT). *Arrows* indicate beginning and ending of PSVT.

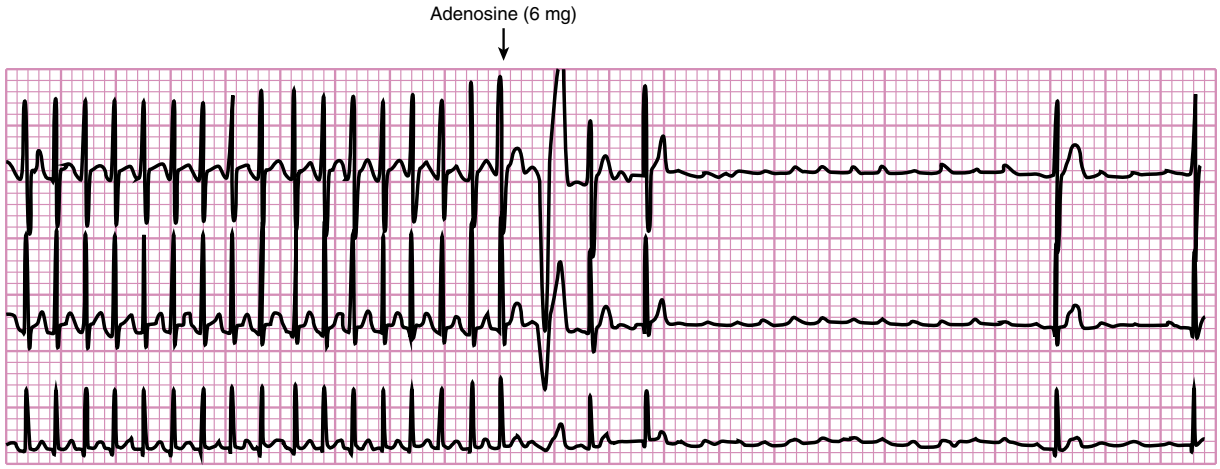

Fig. 39.14 Administration of adenosine rapid IV push. Note that SVT is followed by a brief period of asystole before the return to normal sinus rhythm. This is a common occurrence after adenosine.

with rheumatic heart disease, digitalis toxicity, CAD, and cor pulmonale.

ECG characteristics. In PSVT, the HR is 151 to 220 beats/min. The rhythm is regular or slightly irregular. The P wave may have an abnormal shape or be hidden in the preceding T wave. The PR interval may be shortened or normal. The QRS complex is usually normal.

Clinical significance. The significance of PSVT depends on the associated symptoms. A prolonged episode and HR greater than 180 beats/min will cause decreased CO because of reduced stroke volume. Manifestations include hypotension, palpitations, dyspnea, and angina.

Treatment. Treatment for PSVT includes vagal stimulation and drug therapy. Common vagal maneuvers include Valsalva and coughing. IV adenosine is the drug of choice to convert PSVT to a normal sinus rhythm (Fig. 39.14).[7] This drug has a short half-life (10 seconds) and is well tolerated. IV β-blockers and calcium channel blockers (e.g., diltiazem, verapamil) are options. The patient who becomes hemodynamically unstable undergoes synchronized cardioversion.

DRUG ALERT

Adenosine (Adenocard)

- Explain that the patient may feel chest pressure after receiving the medication.
- Injection site should be as close to the heart as possible (e.g., antecubital area).
- Give IV dose rapidly (over 1 to 2 sec) and follow with a rapid 20-mL normal saline flush. Use a stopcock setup to make sure adenosine gets to the heart quickly.
- Monitor patient's ECG continuously. Brief period of asystole is common (Fig. 39.14).
- Assess the patient for flushing, dizziness, chest pain, or palpitations.

Treatment of recurring PSVT and PSVT in patients with WPW syndrome includes radiofrequency catheter ablation of the accessory pathway.

Atrial Flutter

Atrial flutter is an atrial tachydysrhythmia identified by recurring, regular, sawtooth-shaped flutter waves originating from a

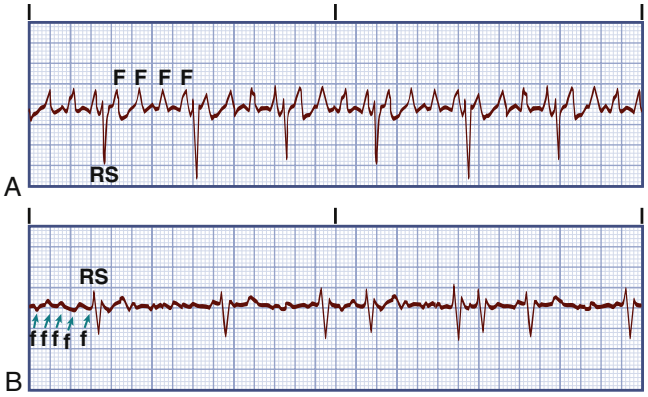

Fig. 39.15 (A) Atrial flutter with a 4:1 conduction (4 flutter *[F]* waves to each QRS complex). (B) Atrial fibrillation with a controlled ventricular response. Note the chaotic fibrillatory *(f)* waves *(arrows)* between the RS complexes. NOTE: Recorded from lead V_1.

single ectopic focus in the right atrium or, less often, the left atrium (Fig. 39.15A).

Clinical associations. Atrial flutter rarely occurs in a healthy heart. It is associated with CAD, hypertension, mitral valve disorders, pulmonary embolus, chronic lung disease, cor pulmonale, cardiomyopathy, hyperthyroidism, and the use of drugs, such as digoxin, quinidine, and epinephrine.

ECG characteristics. Atrial rate is 200 to 350 beats/min. The ventricular rate varies based on the conduction ratio. In 2:1 conduction, the ventricular rate is typically around 150 beats/min. Atrial and ventricular rhythms are usually regular. The atrial flutter waves represent atrial depolarization followed by repolarization. The PR interval is variable and not measurable. The QRS complex is usually normal. There is usually some AV block in a fixed ratio of flutter waves to QRS complexes because the AV node can delay signals from the atria.

Clinical significance. The high ventricular rates (greater than 100 beats/min) and loss of the atrial "kick" (atrial contraction coordinated with ventricular contraction) in atrial flutter decrease CO. This can cause serious problems, such as HF, especially in the patient with underlying heart disease. Patients with atrial flutter have an increased risk for stroke because thrombi (clots) can form in the atria from the stasis of blood. Patients receive warfarin or another anticoagulant to prevent stroke.[5,8] See Chapter 41 for discussion of anticoagulation therapy.

Treatment. The primary goal in treatment of atrial flutter is to slow the ventricular response by increasing AV block. Drugs used to control ventricular rate include calcium channel blockers and β-blockers.[5] Electrical cardioversion may convert the atrial flutter to sinus rhythm in an emergency (e.g., when the patient is clinically unstable) or electively. Antidysrhythmic drugs can convert atrial flutter to sinus rhythm (e.g., ibutilide [Corvert]) or maintain sinus rhythm (e.g., amiodarone, flecainide).

Radiofrequency catheter ablation in an EPS laboratory is the treatment of choice for atrial flutter. Low-voltage, high-frequency electrical energy is used to ablate (or destroy) the ectopic foci through a catheter in the right atrium. This should restore normal sinus rhythm.

Atrial Fibrillation

Atrial fibrillation is characterized by total disorganization of atrial electrical activity because of multiple ectopic foci. It results in loss of effective atrial contraction (Fig. 39.15B). The dysrhythmia may be paroxysmal (beginning and ending spontaneously) or persistent (lasting more than 7 days). Atrial fibrillation is the most common, clinically significant dysrhythmia with respect to morbidity and mortality rates and economic impact. Its prevalence increases with age.

Clinical associations. Atrial fibrillation usually occurs in a patient with underlying heart disease, such as CAD, valvular heart disease, cardiomyopathy, hypertensive heart disease, HF, and pericarditis. It often develops acutely with thyrotoxicosis, alcohol intoxication, caffeine use, electrolyte problems, stress, and after heart surgery.

ECG characteristics. During atrial fibrillation, the atrial rate may be as high as 350 to 600 beats/min. Chaotic, fibrillatory waves replace the P waves. Ventricular rate varies, and the rhythm is usually irregular. When the ventricular rate is between 60 and 100 beats/min, atrial fibrillation has a *controlled ventricular response.* Atrial fibrillation with a ventricular rate greater than 100 beats/min is atrial fibrillation with a *rapid (or uncontrolled) ventricular response.* The PR interval is not measurable. The QRS complex usually has a normal shape and duration. At times, atrial flutter and atrial fibrillation coexist.

Clinical significance. Atrial fibrillation results in a decrease in CO because of ineffective atrial contractions (loss of atrial kick) and/or a rapid ventricular response (RVR). Thrombi may form in the atria because of blood stasis. An embolized clot may move through arteries to the brain, causing a stroke. Atrial fibrillation accounts for 1 in 7 strokes.[9]

Treatment. The goals of atrial fibrillation treatment are to decrease the ventricular response (to less than 100 beats/min), prevent stroke, and convert to sinus rhythm, if possible. Ventricular rate control is a priority. Drugs used for rate control include calcium channel blockers (e.g., diltiazem), β-blockers (e.g., metoprolol), amiodarone, and digoxin (Lanoxin).

Some patients need drug or electrical conversion of atrial fibrillation to a normal sinus rhythm (e.g., reduced exercise tolerance with rate control drugs, contraindications to warfarin). The most common antidysrhythmic drug used for conversion to and maintenance of sinus rhythm is amiodarone.[6]

Electrical cardioversion may convert atrial fibrillation to a normal sinus rhythm. If a patient is in atrial fibrillation for longer than 48 hours, anticoagulation therapy with warfarin is needed for 3 to 4 weeks before the cardioversion.[8] Anticoagulation therapy continues for several weeks because the procedure can cause the clots to dislodge, placing the patient at risk for stroke. A transesophageal echocardiogram may be done to rule out clots in the atria. If no clots are present, anticoagulation therapy may not be needed before the cardioversion.

If drugs or cardioversion does not convert atrial fibrillation to normal sinus rhythm, the patient needs long-term anticoagulation therapy (Table 39.8). Warfarin requires monitoring for therapeutic levels (e.g., international normalized ratio [INR]). Alternatives to warfarin are available that do not require routine laboratory testing. Examples include dabigatran (Pradaxa), apixaban (Eliquis), and rivaroxaban (Xarelto).[8] See Chapter 41 for more on anticoagulation therapy.

TABLE 39.8 Drug Therapy

Antithrombotic Therapy for Atrial Fibrillation and Atrial Flutter

Risk Category	Recommended Therapy
Mechanical heart valve	Warfarin (target INR 2.5–3.5)
CHA_2DS_2-VASc[a] score of 0	No therapy recommended
CHA_2DS_2-VASc score of 1	No therapy recommended. An oral anticoagulant or aspirin (e.g., 81–325 mg/day) may be considered
CHA_2DS_2-VASc score of ≥2 or a history of prior stroke or transient ischemia attack (TIA)	Warfarin (target INR 2.0–3.0) Apixaban (Eliquis) Dabigatran (Pradaxa) Edoxaban (Savaysa) Rivaroxaban (Xarelto)
CHA_2DS_2-VASc score of ≥2 and end-stage kidney disease or on hemodialysis	Warfarin (INR 2.0–3.0) Apixaban (Eliquis)

[a]The CHA_2DS_2-VASc score for nonvalvular atrial fibrillation stroke risk can be calculated at www.mdcalc.com/cha2ds2-vasc-score-for-atrial-fibrillation-stroke-risk/.

CHA_2DS_2-VASc, Congestive heart failure; hypertension; age ≥75 (doubled); diabetes; prior stroke, transient ischemic attack, thromboembolism (doubled); vascular disease; age 65 to 74; sex; *INR,* international normalized ratio.

Modified from January CT, Wann LS, Calkins H, et al.: 2019 AHA/ACC/HRS focused update on the 2014 AHA/ACC/HRS guideline for the management of patients with atrial fibrillation, *Circulation* 140:e125, 2019.

For symptomatic patients with atrial fibrillation refractory to drugs or electrical conversion, radiofrequency catheter ablation, AV nodal ablation, and the Maze procedure are further options. AV nodal ablation involves destruction of the AV node and insertion of a permanent ventricular pacemaker.

The Maze procedure stops atrial fibrillation by interrupting the ectopic foci that are causing the dysrhythmia. Incisions are made in both atria, and *cryoablation* (cold therapy) is used to stop the formation and conduction of ectopic signals and restore normal sinus rhythm.[5]

Left atrial appendage occlusion. The left atrial appendage (LAA) is a pouch that extends off the left atrium. The LAA is a common source of blood clots in patients with atrial fibrillation. LAA occlusion is a treatment strategy to prevent blood clot formation in patients who have atrial fibrillation. Removing or occluding the LAA can decrease the incidence of strokes.

A special stapler can be used to remove the LAA, or the LAA can be occluded manually with sutures or an LAA occlusion device (e.g., Amplatzer Amulet Occluder).[5] These devices are positioned around the LAA and then closed like a clamp that is used to shut off the blood supply. This prevents blood from flowing into and out of the LAA. LAA occlusion is an alternative for patients who cannot use oral anticoagulants.[5]

CHECK YOUR PRACTICE

You are caring for a 72-year-old female patient who was admitted with chest pain. She has continuous EGG monitoring. You are concerned because you think the ECG tracing is hard to interpret, and she may be in atrial fibrillation. Your preceptor tells you that a lot of artifact is present.

- What can you do to improve the ECG tracing?
- How would you determine the patient's rhythm?

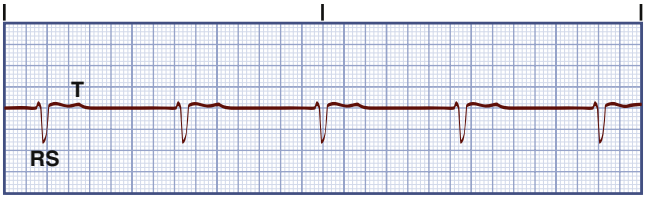

Fig. 39.16 Junctional escape rhythm. P wave is hidden in the RS complex. NOTE: Recorded from lead V_1.

Junctional Dysrhythmias

Junctional dysrhythmias start in the area of the AV node to the bundle of His known as the AV junction. They result because the SA node does not fire, or the signal is blocked. When this occurs, the AV node becomes the pacemaker of the heart. The impulse from the AV node usually moves in a retrograde (backward) fashion. This produces an abnormal P wave that occurs just before or after the QRS complex or is hidden in the QRS complex. The impulse usually moves normally through the ventricles. Junctional premature beats may occur. They are treated like PACs. Other junctional dysrhythmias include junctional escape rhythm (Fig. 39.16), accelerated junctional rhythm, and junctional tachycardia. Their treatment depends on the patient's tolerance of the rhythm and the patient's clinical condition.

Clinical associations. Junctional dysrhythmias are often associated with CAD, HF, cardiomyopathy, electrolyte imbalances, inferior MI, and rheumatic heart disease. Certain drugs (e.g., digoxin, nicotine, amphetamines, caffeine) can also cause junctional dysrhythmias.

ECG characteristics. In junctional escape rhythm, the HR is 40 to 60 beats/min. HR is 61 to 100 beats/min in accelerated junctional rhythm and 101 to 180 beats/min in junctional tachycardia. The rhythm is regular. The P wave is abnormal in shape and inverted. It hidden in the QRS complex (Fig. 35.16). The PR interval is less than 0.12 second when the P wave precedes the QRS complex. The QRS complex is usually normal.

Clinical significance. Junctional escape rhythms serve as a safety mechanism when the SA node has not been effective. Escape rhythms should not be suppressed. Accelerated junctional rhythm is due to sympathetic stimulation to improve CO. Junctional tachycardia indicates a more serious problem. This rhythm may reduce CO, causing the patient to become hemodynamically unstable (e.g., hypotensive).

Treatment. Treatment varies by the type of junctional dysrhythmia. If a patient has symptoms with a junctional escape rhythm, atropine can be used. If accelerated junctional rhythm or junctional tachycardia are caused by drug toxicity, the drug is stopped. In the absence of digitalis toxicity, β-blockers, calcium channel blockers, and amiodarone are used for rate control.

First-Degree AV Block

First-degree AV block is a type of AV block in which every impulse is conducted to the ventricles, but the time of AV conduction is prolonged (Fig. 39.17A). After the impulse moves through the AV node, the ventricles usually respond normally.

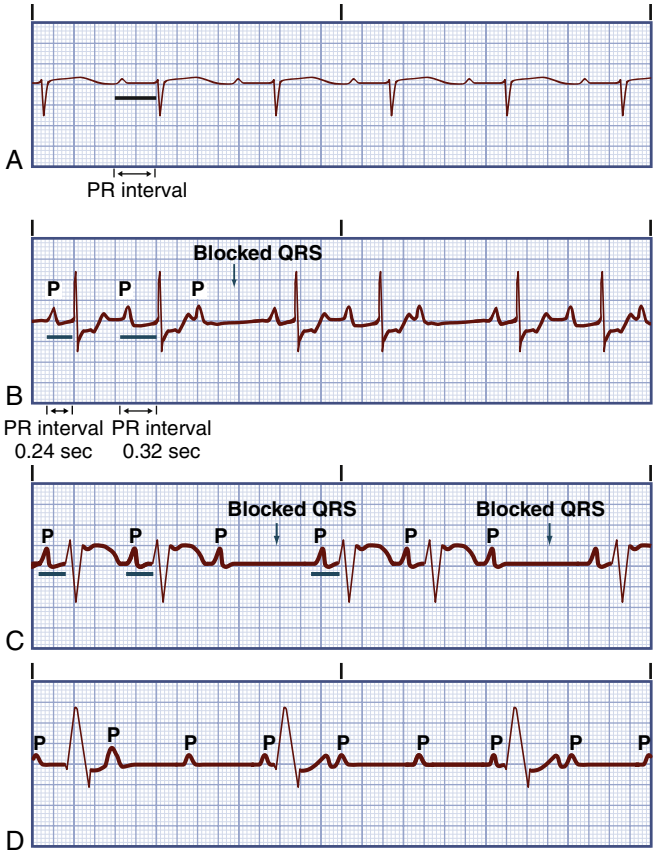

Fig. 39.17 Heart block. (A) First-degree AV block with a PR interval of 0.40 sec. (B) Second-degree AV block, type I, with progressive lengthening of the PR interval until a QRS complex is blocked. (C) Second-degree AV block, type II, with constant PR intervals and variable blocked QRS complexes. (D) Third-degree AV block. Note that there is no relationship between P waves and QRS complexes.

Clinical associations. First-degree AV block is associated with increasing age, MI, CAD, rheumatic fever, hyperthyroidism, electrolyte imbalances (e.g., hypokalemia), vagal stimulation, and drugs, such as digoxin, β-blockers, calcium channel blockers, and flecainide.

ECG characteristics. In first-degree AV block, the HR is normal. The rhythm is regular. The P wave is normal. The PR interval is prolonged (greater than 0.20 second). The QRS complex usually has a normal shape and duration.

Clinical significance. First-degree AV block is usually not serious. Patients are asymptomatic.

Treatment. There is no treatment for first-degree AV block. Treatment of associated conditions may be considered. Monitor patients for changes in heart rhythm (e.g., more serious AV block).

Second-Degree AV Block, Type I

Type I second-degree AV block (Mobitz I or *Wenckebach heart block)* includes a gradual lengthening of the PR interval. AV conduction time is increasingly prolonged until an atrial impulse is not conducted and a QRS complex is blocked (missing) (Fig. 39.17B). Type I AV block most often occurs in the AV node, but it can occur in the His-Purkinje system.

Clinical associations. Type I AV block may result from drugs, such as digoxin or β-blockers. It may be associated with CAD and other diseases that can slow AV conduction.

ECG characteristics. Atrial rate is regular, but ventricular rate may be slower because of non-conducted or blocked QRS complexes resulting in bradycardia. Once a ventricular beat is blocked, the cycle repeats itself with progressive lengthening of the PR intervals until another QRS complex is blocked. Think of the phrase, "longer, longer, longer, drop, now you have a Wenckebach." The rhythm appears on the ECG in a pattern of grouped beats. Ventricular rhythm is irregular. The P wave has a normal shape. The QRS complex has a normal shape and duration.

Clinical significance. Type I AV block is usually a result of myocardial ischemia or inferior MI. It is generally transient and well-tolerated. However, in some patients (e.g., acute MI), it may be a warning sign of a more serious AV conduction problem (e.g., complete heart block).

Treatment. A symptomatic patient may need atropine or a temporary pacemaker to increase HR, especially if the patient has had an MI. If the patient is asymptomatic, observe the rhythm closely. Have a transcutaneous pacemaker (TCP) on standby. Bradycardia is more likely to become symptomatic when hypotension, HF, or shock is already present.

Second-Degree AV Block, Type II

In *type II second-degree AV block (Mobitz II heart block),* a P wave is non-conducted without progressive PR lengthening. This usually occurs when a block in 1 of the bundle branches is present (Fig. 39.17C). On conducted beats, the PR interval is constant. Type II second-degree AV block is a more serious type of block because a certain number of impulses from the SA node are not conducted to the ventricles. This occurs in ratios of 2:1, 3:1, and so on (e.g., 2 P waves to one QRS complex, 3 P waves to 1 QRS complex). It may occur with varying ratios.[5]

Clinical associations. Type II AV block is associated with rheumatic heart disease, CAD, anterior MI, and drug toxicity.

ECG characteristics. Atrial rate is usually normal. Ventricular rate depends on the degree of AV block. Atrial rhythm is regular, but ventricular rhythm may be irregular. The P wave has a normal shape. The PR interval may be normal or prolonged in duration and remains constant on conducted beats. The QRS complex is usually greater than 0.12 second because of bundle branch block.

Clinical significance. Type II AV block often progresses to third-degree AV block. It is associated with a poor prognosis. The reduced HR often results in decreased CO with subsequent hypotension and myocardial ischemia. Type II AV block is an indication for a permanent pacemaker.

Treatment. Transcutaneous pacing or the insertion of a temporary pacemaker may be needed before inserting a permanent pacemaker if the patient is symptomatic (e.g., hypotension, angina).[5,6]

Third-Degree AV Block

Third-degree AV block, or **complete heart block**, is a form of AV dissociation in which no impulses from the atria are conducted

to the ventricles (Fig. 39.17D). The atria are stimulated and contract independently of the ventricles. The ventricular rhythm is an escape rhythm. The ectopic pacemaker may be above or below the bifurcation of the bundle of His.

Clinical associations. Third-degree AV block is associated with severe heart disease, including CAD, MI, myocarditis, cardiomyopathy, and some systemic diseases, such as scleroderma. Some drugs can cause third-degree AV block, such as digoxin, β-blockers, and calcium channel blockers.

ECG characteristics. The atrial rate is usually a sinus rate of 60 to 100 beats/min. The ventricular rate depends on the site of the block. If it is in the AV node, the rate is 40 to 60 beats/min. If it is in the His-Purkinje system, it is 20 to 40 beats/min. Atrial and ventricular rhythms are regular but unrelated to each other. The P wave has a normal shape. The PR interval is variable. There is no relationship between the P wave and the QRS complex. The QRS complex is normal if the escape rhythm starts at the bundle of His or above. It is widened if the escape rhythm starts below the bundle of His.

Clinical significance. Third-degree AV block usually results in reduced CO with subsequent ischemia, HF, and shock. Syncope from third-degree AV block may result from severe bradycardia or even periods of asystole.

Treatment. Symptomatic patients need a TCP until a temporary transvenous pacemaker can be inserted.[5,6] Drugs such as dopamine and epinephrine are interim measures to increase HR and support BP until temporary pacing is started. Patients need a permanent pacemaker as soon as possible. Atropine is not an effective treatment.

Premature Ventricular Contractions

A **premature ventricular contraction (PVC)** is a contraction coming from an ectopic focus in the ventricles. It is the premature (early) occurrence of a QRS complex. A PVC is wide and distorted in shape compared with a QRS complex coming down the normal conduction pathway (Fig. 39.18). PVCs that have the same shape are *unifocal* PVCs. PVCs that arise from different foci appear different in shape from each other. These are *multifocal* PVCs. When every other beat is a PVC, the rhythm is *ventricular bigeminy.* When every third beat is a PVC, it is *ventricular trigeminy.* We call 2 consecutive PVCs a *couplet.*

Ventricular tachycardia (VT) occurs when there are 3 or more consecutive PVCs. *R-on-T phenomenon* occurs when a PVC falls on the T wave of a preceding beat (Fig. 39.19). This is especially dangerous because the PVC is firing during the relative refractory phase of ventricular repolarization. Excitability of the heart cells increases during this time. The risk for the PVC to start VT or ventricular fibrillation (VF) is great.

Clinical associations. PVCs are associated with stimulants, such as caffeine, alcohol, nicotine, aminophylline, epinephrine, and isoproterenol. They can occur with electrolyte imbalances, hypoxia, fever, exercise, and emotional stress. Disease states associated with PVCs include MI, mitral valve prolapse, HF, cardiomyopathy, and CAD.

ECG characteristics. HR varies according to intrinsic rate and number of PVCs. Rhythm is irregular because of premature beats. The P wave is rarely visible. It is usually lost in the QRS complex of the PVC. Retrograde conduction may occur with the P wave seen after the ectopic beat. The PR interval is not measurable. The QRS complex is wide and distorted in shape, lasting more than 0.12 second. The T wave is generally large and opposite in direction to the major direction of the QRS complex.

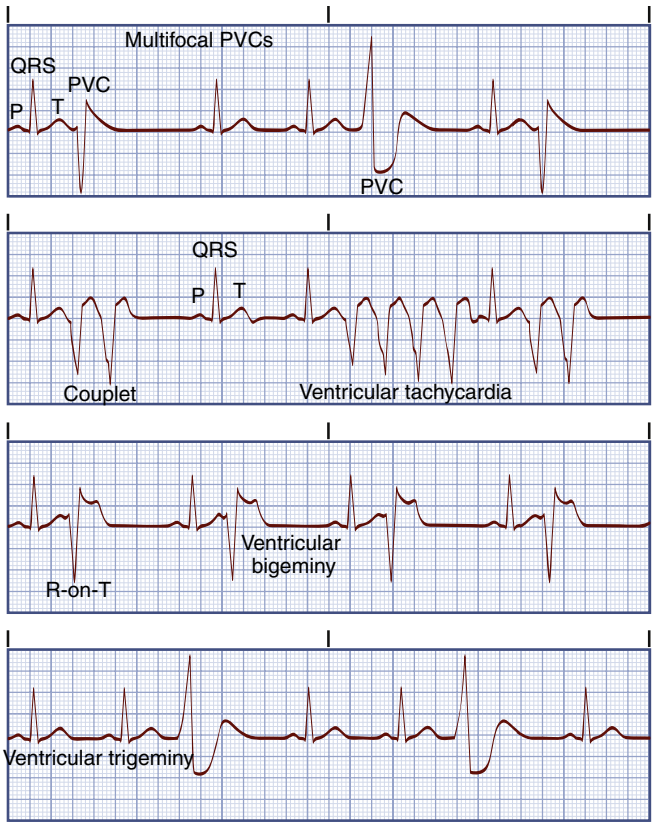

Fig. 39.18 Various types of premature ventricular contractions *(PVCs).*

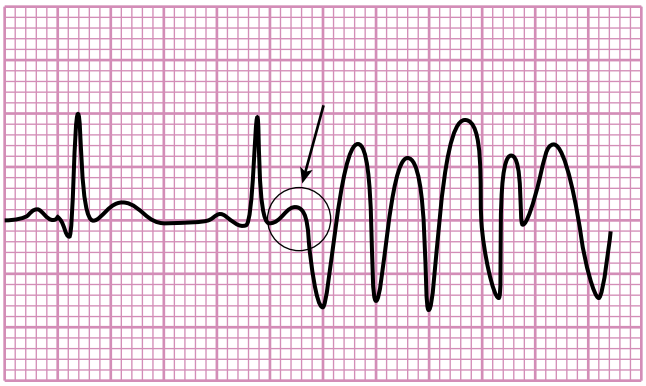

Fig. 39.19 R-on-T phenomenon. The "shock" occurred on the T wave leading to ventricular tachycardia.

Clinical significance. PVCs are usually not harmful in a patient with a normal heart. PVCs in CAD or acute MI indicate ventricular irritability. PVCs may reduce the CO and lead to angina and HF for those with heart disease, so assess the patient's physiologic response. Take the patient's apical-radial pulse rate and determine the pulse deficit since PVCs often do not generate a sufficient ventricular contraction to result in a peripheral pulse.

Treatment. Treatment relates to the cause of the PVCs (e.g., O_2 therapy for hypoxia, electrolyte replacement). Assessing

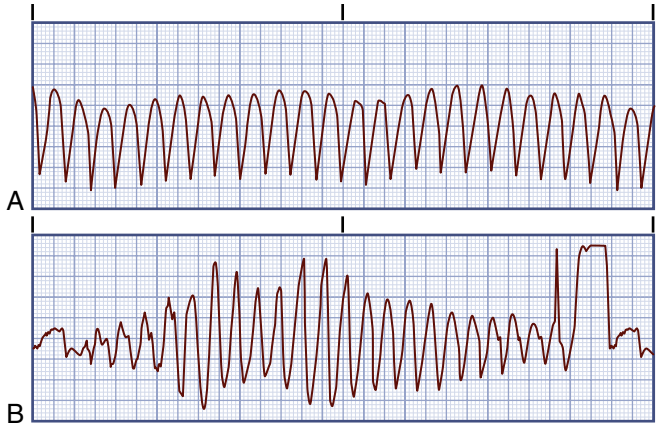

Fig. 39.20 Ventricular tachycardia. (A) Monomorphic. (B) Torsades de pointes (polymorphic).

the patient's hemodynamic status is important to determine if treatment with drug therapy is needed. Drug therapy includes β-blockers, lidocaine, or amiodarone.

Accelerated Idioventricular Rhythm

An *accelerated idioventricular rhythm* (AIVR) can develop when the intrinsic pacemaker (SA node or AV node) rate is slower than that of a ventricular ectopic pacemaker. The rate is between 40 and 100 beats/min.

Clinical associations. It is most often associated with acute MI and reperfusion of the myocardium after thrombolytic therapy or percutaneous coronary interventions (e.g., angioplasty). It can occur with digitalis toxicity.

Treatment. In the setting of acute MI, AIVR is usually self-limiting and well tolerated, and it needs no treatment. If the patient becomes symptomatic (e.g., hypotensive, chest pain), atropine is an option. Temporary pacing may be needed. Drugs that suppress ventricular rhythms (e.g., amiodarone) should not be used since they can further reduce the HR.

Ventricular Tachycardia

A run of 3 or more PVCs defines **ventricular tachycardia (VT).** It occurs when an ectopic focus or foci fire repeatedly and the ventricle takes control as the pacemaker. Different forms of VT exist, depending on QRS configuration. *Monomorphic* VT (Fig. 39.20A) has QRS complexes that are the same in shape, size, and direction. *Polymorphic* VT occurs when the QRS complexes gradually change back and forth from one shape, size, and direction to another over a series of beats. *Torsades de pointes* (French for "twisting of the points") is polymorphic VT associated with a prolonged QT interval of the underlying rhythm (Fig. 39.20B).

We describe VT as sustained (longer than 30 seconds) or nonsustained (less than 30 seconds). The development of VT is an ominous sign. It is a life-threatening dysrhythmia because of decreased CO and the possible development of VF, which is lethal.

Clinical associations. VT is associated with MI, CAD, significant electrolyte imbalances, cardiomyopathy, long QT syndrome, drug toxicity, and central nervous system disorders. It can occur in patients who have no evidence of heart disease.

ECG characteristics. Ventricular rate is 150 to 250 beats/min. Rhythm may be regular or irregular. AV dissociation may be present, with P waves occurring independently of the QRS complex. The ventricles may depolarize the atria in a retrograde fashion. The P wave is usually buried in the QRS complex. The PR interval is not measurable. The QRS complex appears distorted and wide (greater than 0.12 second in duration). The T wave is in the opposite direction of the QRS complex (Fig. 39.20).

Clinical significance. VT can be stable (patient has a pulse) or unstable (patient is pulseless). Sustained VT causes a severe decrease in CO because of decreased ventricular diastolic filling times and loss of atrial contraction. This results in hypotension, pulmonary edema, decreased cerebral blood flow, and cardiopulmonary arrest. VT must be treated quickly, even if it occurs only briefly and stops abruptly. Episodes may recur if prophylactic treatment is not started. VF may develop.

Treatment. Precipitating causes (e.g., electrolyte imbalances, ischemia) must be identified and treated. If the VT is monomorphic and the patient is clinically stable (e.g., pulse is present) with preserved left ventricular function, options include IV procainamide, lidocaine, or amiodarone.[6] These drugs can be given if VT is polymorphic with a normal baseline QT interval.

Treatment for polymorphic VT with a prolonged baseline QT interval includes IV magnesium, isoproterenol, phenytoin, or antitachycardia pacing (discussed later in this chapter). Drugs that prolong the QT interval (e.g., dofetilide [Tikosyn]) should be stopped. Cardioversion is used if drug therapy is ineffective.

VT without a pulse is a lethal dysrhythmia. It is treated the same as VF. Cardiopulmonary resuscitation (CPR) and rapid defibrillation are the first lines of treatment (Box 39.1). This is followed by administering vasopressors (e.g., epinephrine) and antidysrhythmics (e.g., amiodarone) if defibrillation is unsuccessful.[6]

CHECK YOUR PRACTICE

You are assigned to a 69-year-old male patient on a telemetry unit who is recovering from colon surgery. He has a history of 2 MIs, and he has 3 coronary stents in place. You hear his ECG monitor alarm and see what looks like ventricular tachycardia.

- What should you do?

Ventricular Fibrillation

Ventricular fibrillation (VF) is a severe derangement of the heart rhythm characterized on ECG by irregular waveforms of varying shapes and amplitude (Fig. 39.21). This represents the firing of multiple ectopic foci in the ventricle. Mechanically, the ventricle is simply "quivering," with no effective contraction, so no CO occurs. VF is a lethal dysrhythmia.

Clinical associations. VF occurs in acute MI, myocardial ischemia, and chronic diseases such as HF and cardiomyopathy. It may occur during cardiac pacing or cardiac catheterization procedures because of catheter stimulation of the ventricle. It may happen with coronary reperfusion after thrombolytic

BOX 39.1 ETHICAL/LEGAL DILEMMAS

Scope and Standards of Practice

Situation

A young woman with a history of viral cardiomyopathy is admitted to the intensive care unit (ICU) after having several episodes of nonsustained ventricular tachycardia (VT). While she is being stabilized, she codes (pulseless VT) and needs intubation. A nurse anesthetist tries to intubate her 3 times unsuccessfully. There is an unforeseen delay in the arrival of the anesthesiologist. P.F., an ICU nurse who is a paramedic certified in advanced trauma life support (ATLS) and advanced cardiovascular life support (ACLS), intubates the patient. The next day the nursing supervisor questions P.F. about intubating the patient since this is not within the scope of practice for an ICU nurse in that agency.

Ethical/Legal Points for Consideration

- Each state board of nursing defines their own RN *Scope of Practice,* including rules and regulations that guide practice. They can vary from state to state.
- Individual agencies have policies and procedures that describe the scope of practice for nurses. These can be more restrictive than those of the state.
- P.F. has had training, education, and certification beyond the usual nursing role.
- The life-threatening situation is an extenuating circumstance.
- Negligence may have been a factor if P.F., who is a nurse with training and experience, had not acted.

Discussion Questions

1. What would you have done in this situation?
2. How would you respond to the nursing supervisor?
3. What are the legal ramifications for P.F. in this situation?
4. What are the ethical issues in this situation?

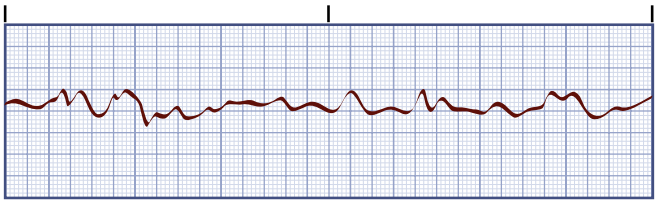

Fig. 39.21 Ventricular fibrillation.

therapy. Other causes are electric shock, hyperkalemia, hypoxemia, acidosis, and drug toxicity.

ECG characteristics. HR is not measurable. Rhythm is irregular and chaotic. The P wave is not visible. The PR interval and the QRS interval are not measurable.

Clinical significance. VF results in an unresponsive, pulseless, and apneic state. If VF is not treated quickly, the patient will not recover.

Treatment. Treatment consists of immediate initiation of CPR and ACLS with the use of defibrillation and definitive drug therapy (e.g., epinephrine, amiodarone). There should be no delay in starting chest compressions and using a defibrillator once available.

Asystole

Asystole is the total absence of ventricular electrical activity. Occasionally, P waves are seen. No ventricular contraction occurs because depolarization does not occur. Patients are unresponsive, pulseless, and apneic. Asystole is a lethal dysrhythmia that needs immediate treatment. VF may masquerade as asystole. Always assess the rhythm in more than 1 lead. The prognosis of a patient with asystole is very poor.

Clinical associations. Asystole is usually a result of advanced heart disease, a severe cardiac conduction system problem, or end-stage HF.

Clinical significance. Generally, the patient with asystole has end-stage heart disease or had prolonged arrest and cannot be resuscitated.

Treatment. Treatment consists of CPR with ACLS measures. These include definitive drug therapy with epinephrine, intubation, and efforts to determine the underlying cause.

Pulseless Electrical Activity

Pulseless electrical activity (PEA) is a situation in which organized electrical activity is seen on the ECG, but there is no mechanical heart activity, and the patient has no pulse. It is the most common dysrhythmia seen after defibrillation. Prognosis is poor unless we quickly identify and treat the underlying cause. Common causes of PEA include hypovolemia, hypoxia, metabolic acidosis, hyperkalemia, hypokalemia, hypoglycemia, hypothermia, toxins (e.g., drug overdose), cardiac tamponade, thrombosis (e.g., MI, pulmonary embolus), tension pneumothorax, and trauma. Treatment begins with CPR, followed by drug therapy (e.g., epinephrine) and intubation. Correcting the underlying cause is critical to prognosis.

Sudden Cardiac Death

The term *sudden cardiac death* (SCD) refers to death from a cardiac cause. Most SCDs result from ventricular dysrhythmias, specifically VT or VF. SCD is discussed in Chapter 37.

❖ INTERPROFESSIONAL AND NURSING MANAGEMENT: DYSRHYTHMIAS

◆ Antidysrhythmic Drug Therapy

Table 39.9 shows antidysrhythmic drugs by their primary effects on the heart cells and the ECG.

Before giving any *antidysrhythmic drug*, perform a thorough assessment with a complete physical assessment, health history, medication allergies, and medication history. Assess for contraindications, cautions, and drug interactions. Obtain a baseline ECG. Assess vital signs, heart and lung sounds, and pulse rate, rhythm, and quality. Assess for signs and symptoms associated with decreased CO because of the dysrhythmia, such as restlessness, syncope, chest pain, dyspnea, and crackles. Review laboratory studies, including electrolytes and liver and kidney function tests.

When giving antidysrhythmics, closely monitor the ECG and vital signs, especially BP and pulse rate. Continue to perform an ongoing physical assessment. Monitor laboratory studies as needed. Give specific instructions for each drug. Teach the patient that oral forms are often better tolerated if taken with food to help decrease GI upset. Tell patients to avoid alcohol, caffeine, and tobacco.

◆ Defibrillation

Defibrillation is the treatment of choice to end VF and pulseless VT. It is most effective when the myocardial cells are not

TABLE 39.9 Drug Therapy

Antidysrhythmic Drugs

Drug	Effects on the Action Potential	Effects on ECG
Class I: Sodium Channel Blockers	Decrease impulse conduction in the atria, ventricles, and His-Purkinje system	
Class IA	Delay repolarization	Widened QRS and prolonged QT interval
disopyramide (Norpace)		
procainamide		
quinidine		
Class IB	Accelerate repolarization	Little or no effect on ECG
lidocaine		
mexiletine		
phenytoin (Dilantin)		
Class IC	Decrease impulse conduction	Pronounced prodysrhythmic actions, widened QRS, prolonged QT interval
flecainide		
propafenone (Rythmol SR)		
Class II: β-Adrenergic Blockers	Decrease automaticity of the SA node, slow impulse conduction in AV node, reduce atrial and ventricular contractility	Bradycardia, prolonged PR interval, AV block
esmolol (Brevibloc)		
metoprolol (Lopressor)		
propranolol (Inderal)		
Class III: Potassium Channel Blockers	Delay repolarization, resulting in prolonged duration of action potential and refractory period	Prolonged PR and QT intervals, widened QRS, bradycardia
amiodarone		
dofetilide (Tikosyn)		
ibutilide (Corvert)		
sotalol[a] (Betapace)		
Class IV: Calcium Channel Blockers	Decrease automaticity of SA node, delay AV node conduction. Reduce myocardial contractility	Bradycardia, prolonged PR interval, AV block
diltiazem (Cardizem)		
verapamil		
Other Agents		
adenosine	Decrease conduction through AV node, reduce automaticity of SA node	Prolonged PR interval, AV block
digoxin (Lanoxin)		
dronedarone (Multaq)[b]	Suppress atrial dysrhythmias though mechanism is unknown	Prolonged QT interval
magnesium	Decrease impulse conduction through AV node	AV block

[a]Sotalol has both class II and class III properties.
[b]Dronedarone has class I through IV properties.

yet anoxic or acidotic. Rapid defibrillation (within 2 minutes) is critical to a successful patient outcome. Defibrillation involves the passage of an electric shock through the heart to depolarize the myocardial cells. The goal is that after repolarization, the SA node will be able to resume the role of pacemaker.

Defibrillators deliver energy using a monophasic or biphasic waveform. Monophasic defibrillators deliver energy in 1 direction. Biphasic defibrillators deliver energy in 2 directions (Fig. 39.22). The shocks delivered are at lower energies and with fewer post-shock dysrhythmias than monophasic defibrillators.

We measure the output of a defibrillator in *joules,* or watts per second. The recommended energy for initial shocks in defibrillation depends on the type of defibrillator. Biphasic defibrillators deliver the first and any successive shocks using 120 to 200 joules. Recommendations for monophasic defibrillators include an initial shock at 360 joules. After the first shock, start CPR immediately, beginning with chest compressions.

We can perform rapid defibrillation using a manual or automatic device (Fig. 39.23). Manual defibrillators require you to interpret heart rhythms, determine the need for a shock, and deliver a shock. An **automatic external defibrillator (AED)** can detect heart rhythms and tell the user to deliver a shock using hands-free defibrillator pads. Proficiency in AED use is part of the basic life support course for health care professionals. Be familiar with the operation of the type of defibrillator used in your clinical setting.

The general steps taken for defibrillation are listed in Table 39.10.

! SAFETY ALERT

Defibrillation and Cardioversion

- Check that the synchronizer switch is OFF for defibrillation.
- Turn the synchronizer switch ON for a cardioversion.
- Never apply defibrillator pads over a pacemaker or implantable cardioverter-defibrillator.
- Be certain that personnel and O_2 equipment are "all clear" before discharging the device.

◆ Synchronized Cardioversion

Synchronized cardioversion is the therapy of choice for the patient with ventricular tachydysrhythmias (e.g., VT with a pulse) or supraventricular tachydysrhythmias (e.g., atrial flutter with a RVR). A synchronized circuit in the defibrillator delivers a shock on the R wave of the QRS complex of the ECG.

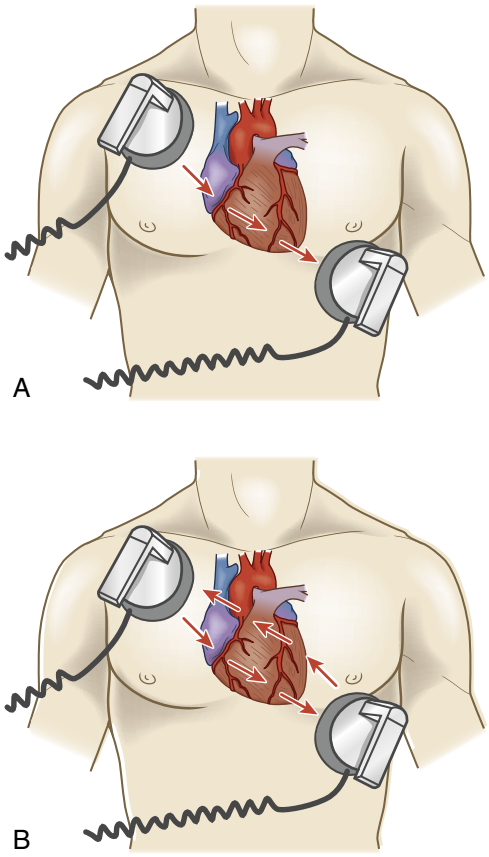

Fig. 39.22 Paddle placement and current flow in monophasic defibrillation (A) and biphasic defibrillation (B).

Fig. 39.23 LifePak contains a monitor, defibrillator, and transcutaneous pacemaker. (Courtesy Medtronic Physio-Control, Redmond, WA.)

The synchronizer switch must be turned on when performing cardioversion.

The procedure for synchronized cardioversion is the same as for defibrillation with a few exceptions (Table 39.11). If synchronized cardioversion is done on a nonemergency basis (e.g., the patient is awake and hemodynamically stable), we sedate the patient with IV agents (e.g., midazolam, fentanyl) beforehand. Strict attention to maintaining the patient's airway is critical. If a patient with SVT or VT with a pulse becomes hemodynamically unstable, synchronized cardioversion should be done as quickly as possible. Start the initial energy for synchronized cardioversion at 50 to 100 joules (biphasic defibrillator) and 100 joules (monophasic defibrillator) and increase if needed. Atrial fibrillation requires a higher starting energy level in joules than SVT or VT with a pulse. If the patient becomes pulseless or the rhythm changes to VF, turn the synchronizer switch off and perform defibrillation.

TABLE 39.10 Defibrillation

The following general steps are taken for defibrillation:

1. Continue CPR until the defibrillator is charged.
2. Apply hands-free defibrillator pads to the chest, one on the upper right chest above the nipple and the other on the left side below the breast tissue. If hands-free pads are not immediately available, apply conductive material (e.g., gel pads) to the chest.
3. Turn the defibrillator on and select the proper energy level.
4. Make sure the synchronizer switch is turned off.
5. Charge the defibrillator using the button on the defibrillator.
6. Call and look to see that everyone is "all clear." Ensure staff are not touching the patient or the bed at the time of discharge, and the O_2 source is away from the patient
7. Deliver the charge by depressing the shock button on the defibrillator or the buttons on the paddles simultaneously while pushing down with at least 15 pounds of pressure (7.5 kg).

TABLE 39.11 NURSING MANAGEMENT

Assisting With Cardioversion

Preprocedure

- Obtain 12-lead ECG and initiate ECG monitoring.
- Perform baseline assessment, including vital signs, pulse oximetry. Note any manifestations of the dysrhythmia.
- Withhold food and fluids per institution policy.
- Assess baseline laboratory values (e.g., cardiac biomarkers, electrolytes).
- Teach patient and caregiver about procedure and postprocedure care.
- Remove all metallic objects, dentures, and transdermal patches. You may need to clip or remove chest hair.
- Establish IV access.
- Give sedative and other drugs, as ordered.

Postprocedure

- Maintain patent airway and administer O_2 as needed.
- Monitor ECG for dysrhythmias or other changes (e.g., ST segment elevation).
- Perform assessment and compare to baseline: vital signs, pulse oximetry, and heart and breath sounds.
- Assess level of consciousness and reorient as needed.
- Administer IV dysrhythmic and analgesic medications as ordered.
- Assess for burns and provide skin care.

Implantable Cardioverter-Defibrillator

The *implantable cardioverter-defibrillator* (ICD) is an important technology for patients who (1) have survived SCD, (2) have spontaneous sustained VT, (3) have syncope with inducible VT or VF during EPS, or (4) are at high risk for future life-threatening dysrhythmias (e.g., have cardiomyopathy). The use of ICDs has significantly decreased mortality rates in these patients.[5,10]

The ICD consists of a lead system placed via a subclavian vein to the endocardium. A battery-powered pulse generator is implanted subcutaneously, usually over the pectoral muscle on the patient's nondominant side. The pulse generator is similar in size to a pacemaker. Most systems are single-lead

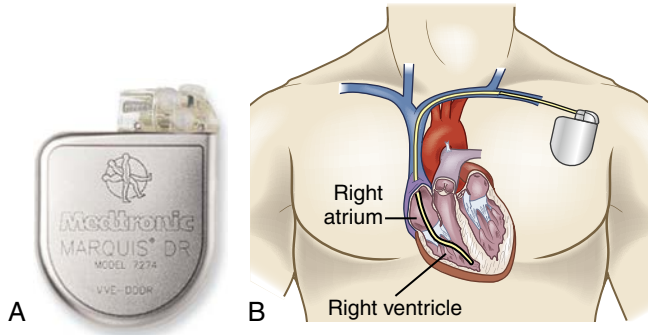

Fig. 39.24 (A) The implantable cardioverter-defibrillator (ICD) pulse generator from Medtronic, Inc. (B) The ICD is placed in a subcutaneous pocket over the pectoral muscle. A single-lead system is placed transvenously from the pulse generator to the endocardium. The single lead detects dysrhythmias and delivers an electric shock to the heart muscle. (Courtesy Medtronic, Inc., Minneapolis, MN.)

systems (Fig. 39.24). The ICD sensing system monitors the HR and rhythm and identifies VT or VF. After the sensing system detects a lethal dysrhythmia, the device delivers a 25-joule or lower shock to the patient's heart. If the first shock is unsuccessful, the device recycles and can continue to deliver shocks.

In addition to defibrillation capabilities, ICDs have *antitachycardia* and *antibradycardia pacing* capabilities. These devices use algorithms that detect dysrhythmias and determine the appropriate response. They can start *overdrive pacing* of SVT and VT, sparing the patient painful defibrillator shocks. They can provide backup pacing for bradydysrhythmias that may occur after defibrillation. Nursing care of the patient undergoing ICD placement is similar to the care of a patient undergoing permanent pacemaker implantation.

Patients with structural or congenital cardiac anomalies may receive a subcutaneous ICD (S-ICD).[11] The S-ICD pulse generator is placed under the skin on the left side of the chest with the electrode under the skin above the sternum. The system delivers a shock if it detects VT or VF. Since the S-ICD does not have any electrodes implanted in the heart, it has no pacing capability.

Teaching the patient who is receiving an ICD and the caregiver is important. Patients may have a variety of emotions. These include fear of body image change, fear of recurrent dysrhythmias, expectation of pain with ICD discharge (described as a feeling of a blow to the chest), and anxiety about going home. Encourage patients and caregivers to take part in local or online ICD support groups. Table 39.12 presents a teaching guide for the patient with an ICD and the caregiver.

TABLE 39.12 PATIENT & CAREGIVER TEACHING

Implantable Cardioverter-Defibrillator (ICD)

Include the following information in the teaching plan for a patient receiving an ICD and the patient's caregiver:

1. Follow up with your HCP for routine checks of the function of the ICD. This is often done by interrogating the device using a telephone.
2. Report any signs of infection at incision site (e.g., redness, swelling, drainage) or fever to your HCP at once.
3. Keep incision dry for 4 days after insertion or as instructed.
4. Avoid lifting arm on ICD side above shoulder until approved.
5. Discuss resuming sexual activity with your HCP. It is usually safe to resume sexual activity once your incision is healed.
6. Do not drive until cleared by your HCP. This decision is usually based on the ongoing presence of dysrhythmias, the frequency of ICD firings, your overall health, and state laws about drivers with ICDs.
7. Avoid direct blows to ICD site.
8. Avoid large magnets and strong electromagnetic fields because these may interfere with the device.
9. You should not have an MRI unless the ICD is approved as MRI safe or there is a protocol in place for patient safety during the procedure.
10. Travel is not restricted. Tell security (e.g., airport, train station, public buildings) of presence of ICD because it may set off the metal detector. Hand-held screening wands should not be placed directly over the ICD. Manufacturer information may vary about the effect of metal detectors on the function of the ICD.
11. Do not stand near antitheft devices in doorways of stores and public buildings. Walk through them at a normal pace.
12. If your ICD fires once, call your HCP right away. If you feel sick or if it fires more than once, contact the emergency response system.
13. Always wear a Medic Alert ID device.
14. Always carry the ICD identification card and a current list of your drugs.
15. Consider joining an ICD support group
16. Caregivers should learn cardiopulmonary resuscitation (CPR).

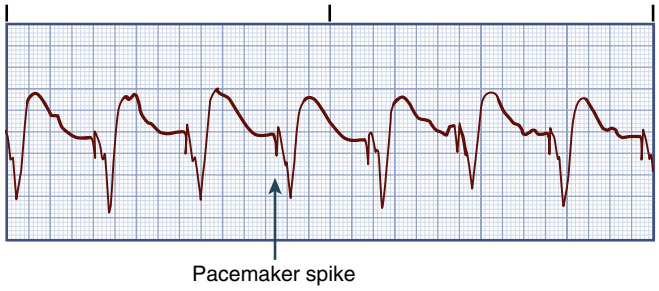

Fig. 39.25 Ventricular capture (depolarization) from signal *(pacemaker spike)* from pacemaker lead in the right ventricle.

Pacemakers

The artificial **cardiac pacemaker** is an electronic device used to pace the heart when the normal conduction pathway is damaged. The basic pacing circuit consists of a power source (battery-powered pulse generator) with programmable circuitry, 1 or more pacing leads, and the myocardium. The electrical signal (stimulus) travels from the pulse generator, through the leads, to the wall of the myocardium. The heart muscle is "captured" and stimulated to contract (Fig. 39.25).

Current pacemakers are small, sophisticated, and precise. They pace the atrium and/or 1 or both ventricles. Most pacemakers are *demand pacemakers*. This means that they sense the heart's electrical activity and fire only when the HR drops below a preset rate. Demand pacemakers have 2 distinct features: (1) a sensing device that inhibits the pacemaker when the HR is adequate and (2) a pacing device that triggers the pacemaker when no QRS complexes occur within a preset time.

In addition to antibradycardia pacing, devices now include antitachycardia and overdrive pacing. *Antitachycardia pacing* involves the delivery of a stimulus to the ventricle to end tachydysrhythmias (e.g., VT). Overdrive pacing involves pacing the

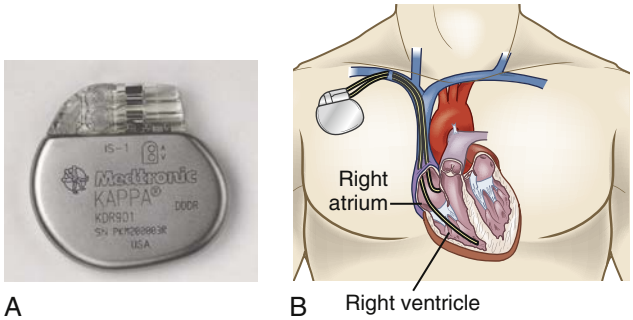

Fig. 39.26 (A) A dual-chamber rate-responsive pacemaker from Medtronic, Inc., is designed to treat patients with chronic heart problems in which the heart beats too slowly to support the body's circulation needs. (B) Pacing leads in both the atrium and the ventricle enable a dual-chamber pacemaker to sense and pace in both heart chambers. (Courtesy Medtronic, Inc., Minneapolis, MN.)

TABLE 39.13 Indications for Permanent Pacemakers

- Acquired AV block
- Second-degree AV block
- Third-degree AV block
- Atrial fibrillation with a slow ventricular response
- Bundle branch block
- Cardiomyopathy
  - Dilated
  - Hypertrophic
- HF
- SA node dysfunction
- Symptomatic bradycardia with unknown cause
- Tachydysrhythmias (e.g., ventricular tachycardia)

Fig. 39.27 Temporary external, dual-chamber demand pacemaker. (Courtesy Medtronic, Inc., Minneapolis, MN.)

atrium at rates of 200 to 500 impulses per minute to try to stop atrial tachycardias (e.g., atrial flutter with an RVR).

Permanent Pacemaker

A *permanent pacemaker* is totally implanted within the body (Fig. 39.26). The power source is placed subcutaneously, usually over the pectoral muscle on the patient's nondominant side. The pacing leads are placed transvenously to the right atrium and/or 1 or both ventricles and attached to the power source. Common reasons for insertion of a permanent pacemaker are found in Table 39.13.

New technology and research are focused on miniaturized, leadless permanent pacemakers. Single-component devices have the battery, sensors, electronics, and stimulating electrodes in a small capsule that is placed in the ventricle using a deflatable sheath. A multicomponent device has a small "seed" that is placed in a cardiac chamber. It acts as an energy transducer while an outside piece beams ultrasound (or radio waves) to the seed. The seed converts the energy to a pacing pulse. The lack of a transvenous lead and subcutaneous pulse generator is a major shift in cardiac pacing.[5,11] Other research is focusing on making permanent pacemakers without batteries.

Cardiac Resynchronization Therapy

Cardiac resynchronization therapy (CRT) is a pacing technique that resynchronizes the heart cycle by pacing both ventricles *(biventricular pacing)*. This promotes improvement in ventricular function (Fig. 38.4). Most HF patients have intraventricular conduction delays causing abnormal ventricular contraction. This causes dyssynchrony between the right and left ventricles and results in reduced systolic function, pump inefficiency, and worsened HF. Patients with severe left ventricular dysfunction may have devices that combine CRT with an ICD.[11]

Temporary Pacemaker

A *temporary pacemaker* is one that has the power source outside the body (Fig. 39.27). There are 3 types of temporary pacemakers: transvenous, epicardial, and transcutaneous. Table 39.14 lists common reasons for temporary pacing.

A *transvenous pacemaker* consists of a lead or leads that are threaded transvenously to the right atrium and/or right ventricle and attached to the external power source (Fig. 39.28). Most of these pacemakers are inserted in the ED or ICU in emergency situations. They provide a bridge to inserting a permanent pacemaker or resolving the underlying cause of the dysrhythmia.

Epicardial pacing involves attaching an atrial and a ventricular pacing lead to the epicardium during heart surgery. The leads are passed through the chest wall and attached to the external power source. Epicardial pacing leads are placed in case a bradydysrhythmia or tachydysrhythmia occurs in the early postoperative period.

TABLE 39.14 Common Indications for Temporary Pacemakers

- Maintain adequate HR and rhythm during special circumstances
  - During surgery and postoperative recovery
  - During cardiac catheterization or coronary angioplasty
  - With drug therapy that may cause bradycardia
  - Before implantation of a permanent pacemaker
- Prophylaxis after open heart surgery
- Acute anterior MI with second- or third-degree AV block or bundle branch block
- Acute inferior MI with symptomatic bradycardia and AV block
- EPS to evaluate patient with bradydysrhythmias and tachydysrhythmias

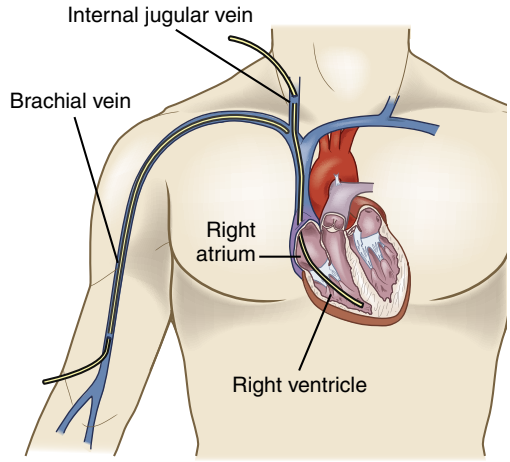

Fig. 39.28 Temporary transvenous pacemaker catheter insertion. A single lead is positioned in the right ventricle through the brachial, subclavian, jugular, or femoral vein.

A *transcutaneous pacemaker* can provide adequate HR and rhythm to the patient in an emergency. Placement of a TCP is a noninvasive, temporary procedure used until a transvenous pacemaker is inserted or more definitive therapy is available.[6]

The TCP consists of a power source and a rate- and voltage-control device that attaches to 2 large, multifunction electrode pads. Position 1 pad on the anterior part of the chest, usually on the V_4 lead position. Place the other pad on the back between the spine and left scapula at the level of the heart (Fig. 39.29). When programming the TCP, use the lowest current that results in a ventricular contraction (capture) to minimize patient discomfort.

Before starting TCP therapy, it is important to tell the patient what to expect. Explain that the muscle contractions created by the pacemaker when the current passes through the chest wall are uncomfortable. Reassure the patient that the TCP is temporary and that it will be replaced by a transvenous or permanent pacemaker as soon as possible. If possible, provide analgesia and/or sedation while the TCP is in use.

Monitoring of Patients With Pacemakers

Patients with temporary or permanent pacemakers are ECG monitored to evaluate the status of the pacemaker. Pacemaker malfunction involves a failure to sense, a failure to capture, or a failure to pace. *Failure to sense* occurs when the pacemaker does not recognize spontaneous atrial or ventricular activity, and it fires inappropriately (Fig. 39.30A). This can result in the pacemaker firing during the excitable period of the cardiac cycle and the potential for VT. Causes of failure to sense include fibrosis around the tip of the pacing lead, battery failure, sensing set too high, or dislodgment of the electrode.

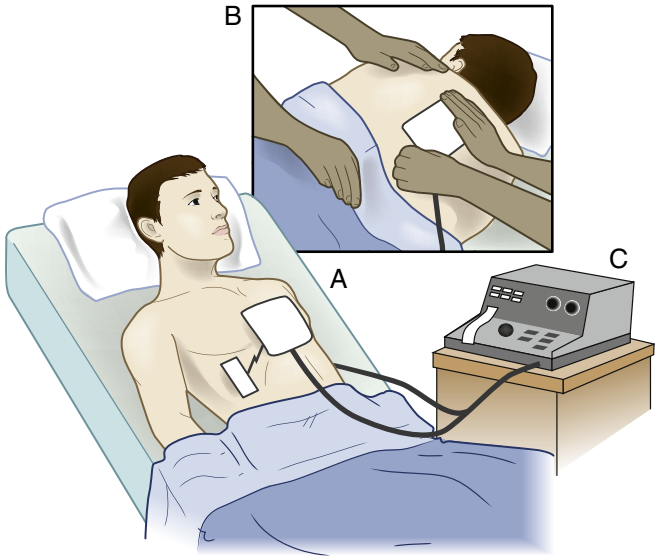

Fig. 39.29 Transcutaneous pacemaker. Pacing electrodes are placed on the patient's anterior (A) and posterior (B) chest walls and attached to an external pacing unit (C).

Failure to capture occurs when the electrical charge to the myocardium is insufficient to produce atrial or ventricular contraction (Fig. 39.30B). This can result in serious bradycardia or asystole. Common causes include pacer lead damage, battery failure, dislodgment of the electrode, electrical charge set too low, or fibrosis at the electrode tip.

Failure to pace occurs when the pacemaker does not initiate an electrical stimulus when it should fire (Fig. 39.30C). This can happen from a wire fracture, lead displacement, oversensing, or electrical interference. Table 39.15 describes pacemaker troubleshooting.

Complications of invasive temporary (e.g., transvenous) or permanent pacemaker insertion include infection and hematoma formation at the insertion site, pneumothorax, failure to sense or capture, perforation of the atrial or ventricular septum by the pacing lead, and appearance of "end-of-life" battery power on testing the pacemaker. Several measures can prevent or assess for complications. These include prophylactic IV antibiotic therapy before and after insertion, postinsertion chest x-ray to check lead placement and to rule out a pneumothorax, careful observation of insertion site, and continuous ECG monitoring of the patient's rhythm.

After pacemaker insertion, the patient can be out of bed once stable. Have the patient limit arm and shoulder activity on the operative side to prevent dislodging the newly implanted pacing leads. Observe the insertion site for signs of bleeding and check that the incision is intact. Note any temperature elevation or pain at the insertion site and treat as ordered. Most patients are discharged by the next day if stable.

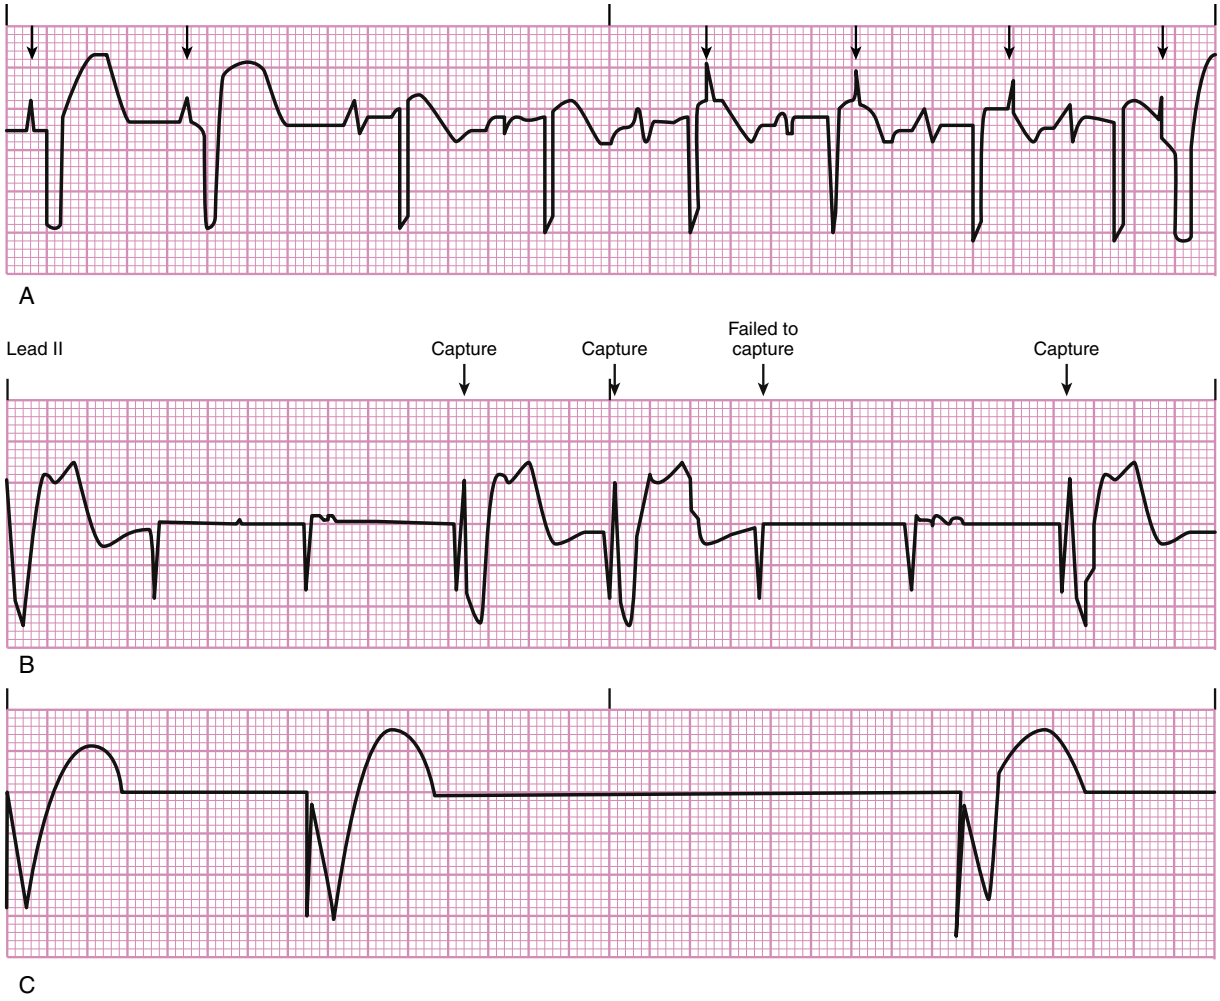

Fig. 39.30 Causes of pacemaker malfunction. (A) Failure to sense: the pacemaker does not sense the patient's own cardiac rhythm and initiates an electrical impulse. Failure to sense manifests as pacer spikes that fall too closely to the patient's own rhythm, earlier than the programmed rate (see *arrows*). (B) Failure to capture: a pacer spike is noted but is not followed by a P wave (atrial pacemaker) or a QRS complex (ventricular pacemaker). (C) Failure to pace: the pacemaker fails to initiate an electrical stimulus when it should fire.

Table 39.16 outlines patient and caregiver teaching for the patient with a pacemaker. The patient with a newly implanted pacemaker and the caregiver may have questions about activity restrictions and concerns about body image. The goals of pacemaker therapy include enhancing physiologic functioning and quality of life. Emphasize this to the patient and caregiver and provide specific advice on activity restrictions.

After discharge, patients need to check pacemaker function on a regular basis. This can include outpatient visits to a pacemaker clinic or home monitoring using telephone transmitter devices. Another method to evaluate pacemaker performance is noninvasive program stimulation. This procedure is done on an outpatient basis in the EPS laboratory.

◆ Radiofrequency Catheter Ablation Therapy

Radiofrequency catheter ablation therapy uses electrical energy to "burn" or ablate areas of the conduction system. Ablation therapy is done after EPS has identified the source of the dysrhythmia. An electrode-tipped ablation catheter ablates accessory pathways or ectopic sites in the atria, AV node, and ventricles. Catheter ablation is a definitive treatment for tachydysrhythmias. It is the nonpharmacologic treatment of choice for atrial dysrhythmias resulting in rapid ventricular rates and AV nodal reentrant tachycardia refractory to drug therapy.[5]

The ablation procedure is an effective treatment with a low complication rate. Nursing care of the patient after ablation therapy is similar to that of a patient undergoing cardiac catheterization (see Chapter 35 and Table 35.11).

SYNCOPE

Syncope is a brief lapse in consciousness accompanied by a loss in postural tone (fainting). The causes of syncope can be cardiovascular or noncardiovascular. The most common cause of syncope is cardioneurogenic syncope, or "vasovagal" syncope (e.g., carotid sinus sensitivity). Other cardiovascular causes relate to dysrhythmias (e.g., tachycardias, bradycardias), prosthetic valve malfunction, pulmonary emboli, and HF. Noncardiovascular causes vary and include stress, hypoglycemia, dehydration, stroke, and seizure.[12]

TABLE 39.15 NURSING MANAGEMENT

Troubleshooting Pacemakers

Problem	Potential Solution
General concern about pacemaker function	• Monitor continuous ECG and patient's vital signs while troubleshooting pacemaker problems • Call emergency response services if needed • Contact HCP immediately if basic troubleshooting does not work, as patient could have a lead wire displaced or a defective lead wire
Temporary pacemaker not firing	• Check to make sure all connections are hooked up correctly and tight • Ensure that hands-free pads have contact with the skin (shave excess hair, dry off perspiration) • Check that the generator has power (plug in the equipment or use a new battery each time)
Temporary pacemaker not capturing	• Check connections • Check for generator power • Turn up the milliamps on the generator, look for capture, and set 10 milliamps above capture • Place patient on left side to promote contact of the transvenous pacing wire with the epicardium
Temporary pacemaker not sensing patient's underlying rhythm	• Check connections • Check for generator power • Turn up sensitivity • Place patient on left side
Permanent pacemaker not working	• Contact HCP • Contact pacemaker company for service if requested by HCP

TABLE 39.16 PATIENT & CAREGIVER TEACHING

Pacemaker

Include the following information in the teaching plan for a patient with a pacemaker and the patient's caregiver:

1. Maintain follow-up care with your HCP to begin regular pacemaker function checks. This is often done by checking the device using a telephone.
2. Report any signs of infection at incision site (e.g., redness, swelling, drainage) or fever to your HCP at once.
3. Keep incision dry for 4 days after implantation, or as ordered.
4. Avoid lifting arm on pacemaker side above shoulder until approved by your cardiologist.
5. Avoid direct blows to pacemaker site.
6. Avoid proximity to high-output electric generators since these can interfere with the function of the pacemaker.
7. You should not have an MRI unless the pacemaker is approved as MRI safe or there is a protocol in place for patient safety during the procedure.
8. Microwave ovens are safe to use and do not interfere with pacemaker function.
9. Avoid standing near antitheft devices in doorways of department stores and public libraries. Walk through them at a normal pace.
10. Travel is not restricted. Tell security (e.g., airport, train station, public buildings) of presence of pacemaker because it may set off the metal detector. Hand-held screening wands should not be placed directly over the pacemaker. Manufacturer information may vary about the effect of metal detectors on the function of the pacemaker.
11. Monitor pulse and tell your HCP if heart rate drops below predetermined rate.
12. Always carry your pacemaker information card and a current list of drugs.
13. Always wear a Medic Alert ID device.
14. Consider joining a pacemaker support group (e.g., www.pacemakerclub.com/).

A diagnostic workup for a patient with syncope from a suspected heart cause begins with ruling out structural and ischemic heart disease. This is done with echocardiography and stress testing. EPS is used to diagnose atrial and ventricular tachydysrhythmias and conduction problems causing bradydysrhythmias, all of which can cause syncope. These problems can be treated with antidysrhythmic drug therapy, pacemakers, ICDs, and/or catheter ablation therapy.

A patient without structural heart disease or in whom EPS testing is not diagnostic may have a *head-up tilt-test*. Normally, an upright position results in gravity displacing 300 to 800 mL of blood to the lower extremities. Specialized nerve fibers called mechanoreceptors are found throughout the vascular system. These respond to the increased blood volume with a reflex increase in sympathetic stimulation and decrease in parasympathetic output. The end results are a slight increase in HR and diastolic BP and a slight decrease in systolic BP.

In cardioneurogenic syncope, the increased venous pooling in the upright position reduces venous return to the heart. This results in a sudden, compensatory increase in ventricular contraction. The brain mistakenly thinks this is a hypertensive state and stops sympathetic stimulation. This produces a paradoxical vasodilation and bradycardia (vasovagal response). The end results are bradycardia, hypotension, cerebral hypoperfusion, and syncope.

In the head-up tilt-test, the patient is placed on a table supported by a belt across the torso and feet. We obtain baseline ECG, BP, and HR with the patient in the horizontal position. Next, the table is tilted 60 to 80 degrees. The patient stays in this upright position for 20 to 60 minutes. We record ECG and HR continuously.[5] BP is measured every 3 minutes throughout the test.

If the patient's BP and HR responses are abnormal and clinical symptoms occur (e.g., faintness), the test is positive. If after 30 minutes there is no response, the table is returned to the horizontal position, and an IV infusion of low-dose isoproterenol may be given to test for a response.

Other diagnostic tests for syncope use recording devices (e.g., Holter monitor or event monitor/loop recorder, see Table 35.10), blood volume determination, hemodynamic testing, and autonomic reflex testing. About 30% of those who have 1 episode of syncope have a recurrence. The underlying cause of syncope and the patient's age and co-morbidities affect the treatment and prognosis.[12]

Case Study

Dysrhythmia: Ventricular Tachycardia

(© iStockphoto/Thinkstock.)

Patient Profile

J.M, a 54-year-old school teacher, came to the emergency department with shortness of breath, chest discomfort, and a "racing heart." J.M. is alert and oriented and able to answer all your questions with short responses.

Subjective Data

- History of hypertension, diabetes type II
- No known drug allergies
- Takes 500 mg Metformin twice daily
- States this has never happened before, and he is scared
- Reports 7/10 midsternal chest pain

Objective Data

Physical Assessment

- Appears anxious, scared, diaphoretic
- BP 86/54 mm Hg, HR 230 beats/min, respirations 24/min,
- Lungs clear bilaterally
- Heart: no murmurs or gallops, regular

Diagnostic Studies

- 12-Lead ECG shows wide complex ventricular tachycardia
- Serum cardiac biomarkers negative
- Serum potassium 2.8 mEq/L (2.8 mmol/L)
- Glucose 162 mg/dL
- One hour after arrival, J.M. suddenly becomes unresponsive with no heart rate or respirations.

Continuous ECG Monitoring

1. ***Recognize***: Interpret the rhythm J.M. is currently in.
2. ***Analyze***: What are the important findings from J.M.'s history?
3. ***Plan***: What treatment would you expect based on J.M.'s condition?
4. ***Prioritize***: What is the most important intervention that needs done immediately for J.M.?
5. ***Act***: What other interventions would you need to you implement for J.M.?
6. ***Evaluate***: What outcome would indicate that the immediate interventions were successful?
7. ***Safety***: What safety precautions would be needed when performing needed interventions?

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient with syncope has continuous ECG monitoring. The rhythm strip shows: Atrial rate 74 beats/min and regular; ventricular rate 62 beats/min and irregular; P wave normal shape; PR interval lengthens progressively until a P wave is not conducted; QRS normal shape. Which intervention would the nurse *prioritize?*
   - **a.** Administer epinephrine 1 mg IV push.
   - **b.** Prepare the patient for synchronized cardioversion.
   - **c.** Observe for symptoms of hypotension and angina.
   - **d.** Apply transcutaneous pacemaker pads on the patient.
2. The ECG monitor of a patient in the cardiac care unit after an MI shows ventricular bigeminy with a rate of 50 beats/min. Which action would the nurse take?
   - **a.** Perform defibrillation.
   - **b.** Administer IV amiodarone.
   - **c.** Prepare for pacemaker insertion.
   - **d.** Assess the patient's response.
3. In the patient with supraventricular tachycardia, which assessment indicates decreased cardiac output?
   - **a.** Hypertension and dyspnea
   - **b.** Chest pain and palpitations
   - **c.** Abdominal distention and tachypnea
   - **d.** Bounding pulses and a systolic murmur
4. The nurse prepares a patient for elective synchronized cardioversion. Which information would the nurse consider in planning for the procedure?
   - **a.** Defibrillation delivers a lower dose of electrical energy.
   - **b.** Cardioversion is a treatment for atrial bradydysrhythmias.
   - **c.** Defibrillation delivers a shock during the QRS complex.
   - **d.** Cardioversion is painful for an awake patient.
5. Which patient teaching points would the nurse include when providing discharge instructions to a patient with a new permanent pacemaker? *(select all that apply)*
   - **a.** Avoid or limit air travel.
   - **b.** Take and record a daily pulse rate.
   - **c.** Obtain and wear a Medic Alert ID device at all times.
   - **d.** Avoid lifting arm on the side of the pacemaker above shoulder.
   - **e.** Do not use a microwave oven because it interferes with pacemaker function.
6. Which information would the nurse teach the patient scheduled for a radiofrequency catheter ablation procedure?
   - **a.** Ventricular bradycardia may be induced and treated during the procedure.
   - **b.** A catheter will be placed in both femoral arteries to allow double-catheter intervention.
   - **c.** The procedure will destroy areas of the conduction system that are causing rapid heart rhythms.

d. General anesthetic will be given to prevent the awareness of any "sudden cardiac death" experiences.

1. c; 2. d; 3. b; 4. d; 5. b, c; d; 6. c.

LEARNING OUTCOMES

1. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with infective endocarditis or pericarditis.
2. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with myocarditis.
3. Distinguish the etiology, pathophysiology, and clinical manifestations of rheumatic fever and rheumatic heart disease.
4. Describe the interprofessional and nursing management of the patient with rheumatic heart disease.
5. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of patients with various types of valvular heart disease.
6. Relate the pathophysiology, clinical manifestations, and interprofessional and nursing management of patients with different types of cardiomyopathy.

KEY TERMS

aortic regurgitation (AR)
aortic stenosis (AS)
cardiac tamponade
cardiomyopathy (CMP)
dilated cardiomyopathy
hypertrophic cardiomyopathy
infective endocarditis (IE)
mitral valve prolapse (MVP)
myocarditis
pericardiocentesis
pericarditis
regurgitation
rheumatic fever (RF)
rheumatic heart disease
stenosis

This chapter focuses on patients with select inflammatory and structural heart problems. Conceptually, these problems can adversely affect perfusion. Inflammatory, infectious, and structural problems impair cardiac output (CO), which leads to decreased tissue perfusion. The patient may have pain, hyperthermia, and decreased functional and cognitive ability. The nurse plays a key role in providing patients with the education needed to manage problems and their effects.

INFLAMMATORY HEART DISORDERS

INFECTIVE ENDOCARDITIS

Infective endocarditis (IE) is a disease of the *endocardium* (the innermost layer of the heart) and the heart valves (Fig. 40.1). IE is associated with a poor prognosis and a decreased life expectancy.[1] There has been an increase in the number of cases of IE. This is largely related to an increase in IV drug use.[2]

Classification

We often classify IE based on the cause (e.g., IV drug use IE [IVDA IE], fungal IE) or site of involvement (e.g., prosthetic valve endocarditis [PVE]). We also describe IE as subacute or acute. The *subacute form* affects those with preexisting valve disease over a period of months. In contrast, the *acute form* affects those with healthy valves and appears as a rapidly progressive illness.

Etiology and Pathophysiology

IE occurs when blood flow allows organisms to contact and infect previously damaged heart valves or other endothelial surfaces.

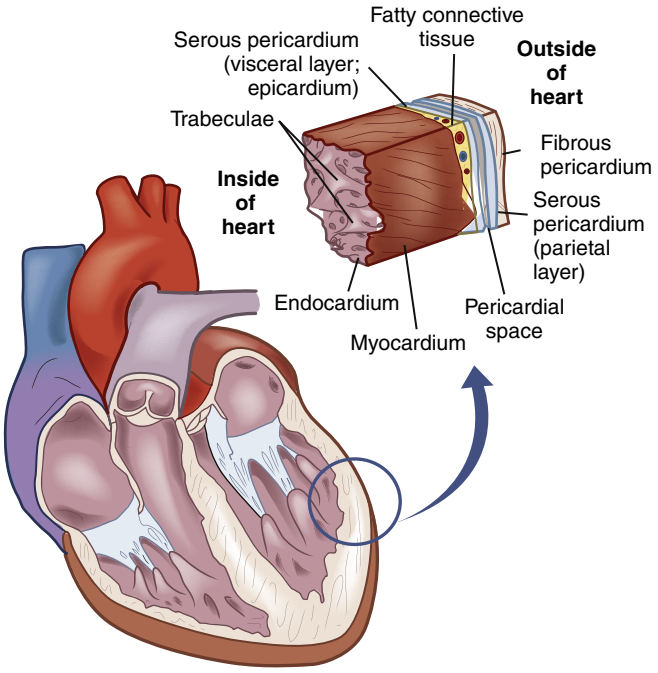

Fig. 40.1 Layers of the heart muscle and pericardium. The section of the heart wall shows the fibrous pericardium, the parietal and visceral layers of the serous pericardium (with the pericardial sac between them), the myocardium, and the endocardium. (Modified from Patton KT, Thibodeau GA: *The human body in health and disease,* ed 5, St Louis, 2010, Mosby.)

TABLE 40.1 Common Risk Factors for Endocarditis

Cardiac Conditions
- Acquired valve disease (e.g., MVP with regurgitation, calcified AS)
- CMP
- Congenital heart disease
- Heart lesions (e.g., ventricular septal defect, asymmetric septal hypertrophy)
- Marfan's syndrome
- Pacemaker
- Prior IE
- Prosthetic heart valve(s)
- Rheumatic heart disease (e.g., mitral valve regurgitation)

Noncardiac Conditions
- Hospital-acquired bacteremia
- IV drug use

Procedure-Associated Risks
- Intravascular devices (e.g., central venous catheter)
- Procedures listed in Table 40.2

About 50% of cases are caused by *Staphylococcus aureus.*[1] Other bacterial causes include *Streptococcus viridans* and coagulase-negative staphylococci. Besides streptococci, other colonizers of the oropharynx, such as the HACEK organisms (*Haemophilus*, *Actinobacillus*, *Cardiobacterium*, *Eikenella*, *Kingella*) can cause IE.[3] The organisms make biofilms, which protect the organisms from immune defenses and make antimicrobials less effective.[1]

Persons with a variety of underlying cardiac and noncardiac conditions can develop IE (Table 40.1). Patients are categorized into high, moderate, or low risk for developing IE or having a poor outcome.[2] The main risk factors for IE include (1) history of IE, (2) IV drug use, (3) having a prosthetic valve, (4) health care–associated infection from use of an intravascular device (e.g., methicillin-resistant *S. aureus* [MRSA]), and (5) renal dialysis.[4]

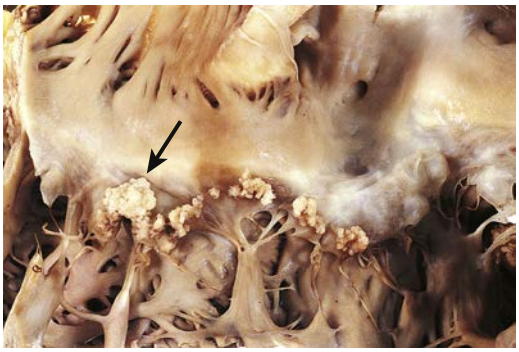

Fig. 40.2 Bacterial IE of the mitral valve. Note the large, irregular vegetations *(arrow)* covering the valve. (From Damjanov I, Linder J: *Pathology: a color atlas,* St Louis, 2000, Mosby.)

IE typically develops in 3 stages: (1) bacteremia, (2) adhesion, and (3) vegetation. *Vegetations,* the primary lesions of IE, consist of fibrin, leukocytes, platelets, and microbes that stick to the valve surface or endocardium (Fig. 40.2). The loss of parts of these fragile vegetations into the circulation results in *emboli.* Up to 10.5% of persons with IE develop embolization.[5] Left-sided heart vegetations move to various organs (e.g., brain, kidneys, spleen) and the extremities, causing limb infarction. Right-sided heart lesions move to the lungs, causing pulmonary emboli.

The infection may spread locally and damage the valves or their supporting structures. This can cause dysrhythmias and valve dysfunction. Invasion of the myocardium can lead to heart failure (HF), sepsis, and heart block (Fig. 40.3).

Clinical Manifestations

The manifestations of IE are nonspecific and involve multiple organ systems. Most patients present with fever.[5] Fever may be low grade or absent in older adults or those who are immunocompromised. Other symptoms include chills, weakness, malaise, fatigue, and anorexia.

Vascular signs include *splinter hemorrhages* (black longitudinal streaks) in the nail beds. Petechiae from microembolization of vegetative lesions can occur on the conjunctivae, lips, buccal mucosa, and palate and over the ankles, feet, and antecubital and popliteal areas. *Osler's nodes* (painful, tender, red or purple, pea-size lesions) are found on the fingertips or toes. *Janeway's lesions* (flat, painless, small, red spots) may be seen on the fingertips, palms, soles of feet, and toes. Eye examination may show hemorrhagic retinal lesions called *Roth's spots.*

Most patients have a new or worsening systolic murmur. Murmurs are usually absent in tricuspid IE because right-sided heart sounds are too low to be heard. HF is common. It occurs in up to 80% of patients with aortic valve IE and 50% of those with mitral valve IE.[5]

Diagnostic Studies

The health history is important in assessing IE. Ask patients if they have had any recent (within the past 3 to 6 months) dental,

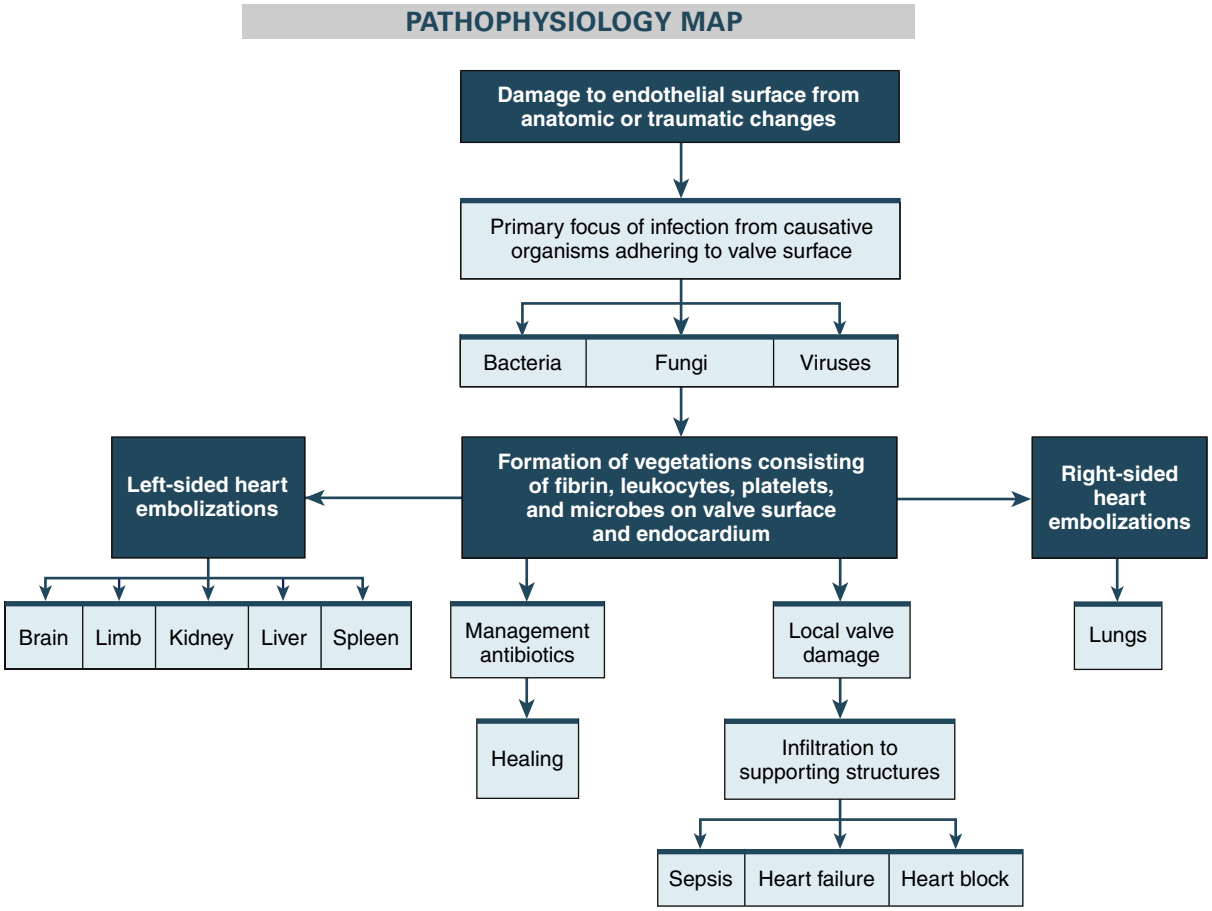

Fig. 40.3 Pathogenesis of IE.

urologic, surgical, or gynecologic procedures, including childbirth. Note any history of IVDA, heart disease, or infections (e.g., skin, respiratory, urinary tract). Have they had a heart catheterization, heart surgery, intravascular device placement, or renal dialysis?

Three blood cultures drawn over a period of 1 hour from 3 different venipuncture sites will be positive in most patients with IE.[6] Culture-negative IE is associated with antibiotic usage within the previous 2 weeks or results from a pathogen not easily detected by standard cultures. Mild leukocytosis occurs in acute IE. The erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels may be increased. Echocardiography can show vegetations.

Guidelines for the diagnosis of IE are based on the Duke Criteria. The patient must have 2 major criteria and 1 minor criterion, or 1 major and 3 minor, or 5 minor criteria. Major criteria include positive blood cultures, typical microorganism for IE from 2 separate blood cultures, evidence of endocardial involvement, and new valvular vegetation. Minor criteria include predisposing heart condition or IV drug use, vascular phenomena, immunologic phenomena, microbiologic evidence, or echocardiographic findings consistent with IE but not meeting major criteria.[7]

Interprofessional Care

Prophylactic Treatment

Situations and conditions that require antibiotic prophylaxis are detailed in Table 40.2.

Drug Therapy

Accurately identifying the causative organism is the key to successful treatment of IE. Long-term treatment is needed to kill dormant bacteria within the valvular vegetations. Complete removal of the organism generally takes weeks. Relapses are common.[1]

Antibiotic therapy is based on blood culture results. The effectiveness of therapy is assessed with subsequent blood cultures. Cultures that stay positive indicate inadequate or inappropriate antibiotics, an aortic root or myocardial abscess, or the wrong diagnosis (e.g., an infection elsewhere). It is reasonable to obtain 2 sets of blood cultures every 24 to 48 hours until the infection is cleared.[5] After completion of antibiotics, follow-up echocardiogram and inflammatory markers are done at 1, 3, 6, and 12 months.[6]

Fungal IE and PVE respond poorly to antibiotic therapy alone. Early valve replacement followed by prolonged (6 weeks or more) antibiotics is needed in these situations. Valve replacement surgery is done in 50% to 60% of cases of IE. Three reasons to perform surgery are for valve dysfunction causing HF, to prevent embolization, or for uncontrolled infection.[6]

Fever that persists after treatment has been started is managed with aspirin, acetaminophen, fluids, and rest (see Table 12.5). Complete bed rest is usually not needed unless the fever continues or there are signs of HF. IE with HF responds poorly to drug therapy and valve replacement, so it can be life-threatening.

TABLE 40.2 Antibiotic Prophylaxis to Prevent Endocarditis

Target Groups for Prophylactic Antibiotics

People with the following heart conditions should receive prophylactic antibiotics when they have the conditions or procedures listed below:

- Congenital heart disease (CHD)
  - Unrepaired cyanotic CHD (including palliative shunts and conduits)
  - Repaired congenital heart defect with prosthetic material or device for 6 months after the procedure
  - Repaired CHD with residual defects at the site or next to the site of prosthetic patch or prosthetic device
- Heart transplant recipients who develop heart valve disease
- History of IE
- Prosthetic heart valve or prosthetic material used to repair heart valve

Conditions or Procedures Requiring Antibiotic Prophylaxis

When the target groups have the following conditions or procedures, they need prophylactic antibiotics:

- Oral
  - Dental manipulation involving the gums or roots of the teeth
  - Dental manipulation involving puncture of the oral mucosa
- Respiratory
  - Respiratory tract incisions (e.g., biopsy)
  - Tonsillectomy and adenoidectomy
- Surgical procedures that involve infected skin, skin structures, or musculoskeletal tissue

Modified from Nishimura RA, Otto CM, Bonow RO, et al.: 2017 Focused update of the 2014 AHA/ACC guidelines for the management of patients with valvular heart disease, *Circ* 135:e1159, 2017.

! SAFETY ALERT

Communicating Test Results

- If blood culture results for a patient diagnosed with IE show that the organism is not susceptible to the ordered antibiotic, immediately notify the HCP.
- A National Patient Safety Goal stresses the importance of communicating critical test results to the right HCP in a timely manner.

❖ NURSING MANAGEMENT: INFECTIVE ENDOCARDITIS

◆ Assessment

Subjective and objective data to obtain from a patient with IE are found in Table 40.3. Assess vital signs together with heart sounds to detect a new murmur, a change in a preexisting murmur, and extra sounds (e.g., S_3).

Arthralgia (joint pain) and myalgias are common. Assess the patient for joint or muscle tenderness and decreased range of motion (ROM). Examine the patient for petechiae, splinter hemorrhages, and Osler's nodes. Complete a general systems assessment for hemodynamic or embolic complications.

◆ Clinical Problems

Clinical problems for the patient with IE may include:

- Impaired cardiac output
- Infection
- Fatigue
- Substance use

TABLE 40.3 NURSING ASSESSMENT

Infective Endocarditis (IE)

Subjective Data

Important Health Information

Health history: Valvular, congenital, or syphilitic heart disease, including valve repair or replacement. Previous IE, childbirth, staphylococcal or streptococcal infections, hospital-acquired bacteremia

Medications: Immunosuppressive therapy

Surgery or other treatments: Recent obstetric or gynecologic procedures. Invasive procedures, including catheterization, cystoscopy. Recent dental or surgical procedures, GI procedures (e.g., endoscopy)

Functional Health Patterns

Health perception–health management: IV drug use, alcohol use. Malaise

Nutritional-metabolic: Weight gain or loss, anorexia. Chills, diaphoresis

Elimination: Bloody urine

Activity-exercise: Exercise intolerance, generalized weakness, fatigue. Cough, dyspnea on exertion, orthopnea, palpitations

Sleep-rest: Night sweats

Cognitive-perceptual: Chest, back, or abdominal pain. Headache, joint tenderness, muscle tenderness

Objective Data

Cardiovascular

Dysrhythmia, tachycardia, new murmurs, S_3, S_4. Retinal hemorrhages

General

Fever

Respiratory

Tachypnea, crackles

Skin

Osler's nodes on extremities, splinter hemorrhages under nail beds, Janeway's lesions on fingertips, palms, soles of feet, and toes. Petechiae of skin, mucous membranes, or conjunctivae. Purpura, peripheral edema, finger clubbing

Possible Diagnostic Findings

Leukocytosis, anemia, ↑ ESR, ↑ CRP and cardiac biomarkers. Positive blood cultures, hematuria. Echocardiogram showing chamber enlargement, valvular dysfunction, and vegetations. Chest x-ray showing cardiomegaly and pulmonary infiltrates. ECG showing ischemia and conduction defects. Signs of systemic embolization or pulmonary embolism

More information on clinical problems and interventions for the patient with IE is in eNursing Care Plan 40.1 on the website for this chapter.

◆ Planning

The overall goals for the patient with IE include (1) normal or baseline cardiac function, (2) ability to perform activities of daily living (ADLs) without fatigue, and (3) an understanding of the treatment plan to prevent recurrence.

◆ Implementation

◆ Health Promotion

Teaching the patient at high risk for IE (Tables 40.1 and 40.2) helps reduce the incidence and recurrence of IE. Tell the patient to avoid people with infections, especially upper respiratory tract infections, and to report cold, flu, and cough symptoms. Stress the importance of avoiding fatigue, planning

rest periods, using good oral hygiene, and scheduling regular dental visits.[5]

Tell the patient to inform HCPs scheduling invasive procedures about the history of IE. Prophylactic antibiotic therapy may be needed. Refer the patient with a history of IVDA for drug rehabilitation.

Ambulatory Care

A patient with IE has many problems that need nursing management. IE generally requires treatment with antibiotics for 4 to 6 weeks. After initial treatment in the hospital, the patient may continue treatment at home if hemodynamically stable and adherent. Assess the home setting for adequate support. Patients who receive outpatient IV antibiotics need vigilant home nursing care.

Assessment findings are often nonspecific (Table 40.3). Tell the patient and caregiver about the importance of monitoring body temperature. Persistent temperature elevations may mean that the antibiotic is ineffective. Patients are at risk for life-threatening complications, such as stroke, pulmonary edema, and HF. Teach patients and caregivers to recognize signs and symptoms of these complications (e.g., change in mental status, dyspnea, chest pain, unexplained weight gain).

The patient needs adequate periods of physical and emotional rest. Bed rest may be needed when the patient has fever or complications (e.g., heart damage). Otherwise, the patient may perform moderate activity. To prevent problems related to decreased mobility, have the patient wear elastic compression stockings, perform ROM exercises, and deep breathe and cough every 2 hours. The patient may have anxiety and fear. Recognize this and begin strategies to help the patient cope with the illness.

Monitor laboratory data, including blood cultures, to determine antibiotic effectiveness. Assess IV lines for patency and signs of complications (e.g., phlebitis). Give antibiotics as prescribed. Monitor the patient for any adverse drug reactions.

Teach the patient and caregiver the nature of the disease and how to reduce the risk for reinfection. Explain the relationship between follow-up care, good nutrition and dental care, and prompt treatment of common infections (e.g., colds) to stay healthy. Teach the patient about symptoms to report that may indicate another infection (e.g., fever, fatigue, chills). Finally, explain the importance of prophylactic antibiotic therapy before certain invasive procedures (see Table 40.2).

Evaluation

The expected outcomes are that the patient with IE will

- Maintain adequate tissue and organ perfusion
- Maintain normal body temperature
- Report an increase in physical and emotional comfort

ACUTE PERICARDITIS

Pericarditis is a condition caused by inflammation of the pericardial sac (pericardium), often with fluid accumulation. The pericardium is composed of the inner serous membrane (visceral pericardium) and the outer fibrous (parietal) layer (Fig. 40.1). The pericardial space between these 2 layers normally holds 10 to 15 mL of serous fluid. The pericardium anchors the heart, provides lubrication to decrease friction between heart contractions, and helps to prevent excess dilation of the heart during diastole.

TABLE 40.4 Common Causes of Pericarditis

Infectious

- Bacterial: Pneumococci, staphylococci, streptococci, *Neisseria gonorrhoeae, Legionella pneumophila, Mycobacterium tuberculosis,* septicemia from gram-negative organisms
- Fungal: Histoplasma, *Candida* species
- Viral: Coxsackie A and B virus, echovirus, adenovirus, mumps, hepatitis, Epstein-Barr, varicella-zoster, human immunodeficiency virus
- Others: Toxoplasmosis, Lyme disease

Noninfectious

- Acute MI
- Cancers: Lung, breast, leukemia, Hodgkin lymphoma, non-Hodgkin lymphoma
- Dissecting aortic aneurysm
- Myxedema
- Radiation
- Renal failure
- Trauma: Thoracic surgery, pacemaker insertion, cardiac diagnostic procedures

Hypersensitive or Autoimmune

- Dressler syndrome
- Drug reactions (e.g., procainamide, hydralazine)
- Postpericardiotomy syndrome
- Rheumatic fever
- Rheumatologic diseases: Rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis (scleroderma), ankylosing spondylitis

Etiology and Pathophysiology

Common causes of acute pericarditis are listed in Table 40.4. Most often, the cause of acute pericarditis is *idiopathic* (unknown) or viral. About 20% of cases are due to post-cardiac injury.[8]

There are 3 types of pericarditis: acute, subacute, and chronic. Acute pericarditis develops rapidly, causing the pericardial sac to become inflamed and leak fluid (pericardial effusion). The characteristic pathologic finding in acute pericarditis is inflammation. There is an influx of neutrophils, increased pericardial vascularity, and, eventually, fibrin deposition on the epicardium (Fig. 40.4). Subacute pericarditis occurs weeks to months after an event. Pericarditis lasting more than 6 months is considered chronic.[9]

Post-MI syndrome (Dressler syndrome) pericarditis can occur 4 to 6 weeks after transmural MI (see Chapter 37). This syndrome is more common after a large anterior infarct. Viral pericarditis is often seen after respiratory or GI illness.[10]

Clinical Manifestations

Symptoms include progressive, severe, sharp chest pain.[10] The pain is often worse with deep inspiration and when lying flat. Sitting up and leaning forward relieves the pain. The pain may radiate to the neck, arms, or left shoulder, making it hard to distinguish from angina. One distinction is that the pain from pericarditis can be referred to the trapezius muscle (shoulder, upper back). Dyspnea is related to the patient's breathing in rapid, shallow breaths to avoid chest pain. Fever and anxiety may worsen dyspnea.

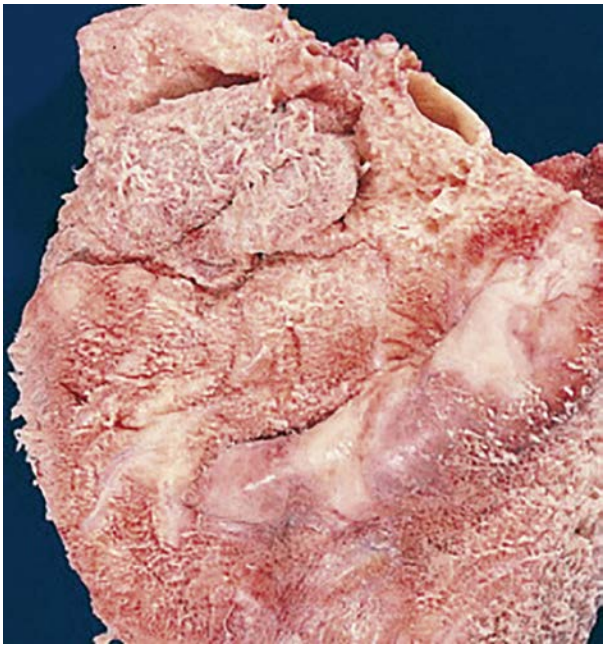

Fig. 40.4 Acute pericarditis. Note shaggy coat of fibers covering surface of heart. (From Carter T, Riegel B: *Cardiac nursing: a companion to Braunwald's heart disease*, St Louis, 2008, Mosby.)

The hallmark finding in acute pericarditis is a *pericardial friction rub.* The rub is a scratching, grating, high-pitched sound believed to result from friction between the roughened pericardial and epicardial surfaces. It is best heard with the stethoscope at the lower left sternal border of the chest with the patient leaning forward. Since it is hard to tell a pericardial friction rub from a pleural friction rub, ask the patient to hold their breath. If you still hear the rub, it is cardiac. Pericardial friction rubs may be hard to identify because they are often intermittent.

Complications

The major complications are pericardial effusion and cardiac tamponade. *Pericardial effusion* is a build-up of fluid in the pericardium. It can occur rapidly (e.g., chest trauma) or slowly (e.g., tuberculosis pericarditis). Large effusions compress nearby structures. Pulmonary tissue compression can cause cough, dyspnea, and tachypnea. Phrenic nerve compression can cause hiccups. Compression of the laryngeal nerve may cause hoarseness. Heart sounds are distant and muffled. BP is usually maintained.

Cardiac tamponade develops as the pericardial effusion volume increases and compresses the heart. The speed of fluid accumulation affects the severity of clinical signs. Tamponade can occur acutely (e.g., rupture of heart, trauma) or subacutely (e.g., from renal failure, cancer).

The patient may report chest pain. They are often confused, anxious, and restless. As the compression of the heart increases, there is decreased CO, muffled heart sounds, narrowed pulse pressure, tachypnea, and tachycardia. Increased jugular venous pressure causes neck vein distention. *Pulsus paradoxus,* if present, is a large decrease in systolic BP during inspiration (Table 40.5). In a patient with a slow onset of a tamponade, dyspnea may be the only sign.

TABLE 40.5 Measuring Pulsus Paradoxus

1. Position the patient in a semirecumbent position.
2. Have patient breathe normally.
3. Using a manually operated BP cuff, measure systolic BP.
4. Inflate BP cuff at least 20 mm Hg above systolic BP.
5. Deflate cuff slowly until you hear sounds throughout the respiratory cycle (inspiration and expiration) and note the pressure.
6. Determine the difference between the measurements taken in steps 3 and 5. This will equal the amount of paradox:

Sounds heard on expiration at	110 mm Hg
Sounds heard throughout cycle at	–82 mm Hg
Amount of paradox	28 mm Hg

The difference is normally <10 mm Hg. If the difference is >10 mm Hg, cardiac tamponade may be present.

Diagnostic Studies

The ECG is useful in diagnosing acute pericarditis, with changes noted in 90% of cases. The most sensitive ECG changes include diffuse (widespread) ST segment elevations. This reflects the abnormal repolarization from the pericardial inflammation. These changes are different from the ST changes seen in MI. In myocardial ischemia, there are usually localized ST segment changes. In acute pericarditis, serial ECGs do not show evolving changes, such as those with MI.

An echocardiogram can determine the presence of a pericardial effusion or cardiac tamponade. Doppler imaging and color M-mode can assess diastolic function and diagnose constrictive pericarditis. A CT scan and MRI can visualize the pericardium and pericardial space. Chest x-ray findings are generally normal, but a large pericardial effusion may appear as cardiomegaly (Fig. 40.5).

Common laboratory findings include leukocytosis and increased CRP and ESR. Troponin levels may be increased in patients with ST segment elevation and acute pericarditis, which could indicate concurrent heart damage. Fluid obtained during pericardiocentesis or tissue from a pericardial biopsy may be studied to determine the cause of the pericarditis.

Interprofessional Care

Management is aimed at identifying and treating the underlying problem and symptoms (Table 40.6). Antibiotics treat bacterial pericarditis. Nonsteroidal antiinflammatory drugs (NSAIDs) control the pain and inflammation. Corticosteroids are used for patients with pericarditis from systemic lupus erythematosus, patients already taking corticosteroids for autoimmune conditions, or patients who do not respond to NSAIDs. They are used cautiously because of their many side effects. Aspirin is recommended for treatment of pericarditis after ST elevation.[10] Colchicine, an antiinflammatory drug used for gout, may help patients with pericarditis present more than 10 days or who have recurrent pericarditis.[10]

Pericardiocentesis is usually done for pericardial effusion with acute cardiac tamponade, purulent pericarditis, or suspected cancer. Hemodynamic support for the patient before the procedure may include giving volume expanders and inotropic agents (e.g., dopamine) and stopping any anticoagulants. The procedure is done rapidly and safely using a percutaneous

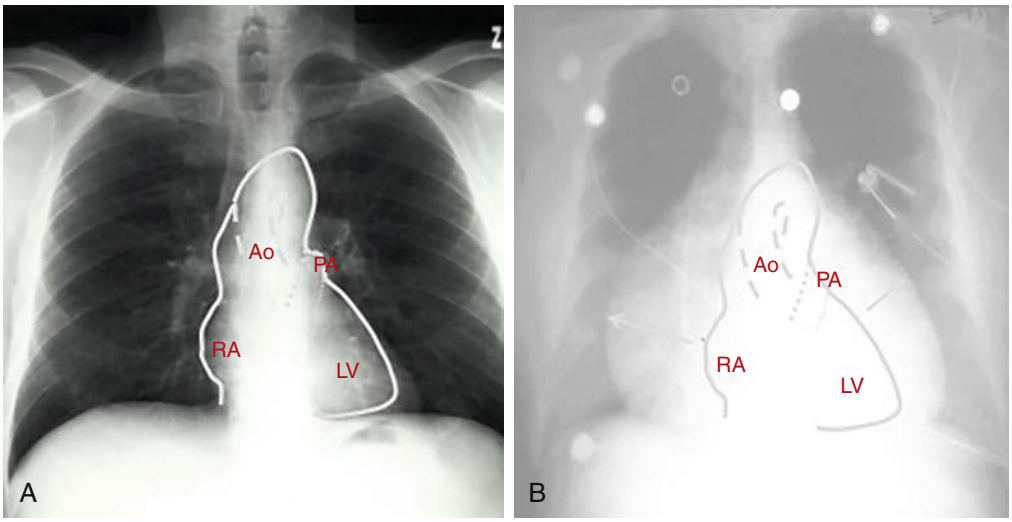

Fig. 40.5 (A) X-ray of a normal chest. (B) Pericardial effusion is present. Note the classic "water bottle shape" heart *(arrows)*. Select structures and great vessels are labeled: *Ao,* ascending aorta; *LV,* left ventricle; *PA,* pulmonary artery; *RA,* right atrium. (From Appleton C, Gilliam L: Cardiac tamponade, *Cardiol Clin* 35:525, 2017.)

TABLE 40.6 Interprofessional Care

Acute Pericarditis

Diagnostic Assessment

- History and physical assessment (note pericardial friction rub, pulsus paradoxus)
- Laboratory: CRP, ESR, white blood cell count
- ECG
- Chest x-ray
- Echocardiogram
- CT scan
- MRI
- Pericardiocentesis, pericardial window
- Pericardial biopsy

Management

- Treatment of underlying disease
- Bed rest
- Drug therapy
  - NSAIDs
  - Corticosteroids
  - Antibiotics (for bacterial infection)
- Pericardiocentesis (for tamponade)
- Pericardial window (for tamponade or ongoing pericardial effusion)

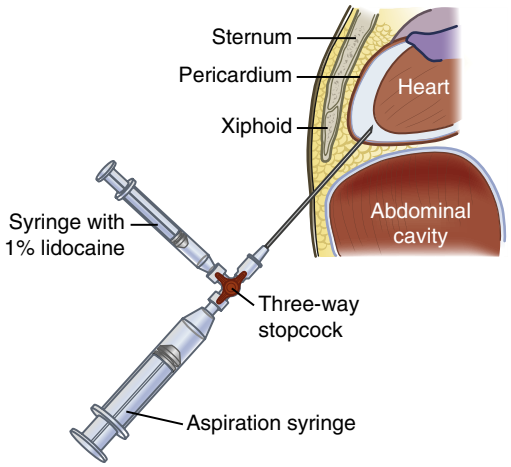

Fig. 40.6 Pericardiocentesis performed under sterile conditions in conjunction with ECG and hemodynamic measurements.

approach guided by echocardiography (Fig. 40.6). A needle is inserted into the pericardial space to remove fluid for analysis and relieve heart pressure. Complications include dysrhythmias, further cardiac tamponade, pneumomediastinum, pneumothorax, myocardial laceration, and coronary artery laceration.

A *pericardial window* is a surgical procedure for diagnosis or drainage of excess fluid. Cutting a "window," or part of the pericardium, allows the fluid to drain continuously into the peritoneum or chest.

❖ NURSING MANAGEMENT: ACUTE PERICARDITIS

Managing the patient's pain and anxiety during acute pericarditis is your key nursing consideration. Assess the pain to distinguish angina (myocardial ischemia) (see Table 37.8) from the pain of pericarditis. Pericarditis pain is usually found in the precordium or left trapezius region. It has a sharp quality that increases with inspiration. Pain is often relieved when the patient sits up or leans forward and is worse when lying flat.

Pain relief measures include keeping the patient on bed rest with the head of the bed raised to 45 degrees and providing an overbed table for support. Antiinflammatory drugs can help control the pain. Give these drugs with food or milk. Tell the patient to avoid alcohol because of the risk of GI bleeding. Other drugs, such as a proton pump inhibitor (e.g., pantoprazole, omeprazole), can reduce stomach acid.

Provide simple, complete explanations of procedures and possible causes of the pain to help reduce anxiety. These explanations are particularly important when the patient is undergoing testing and for the patient who has previously had angina or an MI.

The patient with acute pericarditis is at risk for cardiac tamponade and decreased CO. Monitor for signs of tamponade and prepare for possible pericardiocentesis.

CHECK YOUR PRACTICE

You are assigned to a 58-year-old male patient who had an MI 3 days ago. He has now developed pericarditis. When you are making rounds, you assess that the patient is slightly confused and has prominent neck veins. His heart rate is 118 beats/min.

- What should you do next?

CHRONIC CONSTRICTIVE PERICARDITIS

Etiology and Pathophysiology

Chronic constrictive pericarditis is a condition in which fibrosis and rigidity of the pericardium result in decreased pericardial elasticity and restricted ventricular filling. The cause may be tuberculosis, recent heart surgery, mediastinal radiation therapy, or idiopathic.[11] The condition is characterized by pericardial effusion that is slowly reabsorbed with progression to fibrous scarring, thickening of the pericardium from calcium deposits, and eventual destruction of the pericardial space. The fibrotic, thickened, and adherent pericardium encases the heart and prevents adequate atrial and ventricular stretch.

Clinical Manifestations and Diagnostic Studies

Manifestations of chronic constrictive pericarditis mimic HF and cor pulmonale. Decreased CO accounts for many of the manifestations. These include dyspnea on exertion, peripheral edema, ascites, fatigue, anorexia, and weight loss. The most prominent finding is jugular venous distention (JVD).

Echocardiography is recommended to diagnose constrictive pericarditis.[11] CT and MRI can be used to measure pericardial thickness and assess diastolic filling patterns. ECG changes are often nonspecific in chronic constrictive pericarditis. The heart on the chest x-ray may be normal or enlarged.

Interprofessional Care

The treatment of choice for symptomatic chronic constrictive pericarditis is a *pericardiectomy.* This involves complete resection of the pericardium through a median sternotomy with the use of cardiopulmonary bypass (see Chapter 37). Some patients show immediate improvement. Others may take weeks. The prognosis improves when the patient has surgery before becoming clinically unstable. Diuretics are used in patients who are not surgical candidates.[11]

MYOCARDITIS

Etiology and Pathophysiology

Myocarditis is a focal or diffuse inflammation of the myocardium. Causes include viruses, bacteria, fungi, radiation therapy, and pharmacologic and chemical factors. Coxsackie A and B viruses are the most common causative agents. Autoimmune disorders (e.g., polymyositis) have been linked with the development of myocarditis. It also may be idiopathic.

When the myocardium becomes infected, the causative agent invades the myocytes and causes cellular damage and necrosis. This activates the immune response. Cytokines and O_2 free radicals are released. As the infection progresses, an autoimmune response is activated. This causes further destruction of myocytes and heart dysfunction.

Clinical Manifestations

The features of myocarditis vary from a benign course without overt symptoms to progressive HF, dysrhythmias, or sudden cardiac death (SCD). Fever, fatigue, malaise, myalgias, pharyngitis, dyspnea, lymphadenopathy, and nausea and vomiting are early manifestations of the viral illness.

Early cardiac signs appear 7 to 10 days after viral infection. Pericarditis often accompanies myocarditis. Signs include pleuritic chest pain with a pericardial friction rub and effusion. Late signs relate to the development of HF and include an S_3 heart sound, crackles, JVD, syncope, peripheral edema, and angina.

Diagnostic Studies and Interprofessional Care

The ECG changes with myocarditis are often nonspecific but reflect pericardial involvement (e.g., diffuse ST segment changes). Dysrhythmias and conduction problems may be present. Laboratory findings are often inconclusive. They may include mild to moderate leukocytosis and atypical lymphocytes, high viral titers, and increased ESR, CRP levels, and levels of cardiac biomarkers, such as troponin. The virus is generally present in tissue and pericardial fluid samples only during the first 8 to 10 days of illness.

Endomyocardial biopsy provides histologic confirmation of myocarditis.[12] A biopsy is most diagnostic during the first 6 weeks of acute illness, when lymphocytic infiltration and myocyte damage are present. Nuclear scans, echocardiography, and MRI are used to assess heart function.

Treatment consists of managing symptoms. Angiotensin-converting enzyme (ACE) inhibitors and β-adrenergic receptor blockers (β-blockers) are used if the heart is enlarged or to treat HF (see Chapter 38). Diuretics reduce fluid volume and preload. If the patient is not hypotensive, IV drugs such as nitroprusside and milrinone reduce afterload and improve CO by decreasing systemic vascular resistance. Digoxin improves heart contractility and reduces HR. It is used with caution because of increased sensitivity to the adverse effects (e.g., dysrhythmias) and the potential toxicity. Anticoagulation reduces the risk for clot formation from blood stasis in patients with a low ejection fraction (EF).

DRUG ALERT

Digoxin (Lanoxin)

1. Use cautiously in patients with myocarditis.
2. Myocarditis predisposes to drug-related dysrhythmias and toxicity.

Myocarditis with an autoimmune basis is treated with immunosuppressive agents to reduce heart inflammation and damage. Antivirals may be used as adjunct therapy.

General supportive measures include O_2 therapy, bed rest, and restricted activity. In cases of severe HF, intraaortic balloon pump therapy and ventricular assist devices (VAD) may be needed (see Chapters 35 and 38).

❖ NURSING MANAGEMENT: MYOCARDITIS

Focus your interventions on improving CO and managing the signs and symptoms of HF. Select nursing measures to decrease cardiac workload. These include placing the patient in a semi-Fowler's position, spacing activity and rest periods, and providing a quiet environment. Carefully monitor drugs that increase the heart's contractility and decrease preload, afterload, or both. Evaluate the effectiveness of your interventions on an ongoing basis.

The patient may be anxious about the diagnosis. Assess the level of anxiety, take measures to decrease anxiety, and keep the patient and caregiver informed about the therapeutic plan.

The patient who receives immunosuppressive therapy is at increased risk for infection. Monitor for complications and provide the patient with proper infection control procedures.

Although most patients recover spontaneously, some develop dilated cardiomyopathy. If severe HF occurs, the patient may need a heart transplant.

RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

Rheumatic fever (RF) is an acute inflammatory disease that can involve all the heart layers. **Rheumatic heart disease** is chronic scarring and deformity of the heart valves resulting from RF. Over 15 million people worldwide have evidence of RHD.[13]

Etiology and Pathophysiology

RF occurs as a complication 2-3 weeks after a group A streptococcal pharyngitis. RHD is the result of valve damage from an abnormal immune response to Streptococcus.[13] RF affects the heart, skin, joints, and CNS. Rheumatic heart disease, caused by RF, mainly affects children and young adults.

Cardiac Lesions and Valve Deformities

About 50% of RF episodes are *rheumatic pancarditis,* involving all layers of the heart (endocardium, myocardium, and pericardium) (see Fig. 40.1).[14]

Rheumatic IE is found mainly in the valves, with swelling and erosion of the valve leaflets. Vegetation forms from deposits of fibrin and blood cells in areas of erosion. The lesions initially create a thickening of the valve leaflets, fusion of commissures and chordae tendineae, and fibrosis of the papillary muscle. Valve leaflets may become calcified, resulting in stenosis. The less mobile valve leaflets may not close properly, resulting in regurgitation. The mitral and aortic valves are most often affected.

Nodules, called *Aschoff's bodies,* are formed by a reaction to inflammation with swelling and destruction of collagen fibers. As Aschoff's bodies age, they become more fibrous, and scar tissue forms in the myocardium. Rheumatic pericarditis develops and affects both layers of the pericardium. The layers become thick and covered with fibrinous exudate. A serosanguineous pericardial effusion may develop. When healing occurs, fibrosis and adhesions develop that partially or completely destroy the pericardial sac. Damage to the heart begins during the first attack of RF. Recurrent infections cause further structural damage.

TABLE 40.7 Diagnostic Criteria

Revised Jones Criteria for Rheumatic Fever

These criteria apply to the initial episode of rheumatic fever in moderate- or high-risk populations.

Major Criteria
- Carditis: Clinical and/or subclinical
- Arthritis
  - Monoarthritis or polyarthritis
  - Polyarthralgia
- Erythema marginatum
- Subcutaneous nodules
- Sydenham's chorea

Minor Criteria
- Monoarthralgia
- Fever
- Laboratory findings: ↑ ESR and/or ↑ CRP
- ECG findings: Prolonged PR interval after accounting for age variability (unless carditis is a major criterion)

Evidence of Group A Streptococcal Infection
- Laboratory findings
  - ↑ Antistreptolysin-O titer, positive throat culture, or positive rapid antigen test for group A streptococci

Modified from Gewitz MH, Baltimore RS, Tani LY, et al.: Revision of the Jones criteria for the diagnosis of acute rheumatic fever in the era of Doppler echocardiography: A scientific statement from the AHA, *Circ* 131:1806, 2015.

Extracardiac Lesions

The systemic lesions of RF involve the skin, joints, and CNS. Painless subcutaneous nodules, arthralgias or arthritis, and chorea may develop.

Clinical Manifestations

Jones criteria are used to diagnose acute RF.[14] The presence of 2 major criteria or 1 major and 2 minor criteria plus evidence of a preceding group A streptococcal infection indicate a high probability of acute RF (Table 40.7).

Major Criteria

Carditis is the most important manifestation of RF. It results in 3 signs: (1) heart murmur or murmurs of mitral or aortic regurgitation, or mitral stenosis; (2) heart enlargement and HF from myocarditis; and (3) pericarditis resulting in muffled heart sounds, chest pain, pericardial friction rub, or signs of effusion.

Monoarthritis or *polyarthritis* is the most common finding in RF. It occurs in up to 75% of patients.[14] The inflammatory process affects the synovial membranes of the joints. This causes swelling, heat, redness, tenderness, and limitation of motion. The larger joints, particularly the knees, ankles, elbows, and wrists, are most often affected.

Sydenham's chorea is the major CNS manifestation.[14] It is characterized by involuntary movements, especially of the face and limbs, muscle weakness, and speech and gait problems.

Erythema marginatum lesions are a less common feature of RF. They occur in less than 10% of RF patients.[15] The

  - NSAIDs
  - Salicylates
  - Corticosteroids

bright pink, nonpruritic, maplike macular lesions occur mainly on the trunk and proximal extremities. They intensify with heat (e.g., warm bath). *Subcutaneous nodules* associated with severe carditis are small, hard, painless swellings found over extensor surfaces of joints, particularly the knees, wrists, and elbows.

Minor Criteria

Minor clinical manifestations (Table 40.7) are helpful in diagnosing the disease. The minor criteria confirm the presence of RF when only 1 major criterion is present.

Evidence of Infection

In addition to the major and minor criteria, there must be evidence of a preceding group A streptococcal infection. Table 40.7 lists the various laboratory tests used to confirm evidence of infection.

Complications

Chronic rheumatic carditis results from changes in valve structure months to years after an episode of RF. Rheumatic IE can result in fibrous tissue growth in valve leaflets and chordae tendineae with scarring and contractures. The mitral valve is most often involved. The aortic and tricuspid valves may be affected.

Diagnostic Studies and Interprofessional Care

No single diagnostic test exists for RF. An echocardiogram may show valvular insufficiency and pericardial fluid or thickening.[15] A chest x-ray may show an enlarged heart. The most consistent ECG change is a prolonged PR interval from delayed AV conduction.

Treatment consists of drug therapy and supportive measures (Table 40.8). Antibiotic therapy does not change the course of the acute disease or the development of carditis. It eliminates residual group A streptococci in the tonsils and pharynx and prevents the spread of organisms through close contact. Salicylates, NSAIDs, and corticosteroids are the 3 inflammatory agents most widely used to control fever and joint manifestations.[15]

TABLE 40.9 NURSING ASSESSMENT

Rheumatic Fever and Rheumatic Heart Disease

Subjective Data

Important Health Information

Health history: Recent streptococcal infection, history of RF or rheumatic heart disease

Functional Health Patterns

Health perception–health management: Family history of RF. Malaise

Nutritional-metabolic: Anorexia, weight loss

Activity-exercise: Palpitations, generalized weakness, fatigue, impaired coordination

Cognitive-perceptual: Chest pain, widespread joint pain, and tenderness (especially large joints)

Objective Data

Cardiovascular

Tachycardia, pericardial friction rub, muffled heart sounds, murmurs, peripheral edema

General

Fever

Musculoskeletal

Signs of monoarthritis or polyarthritis, including swelling, heat, redness, limitation of motion (especially of knees, ankles, elbows, shoulders, wrists)

Neurologic

Chorea (involuntary, purposeless, rapid motions; facial grimaces)

Skin
- Subcutaneous nodules and erythema marginatum

Possible Diagnostic Findings

Cardiomegaly on chest x-ray. Prolonged PR interval on ECG. Valve abnormalities, chamber dilation, and pericardial effusion on echocardiogram. ↑ Antistreptolysin-O titer, positive throat culture, positive rapid antigen test for group A streptococci, ↑ ESR, ↑ CRP, leukocytosis.

❖ NURSING MANAGEMENT: RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

◆ Assessment

Table 40.9 presents the subjective and objective data to obtain from a patient with RF and rheumatic heart disease.

Inspect the skin for subcutaneous nodules and erythema marginatum. Palpate for subcutaneous nodules over all bony surfaces and along extensor tendons of the hands and feet. The nodules range in size from 1 to 4 cm and are hard, painless, and freely movable. Erythema marginatum can occur on the trunk and inner aspects of the upper arm and thigh. Assess for these bright pink maculae in good light because the rash is hard to see, especially in patients with dark skin.

◆ Clinical Problems

Clinical problems for the patient with RF and rheumatic heart disease include:
- Fatigue

- Impaired cardiac function
- Infection

Planning

The goals for a patient with RF and rheumatic heart disease include (1) normal or baseline heart function, (2) resumption of daily activities without joint pain, and (3) ability to manage the long-term antibiotic therapy.

Implementation

Health Promotion

Early detection and immediate treatment of group A streptococcal pharyngitis can prevent RF. Treatment with an initial dose of intramuscular Benzathine Penicillin G is the most widely used antibiotic to treat RHD.[14] If the patient is allergic to penicillin, a narrow-spectrum cephalosporin (e.g., cephalexin), clindamycin (Cleocin), or azithromycin (Zithromax) is used.[16] Therapy requires strict adherence to the full course of treatment. Teach people in the community to seek prompt medical care for symptoms of streptococcal pharyngitis.

Acute Care

Give antibiotics as prescribed to treat the streptococcal infection. Teach the patient that completing the full course of antibiotics is vital to successful treatment (see Table 15.9).

Promote optimal rest. This reduces cardiac workload and metabolic needs. Position painful joints for proper alignment and apply heat for comfort. Give salicylates, NSAIDs, and corticosteroids as prescribed for joint pain. Implement measures to manage fever (see Table 12.5). Stress the importance of gentle activities during recovery.

CHECK YOUR PRACTICE

Your 28-year-old male patient is recovering from carditis after RF. As you are preparing him for discharge from the hospital, he is pacing the floor and seems quite upset. You ask him to sit down so you can talk. He tells you, "I'm a heart cripple. I will never be able to play ball with my sons or go skiing again. I might as well just go to bed and stay there."

- What are the key elements to include in your teaching plan?

Ambulatory Care

The aim of secondary prevention is to stop a recurrence of RF. Prior history of RF makes the patient more susceptible to a second attack after a streptococcal infection. The best prevention is treatment with prophylactic antibiotics. Patients with RF without carditis need prophylaxis until age 20 and for a minimum of 5 years. Patients with rheumatic carditis and residual heart disease (e.g., persistent valve disease) need lifelong prophylaxis.[16]

Teach the patient with a history of RF about the disease process and the need for ongoing antibiotic prophylaxis. Teach the patient about good nutrition, hygienic practices, and adequate rest. Caution the patient about the possible development of heart valve disease. Tell the patient to seek medical care for symptoms, such as excessive fatigue, dizziness, palpitations, unexplained weight gain, or exertional dyspnea.[16]

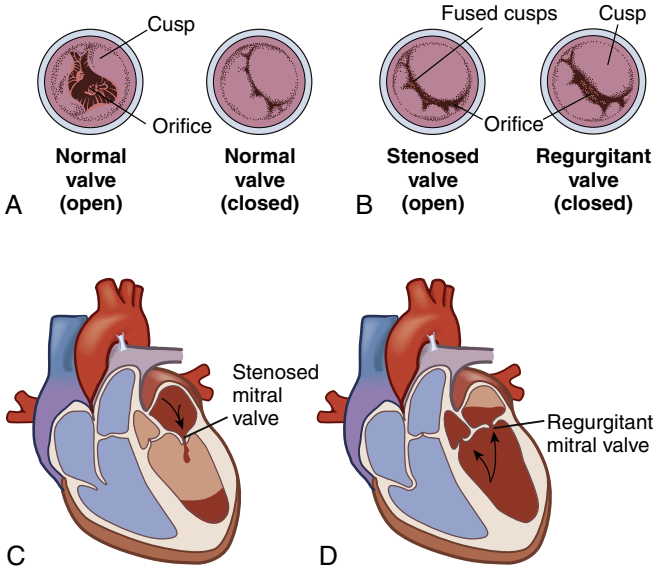

Fig. 40.7 Valvular stenosis and regurgitation. (A) Normal position of the valve leaflets when the valve is open and closed. (B) Open position of a stenosed valve *(left)* and closed position of regurgitant valve *(right)*. (C) Hemodynamic effect of mitral stenosis. The stenosed valve is unable to open sufficiently during left atrial systole, inhibiting left ventricular filling. (D) Hemodynamic effect of MR. The mitral valve does not close completely during left ventricular systole, letting blood reenter the left atrium. At the same time, blood is moving forward through the aortic valve. (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children*, ed 6, St Louis, 2010, Mosby.)

Evaluation

The expected outcomes are that the patient with RF and rheumatic heart disease will

- Be able to perform ADLs with minimal fatigue and pain
- Adhere to the treatment plan
- Express confidence in managing disease
- Use measures to prevent complications

VALVULAR HEART DISEASE

Two AV valves (mitral and tricuspid) and 2 semilunar valves (aortic and pulmonic) control blood flow through the heart (see Fig. 35.1). The pressure on either side of an open valve is normally equal. However, in a stenotic valve, the valve opening is smaller due to limited leaflet opening. The forward flow of blood is impaired. This creates a difference in pressure on the 2 sides of the open valve. The amount of **stenosis** (constriction or narrowing) is seen in the pressure differences (the higher the difference, the greater the stenosis). When **regurgitation** occurs (referred to as *incompetence* or *insufficiency*), there is incomplete closure of the valve and backward flow of blood (Fig. 40.7).

Congenital heart conditions are the most common cause of valve disorders in children and teens. Aortic stenosis and mitral regurgitation (MR) often occur in older adults who have some form of heart disease. Other causes of valve disease in adults are related to endocarditis, rheumatic heart disease, hypertension, and autoimmune disorders.

TABLE 40.10 Manifestations of Valvular Heart Disease

Type	Manifestations
Mitral valve prolapse	Palpitations, dyspnea, chest pain, activity intolerance, syncope, holosystolic murmur
Mitral valve regurgitation	*Acute:* Generally poorly tolerated. New systolic murmur with pulmonary edema. Cardiogenic shock develops rapidly *Chronic:* Weakness, fatigue, exertional dyspnea, edema. Palpitations, S_3 gallop, holosystolic murmur
Mitral valve stenosis	Dyspnea on exertion. Hoarseness, hemoptysis, fatigue. Atrial fibrillation on ECG. Palpitations. Loud, accentuated S_1. Low-pitched, diastolic murmur
Aortic valve regurgitation	*Acute:* Abrupt onset of profound dyspnea, chest pain, left ventricular failure, and cardiogenic shock *Chronic:* Fatigue, exertional dyspnea, orthopnea, PND. Water-hammer pulse, heaving precordial impulse, ↓ or absent S_1, S_3, or S_4. Soft, high-pitched diastolic murmur, Austin Flint murmur
Aortic valve stenosis	Angina, syncope, dyspnea on exertion, HF, normal or soft S_1, ↓ or absent S_2, systolic murmur, prominent S_4
Tricuspid and pulmonic stenosis	*Tricuspid:* Peripheral edema, ascites, hepatomegaly. Diastolic low-pitched murmur with increased intensity during inspiration *Pulmonic:* Fatigue, loud midsystolic murmur

PND, Paroxysmal nocturnal dyspnea.

MITRAL VALVE STENOSIS

Etiology and Pathophysiology

Worldwide, the most common cause of mitral stenosis is rheumatic heart disease.[17] Rheumatic mitral stenosis is widespread in developing countries. Less common causes are congenital mitral stenosis, rheumatoid arthritis, radiation exposure, and systemic lupus erythematosus. Rheumatic IE causes scarring of the valve leaflets and the chordae tendineae. Contractures and adhesions develop between the commissures (the junctional areas). The stenotic mitral valve takes on a "fish mouth" shape because of the thickening and shortening of the mitral valve structures. Severe mitral annular calcification can cause stenosis in older adults.

These deformities block the blood flow and create a pressure difference between the left atrium and left ventricle during diastole. As a result, left atrial pressure and volume increase. This causes higher pulmonary vasculature pressure. The overloaded left atrium places the patient at risk for atrial fibrillation. In chronic mitral stenosis, pressure overload occurs in the left atrium, pulmonary bed, and right ventricle.

Clinical Manifestations

The main symptom is exertional dyspnea from reduced lung compliance (Table 40.10). Heart sounds include a loud 1st heart sound and a low-pitched, diastolic murmur (best heard at the apex with the stethoscope). Less often, patients may have hoarseness (from atrial enlargement pressing on the laryngeal nerve), hemoptysis (from pulmonary hypertension), and chest pain (from decreased CO and coronary perfusion). Emboli can form in the left atrium from atrial fibrillation and cause a stroke. Fatigue and palpitations from atrial fibrillation may occur.

MITRAL VALVE REGURGITATION

Etiology and Pathophysiology

Mitral valve function depends on intact mitral leaflets, mitral annulus, chordae tendineae, papillary muscles, left atrium, and left ventricle. A defect in any of these structures can cause regurgitation. MR may result from problems with the leaflets or from the surrounding structures. In primary (degenerative) MR, a problem with the leaflets causes the regurgitation. In secondary (functional) MR, myocardial disease causes the regurgitation.[17] Most cases are caused by MI, chronic rheumatic heart disease, mitral valve prolapse, ischemic papillary muscle dysfunction, and IE. MI with left ventricular failure increases the risk for rupture of the chordae tendineae and acute MR.

MR allows blood to flow backward from the left ventricle to the left atrium because of incomplete valve closure during systole. Both the left ventricle and left atrium must work harder to preserve an adequate CO. In acute MR, the sudden increase in pressure and volume transmits back to the pulmonary bed. This results in pulmonary edema and, if not treated, cardiogenic shock. In chronic MR, the added volume results in left atrial enlargement, left ventricular dilation and hypertrophy, and, finally, a decrease in CO.

Clinical Manifestations

The nature of its onset determines the clinical course of MR (Table 40.10). Patients with acute MR have thready peripheral pulses and cool, clammy extremities. A low CO may mask a new systolic murmur. Rapid assessment (e.g., heart catheterization) and intervention (e.g., valve repair or replacement) are critical.

Patients with chronic MR may remain asymptomatic for many years. Early symptoms of left ventricular failure may include weakness, fatigue, palpitations, and dyspnea. These gradually progress to orthopnea, paroxysmal nocturnal dyspnea, and peripheral edema. Increased left ventricular volume leads to an audible 3rd heart sound (S_3), even with normal left ventricular function. The murmur is a loud holosystolic murmur at the apex radiating to the left axilla. Patients with asymptomatic MR must be monitored carefully.

Treatment for MR depends on the cause of the regurgitation. Primary MR typically requires valve repair or replacement before significant left ventricular failure or pulmonary hypertension develops.[17] Medical management includes guideline-directed medical therapy (GDMT).

MITRAL VALVE PROLAPSE

Etiology and Pathophysiology

Mitral valve prolapse (MVP) is an abnormality of the mitral valve leaflets and the papillary muscles or chordae that allows the leaflets to prolapse, or buckle, back into the left atrium during systole (Fig. 40.8). MVP affects 2% to 3% of the general population.

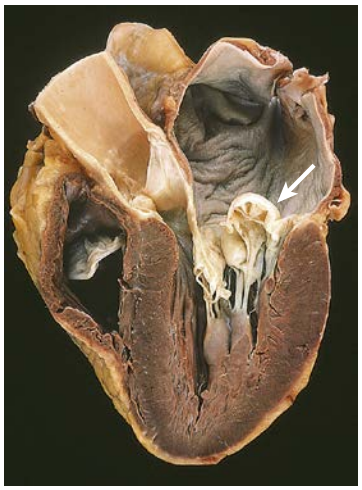

Fig. 40.8 MVP. In this valvular abnormality, the mitral leaflets have prolapsed back into the left atrium. There is hooding *(arrow)*. The left ventricle is on the right. (From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

The use of the term *prolapse* can be misleading because it is used even when the valve is working normally. MVP is usually benign, but serious complications can occur, including MR, IE, SCD, HF, and cerebral ischemia.

Genetic Link

Although the cause of MVP is unknown, there is an increased familial incidence. The genetic inheritance is often autosomal dominant (see Chapter 13). MVP in this group results from a connective tissue defect affecting only the valve, as part of Marfan's syndrome, or another hereditary condition that affects collagen structure.

Clinical Manifestations

MVP has a broad range of severity. Most patients are asymptomatic for their entire lives. About 10% of those with MVP become symptomatic. A characteristic of MVP is a regurgitation murmur that is louder during systole. MVP does not alter S_1 or S_2 heart sounds. Severe MR is an uncommon but serious complication of MVP.

M-mode and 2-D echocardiography can confirm MVP. Dysrhythmias, such as premature ventricular contractions, paroxysmal supraventricular tachycardia, and ventricular tachycardia, may cause palpitations, lightheadedness, and syncope. IE may occur in patients with MR associated with MVP.

Patients may have chest discomfort caused by abnormal tension on the papillary muscles.[18] Chest pain episodes tend to occur in clusters, especially during periods of stress. Dyspnea, palpitations, and syncope sometimes accompany the chest pain and do not respond to antianginal treatment (e.g., nitrates). β-Blockers may control palpitations and chest pain. Encourage the patient to stay hydrated, exercise regularly, and avoid caffeine.

Most patients with MVP have a benign, manageable course. For those who do develop symptomatic MR, no current therapy delays the need for valve surgery. A teaching plan for patients with MVP is outlined in Table 40.11.

TABLE 40.11 PATIENT & CAREGIVER TEACHING

Mitral Valve Prolapse (MVP)

Include the following information in the teaching plan for a patient with MVP and the patient's caregiver:

- Take drugs as prescribed (e.g., β-blockers to control palpitations, chest pain).
- Adopt healthy eating habits.
- Avoid caffeine. It is a stimulant and may worsen symptoms.
- If you use diet pills or other over-the-counter drugs, check for common ingredients that are stimulants (e.g., caffeine, ephedrine) since these can worsen symptoms.
- Begin, or maintain, an exercise program to achieve optimal health.
- Contact the HCP or emergency response system (ERS) if symptoms develop or worsen (e.g., palpitations, fatigue, shortness of breath, anxiety).

AORTIC VALVE STENOSIS

Etiology and Pathophysiology

Congenital **aortic stenosis (AS)** is generally found in childhood, adolescence, or young adulthood. In older adults, AS is a result of RF or degeneration, similar to coronary artery disease. AS is the most frequent degenerative valve disorder, affecting 3% of people over 65 years of age.[19] In rheumatic valve disease, fusion and calcification cause the valve leaflets to stiffen and retract, resulting in stenosis. AS due to rheumatic heart disease accompanies mitral valve disease. Isolated AS is usually nonrheumatic.

AS causes obstruction of blood flow from the left ventricle to the aorta during systole. The result is left ventricular hypertrophy and increased myocardial O_2 consumption because of the increased myocardial mass. As the disease progresses and compensation fails, reduced CO leads to decreased tissue perfusion, pulmonary hypertension, and HF. Left untreated, severe AS has a poor prognosis.

Clinical Manifestations

Manifestations (Table 40.10) develop when the valve orifice becomes about one-third of its normal size. They include the classic triad of angina, syncope, and exertional dyspnea, reflecting left ventricular failure.[19] Auscultation often reveals a crescendo-decrescendo, holosystolic murmur that may radiate to the carotids.

Some patients may be asymptomatic. The prognosis is poorer for patients with symptoms and those whose valve obstruction is not fixed. Nitroglycerin is used cautiously to treat angina in patients with AS. It can significantly reduce BP and worsen chest pain.

DRUG ALERT

Nitroglycerin

- Use cautiously in patients with AS since significant hypotension may occur.
- The drug can worsen chest pain due to the decrease in preload and drop in BP.

AORTIC VALVE REGURGITATION

Etiology and Pathophysiology

Aortic regurgitation (AR) may be the result of primary disease of the aortic valve leaflets, the aortic root, or both.[20] Trauma, IE, or aortic dissection can cause acute AR, which is a life-threatening emergency. Chronic AR generally results from rheumatic heart disease, a congenital bicuspid aortic valve, syphilis, a connective tissue problem, or a postsurgical cause.[20]

AR causes retrograde (backward) blood flow from the ascending aorta into the left ventricle during diastole. This results in volume overload. The left ventricle initially compensates for chronic AR by dilation and hypertrophy. Myocardial contractility eventually declines, and blood volume in the left atrium and pulmonary bed increases. This leads to pulmonary hypertension and right ventricular (RV) failure.

Clinical Manifestations

Patients with acute AR have sudden signs of cardiovascular collapse (Table 40.10). The patient develops severe dyspnea, chest pain, and hypotension, indicating left ventricular failure and cardiogenic shock, a life-threatening emergency.

Patients with chronic, severe AR develop a *water-hammer pulse* (strong, quick beat that collapses immediately). Heart sounds may include a soft or absent S_1, S_3, or S_4 and a soft, high-pitched diastolic murmur.

The patient with chronic AR generally is asymptomatic for years.[20] Exertional dyspnea, orthopnea, and paroxysmal nocturnal dyspnea develop only after considerable heart dysfunction has occurred (Table 40.10). Angina occurs less often than in AS.

TRICUSPID AND PULMONIC VALVE DISEASE

Etiology and Pathophysiology

Tricuspid regurgitation (TR) can be primary or secondary. Primary TR is less common. It is typically due to IE or congenital malformation. Secondary TR is caused by RV dilatation from pulmonary hypertension, cor pulmonale, or pulmonary outflow tract obstruction. The patient does not show JVD, enlarged liver, and peripheral edema until regurgitation is severe. Diagnosis is made by history, physical, and echocardiogram. The prognosis is poor for severe TR.

Tricuspid stenosis is usually caused by RF. Signs and symptoms include a fluttering discomfort in the neck, fatigue, and possible right upper quadrant pain.

Pulmonary regurgitation is often asymptomatic. A crescendo-decrescendo murmur is present. Potential causes include pulmonary hypertension, surgical repair of tetralogy of Fallot (TOF), or congenital valve disease. It can cause RV dilation.

Pulmonic stenosis is often due to congenital heart disease. It results in RV hypertension and hypertrophy (Table 40.10). It is largely asymptomatic. When symptoms develop, they are similar to those of AS (syncope, dyspnea, angina). Symptoms typically do not present until adulthood.

TABLE 40.12 Interprofessional Care

Valvular Heart Disease

Diagnostic Assessment
- History and physical assessment
- Chest x-ray
- Complete blood count
- ECG
- Echocardiography (Doppler, transesophageal)
- Heart catheterization

Management

Conservative Therapy
- Prophylactic antibiotic therapy (Table 40.2)
  - RF
  - IE
- Sodium restriction
- Drug therapy to treat or control HF
  - Vasodilators (e.g., nitrates, ACE inhibitors)[a]
  - Positive inotropes (e.g., digoxin)
  - Diuretics
  - β-Blockers
- Anticoagulation therapy (see Table 41.10)
- Antidysrhythmic drugs (see Table 39.9)
- Percutaneous transluminal balloon valvuloplasty
- Percutaneous valve replacement

Surgical Therapy
- Valve repair
  - Annuloplasty
  - Commissurotomy (valvulotomy)
  - Valvuloplasty
- Valve replacement

[a]Use cautiously in patients with aortic stenosis.

DIAGNOSTIC STUDIES: VALVULAR HEART DISEASE

Diagnosis of valvular heart disease includes information from the history and physical assessment and a variety of tests (Table 40.12). An echocardiogram shows valve structure, function, and heart chamber size. Transesophageal echocardiography and Doppler color-flow imaging help diagnose and monitor valvular heart disease progression. Real-time 3D echocardiography can help assess mitral valve and congenital heart disease.

Chest x-ray shows the heart size, altered pulmonary circulation, and valve calcification. An ECG identifies HR, rhythm, and any ischemia or ventricular hypertrophy. Heart catheterization detects pressure changes in the heart chambers, records pressure differences across the valves, and measures the size of valve openings.

INTERPROFESSIONAL CARE: VALVULAR HEART DISEASE

Conservative Therapy

Overall treatment focuses on preventing exacerbations of HF, acute pulmonary edema, thromboembolism, and recurrent RF and IE (Table 40.12). HF is treated with vasodilators, positive

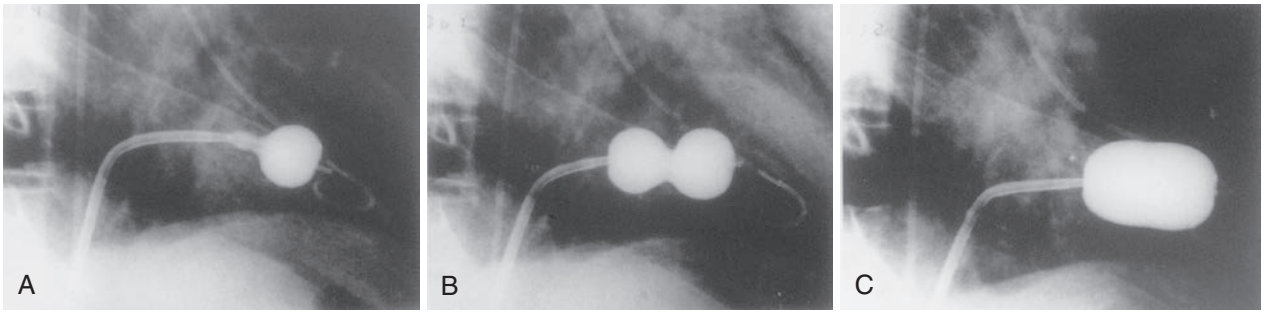

Fig. 40.9 Mitral valvuloplasty performed by the Inoue technique. The catheter is placed in the mitral valve and the distal part of the Inoue balloon inflated (A). The balloon is then pulled back in the mitral valve and inflated for 10 to 15 seconds under fluoroscopic control (B) until the waist of the balloon is no longer visible (C) and the balloon falls back into the left atrium. (From Crawford MH, DiMarco JP, Paulus WJ: *Cardiology,* ed 3, Edinburgh, 2010, Mosby.)

inotropes, β-blockers, diuretics, and a low-sodium diet (see Chapter 38).

Atrial dysrhythmias are common. They are treated with calcium channel blockers, β-blockers, antidysrhythmic drugs, or electrical cardioversion (see Chapter 39). Anticoagulant therapy is used in patients with atrial fibrillation to prevent systemic or pulmonary emboli.

Percutaneous Transluminal Balloon Valvuloplasty

An alternative treatment for some patients with valvular heart disease is *percutaneous transluminal balloon valvuloplasty* (PTBV). During PTBV, the fused commissures are split open. Balloon valvuloplasty treats mitral, tricuspid, pulmonic, and AS.[20]

The PTBV procedure is typically done in the cardiac catheterization laboratory. It involves threading a balloon-tipped catheter from the femoral artery or vein to the stenotic valve. The balloon is inflated to separate the valve leaflets. A single- or double-balloon technique may be used. Using a single Inoue balloon with an hourglass shape allows sequential inflation. This technique is the most popular because it is easy and has good results with few complications. It is not a permanent fix for stenosis (Fig. 40.9).

Surgical Therapy

The decision for valve repair or replacement depends on the patient's symptoms using the New York Heart Association classification system for functional disability (see Table 38.3).[20] The procedure used depends on the (1) valves involved, (2) pathology and severity of the disease, and (3) patient's clinical condition (Box 40.1).

Valve Repair

Valve repair is preferred over replacement when clinically appropriate. Repair has a lower operative mortality rate than valve replacement. It is often used in mitral or tricuspid valve disease.[20] Although repair avoids the risks of replacement, it may not restore total valve function.

Open surgical *valvuloplasty* involves repair of the valve by suturing the torn leaflets, chordae tendineae, or papillary muscles. It is mainly used to treat mitral or TR.

Minimally invasive valve surgery involves a mini-sternotomy or parasternal approach. It may include robotic and thoracoscopic surgical systems. Advantages include shorter lengths of stay, fewer blood transfusions, less pain, and lower risk for sternal infection and postoperative atrial fibrillation.

For patients with mitral or TR, further valve repair or reconstruction using annuloplasty is an option. *Annuloplasty* involves reconstruction of the annulus, with or without the aid of prosthetic rings.

BOX 40.1 ETHICAL/LEGAL DILEMMAS

Do Not Resuscitate

Situation

J.L., a 68-year-old man, is admitted for a second mitral valve repair and coronary artery bypass graft surgery. He did not adhere to the treatment plan after his original surgery 7 years ago. You are worried about his future adherence to drugs, diet, and exercise. He is now on dialysis, making him a high-risk open surgical patient. J.L. and his caregiver request all treatment and decline to discuss advance directives (ADs) or do-not-resuscitate (DNR) orders.

Ethical/Legal Points for Consideration

- Patient adherence to past treatment plans is not a factor when considering DNR decisions. Many circumstances related to nonadherence are outside the patient's control, such as finances, transportation, availability of help, and declining physical and medical capabilities.
- Based on their expertise, HCPs have the right to refuse to provide treatment that offers no benefit to the patient.
- ADs do not include a DNR order. If the patient is unable to speak for himself or herself, the HCP can start a DNR order only after a conversation with the health care proxy and/or nearest kin. The decision usually depends on evidence of the patient's preferences (substituted judgment standard) or what is thought to be in the best interest of the patient.
- If there is an AD refusing resuscitation, the HCP is required to act accordingly but is not compelled to enact a DNR without clear direction from the patient or proxy.
- If the involved parties disagree about the patient's treatment plan, a referral can be made to an ethics committee, they can seek treatment from another HCP, or they may seek legal intervention by way of a court order.

Discussion Questions

- How can a lack of understanding or limited financial resources contribute to nonadherence with the plan of care?
- What type of information should be given to a patient and caregiver in discussions about ADs and DNR orders? Who should provide this information?
- Who can initiate a referral to an ethics committee?

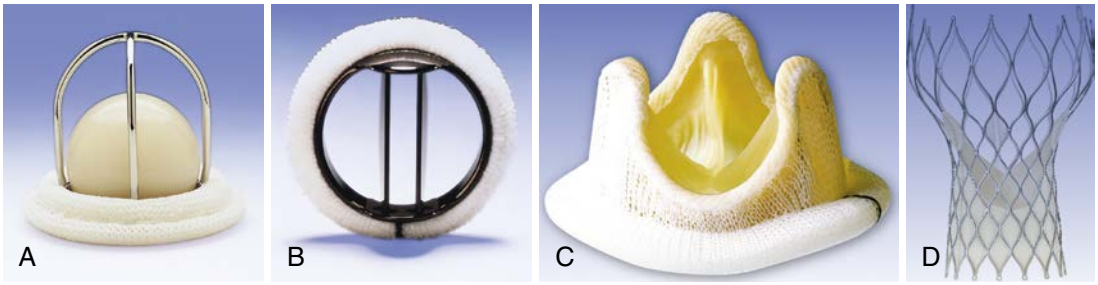

Fig. 40.10 Types of prosthetic heart valves. (A) Starr-Edwards caged ball valve. (B) St. Jude bi-leaflet valve. (C) Carpentier-Edwards porcine valve. (D) CoreValve transcatheter aortic valve (CV26 Hero), Medtronic 2015. (*A, B,* and *C,* From Bonow RO, Mann DL, Zipes DP, et al.: *Braunwald's heart disease: a textbook of cardiovascular medicine,* ed 9, Philadelphia, 2012, Saunders.)

Valve Replacement

Valve replacement may be needed for mitral, aortic, tricuspid, and pulmonic valve disease. Desirable valves are nonthrombogenic, durable, and create minimal stenosis. A wide variety of prosthetic mechanical or biologic (tissue) valves are available. (Fig. 40.10).

Mechanical valves are made from artificial materials. They consist of combinations of metal alloys, pyrolytic carbon, and Dacron. *Biologic valves* are made from bovine, porcine, or human (cadaver) heart tissue. They usually contain some human-made materials. A "decellularizing" process allows for decreased calcification of the bioprosthetic valve. They produce a more natural pattern of blood flow compared with mechanical valves.

Mechanical valves are more durable and last longer than biologic valves. However, they have an increased risk for thromboembolism. Patients need long-term anticoagulation therapy, which increases the risk of bleeding. Anticoagulation therapy is not needed with biologic valves because of their low thrombogenicity. However, they are less durable and tend to cause early calcification, tissue degeneration, and stiffening of the leaflets. Both valve types are subject to leaking and risk of IE.

Transcatheter therapies are another option for treating valvular heart disease. They are used to treat patients at high risk for surgery who have aortic or mitral bioprosthetic valve failure. Transcatheter edge-to-edge repair is available for patients with severe MR who are very high risk for open surgery. Transcatheter pulmonary valve replacement is approved for use in pediatric and adult patients with pulmonary valve disease caused by congenital heart disease.

Transcatheter aortic valve replacement (TAVR) is an option for patients with severe, symptomatic AS. In over 90% of patients, the procedure is done using a transfemoral approach. The evaluation for TAVR includes an echocardiogram, coronary CT angiogram, and potentially a heart catheterization.[17] Imaging can determine valve size and help in planning the procedure. Currently, there are 3 commercially available TAVR valves in the United States. The Edwards Sapien 3 valve is made of bovine pericardial tissue. It is a balloon-expandable valve (Fig. 40.11).[21] The CoreValve transcatheter aortic valve is a self-expanding valve made of porcine pericardial tissue (Fig. 40.10D).[22] The 3rd valve, Lotus, is available for use in patients deemed high risk for open surgery. It is currently in clinical trials for patients at a lower surgical risk.

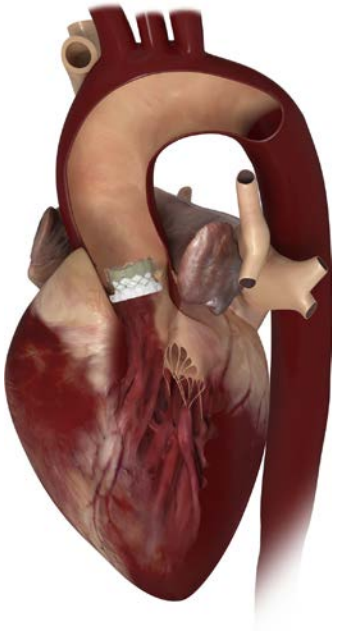

Fig. 40.11 Edwards Sapien 3 Transcatheter Heart Valve. (Courtesy Edwards Lifesciences LLC, Irvine, CA.)

Patients with biologic valves who have atrial fibrillation need long-term anticoagulation. Some patients with biologic valves or annuloplasty with prosthetic rings may need anticoagulation the first few months after surgery until endothelial cells cover the suture lines (endothelialized).

The choice of valves depends on many factors. A mechanical valve may be best for a younger patient because it is more durable. If a patient cannot take an anticoagulant (e.g., women of childbearing age), a biologic valve is an option. Frail patients with co-morbidities need to be evaluated by a qualified heart team for a full evaluation before considering surgery.[23] Encourage patients to discuss short- and long-term consequences of valve choices with their HCPs.

❖ NURSING MANAGEMENT: VALVULAR DISORDERS

◆ Assessment

Table 40.13 presents the subjective and objective data to obtain from a patient with valve disease.

TABLE 40.13 NURSING ASSESSMENT

Valvular Heart Disease

Subjective Data

Important Health Information

Health history: RF, IE; congenital defects, MI, chest trauma, CMP; syphilis, Marfan's syndrome, streptococcal infections

Functional Health Patterns

Health perception–health management: IV drug use, fatigue

Activity-exercise: Palpitations, generalized weakness, activity intolerance, dizziness, fainting, dyspnea on exertion, cough, hemoptysis, orthopnea

Sleep-rest: Paroxysmal nocturnal dyspnea

Cognitive-perceptual: Angina or atypical chest pain

Objective Data

Cardiovascular

Abnormal heart sounds, including murmurs, S_3, and S_4. Dysrhythmias, including atrial fibrillation, premature ventricular contractions. Tachycardia. ↑ or ↓ in pulse pressure, hypotension, water-hammer or thready peripheral pulses

Gastrointestinal

Ascites, hepatomegaly, unexplained weight gain

General

Fever

Respiratory

Crackles, wheezes, hoarseness

Skin

Diaphoresis, flushing, cyanosis, clubbing, peripheral edema

Possible Diagnostic Findings

Cardiomegaly on chest x-ray. ECG abnormalities specific to involved valve. Echocardiogram (valve disorders, chamber dilation), heart catheterization (abnormal valves, chamber pressures, CO, and blood flow, depending on involved valve)

Clinical Problems

Clinical problems for the patient with valvular heart disease include:

1. Impaired cardiac function
2. Fatigue
3. Fluid imbalance

More information on clinical problems and interventions is in eNursing Care Plan 40.2, available on the website for this chapter.

Planning

The overall goals for the patient with valve disease include (1) normal heart function, (2) improved activity tolerance, and (3) an understanding of the disease process and health maintenance measures.

Implementation

Health Promotion

Encouraging early treatment of streptococcal infections and providing prophylactic antibiotics for patients with a history of RF are critical in preventing acquired rheumatic valve disease. The patient at risk for IE and any patient with certain heart conditions must receive prophylactic antibiotics (Table 40.2). Teach the person with a history of RF, IE, or congenital heart disease to report symptoms of valvular heart disease.

Acute Care and Ambulatory Care

A patient with progressive valvular heart disease may need outpatient care or hospitalization for management of HF, IE, embolic disease, or dysrhythmias. HF is the most common reason for ongoing medical care.

Design activities considering the patient's limitations. An appropriate exercise plan can increase cardiac tolerance. The patient should limit activities that cause fatigue and dyspnea. They need to avoid strenuous physical exercise because damaged valves may not handle the increased CO. Develop your patient's care plan to emphasize conserving energy, setting priorities, and taking planned rest periods. Discourage tobacco use. Consider a referral to a vocational counselor if the patient has a physically or emotionally demanding job.

Perform ongoing cardiac assessments to monitor the effectiveness of drugs. Teach the actions and side effects of drugs to increase adherence. The patient must understand the importance of prophylactic antibiotic therapy to prevent IE (Table 40.2).

When valvular heart disease can no longer be managed medically, surgery is needed. See Chapter 37 for the care of a patient having heart surgery. The patient on anticoagulants (e.g., warfarin) after surgery for valve replacement must have the international normalized ratio (INR) checked regularly to determine proper dosage and adequacy of therapy. INR values of 2.5 to 3.5 are therapeutic for patients with most mechanical valves.

Table 41.15 outlines teaching related to anticoagulant therapy. Teach the patient to follow up with an HCP regularly and when to seek urgent medical care. Tell the patient to notify the HCP of any signs of infection, HF, or bleeding and any planned invasive or dental work. Last, encourage patients to wear a Medic Alert device or bracelet and carry the manufacturer's valve information card.

Evaluation

The expected outcomes are that a patient with valvular heart disease will

1. Maintain adequate tissue and organ perfusion
2. Achieve fluid balance
3. Achieve an optimal level of activity
4. Describe disease process and measures to prevent complications

CARDIOMYOPATHY

Cardiomyopathy (CMP) is a group of diseases that directly affect myocardial structure or function. We classify CMP as primary or secondary. *Primary CMP* refers to idiopathic conditions involving only the heart muscle. In *secondary CMP,*

TABLE 40.14 Causes of Cardiomyopathy

Dilated CMP
- Cardiotoxic agents: alcohol, cocaine, doxorubicin
- Coronary artery disease
- Genetic (autosomal dominant)
- Hypertension
- Metabolic problems
- Muscular dystrophy
- Myocarditis
- Pregnancy
- Valve disease

Hypertrophic CMP
- AS
- Genetic (autosomal dominant)
- Hypertension

Restrictive CMP
- Amyloidosis
- Cancer
- Endomyocardial fibrosis
- Post-radiation therapy
- Sarcoidosis
- Ventricular thrombus

another disease process causes myocardial disease. Common causes of secondary CMP are shown in Table 40.14.

Three major types of CMP are dilated, hypertrophic, and restrictive. Each type has its own pathogenesis, clinical presentation, and treatment protocols (Tables 40.15 and 40.16). CMP that leads to cardiomegaly and HF is the main reason for heart transplants.

Takotsubo cardiomyopathy is a transient heart syndrome that causes apical akinesis and mimics acute coronary syndrome.[24] Patients often have chest pain, ST segment elevation on ECG, and elevated cardiac biomarkers consistent with an MI. However, when the patient undergoes heart catheterization, there is no significant coronary artery disease. It is an acute, stress-related syndrome that is more common in postmenopausal women. Treatment is largely supportive. Around 5% of patients need anticoagulation.[24]

DILATED CARDIOMYOPATHY

Etiology and Pathophysiology

Dilated cardiomyopathy is the most common type of CMP, with a prevalence of 5 to 8 cases per 100,000 people in the United States. It causes HF in 20% to 45% of cases.[25] Dilated CMP is a primary myocardial disorder with genetic or acquired origins. Alcohol-related dilated CMP has its own unique presentation and treatment. Other common causes of dilated CMP are shown in Table 40.14.

Dilated CMP appears with diffuse inflammation and rapid degeneration of heart fibers. This results in ventricular dilation, impaired systolic function, atrial enlargement, and blood stasis in the left ventricle. SCD from dysrhythmias is a leading cause of death in idiopathic dilated CMP. Ventricular dilation causes *cardiomegaly* (Fig. 40.12) and contractile dysfunction. In contrast to HF, the walls of the ventricles do not hypertrophy.

Clinical Manifestations

The signs and symptoms of dilated CMP may develop acutely after an infection or slowly over time. Symptoms can include decreased exercise capacity, fatigue, dyspnea at rest, paroxysmal nocturnal dyspnea, and orthopnea. As the disease progresses, the patient may have a dry cough, palpitations, abdominal

TABLE 40.15 Types of CMP

Dilated	Hypertrophic	Restrictive
Cardiac Output		
↓	Normal or decreased	Normal or ↓
Cardiomegaly		
Moderate to severe	Mild to moderate	Mild
Contractility		
↓	↑ or ↓	Normal or ↓
Dysrhythmias		
Sinus tachycardia, atrial and ventricular dysrhythmias	Atrial and ventricular dysrhythmias	Atrial and ventricular dysrhythmias
Major Manifestations		
Fatigue, weakness, palpitations, dyspnea	Exertional dyspnea, fatigue, angina, syncope, palpitations	Dyspnea, fatigue
Outflow Tract Obstruction

TABLE 40.16 Interprofessional Care

Cardiomyopathy

Diagnostic Assessment
- History and physical assessment
- ECG
- b-Type natriuretic peptide (BNP)
- Chest x-ray
- Echocardiogram
- Nuclear imaging studies
- Heart catheterization
- Endomyocardial biopsy

Management
- Drug therapy
  - Nitrates (except in hypertrophic cardiomyopathy)
  - β-Blockers
  - Antidysrhythmics
  - ACE inhibitors
  - Calcium channel blockers
  - Diuretics
  - Digitalis (except in hypertrophic CMP unless used to treat atrial fibrillation)
  - Anticoagulants (if indicated)
- VAD
- Cardiac resynchronization therapy
- Implantable cardioverter-defibrillator
- Surgical repair
- Heart transplant
- Cardiac rehabilitation
- Palliative and hospice care

bloating, nausea, vomiting, and anorexia. Signs can include an abnormal S_3 and/or S_4, dysrhythmias, heart murmurs, pulmonary crackles, edema, weak peripheral pulses, pallor, hepatomegaly, and JVD. Decreased blood flow through an enlarged heart promotes stasis and blood clot formation and may lead to systemic embolization.

Diagnostic Studies

The diagnosis of dilated CMP is based on the patient's history and exclusion of other causes of HF. Echocardiography is usually the basis for diagnosing dilated CMP. EF less than 20% has a 50% mortality rate within 1 year. The chest x-ray may show cardiomegaly with signs of pulmonary venous hypertension and pleural effusion. The ECG may show tachycardia, bradycardia, and dysrhythmias with conduction problems. Laboratory studies may show increased b-type natriuretic peptide (BNP) levels if HF is present.

Heart catheterization evaluates the patient for coronary artery disease. An endomyocardial biopsy done at the time of the right-sided heart catheterization can identify any infectious organisms or other causes of disease.

❖ Interprofessional and Nursing Care

Interventions focus on controlling HF by enhancing heart contractility and decreasing preload and afterload. This is similar to how we manage chronic HF. Treatment guidelines are based on the specific stage of disease progression (see Table 38.3). Treatment of patients with Class IV (stage D) HF is more palliative than curative.

Several different types of drugs are available to manage HF (see Table 38.7). Nitrates (e.g., nitroglycerin) and diuretics (e.g., furosemide) decrease preload. ACE inhibitors reduce afterload. β-Blockers (e.g., metoprolol) and aldosterone antagonists (e.g., spironolactone) control the neurohormonal stimulation that occurs in HF. Dysrhythmias are treated with the appropriate antidysrhythmic (see Chapter 39). Anticoagulation therapy reduces the risk for systemic embolization from clots that form in the heart chambers.

Drug and nutrition therapy and cardiac rehabilitation may help lessen symptoms of HF and improve CO and quality of life. A patient with secondary dilated CMP is treated for the underlying disease process. For example, teach the patient with alcohol-related dilated CMP to abstain from alcohol. See Chapter 11 for more on alcohol use.

Unfortunately, dilated CMP does not respond well to therapy, and patients have multiple episodes of HF. Patients may be hospitalized for infusions of dobutamine or milrinone, followed by aggressive diuresis. Sometimes these treatments are done in an outpatient setting or in the home under nursing supervision. After treatment, many patients see an improvement in symptoms for several weeks. Medical management is based on clinical guidelines for HF. Statins may be helpful (see Table 37.6).

Patients may benefit from nondrug therapies. A VAD allows the heart to rest and recover from acute HF or serves as a bridge to a heart transplant. Other options include cardiac resynchronization therapy and an implantable cardioverter-defibrillator (ICD) (see Chapter 38).

A heart transplant may be considered in the patient with terminal or end-stage CMP. A permanent, implantable VAD, known as *destination therapy,* is an option for patients with advanced disease who are not candidates for a heart transplant (see Chapter 38). Currently, about 50% of heart transplants are done to treat CMP. Heart transplant recipients have a good prognosis. However, donor hearts are scarce. Many patients with dilated CMP die before receiving a heart.

Patients with dilated CMP are very ill and have a grave prognosis. Your expert nursing care is critical. Observe for signs and symptoms of worsening HF, dysrhythmias, embolus formation, and drug effectiveness. The goals of therapy are to keep the patient at an optimal level of functioning and out of the hospital. Always include caregivers when planning a patient's care. Encourage caregivers to learn cardiopulmonary resuscitation (CPR). Teach them when and how to access emergency care.

Home health and hospice nursing can provide the patient and caregiver with palliative care. This includes strategies to maximize and maintain functional status or end-of-life care to prepare for a peaceful death.

HYPERTROPHIC CARDIOMYOPATHY

Etiology and Pathophysiology

Hypertrophic cardiomyopathy is a genetic disorder that causes asymmetric left ventricular hypertrophy without ventricular dilation.[25] In one form of the disease, the septum between the 2 ventricles becomes enlarged and blocks the blood flow from the left ventricle. We call this *hypertrophic obstructive cardiomyopathy* (HOCMP) or *asymmetric septal hypertrophy* (ASH).

Hypertrophic CMP occurs less often than dilated CMP. It is more common in men than in women. It is usually diagnosed in young adults and, most often, in active, athletic persons. Hypertrophic CMP is the most common cause of SCD in otherwise healthy young people. It accounts for 3% of deaths in young competitive athletes. 1st-degree relatives of patients with HOCMP need to be screened for the disease.

Early identification is important (Table 40.14). The 4 main characteristics of hypertrophic CMP are (1) massive ventricular hypertrophy; (2) rapid, forceful contraction of the left ventricle; (3) impaired relaxation (diastole); and (4) obstruction to aortic outflow (not present in all patients).[25] Ventricular hypertrophy is associated with a thickened intraventricular septum and ventricular wall (Fig. 40.12). The result is poor filling of the stiff ventricle. Decreased ventricular filling and obstruction to outflow decreases CO, especially during exertion.

Clinical Manifestations

Some patients with hypertrophic CMP may be asymptomatic. Others have exertional dyspnea, fatigue, angina, and syncope. The most common symptom is dyspnea caused by an elevated left ventricular diastolic pressure. Fatigue

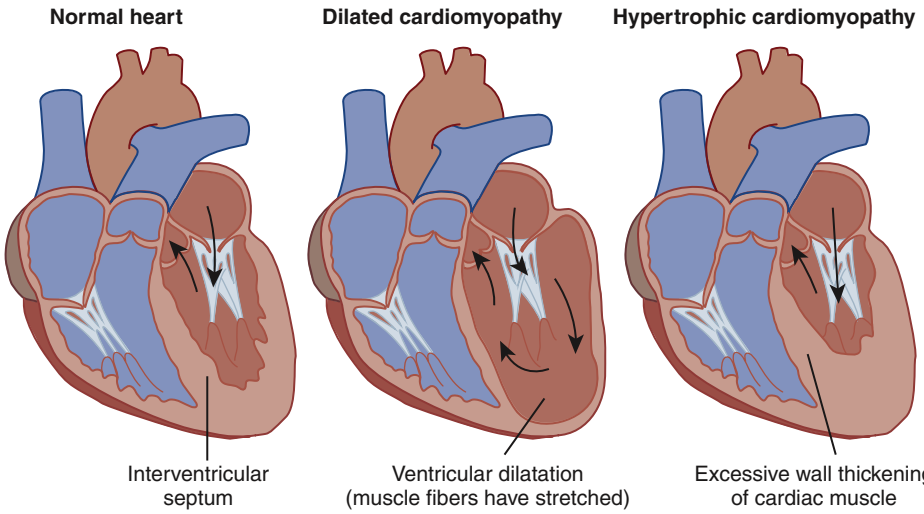

Fig. 40.12 The normal heart, compared with dilated CMP and hypertrophic CMP.

occurs because of the resulting decrease in CO and in exercise-induced flow obstruction. Angina can be caused by the increased left ventricular mass or compression of the small coronary arteries by the hypertrophic ventricular myocardium. The patient may have syncope from obstruction to aortic outflow during increased activity. This results in decreased CO and cerebrovascular circulation. Syncope also can be caused by dysrhythmias, such as supraventricular tachycardia, atrial fibrillation, ventricular tachycardia, and ventricular fibrillation (see Chapter 39).

Diagnostic Studies

Clinical findings may be unremarkable. On chest palpation, the apical impulse can be exaggerated and displaced to the left. Auscultation may reveal an S_4 and a systolic murmur between the apex and sternal border at the 4th intercostal space. ECG findings usually show ventricular hypertrophy, ST-T wave abnormalities, prominent Q waves in the inferior or precordial leads, and dysrhythmias (see Chapter 39).

The echocardiogram is the main diagnostic tool used to confirm hypertrophic CMP. It may show wall motion abnormalities and diastolic dysfunction. Heart catheterization and nuclear stress testing may help diagnose and guide the treatment of hypertrophic CMP.

❖ Interprofessional and Nursing Care

The goals of care are to improve ventricular filling by reducing ventricular contractility and relieving left ventricular outflow obstruction. These can be achieved with β-blocker (e.g., metoprolol) or calcium channel blocker (e.g., verapamil) therapy.[25] Amiodarone or sotalol (Betapace) are effective antidysrhythmic drugs but do not prevent SCD. Patients at risk for SCD need a cardioverter-defibrillator (see Chapter 39).

AV pacing is helpful for patients with hypertrophic CMP and outflow obstruction. When the ventricles are paced from the apex of the right ventricle, septal depolarization occurs first. This allows the septum to move away from the left ventricular wall and reduces the degree of obstruction of the outflow tract.

Some patients with severe symptoms unresponsive to therapy may be candidates for surgical treatment of their hypertrophied septum. A *ventriculomyotomy and myectomy* involve cutting into the thickened septal muscle and removing some of the ventricular muscle. Most patients have an improvement in symptoms and exercise tolerance after surgery.

An alternative nonsurgical procedure to reduce symptoms and the left ventricular outflow obstruction is *percutaneous transluminal septal myocardial ablation* (PTSMA). This procedure consists of injecting alcohol into the first septal artery branching off the left anterior descending artery to cause ischemia and septal wall infarction. Ablation of the septal wall decreases the obstruction to flow, and the patient's symptoms decrease. The procedure can improve HF symptoms and exercise capacity. Potential complications of PTSMA include conduction problems (e.g., heart block) and MI.

Interventions for hypertrophic CMP focus on relieving symptoms, observing for and preventing complications, and providing emotional support. Focus your teaching on helping patients plan to avoid strenuous activity and dehydration. Any activity that causes an increase in systemic vascular resistance (thus increasing the obstruction to forward flow) is dangerous. Rest and elevation of the feet to improve venous return to the heart can help manage chest pain. Vasodilators, such as nitroglycerin, may worsen the chest pain by decreasing venous return and further increasing obstruction of blood flow from the heart.

RESTRICTIVE CARDIOMYOPATHY

Etiology and Pathophysiology

Restrictive cardiomyopathy is the least common type of CMP. It is a disease of the myocardium that impairs diastolic filling and stretch. Systolic function stays unchanged. The specific cause of restrictive CMP is unknown, but several pathologic processes may be involved. Myocardial fibrosis, hypertrophy, and infiltration stiffen the ventricular wall with loss of ventricular compliance. Secondary causes of restrictive CMP include amyloidosis, endocardial fibrosis, sarcoidosis, and

radiation to the thorax. With restrictive CMP, the ventricles are resistant to filling and require high diastolic filling pressures to maintain CO.

Clinical Manifestations and Diagnostic Studies

Classic manifestations of restrictive CMP are fatigue, exercise intolerance, and dyspnea. These occur because the heart cannot increase CO by increasing the HR without further compromising ventricular filling. Other symptoms may include angina, orthopnea, syncope, and palpitations. The patient may have signs of HF, including dyspnea, peripheral edema, weight gain, ascites, hepatomegaly, and JVD.

The chest x-ray may be normal, or it may show cardiomegaly from atrial enlargement. Pleural effusions and pulmonary congestion may occur as the patient progresses to HF. The most common dysrhythmias are supraventricular (atrial fibrillation) or AV block. Echocardiography may show a left ventricle that is normal size with a thickened wall, slightly dilated right ventricle, and dilated atria. Endomyocardial biopsy, CT scan, and nuclear imaging may help in the diagnosis.

TABLE 40.17 PATIENT & CAREGIVER TEACHING

Cardiomyopathy

Include the following information in the teaching plan for a patient with cardiomyopathy and the patient's caregiver.

- Take all drugs as prescribed and regularly follow up with HCP.
- Follow a low-sodium diet (if prescribed) and read all product labels (food and over-the-counter drugs) for sodium content.
- Drink 6 to 8 glasses of water a day unless fluids are restricted.
- Achieve and maintain a reasonable weight and avoid large meals.
- Avoid alcohol, caffeine, diet pills, and over-the-counter cold medicines that may contain stimulants.
- Balance activity and rest periods.
- Avoid heavy lifting or vigorous isometric exercises and check with HCP for exercise guidelines.
- Use stress management techniques: relaxation breathing, guided imagery.
- Report any signs of HF to HCP, including weight gain, edema, shortness of breath, and increased fatigue.
- Encourage caregivers to learn CPR because of the potential for cardiac arrest (see Appendix A).
- Access emergency response system (ERS) according to the HCP's instructions.

Interprofessional and Nursing Care

There is no specific treatment for restrictive CMP. Treatments aim to improve diastolic filling and the underlying disease process. Treatment includes conventional therapy for HF and dysrhythmias. A heart transplant may be an option. Nursing care is similar to the care of a patient with HF. As in the treatment of patients with hypertrophic CMP, teach the patient to avoid situations that impair ventricular filling and increase systemic vascular resistance, such as strenuous activity and dehydration.

Nursing care of a patient with CMP includes patient-specific teaching based on their manifestations. All patients with CMP are at risk for IE from any procedure that may cause bacteremia. Teach the patient about the need for prophylactic antibiotics (see Table 40.2). A guide for patient and caregiver teaching is outlined in Table 40.17.

Case Study

Valvular Heart Disease

(© JennaDub/ iStock/Thinkstock.)

Patient Profile

R.B. is a 50-year-old man admitted to the hospital for acute decompensated HF due to valvular heart disease.

Subjective Data

- History of IV drug use
- Reports regular alcohol use of 1 pint of whiskey per day
- States, "I'm short of breath all the time. I can't sleep when I lay down."
- Describes chest pain with minimal exertion
- Recently unemployed
- States, "I'm always tired."
- States, "The prescribed drugs are too expensive. I can't afford them."
- 35 pack year history

Objective Data

Physical Assessment

- 3rd heart sound (S_3)
- Loud holosystolic murmur of mitral regurgitation
- Missing all teeth from periodontal disease
- Vital signs: Temp 99.0°F (37.2°C); apical-radial pulse equal at 110 beats/min, irregular; respirations 24; BP 104/58 mm Hg

Diagnostic Studies

- ECG shows atrial fibrillation with a rapid ventricular response
- Chest x-ray shows pulmonary congestion and cardiomegaly
- Transesophageal echocardiography shows left atrial and ventricular hypertrophy and mitral and aortic regurgitation. EF 30%

Discussion Questions

1. ***Recognize:*** Distinguish between mitral and aortic regurgitation.
2. ***Analyze***: Identify the cause and course of R.B.'s disease based on his history and current assessment.
3. ***Plan:*** What medical treatments or surgical procedures will R.B. need as his condition worsens?
4. ***Prioritize:*** Identify the priority interventions for R.B.
5. ***Act***: Identify the tasks that you would delegate to assistive personnel (AP).
6. ***Evaluate:*** What information would indicate that R.B. understands why he will need to continue taking anticoagulants after the valve replacement surgery?
7. ***Safety***: What safety precautions would we initiate for R.B.?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which findings would the nurse expect when assessing a patient with infective endocarditis? *(select all that apply)*
   - **a.** Retinal hemorrhages
   - **b.** Splinter hemorrhages
   - **c.** Presence of Osler's nodes
   - **d.** Painless nodules over bony prominences
   - **e.** Erythematous macules on the palms and soles
2. Which intervention is *a priority* in nursing management of a patient with myocarditis?
   - **a.** Providing meticulous skincare
   - **b.** Assuring tight glycemic control
   - **c.** Administering antibiotic prophylaxis
   - **d.** Monitoring oxygenation and ventilation
3. Which condition would the nurse teach the patient is a possible long-term consequence of rheumatic fever?
   - **a.** Valvular heart disease
   - **b.** Pulmonary hypertension
   - **c.** Superior vena cava syndrome
   - **d.** Hypertrophy of the right ventricle
4. Which is a *priority* intervention for a patient during the acute phase of rheumatic fever?
   - **a.** Giving IV antibiotics as prescribed
   - **b.** Managing pain with opioid analgesics
   - **c.** Encouraging fluid intake for hydration
   - **d.** Performing frequent active range-of-motion exercises
5. A patient is diagnosed with mitral stenosis and new-onset atrial fibrillation. Which interventions could the nurse delegate to assistive personnel (AP)? *(select all that apply)*
   - **a.** Obtain and record daily weight.
   - **b.** Determine apical-radial pulse rate.
   - **c.** Observe for overt signs of bleeding.
   - **d.** Teach the patient how to avoid bruising and bleeding.
   - **e.** Obtain and record vital signs, including pulse oximetry.
6. The nurse is caring for a patient newly admitted with heart failure secondary to dilated cardiomyopathy. Which intervention would be a *priority*?
   - **a.** Encourage caregivers to learn CPR.
   - **b.** Consider a consultation with hospice for palliative care.
   - **c.** Monitor the patient's response to prescribed medications.
   - **d.** Arrange for the patient to enter a cardiac rehabilitation program.

1. a, b, c, e; 2. d; 3. a; 4. a; 5. a, c, e; 6. c.

CONCEPTUAL FOCUS

Glucose Regulation
Perfusion
Tissue Integrity

LEARNING OUTCOMES

1. Relate the etiology and pathophysiology of peripheral artery disease (PAD) to the major risk factors.
2. Describe the clinical manifestations and interprofessional and nursing management of the patient with PAD of the lower extremities
3. Plan appropriate nursing and interprofessional management for the patient with acute arterial ischemic disorders
4. Distinguish the pathophysiology, clinical manifestations, and nursing and interprofessional management of the patient with thromboangiitis obliterans (Buerger disease) and Raynaud phenomenon.
5. Distinguish the pathophysiology, clinical manifestations, and interprofessional and nursing management of patients with different types of aortic aneurysms.
6. Select appropriate nursing interventions for a patient undergoing an aortic aneurysm repair.
7. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with aortic dissection.
8. Evaluate the patient's risk factors for developing superficial vein thrombosis or venous thromboembolism (VTE).
9. Distinguish between the clinical characteristics of superficial vein thrombosis and VTE.
10. Outline the interprofessional and nursing management of patients with superficial vein thrombosis and VTE.
11. Prioritize the key aspects of nursing management for the patient receiving anticoagulant therapy.
12. Relate the pathophysiology and clinical manifestations to the interprofessional care of patients with varicose veins, chronic venous insufficiency, and venous leg ulcers.

KEY TERMS

acute arterial ischemia
aneurysm
aortic dissection
chronic venous insufficiency (CVI)
critical limb ischemia
deep vein thrombosis (DVT)
intermittent claudication
peripheral artery disease (PAD)
post-thrombotic syndrome (PTS)
superficial vein thrombosis
thromboangiitis obliterans (Buerger disease)
varicose veins
venous thromboembolism (VTE)
venous thrombosis
Virchow's triad

Vascular system problems include disorders of the arteries, veins, and lymphatic vessels. These problems can result in decreased perfusion and ischemia of the peripheral tissues. Patients often have pain and difficulties with mobility and activities of daily living. Education is a key part of management. Proper nutrition, smoking cessation, and exercise are important health promotion behaviors. Following measures to promote safety, especially for those on anticoagulant therapy, is critical.

We classify arterial disorders as atherosclerotic, aneurysmal, and nonatherosclerotic vascular diseases. Atherosclerotic vascular disease is divided into coronary, cerebral, peripheral, mesenteric, and renal artery disease.[1] This chapter discusses peripheral artery disease, aortic aneurysm and dissection, and venous diseases.

PERIPHERAL ARTERY DISEASE

Peripheral artery disease (PAD) involves thickening of artery walls. This results in a progressive narrowing of the arteries of the upper and lower extremities. PAD prevalence increases with age. It typically becomes symptomatic between ages 50 and 70

years. In people with diabetes, PAD occurs earlier. In the United States, about 8.5 million people over age 40 have PAD. The prevalence is highest in Blacks.[2,3]

PAD is strongly related to other types of cardiovascular disease (CVD) and their risk factors. Patients with PAD have a significantly higher risk for general mortality, CVD mortality, major coronary events, and stroke.[3] PAD is a marker of advanced systemic atherosclerosis. Patients with PAD are more likely to have coronary artery disease (CAD) and/or cerebral artery disease.

Unfortunately, many people in the United States are unaware of PAD and its risk factors. PAD remains underdiagnosed and undertreated.

Etiology and Pathophysiology

The leading cause of PAD is *atherosclerosis*. It is a gradual thickening of the *intima* (the innermost layer of the arterial wall) and *media* (middle layer of the arterial wall). This results from cholesterol and lipids deposited within the vessel walls, leading to narrowing of the artery (see Fig. 37.1). Although we do not know the exact cause of atherosclerosis, inflammation and endothelial injury play a major role (see Chapter 37). Atherosclerosis often affects certain segments of the arterial tree. These include the coronary, carotid (see Chapter 62), and lower extremity arteries. Symptoms occur when vessels are 60% to 75% blocked.

Other risk factors for PAD are similar, but not identical, to those for CAD. Key risk factors for PAD are tobacco use (most important), diabetes, hypertension, high cholesterol, and age over 60 (Box 41.1).[2] Having multiple risk factors dramatically increases the risk for PAD.

BOX 41.1 BIOLOGIC SEX CONSIDERATIONS

Vascular Disorders

Men

- Thromboangiitis obliterans (Buerger disease) occurs most often in men younger than 40 years of age
- Abdominal aortic aneurysms (AAAs) and aortic dissections are more common in men
- Men with AAAs are more likely to undergo endovascular aneurysm repair or open aneurysm repair
- Sexual problems are common after aortic surgery.

Women

- Women with PAD have poorer social functioning and higher rates of depression than men with PAD[4]
- Women with PAD have faster functional decline and greater mobility loss than men with PAD
- Raynaud's phenomenon occurs mainly in women between 15 and 40 years of age.
- Risk for VTE is greater in women over age 35 who use tobacco and oral contraceptives or oral hormone therapy, are pregnant or postpartum, or have a family history of VTE
- Primary varicose veins are more common and more symptomatic in women
- Women with AAAs are at higher risk for rupture
- In-hospital mortality is higher in women undergoing revascularization
- Women have more graft thrombosis and amputation after lower extremity bypass surgery

PERIPHERAL ARTERY DISEASE OF THE LOWER EXTREMITIES

Lower extremity PAD may affect the iliac, femoral, popliteal, tibial, or peroneal arteries, or any combination of these arteries (Fig. 41.1). The femoral popliteal area is the most common site in patients without diabetes. Those with diabetes tend to develop PAD in the arteries below the knee. Those with advanced PAD often have multiple arterial occlusions.

Clinical Manifestations

The severity of PAD symptoms depends on the site and extent of the blockage and the amount of collateral circulation. The classic symptom of lower extremity PAD is **intermittent claudication.** This ischemic muscle pain is caused by exercise, resolves within 10 minutes or less with rest, and is reproducible. The pain is due to the buildup of lactic acid from anaerobic metabolism. Once the patient stops exercising, the lactic acid clears, and the pain subsides. PAD of the iliac arteries causes pain in the buttocks and thighs. Calf pain occurs with femoral or popliteal artery involvement.

As many as one-third of patients with PAD have classic symptoms. Others have no symptoms or present with atypical leg symptoms (e.g., burning, heaviness, pressure, soreness, tightness, weakness) in atypical locations (e.g., ankle, foot, hamstring, hip, knee, shin). PAD involving the internal iliac arteries may result in erectile dysfunction.

Paresthesia (numbness or tingling) in the toes or feet may result from nerve tissue ischemia. True peripheral neuropathy occurs more often in patients with diabetes and in those with long-standing ischemia. Neuropathy causes severe shooting

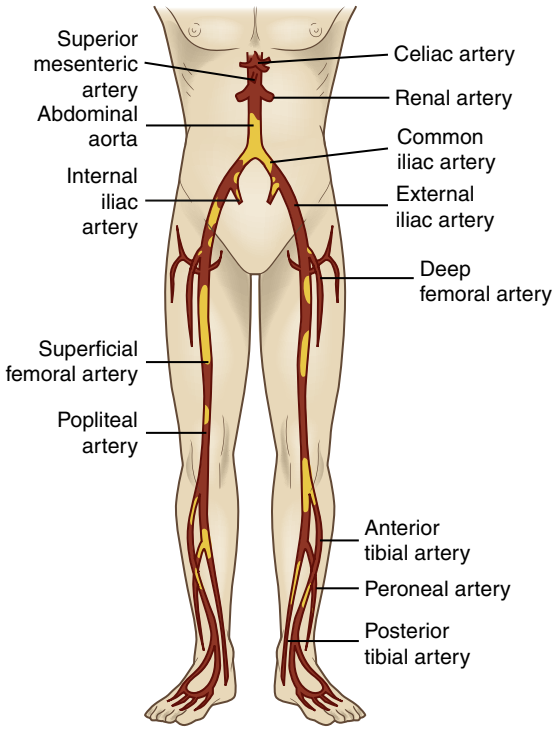

Fig. 41.1 Common anatomic locations of atherosclerotic lesions (shown in *yellow*) of the abdominal aorta and lower extremities.

or burning pain in the extremity. It does not follow particular nerve roots and may be present near ulcerated areas. Gradual, reduced blood flow to neurons causes loss of sensation to pressure and deep pain. So, patients may not notice lower extremity injuries.

The limb's appearance gives vital information about reduced blood flow. The skin becomes thin, shiny, and taut. The lower legs lose their hair. Pedal, popliteal, or femoral pulses are decreased or absent. Pallor (blanching of the foot) develops when the leg is elevated *(elevation pallor)*. Conversely, *reactive hyperemia* (redness of the foot) develops when the limb is in a dependent position *(dependent rubor)* (Table 41.1).

As PAD progresses and involves multiple arterial segments, continuous pain develops at rest. *Rest pain* most often occurs in the foot or toes. It is worse with limb elevation. Rest pain occurs when blood flow does not meet basic metabolic needs of the distal tissues. It occurs more often at night because cardiac output tends to drop during sleep and the limbs are at heart level. Patients often try to relieve pain by gravity. They dangle the leg over the side of the bed or sleep in a chair.

TABLE 41.1 Comparison of Peripheral Artery and Venous Disease

Characteristic	Peripheral Artery Disease	Venous Disease
Ankle-brachial index	≤0.90	>0.90
Capillary refill	>3 sec	<3 sec
Dermatitis	Rarely occurs	Often occurs
Edema	Absent unless leg constantly in dependent position	Lower leg edema
Hair	Loss of hair on legs, feet, toes	Hair may be present or absent
Nails	Thickened, brittle	Normal or thickened
Pain	Intermittent claudication or rest pain in foot	Dull ache or heaviness in calf or thigh
	Ulcer may or may not be painful	Ulcer often painful
Peripheral pulses	Decreased or absent	Present, may be hard to palpate with edema
Pruritus	Rarely occurs	Often occurs
Skin color	Dependent rubor, elevation pallor	Bronze-brown pigmentation
		Varicose veins may be visible
Skin temperature	Cool, temperature gradient down the leg	Warm, no temperature gradient
Skin texture	Thin, shiny, taut	Skin thick, hardened, and indurated
Ulcer		
• Location	Tips of toes, foot, or lateral malleolus	Near medial malleolus
• Margin	Rounded, smooth, looks "punched out"	Irregularly shaped
• Drainage	Minimal	Moderate to large amount
• Tissue	Black eschar or pale pink granulation	Yellow slough or dark red, "ruddy" granulation

Critical limb ischemia (CLI) is a condition characterized by chronic ischemic rest pain lasting more than 2 weeks, nonhealing arterial leg ulcers, or gangrene of the leg from PAD. Patients with PAD who have diabetes, heart failure (HF), and a history of a stroke have a higher risk for CLI.[3]

Complications

Lower extremity PAD progresses slowly. Prolonged ischemia leads to atrophy of the skin and underlying muscles. Minor trauma to the feet (e.g., stubbing one's toe, blister from shoes) can result in delayed healing, wound infection, and tissue necrosis, especially in the patient with diabetes. Arterial (ischemic) ulcers most often occur over bony prominences on the toes, feet, and lower legs (Table 41.1). Nonhealing arterial ulcers and gangrene are the most serious complications. If PAD develops over an extended period, collateral circulation may prevent gangrene.

Amputation may be needed if adequate blood flow is not restored or if severe infection occurs. Uncontrolled pain and severe, spreading infection are indicators for amputation in people who are not candidates for revascularization.

Diagnostic Studies

Various tests assess blood flow and the vascular system (Table 41.2). Doppler ultrasound with duplex imaging maps blood flow throughout an entire arterial region. It can determine the degree of blood flow when we have difficulty palpating a peripheral pulse due to severe PAD.

Segmental BPs are obtained using Doppler ultrasound and a sphygmomanometer at the thigh, below the knee, and at ankle level while the patient is supine. A drop in segmental BP of greater than 30 mm Hg suggests PAD. Angiography and magnetic resonance angiography show the location and extent of PAD (see Table 35.10).

The *ankle-brachial index* (ABI) is a PAD screening tool. It is done using a hand-held Doppler. Calculate the ABI for each leg by dividing the ankle systolic BP (SBP) by the higher of the brachial SBPs. PAD guidelines recommend uniform reporting of ABI results (Table 41.3).[3] Calcified and stiff arteries in patients who are older or have diabetes often show a falsely elevated ABI.

Interprofessional Care

Table 41.2 outlines the interprofessional care for a patient with PAD.

Risk Factor Modification

The first treatment goal for patients with PAD is to reduce CVD risk factors. This may require both lifestyle changes and drug therapy (see Tables 37.2 to 37.6). Hypertension is a well-known risk factor for PAD progression. Encourage reducing sodium intake and following the dietary approaches to stop hypertension (DASH) or Mediterranean diet. Chapter 36 discusses hypertension.

Tobacco cessation is essential to reduce the risk for CVD events, PAD progression, and death. This is a difficult process with a high incidence of relapse. Suggest tobacco cessation strategies (see Tables 11.3–11.6).

TABLE 41.2 Interprofessional Care

Peripheral Artery Disease

Diagnostic Assessment

- Health history and physical assessment, including palpation of peripheral pulses
- Doppler ultrasound studies
- Segmental BPs
- ABI (Table 41.3)
- Duplex imaging
- Angiography
- Magnetic resonance angiography

Management

- CVD risk factor modification
  - Tobacco cessation
  - Regular physical exercise
  - Achieve or maintain ideal body weight
  - Follow Dietary Approaches to Stop Hypertension (DASH) diet or Mediterranean diet
  - Tight glucose control with diabetes, including Hb A1C monitoring
  - Tight BP control
  - Treatment of hyperlipidemia and hypertriglyceridemia (see Table 37.6)
  - Antiplatelet agent (aspirin, clopidogrel [Plavix])
  - ACE inhibitors (see Table 36.6)
- Treatment of claudication symptoms
  - Structured walking or exercise program
  - Cilostazol or pentoxifylline
- Nutrition therapy
- Physical/occupational therapy
- Proper foot care (see Table 53.23)

Surgical Therapy

- Percutaneous transluminal balloon angioplasty with or without stent
- Percutaneous transluminal atherectomy
- Percutaneous transluminal cryoplasty
- Peripheral artery bypass surgery
- Patch graft angioplasty, often in conjunction with bypass surgery
- Endarterectomy (for localized stenosis; rarely done as a stand-alone procedure)
- Thrombolytic therapy or mechanical clot extraction therapy (for acute ischemia only)
- Sympathectomy (for pain management only)
- Amputation

TABLE 41.3 Interpreting Ankle-Brachial Index Results

(ABI	Clinical Significance
>1.30	Noncompressible arteries
1.00–1.30	Normal ABI
0.91–0.99	Borderline ABI
≤0.90	Abnormal ABI
Classification of PAD Severity	
0.90–0.71	Mild PAD
0.70–0.41	Moderate PAD
≤0.40	Severe PAD

Diabetes is a major risk factor for PAD. It increases the risk for amputation. Patients with diabetes should maintain a glycosylated hemoglobin (A1C) below 7.0%.[5] Chapter 53 discusses diabetes.

Support aggressive lipid management for all patients with PAD. Both diet interventions and drug therapy are needed. Statins (e.g., simvastatin) and a fibric acid derivative (gemfibrozil) may be used (see Table 37.6).

Drug Therapy

Angiotensin-converting enzyme (ACE) inhibitors (e.g., ramipril) can reduce PAD symptoms. Antiplatelet agents are critical to reduce the risks for CVD events and death. Oral antiplatelet therapy should include low-dose aspirin therapy. Aspirin-intolerant patients may take clopidogrel (Plavix) daily. Combination antiplatelet therapy with aspirin and clopidogrel may be used by select high-risk patients. Anticoagulants (e.g., warfarin) are not recommended for preventing CVD events in patients with PAD.

DRUG ALERT

Clopidogrel (Plavix) and Omeprazole (Prilosec)

- Taking omeprazole with clopidogrel reduces the antiplatelet effect by half.
- This reduced effect increases the risk for myocardial infarction (MI) and stroke.

Two drugs are available to treat intermittent claudication: cilostazol and pentoxifylline. Cilostazol—a phosphodiesterase inhibitor—inhibits platelet aggregation and increases vasodilation. Pentoxifylline—a synthetic dimethylxanthine derivative—improves the flexibility of RBCs and decreases fibrinogen concentration, platelet adhesiveness, and blood viscosity. It is not as effective as cilostazol. Most take cilostazol less than 3 months due to side effects.[3]

DRUG ALERT

Cilostazol

- Contraindicated in patients with HF.

Exercise Therapy

A supervised exercise program is recommended as part of the initial treatment for all patients with intermittent claudication. The patient should exercise for 30 to 45 min/day, at least 3 times/week, for a minimum of 3 months. Although we most often prescribe walking, other modes of exercise (e.g., cycling) improve walking ability and quality of life.[3]

Encouraging exercise is especially important for women, because they have faster functional decline and greater mobility loss than men with PAD. Overall, patients with PAD who have higher levels of daily physical activity have better survival rates.[3,4]

Nutrition Therapy

Teach patients with PAD to maintain a body mass index (BMI) less than 25 kg/m^2 and a waist circumference less than 40 inches for men and less than 35 inches for women. Even modest, sustained weight loss of 3% to 5% yields important reductions in triglycerides, glucose, A1C, and the risk for developing type 2

diabetes. Greater weight loss has greater benefits. Recommend a diet reduced in calories and salt for obese or overweight persons.

Care of the Patient With Critical Limb Ischemia

Optimal therapy for the patient with CLI is revascularization via bypass surgery using an *autogenous* (native) vein. An alternative is percutaneous transluminal angioplasty (PTA).[3] Patients with CLI who are not candidates for surgery or PTA may receive IV prostanoids (e.g., iloprost [Ventavis]).[6,7] However, the FDA has not approved this drug for CLI treatment. Patients with CLI should continue optimal drug therapy (e.g., statin, antiplatelet, ACE inhibitor, β-blocker) to reduce the risk for a CVD event.

Conservative management includes protecting the extremity from trauma, decreasing ischemic pain, preventing and controlling infection, and improving perfusion. Carefully inspect, cleanse, and lubricate feet to prevent skin cracking and infection. Avoid lubrication between the toes and soaking the patient's feet to prevent skin *maceration* (or breakdown). Keep the affected foot clean and dry. Cover any ulcers with a dry, sterile dressing. We use a variety of wound care products to treat deep ulcers. Healing is unlikely without increasing the blood flow.

Encourage the patient to wear soft, roomy, and protective footwear and avoid extremes of heat and cold. Keep the patient's heels free of pressure. Place a pillow under the calves so that the heels are off the mattress or use a heel protection device. Giving analgesics and placing the bed in the reverse Trendelenburg position may control pain and increase perfusion to the lower extremities.

Spinal cord stimulation may help manage pain for patients with CLI. Other promising strategies include growth factors and gene and stem cell therapy to stimulate blood vessel growth *(angiogenesis)*. Unfortunately, almost half of the patients with CLI will die within 5 years.[7]

Interventional Radiology Catheter-Based Procedures

Interventional radiology catheter-based procedures are alternatives to surgery for treating lower extremity PAD. These procedures take place in a catheterization. They are similar to angiography in that they involve inserting a specialized catheter into the femoral artery. The PTA procedure uses a catheter with a balloon at the tip. The tip of the catheter is moved to the narrowed (stenotic) area of the artery. The balloon is then inflated, compressing the atherosclerotic intimal lining.[3]

Stents—expandable metallic devices—are placed within the artery after the balloon angioplasty. The stent holds the artery open. Angioplasty balloons and peripheral stents may be coated with a drug (e.g., paclitaxel) to limit new tissue growth in the treated area and improve long-term patency rates.[3]

Atherectomy is the removal of the obstructing plaque. A directional atherectomy device uses a high-speed cutting disk that cuts long strips of the atheroma. Laser atherectomy uses ultraviolet energy to break up the atheroma. Another type of atherectomy catheter has a diamond-coated tip that rotates at a high speed like a drill.

Cryoplasty combines PTA and cold therapy. A specialized balloon is filled with liquid nitrous oxide, which changes to gas as it enters the balloon. Expansion of the gas results in cooling to 14°F (−10°C). The cold temperature limits restenosis by reducing smooth muscle cell activity.

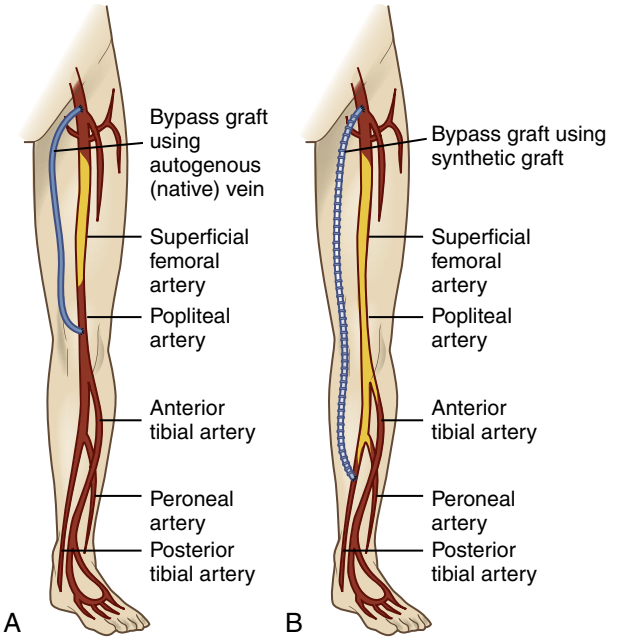

Fig. 41.2 (A) Femoral-popliteal bypass graft around an occluded superficial femoral artery. (B) Femoral–posterior tibial bypass graft around occluded superficial femoral, popliteal, and proximal tibial arteries.

Nursing care is the same as for diagnostic angiography (see Tables 35.10 and 35.12). Antiplatelet agents are given afterwards to reduce the risk for restenosis. Long-term, low-dose aspirin therapy or clopidogrel is recommended.

Surgical Therapy

Various surgical approaches are used to improve blood flow beyond a blocked artery. When possible, peripheral artery bypass surgery is done with an autogenous vein to bypass (carry blood around) the lesion (Fig. 41.2). Synthetic grafts are used for long routes, such as an axillary-femoral bypass. When a person's own vein is not available, a human umbilical vein or a composite sequential bypass graft (native vein plus synthetic graft) can be used.[3] PTA with stenting may be done in combination with bypass surgery.

Other options include *endarterectomy* (opening the artery and removing the obstructing plaque) and *patch graft angioplasty* (opening the artery, removing plaque, and sewing a patch to the opening to widen the lumen). In-hospital mortality is higher in women undergoing revascularization than men, regardless of disease severity or surgical procedure.[4]

Amputation may be needed if tissue necrosis is extensive, gangrene or osteomyelitis develops, or all major arteries in the limb are blocked. Preserving as much of the limb as possible improves rehabilitation potential. Amputation is discussed in Chapter 67.

❖ NURSING MANAGEMENT: LOWER EXTREMITY PERIPHERAL ARTERY DISEASE

◆ Assessment

Table 41.4 presents subjective and objective data that you should obtain from a patient with PAD.

TABLE 41.4 NURSING ASSESSMENT

Peripheral Artery Disease

Subjective Data

Important Health Information

Health history: Tobacco use, diabetes, hypertension, hyperlipidemia, hypertriglyceridemia, hyperuricemia, impaired renal function, obesity. ↑ High-sensitivity C-reactive protein, homocysteine, or lipoprotein (a) [Lp(a)] levels. Positive family history, sedentary lifestyle, stress

Functional Health Patterns

Health perception–health management: Family history of CVD. Tobacco use, including exposure to environmental smoke

Nutritional-metabolic: High sodium, saturated fat, and cholesterol intake. Elevated Hb A1C

Activity-exercise: Exercise intolerance

Cognitive-perceptual: Buttock, thigh, or calf pain that is precipitated by exercise and that subsides with rest (intermittent claudication) or progresses to pain at rest. Burning pain in feet and toes at rest. Numbness, tingling, sensation of cold in legs or feet. Progressive loss of sensation and deep pain in extremities

Sexuality-reproductive: Erectile dysfunction

Objective Data

Cardiovascular

Decreased or absent peripheral pulses. Feet cool to touch. Capillary refill >3 s. Bruits may be present at pulse sites

Neurologic

Impaired mobility or sensation

Skin

Loss of hair on legs and feet. Thick toenails. Pallor with elevation. Dependent rubor. Thin, cool, shiny skin with muscle atrophy. Skin breakdown and arterial ulcers, especially over bony areas. Gangrene

Possible Diagnostic Findings

Arterial stenosis evident with duplex imaging, ↓ Doppler pressures, ↓ ABI, angiography shows peripheral atherosclerosis

Clinical Problems

Clinical problems for the patient with PAD may include:

- Activity intolerance
- Impaired tissue integrity
- Inadequate tissue perfusion
- Musculoskeletal problem
- Pain

Additional information on clinical problems and interventions for the patient with PAD of the lower extremities is presented in eNursing Care Plan 41.1 on the website for this chapter.

Planning

Nursing care focuses on the priority problems of poor tissue perfusion and pain. The overall goals for the patient who has lower extremity PAD include (1) adequate tissue perfusion; (2) pain relief; (3) increased exercise tolerance; (4) intact, healthy skin on the extremities; and (5) knowledge of disease and treatment plan.

Implementation

Health Promotion

Assess the patient for and provide instructions on how to control CVD risk factors (see Table 37.2). Teach diet modification to reduce cholesterol, saturated fat, and salt (see Tables 37.4 and 37.5). Teach proper foot care and injury prevention. Encourage patients with positive family histories of cardiac, diabetes, or vascular disease to obtain regular follow-up care.

Acute Care

After surgical or radiologic intervention, observe the patient in a recovery area. Check the operative extremity every 15 minutes initially and then hourly. Assess color, temperature, capillary refill, peripheral pulses, and sensation and movement. Immediately notify the HCP of any loss of palpable pulses or change in the Doppler sound over a pulse. We do not obtain postoperative ABI measurements as they place the patient at risk for graft thrombosis. Compare assessment findings with the patient's baseline and with findings in the opposite limb.

PAD patients with a history of chronic ischemic rest pain may have tolerance to opioids. Thus, aggressive pain management may be needed after surgery.

After the patient leaves the recovery area, continue to monitor extremity perfusion. Assess for complications, such as bleeding, hematoma, thrombosis, embolization, and compartment syndrome. A dramatic increase in pain, loss of previously palpable pulses, extremity pallor or cyanosis, numbness or tingling, or a cold extremity suggests graft or stent blockage. Report these findings to the HCP at once.

CHECK YOUR PRACTICE

You are caring for a 74-year-old male patient who is recovering from left femoral-popliteal bypass graft surgery. When you respond to the patient's call bell, the patient reports severe pain in the operative leg. On assessment, you cannot palpate the dorsalis pedis and posterior tibial pulses. The foot is cold to touch.

- What are your next actions?

Do not place the patient in a knee-flexed position except for exercise. Turn the patient and position frequently with pillows to support the incision. On postoperative day 1, assist the patient out of bed several times. Walking even short distances is desirable. A walker may be helpful, especially for frail, older patients. Discourage prolonged sitting with legs lowered, since it may cause pain and edema, increase the risk for venous thrombosis, and place stress on the suture lines. Graduated compression stockings may help control leg edema. If edema develops, position the patient supine, and elevate the leg above heart level.

Surgical site infection (SSI) is a serious complication. Careful postoperative assessment and wound care are important. SSIs are associated with early graft loss, longer hospitalization, reoperation, and sepsis.

Ambulatory Care

Assess for CVD risk factors and teach health promotion strategies. Continued tobacco use dramatically decreases the patency rates of grafts and stents and increases the risk for an MI or stroke.

Long-term antiplatelet therapy with aspirin or clopidogrel is used after surgery. Patients having distal peripheral bypass surgery (i.e., below the knee) using synthetic graft materials receive dual antiplatelet therapy (clopidogrel plus aspirin) for 1 to 3 months, followed by lifelong single antiplatelet therapy.

Encourage supervised exercise training after revascularization. Explain that exercise decreases CVD risk factors, including hypertension, hyperlipidemia, obesity, and glucose levels. Foot care is especially important in the patient with diabetes and PAD (see Table 53.21). Diabetic neuropathy increases the patient's risk for injury. Tell patients to inspect their legs and feet daily for changes in skin color or texture. Show patients how to palpate pulses and check skin temperature and capillary refill. Stress reporting any changes or the presence of ulceration or inflammation to the HCP.

Thick or overgrown toenails and calluses are potentially serious and need regular attention by an HCP (e.g., podiatrist). Patients who have poor eyesight, back problems, obesity, or arthritis may need help with foot care. Encourage patients to wear clean, all-cotton or all-wool socks and comfortable shoes with rounded (not pointed) toes and soft insoles. Tell patients to lace shoes loosely and to break in new shoes gradually (Table 41.5).

TABLE 41.5 PATIENT & CAREGIVER TEACHING

Peripheral Artery Bypass Surgery

Include the following information in the teaching plan for a patient undergoing peripheral artery bypass surgery and the patient's caregiver:

1. Reduce risk factors by stopping tobacco use, controlling blood glucose levels with diabetes, controlling BP, lowering cholesterol and triglyceride levels, achieving or maintaining ideal body weight, and exercising regularly.
2. Provide teaching about the basic mechanism of action (why prescribed for patient), side effects, and safety precautions for drugs such as antiplatelets, antihypertensives, lipid-lowering therapy, and pain medication.
3. Eat healthy—it is essential to recovery. Drink plenty of fluids, eat a well-balanced diet (e.g., foods high in protein, vitamins C and A, and zinc; high-fiber foods; fresh fruits and vegetables), eat fewer high-fat foods, and reduce salt intake.
4. Take part in a supervised exercise program or take a daily walk. In the beginning, take several short walks a day and rest between activities. Gradually increase your walking to 30 to 40 min/day, 3 to 5 days/week.
5. Care for feet and legs. Inspect feet and wash them daily. Wear clean cotton or wool socks and well-fitting shoes. File toenails straight across. Avoid sitting with legs crossed, extreme hot and cold temperatures, and prolonged standing.
6. Follow routine postoperative wound care that includes keeping incision clean and dry; do not disturb Steri-Strips (if present).
7. Monitor for signs and symptoms of impaired healing or infection of the leg incision, and notify HCP if any of the following occur:
   - Prolonged drainage or pus from the incision
   - Increased redness, warmth, pain, or hardness along incision
   - Separation of wound edges
   - Temperature >100°F (37.8°C)
8. Keep all follow-up appointments with HCP.
9. Notify HCP at once of increased leg or foot pain or a change in the color or temperature of leg or foot.

◆ Evaluation

The expected outcomes are that a patient with PAD of the lower extremities will have

- Adequate peripheral tissue perfusion
- Increased activity tolerance
- Effective pain management
- Knowledge of disease and treatment plan

ACUTE ARTERIAL ISCHEMIC DISORDERS

Etiology and Pathophysiology

Acute arterial ischemia is a sudden interruption in the arterial blood supply to a tissue, an organ, or an extremity that—if left untreated—can result in tissue death. It is caused by embolism, thrombosis of an atherosclerotic artery, or trauma. *Embolization* of a thrombus from the heart is the most frequent cause of acute arterial occlusion. Heart conditions in which thrombi can develop include infective endocarditis, mitral valve disease, atrial fibrillation, cardiomyopathies, and prosthetic heart valves. Noncardiac sources of emboli include aneurysms, ulcerated atherosclerotic plaque, recent endovascular procedures, and venous thrombi.

Thrombi that originate in the left side of the heart may dislodge and travel anywhere in the systemic circulation. Most emboli block an artery of the leg where vessels branch (e.g., iliofemoral, popliteal, tibial) or narrow. Sudden local thrombosis may occur at the site of an atherosclerotic plaque. Hypovolemia (e.g., shock), hyperviscosity (e.g., polycythemia), and hypercoagulability (e.g., chemotherapy) predispose a person to thrombotic arterial occlusion.

Traumatic injury to an extremity may cause partial or total arterial blockage. Acute arterial occlusion may develop from arterial dissection in the carotid artery or aorta or from a procedure-related arterial injury (e.g., after angiography).

Clinical Manifestations

Manifestations of acute arterial ischemia include the *6 Ps: pain, pallor, pulselessness, paresthesia, paralysis,* and *poikilothermia* (adaptation of the limb to the environmental temperature, most often cool). If you detect these signs, immediately notify the HCP. Without immediate intervention, ischemia may progress to tissue necrosis and gangrene within a few hours.

Paralysis is a late sign of acute arterial ischemia and signals the death of nerves supplying the extremity. Foot drop occurs from nerve damage. Because nerve tissue is very sensitive to hypoxia, limb paralysis or ischemic neuropathy may persist even after revascularization.

Interprofessional Care

Early diagnosis and treatment are essential to keep the affected limb viable during acute arterial ischemia. Anticoagulant therapy with IV unfractionated heparin (UH) is started to prevent thrombus growth and inhibit further embolization. In patients undergoing embolectomy, UH should be followed by long-term anticoagulation.

To restore blood flow, the thrombus is removed as soon as possible. Options consist of surgical thrombectomy (recommended

procedure), percutaneous catheter-directed thrombolytic therapy, percutaneous mechanical thrombectomy with or without thrombolytic therapy, or surgical bypass.[7]

Percutaneous catheter-directed thrombolytic therapy using alteplase or urokinase is recommended for acute arterial ischemia of less than 14 days. The HCP inserts a catheter into the femoral artery and moves it to the site of the clot. The thrombolytic drug is continuously infused. Thrombolytics work by directly dissolving the clot over a period of 24 to 48 hours. (Chapter 37 discusses thrombolytic therapy.) Close monitoring is required to make sure the catheter does not move and the patient does not bleed from the catheter insertion site.

Surgical revascularization may be used in a patient with trauma (e.g., lacerated artery) or with significant arterial blockage. Amputation is done for patients with ischemic rest pain and tissue loss in those whom limb salvage is not possible. If the patient is at risk for further embolization from a persistent source (e.g., chronic atrial fibrillation), long-term anticoagulation is recommended.

THROMBOANGIITIS OBLITERANS

Thromboangiitis obliterans (Buerger's disease) is a nonatherosclerotic, segmental, recurrent inflammatory disorder of the small and medium arteries and veins of the arms and legs. Cerebral, coronary, mesenteric, pulmonary, and/or renal arteries are rarely involved. The disease occurs mostly in men younger than 45 years of age with a long history of tobacco and/or marijuana use without other CVD risk factors (e.g., hypertension, hyperlipidemia, diabetes).[8]

In the acute phase of Buerger disease, an inflammatory thrombus blocks the vessel. Over time, the thrombus becomes more organized and the inflammation in the vessel wall subsides.[8] During the chronic phase, thrombosis and fibrosis in the vessel cause tissue ischemia.

The symptoms of Buerger disease often are confused with PAD and other autoimmune diseases (e.g., scleroderma). Patients may have intermittent claudication of the feet, hands, or arms. As the disease progresses, rest pain and ischemic ulcerations develop. Other signs and symptoms may include color and temperature changes of the limbs, paresthesia, superficial vein thrombosis, and cold sensitivity.

There are no laboratory or diagnostic tests specific to Buerger disease. The diagnosis is based on age of onset; history; symptoms; involvement of distal vessels; presence of ischemic ulcerations; and exclusion of autoimmune disease, diabetes, thrombophilia (inherited tendency to clot) and other sources of emboli, such as atherosclerosis and aneurysm.[8]

The main treatment is the complete cessation of tobacco and marijuana use in any form. Use of nicotine replacement products is contraindicated. Conservative management includes avoiding limb exposure to cold temperatures, a supervised walking program, antibiotics to treat any infected ulcers, and analgesics to manage the ischemic pain. Teach patients to avoid trauma to the extremities.

IV iloprost (Ventavis)—a prostaglandin analog that promotes vasodilation—is used to manage rest pain, promote healing of ischemic ulcers, and decrease the need for amputation.[8] Surgical options include lumbar sympathectomy (transection of a nerve, ganglion, and/or plexus of the sympathetic nervous system), implanting a spinal cord stimulator, and bypass surgery.[8] Sympathectomy and a spinal cord stimulator can improve distal blood flow, reduce pain, and decrease the rate of amputation. Neither alters the inflammatory process. Bypass surgery may be used in select patients with severe ischemia. Stem cell therapy promotes ulcer healing, new blood vessel formation, and nerve cell regeneration.[8]

Painful ulcerations may require finger or toe amputations. Amputation below the knee may be needed in severe cases. The rate of amputation in those who continue tobacco or marijuana use after diagnosis is much higher than in those who stop.

RAYNAUD'S PHENOMENON

Raynaud's phenomenon is an episodic vasospastic disorder of small cutaneous arteries, most often involving the fingers and toes. It occurs more often in women, especially those between 15 and 40 years of age. The pathogenesis of Raynaud phenomenon is due to abnormalities in the vascular, intravascular, and neuronal mechanisms that cause vasodilation.[9,10]

Raynaud's phenomenon may occur in isolation (primary Raynaud phenomenon) or with an underlying disease (e.g., thyroid conditions, scleroderma, systemic lupus erythematosus) (secondary Raynaud phenomenon). Other contributing factors include the use of vibrating machinery or work in cold environments, exposure to heavy metals (e.g., lead), and high homocysteine levels.

Diagnosis is based on persistent symptoms for at least 2 years. Patients with Raynaud phenomenon should have routine follow-up to monitor for development of connective tissue or autoimmune diseases.

Raynaud phenomenon is characterized by vasospasm-induced color changes (white, blue, and red) of fingers, toes, ears, and nose. Decreased perfusion results in pallor (white). The digits then appear cyanotic (bluish purple) (Fig. 41.3). These changes are followed by rubor (red), a hyperemic response when blood flow is restored. The patient usually describes coldness

Fig. 41.3 Raynaud's phenomenon. (From James WD, Elston DM, Dirk M: *Andrews' diseases of the skin clinical atlas*, St Louis, 2018, Elsevier.)

and numbness in the vasoconstrictive phase. This is followed by throbbing, aching pain, tingling, and swelling in the hyperemic phase. An episode usually lasts only minutes but may last for several hours. Triggers include cold exposure, emotional upsets, tobacco use, and caffeine.

After frequent, prolonged attacks, the skin may become thickened and the nails brittle. Complications include *punctate* (small hole) lesions of the fingertips and superficial gangrenous ulcers.

Patient teaching about preventing episodes is the focus of nursing care. Tell patients to avoid temperature extremes and wear loose, warm clothing as protection from the cold, including gloves when handling cold objects. Immersing hands in warm water often decreases the vasospasm. The patient should stop using all tobacco products and avoid caffeine and other drugs that have vasoconstrictive effects (e.g., amphetamines, ergotamine, pseudoephedrine). Suggest appropriate stress management strategies.

Sustained-release calcium channel blockers (e.g., nifedipine [Procardia]) are the first-line drug therapy. They relax smooth muscles of the arterioles by blocking the influx of calcium into the cells. This reduces the frequency and severity of vasospastic attacks. If symptoms persist, other vasodilators (e.g., phosphodiesterase-5 inhibitors [sildenafil]) or topical nitroglycerin 2% ointment may be used.[10] Calcium channel blockers can be taken with nitroglycerin topical ointment. Phosphodiesterase-5 inhibitors are not used with topical nitroglycerin due to risk for hypotension.

Prompt intervention is needed for patients with digital ulceration or critical ischemia. Treatment options include prostacyclin infusion therapy (e.g., iloprost), antibiotics, analgesics, and surgical debridement of necrotic tissue. Botulinum toxin A and statins may lessen the severity of Raynaud phenomenon.[9] Sympathectomy is done only in severe cases refractory to medical treatment when digit survival is threatened.

AORTIC ANEURYSMS

The aorta is the largest artery. It supplies O_2, nutrients, and blood to all vital organs. One of the most common problems affecting the aorta is an **aneurysm,** which is a permanent, localized outpouching or dilation of the vessel wall. Aneurysms occur more often in men and in whites. The incidence increases with age.[11] Aneurysms may occur in more than 1 location.

Etiology and Pathophysiology

Aortic aneurysms may involve the aortic arch and thoracic and/or abdominal aorta. Three-fourths of aortic aneurysms occur in the abdominal aorta (Fig. 41.4). Most abdominal aortic aneurysms (AAAs) occur below the renal arteries.

A variety of disorders are associated with aortic aneurysms. The main causes are classified as degenerative, congenital, infectious, mechanical (e.g., penetrating or blunt trauma), or inflammatory (e.g., aortitis). Risk factors for aortic aneurysms include age, male gender, hypertension, CAD, family history, tobacco use, high cholesterol, lower extremity PAD, carotid artery disease, previous stroke, and obesity. Tobacco use is the most important modifiable risk factor.[11] The larger the aneurysm, the greater is the risk for rupture.

Genetic Link

Both aortic aneurysm and aortic dissection have a strong genetic component. The familial tendency is related to several congenital anomalies. Examples include bicuspid aortic valve, coarctation of the aorta, Turner syndrome, autosomal dominant polycystic kidney disease, specific collagen defects (e.g., Ehlers-Danlos syndrome), and premature breakdown of vascular elastic tissue (e.g., Marfan syndrome).[11]

Classification

Aneurysms are classified as true or false aneurysms (Fig. 41.5A–C). A *true aneurysm* is one in which the wall of the artery forms the aneurysm, with at least 1 vessel layer still intact. True aneurysms are subdivided into fusiform and saccular types. A *fusiform aneurysm* is circumferential and relatively uniform in shape. A *saccular aneurysm* is pouchlike with a narrow neck connecting the bulge to 1 side of the arterial wall.

A *false aneurysm,* or *pseudoaneurysm,* is not an aneurysm. It is a disruption of all arterial wall layers with bleeding that is contained by surrounding anatomic structures. False aneurysms may result from trauma, infection, peripheral artery bypass graft surgery (at the site of the graft-to-artery anastomosis), or arterial leakage after removal of a cannula (e.g., femoral artery catheter, intraaortic balloon pump).

Clinical Manifestations

Thoracic aortic aneurysms (TAAs) are often asymptomatic. When present, symptoms include deep, diffuse chest pain that may extend to the interscapular area. Ascending aorta and aortic arch aneurysms can cause (1) angina from decreased blood flow to the coronary arteries; (2) transient ischemic attacks from decreased blood flow to the carotid arteries; and (3) coughing,

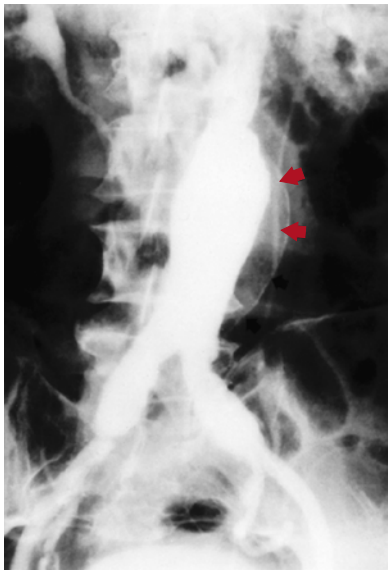

Fig. 41.4 Angiography showing fusiform abdominal aortic aneurysm. Note calcification of the aortic wall *(arrows)* and extension of the aneurysm into the common iliac arteries. (Courtesy Jo Menzoian, Boston, MA.)

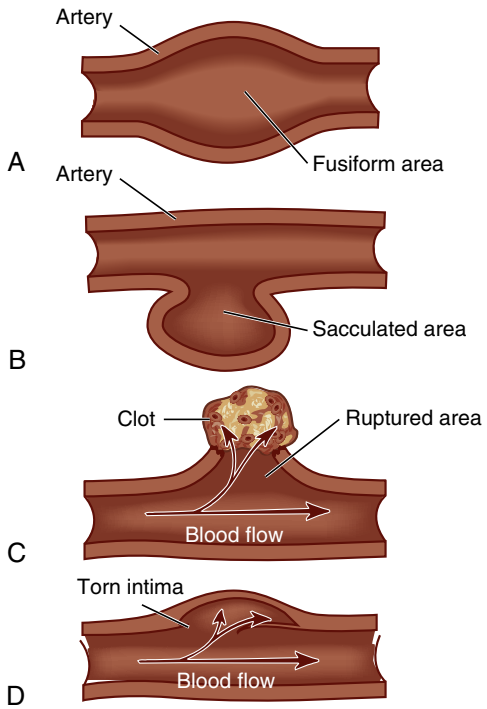

Fig. 41.5 (A) True fusiform abdominal aortic aneurysm. (B) True saccular aortic aneurysm. (C) False aneurysm, or pseudoaneurysm. (D) Aortic dissection.

shortness of breath, hoarseness, and/or difficulty swallowing from pressure on the laryngeal nerve. If the aneurysm presses on the superior vena cava, decreased venous return can result in jugular venous distention and edema of the face and arms.

AAAs are often asymptomatic. They are often found during routine physical assessment or evaluation for another problem (e.g., abdominal x-ray, CT scan). A pulsatile mass in the periumbilical area slightly to the left of the midline may be present. Bruits may be auscultated over the aneurysm. Physical findings may be hard to detect in obese persons.

AAA symptoms may mimic pain associated with abdominal or back disorders. Compression of nearby anatomic structures and nerves may cause symptoms, such as back pain, epigastric discomfort, altered bowel elimination, and intermittent claudication. Sometimes, aneurysms spontaneously embolize plaque, causing "blue toe syndrome" (patchy mottling of the feet and toes in the presence of palpable pedal pulses).

Complications

Aneurysm rupture is more likely to occur in people who smoke tobacco.[11] If rupture occurs into the retroperitoneal space, bleeding may be controlled by surrounding anatomic structures, preventing exsanguination and death. In this case, the patient often has severe back pain. Back or flank bruising *(Grey Turner sign)* may be present.

If rupture occurs into the thoracic or abdominal cavity, patients can die from massive hemorrhage. The patient who reaches the hospital will be in hypovolemic shock with tachycardia, hypotension, pale clammy skin, decreased urine output, altered level of consciousness, and abdominal tenderness. Shock is discussed in Chapter 42. In this situation, simultaneous resuscitation and immediate surgical repair are needed. For patients admitted to the hospital with a ruptured AAA, in-hospital mortality is high at 53%.[11]

Diagnostic Studies

Chest x-rays may reveal abnormal widening of the thoracic aorta. An abdominal x-ray may show calcification within the aortic wall. An ECG may rule out MI, since thoracic aneurysm or dissection symptoms can mimic angina. Echocardiography assesses the function of the aortic valve. Ultrasound is useful for aneurysm screening and to monitor aneurysm size. A CT scan or MRI can diagnose and assess the location and severity of aneurysms. Angiography gives helpful information by using contrast imaging to map the entire aortic system (see Table 35.10).

Interprofessional Care

The main goal of care is to prevent the rupture of an aneurysm. Early detection and prompt treatment are essential. Conservative medical therapy of small, asymptomatic AAAs (less than 5.4 cm) is the best practice.[11] This consists of risk factor modification (ceasing tobacco use, decreasing BP, optimizing lipid profile, gradually increasing physical activity).[11] Patients should receive management for hypertension, hyperlipidemia, diabetes, and other CVD risk factors. A statin and an ACE inhibitor may be prescribed. Those with small aneurysms—4.0 to 5.4 cm—should have monitoring of aneurysm size using ultrasound or CT every 6 to 12 months. Ultrasound monitoring every 3 years is done for patients with AAAs smaller than 4.0 cm in diameter.

Surgical repair is recommended in patients with asymptomatic aneurysms 5.5 cm in diameter or larger. Surgical intervention may occur sooner if the patient has a genetic disorder (e.g., Marfan, Ehlers-Danlos syndrome), the aneurysm expands rapidly, the patient becomes symptomatic, or the risk for rupture is high. A careful review of body systems is needed to identify any comorbidities that affect the patient's surgical risk. Existing carotid or coronary artery blockages may be corrected before aneurysm repair.

Surgical Therapy

For elective aneurysm repair surgery, the patient should be well hydrated with normal electrolytes, coagulation, and hematocrit. If the aneurysm ruptures, emergent surgery is required.

Open aneurysm repair (OAR) involves a large abdominal incision through which the surgeon (1) cuts into the diseased aortic segment, (2) removes any thrombus or plaque, (3) sutures a synthetic graft to the aorta proximal and distal to the aneurysm, and (4) sutures the native aortic wall around the graft to act as a protective cover (Fig. 41.6). For iliac artery aneurysms, a bifurcated graft replaces the entire diseased segment. With saccular aneurysms, it may be possible to excise only the bulbous lesion and repair the artery by primary closure (suturing the artery together) or applying an autogenous or synthetic patch graft.

All OARs require aortic cross-clamping proximal and distal to the aneurysm. Most resections are done in 30 to 45 minutes. Then the clamps are removed, and blood flow is restored.

The risk for postoperative complications, such as acute kidney injury, increases in patients who have OAR of AAAs above the level of the renal arteries.

Endovascular graft procedure. Minimally invasive endovascular aneurysm repair (EVAR) is an alternative to OAR for select patients. EVAR involves the placement of a sutureless aortic graft into the abdominal aorta inside the aneurysm via the femoral artery. Grafts are made of various materials, such as a Dacron cylinder consisting of several sections, and supported with multiple rings of flexible wire. Eligibility criteria include iliofemoral vessels that allow for safe graft insertion and vessels of sufficient length and width to support the graft.[11]

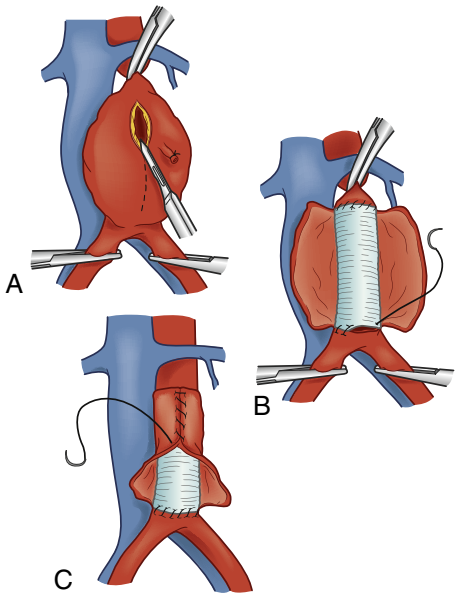

Fig. 41.6 Surgical repair of an abdominal aortic aneurysm. (A) Incising the aneurysmal sac. (B) Insertion of synthetic graft. (C) Suturing native aortic wall over synthetic graft.

The main section of the graft is bifurcated. It is delivered through a femoral artery catheter. The second part of the graft is inserted through the opposite femoral artery. When all graft components are in place, they are deployed against the vessel wall by balloon inflation. The blood then flows through the endovascular graft, preventing further expansion of the aneurysm (Fig. 41.7).

Angiography is done afterward to check for leaks and to confirm patency of all stent-graft components. The aneurysmal wall shrinks over time because the blood is diverted through the endograft. EVAR is less invasive than OAR and requires a shorter hospital stay. EVAR also has fewer complications, such as paraplegia and death.

Complications. The most common complication of AAA repair is *endoleak,* the seepage of blood back into the old aneurysm. This may result from an inadequate seal at either graft end, a tear through the graft fabric, or leakage between overlapping graft segments. Repair may require coil embolization (insertion of beads) for hemostasis.

Other complications include aneurysm growth above or below the graft, aneurysm rupture, aortic dissection, bleeding, renal artery occlusion caused by stent migration, graft thrombosis, incisional site hematoma, and incisional infection. Patients undergoing EVAR need periodic imaging for the rest of their lives to monitor for an endoleak, assess stability of the aneurysm, and determine the need for surgery.

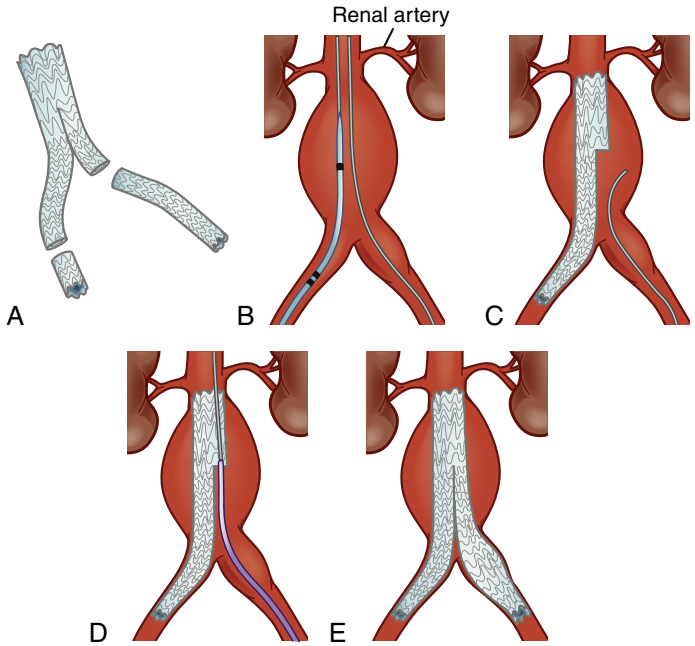

Fig. 41.7 Bifurcated (2-branched) endovascular stent grafting of an aneurysm. (A) Insertion of a woven polyester graft covered by a tubular metal web (stent). (B) The stent graft is inserted through a large blood vessel (e.g., femoral artery) using a delivery catheter. The catheter is positioned below the renal arteries in the area of the aneurysm. (C) The stent graft is slowly released into the blood vessel. When the stent comes in contact with the blood vessel, it expands to a preset size. (D) A second stent graft can be inserted in the opposite vessel, if needed. (E) Fully deployed bifurcated stent graft.

A potentially lethal complication in an emergency repair of a ruptured AAA is the development of *intraabdominal hypertension* (IAH) with associated *abdominal compartment syndrome*. Persistent IAH reduces blood flow to the viscera. Abdominal compartment syndrome refers to the impaired organ perfusion caused by IAH and resulting multisystem organ failure. IAH is confirmed by measuring the patient's intraabdominal pressure indirectly through a catheter and transducer system.

Treatment goals include controlling situations that lead to IAH. Interventions include open (surgical) decompression, percutaneous drainage, and percutaneous drainage combined with a thrombolytic infusion. Conservative measures, such as intubation, ventilation, patient positioning, gastric decompression, cautious fluid resuscitation, pain management, and temporary hemofiltration, are used.

❖ NURSING MANAGEMENT: AORTIC ANEURYSMS

◆ Assessment

Begin by doing a thorough history and physical assessment. Because atherosclerosis is a systemic disease, look for signs of coexisting cardiac, pulmonary, cerebral, and lower extremity vascular problems. Monitor the patient for signs of aneurysm rupture. These include diaphoresis; pallor; weakness; tachycardia; hypotension; abdominal, back, groin, or periumbilical pain; changes in level of consciousness; or a pulsating abdominal mass.

Obtain baseline data to compare with later assessments. Pay special attention to the character and quality of the patient's peripheral pulses and renal and neurologic status. Before surgery, mark pedal pulse sites (dorsalis pedis, posterior tibial) with a marker. Note any skin lesions on the lower extremities.

◆ Planning

The overall goals for a patient undergoing aortic surgery include (1) normal tissue perfusion; (2) intact motor and sensory function; and (3) no complications related to surgical repair, such as thrombosis, infection, or rupture.

◆ Implementation

◆ Health Promotion

To promote overall health, encourage the patient to reduce CVD risk factors (see Table 37.2). These include controlling BP, ceasing tobacco use (see Chapter 11), and maintaining normal body weight and serum lipid levels. These measures also help ensure continued graft patency after surgical repair. Counsel the patient about taking part in moderate physical activity.

◆ Acute Care

Before surgery, provide emotional support and teaching to the patient and caregiver (see Chapter 18). In general, aortic surgery patients have a bowel preparation and skin cleansing with an antimicrobial agent the day before surgery. They are NPO after midnight the day of surgery and receive IV antibiotics before the first incision. Patients with a history of CVD should receive a β-blocker (e.g., metoprolol).

After surgery, patients typically go to an ICU for 24 to 48 hours for close monitoring. When the patient arrives in the ICU, various devices are in place. These include an endotracheal tube for mechanical ventilation, an arterial line, a central venous pressure (CVP) catheter, peripheral IV lines, an indwelling urinary catheter, and a nasogastric (NG) tube. The patient needs continuous ECG and pulse oximetry monitoring. If the thorax is opened during surgery, chest tubes will be in place. The patient may have a lumbar catheter draining cerebrospinal fluid to prevent neurologic problems. Pain medication is given via subcutaneous infusion into incision site (e.g., On-Q pain pump), epidural catheters, or IV patient-controlled analgesia (PCA).

In addition to the usual goals of care for a postoperative patient (e.g., maintaining adequate respiratory function, fluid and electrolyte balance, and pain control [see Chapter 20]), check for graft patency and renal perfusion. Watch for and intervene to limit or treat cardiac ischemia, dysrhythmias, infections, VTE, and neurologic complications. eNursing Care Plan 41.2 for the patient with an aneurysm repair or other aortic surgery is available on the website for this chapter.

Graft patency. An adequate BP is important to maintain graft patency. Prolonged low BP may result in graft thrombosis. Give IV fluids and blood components as ordered to maintain adequate blood flow. Monitor CVP or PA pressures and urine output hourly in the immediate postoperative period to assess the patient's hydration and perfusion status.

Avoid severe hypertension which may stress the arterial anastomoses. This can result in leakage of blood or rupture at the suture lines. Drug therapy with IV diuretics (e.g., furosemide) or IV antihypertensive agents (e.g., labetalol, hydralazine, sodium nitroprusside) may be indicated.

Cardiovascular status. Myocardial ischemia or infarction may occur in the perioperative period from decreased myocardial O_2 supply or increased myocardial O_2 demands. Dysrhythmias may occur because of electrolyte imbalances, hypoxemia, hypothermia, or myocardial ischemia. Maintain continuous ECG monitoring. Administer O_2 per protocol. Other care includes frequent electrolyte and arterial blood gas determinations and giving IV antidysrhythmics, antihypertensives, and electrolytes as needed. Provide adequate pain control.

Infection. A prosthetic vascular graft infection is a rare but potentially life-threatening complication. Nursing interventions to prevent infection include giving a broad-spectrum antibiotic as prescribed (see Table 15.8). Assess temperature regularly, and promptly report fever. Monitor laboratory results for a high WBC count, which may be the first sign of an infection. Ensure adequate nutrition. Assess the surgical incision for signs of infection (e.g., redness, swelling, drainage). Keep surgical incisions clean and dry and perform wound care as prescribed.

Use good hand-washing and strict aseptic technique in the care of all peripheral, arterial, and CVP catheter insertion sites. These are ports of entry for bacteria. Meticulous perineal care for the patient with an indwelling urinary catheter and early catheter removal are essential to minimize the risk for urinary tract infection.

Gastrointestinal status. After OAR, postoperative ileus may develop because of anesthesia and the handling of the bowel

during surgery. The intestines may become swollen and bruised. Peristalsis ceases for variable intervals. A retroperitoneal surgical approach decreases the risk for bowel complications.

An NG tube may be present and connected to low, intermittent suction to decompress the stomach, prevent aspiration of stomach contents, and decrease pressure on suture lines. Record the amount and character of the NG output. While the patient is NPO, provide frequent oral care. Ice chips or lozenges can help soothe a dry or irritated throat. Assess for bowel sounds every 4 hours. Note the passing of flatus as it signals returning bowel function. Encourage early ambulation to help the return of bowel function. A postoperative ileus rarely lasts beyond the fourth postoperative day.

If the blood supply to the bowel is disrupted during surgery, ischemia or infarction (death) of intestinal tissue may result. Manifestations of this rare, but serious, complication include absent bowel sounds, fever, abdominal distention and pain, diarrhea, and bloody stools. If bowel infarction occurs, immediate reoperation is needed to restore blood flow and resect the infarcted area of bowel.

Neurologic status. Neurologic complications can occur after aortic surgery. When the ascending aorta and aortic arch are involved, assess the patient's level of consciousness, pupil size and response to light, facial symmetry, tongue position, speech, upper extremity movement, and quality of hand grasps. When the descending aorta is involved, perform a neurovascular assessment of the lower extremities. Record all assessments and report changes from baseline to the HCP immediately.

Peripheral perfusion status. The location of the aneurysm determines the type of peripheral perfusion assessment. Check and record all peripheral pulses hourly for several hours and then routinely (based on agency policy). When the ascending aorta and aortic arch are involved, assess the carotid, radial, and temporal artery pulses. For surgery of the descending aorta, assess the femoral, popliteal, posterior tibial, and dorsalis pedis pulses (see Fig. 35.6). You may need a Doppler to assess peripheral pulses. Check skin temperature and color, capillary refill time, and sensation and movement of the extremities.

Sometimes, lower extremity pulses may be absent for a short time after surgery because of vasospasm and hypothermia. A decreased or absent pulse together with a cool, pale, mottled, or painful extremity may indicate embolization or graft occlusion. Report these findings to the HCP at once. Graft occlusion requires reoperation if identified early. It is essential to compare your findings with the preoperative status to determine the cause of a decreased or absent pulse and the proper treatment. In some patients, pulses may have been absent before surgery because of coexistent PAD.

Renal perfusion status. The patient will have an indwelling urinary catheter after surgery. In the immediate postoperative period, record hourly urine output. Further evaluate renal function by monitoring daily BUN and serum creatinine levels. CVP pressures give vital information about hydration status. Maintain accurate fluid intake and output and record daily weights until the patient resumes a regular diet.

Decreased renal perfusion can occur from embolization of an aortic thrombus or plaque to either or both renal arteries. Hypotension, dehydration, prolonged aortic clamping during surgery, or blood loss can lead to kidney ischemia. Irreversible renal failure may occur after surgery, particularly in high-risk people (e.g., patients with diabetes).

Ambulatory Care

Teach the patient and caregiver to gradually increase activities. They should avoid heavy lifting for 6 weeks. Fatigue, poor appetite, and irregular bowel patterns are common.

Teach the patient and caregiver to look for changes in color or warmth of the extremities. They can learn to palpate peripheral pulses to assess changes in pulse quality. Report any redness, swelling, increased pain, drainage from incisions, or fever greater than 100°F (37.8°C) to the HCP.

Sexual problems in male patients are common after aortic surgery. A referral to a urologist and counseling may be useful if erectile dysfunction occurs.

Evaluation

Expected outcomes are that the patient who undergoes aortic surgery will have:

- Patent arterial graft with adequate distal perfusion
- Adequate urine output
- No signs of infection

AORTIC DISSECTION

Aortic dissection, often called *"dissecting aneurysm,"* is not a type of aneurysm. Rather, dissection results from the creation of a false lumen between the intima (inner lining) and the media (middle layer) of arterial wall (Figs. 41.5D and 41.8). We classify aortic dissection based on the location of the dissection and duration of onset. *Type A dissection* affects the ascending

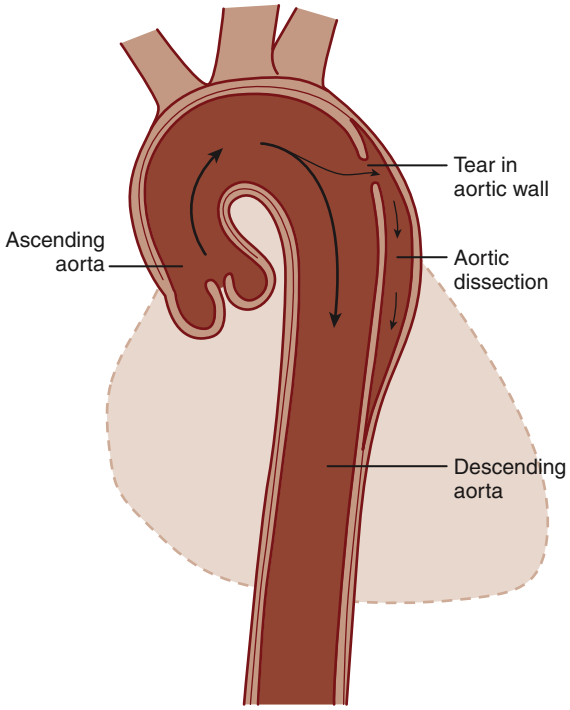

Fig. 41.8 Aortic dissection.

aorta and arch, requiring emergency surgery. *Type B dissection* begins in the descending aorta, allowing for potential conservative management.[12] Dissections are acute (first 14 days), subacute (14 to 90 days), or chronic (greater than 90 days) based on symptom onset.

Etiology and Pathophysiology

Nontraumatic aortic dissection is caused by weakened elastic fibers in the arterial wall. Chronic hypertension hastens this process. In aortic dissection, a tear develops in the inner layer of the aorta. Blood surges through this tear into the middle layer of the aorta, causing the inner and middle layers to separate (dissect). If the blood-filled channel ruptures through the outside aortic wall, aortic dissection is often fatal.

As the heart contracts, each pulsation increases the pressure on the damaged area and worsens the dissection. Extension of the dissection may cut off blood supply to the brain, kidneys, spinal cord, and extremities. The false lumen may remain patent, become thrombosed (clotted), rejoin the true lumen by way of a distal tear, or rupture.

Men have a higher risk for developing aortic dissection than women.[13] Women who develop aortic dissection are older and more likely than men to present with HF, coma, or altered mental status.[13] Hypertension is the most important risk factor for aortic dissection.[12,13] Other risk factors include age, aortic diseases (e.g., aortitis, coarctation, arch hypoplasia), atherosclerosis, blunt trauma, tobacco use, cocaine or methamphetamine use, congenital heart disease (e.g., bicuspid aortic valve), connective tissue disorders (e.g., Marfan's syndrome), family history, history of heart surgery, and pregnancy.

Clinical Manifestations

About 80% of patients with an acute type A aortic dissection report an abrupt onset of severe anterior chest or back pain. Patients with acute type B aortic dissection are more likely to report pain in their back, abdomen, or legs. Pain location may overlap between type A and B dissections. The pain may be described as "sharp" and "worst ever," or as "tearing," "ripping," or "stabbing." As the dissection progresses, pain may follow the path of the dissection. Older patients are less likely to have an abrupt onset of pain and more likely to have hypotension and vague symptoms. Some patients have a painless aortic dissection, emphasizing the importance of the physical assessment.

If the aortic arch is involved, the patient may have neurologic problems. These include altered level of consciousness, weakened or absent carotid and temporal pulses, dizziness, and syncope. Type A aortic dissection usually disrupts blood flow in the coronary arteries and causes aortic valve insufficiency. When either subclavian artery is involved, the radial, ulnar, and brachial pulse quality and BP readings may be different between the left and right arms. As the dissection progresses down the aorta, the abdominal organs and lower extremities show evidence of decreased tissue perfusion.

Complications

A severe and life-threatening complication of an acute ascending aortic dissection is *cardiac tamponade.* This occurs when blood from the dissection leaks into the pericardial sac. Manifestations of tamponade include hypotension, narrowed pulse pressure, jugular venous distention, muffled heart sounds, and pulsus paradoxus (see Chapter 40).

An aorta weakened by dissection may rupture. Hemorrhage may occur into the mediastinal, pleural, or abdominal cavities. Aortic rupture typically results in exsanguination and death.

Aortic dissection can lead to occlusion of the blood supply to vital organs. Spinal cord ischemia leads to weakness and decreased sensation. Rarely, lower extremity paralysis may occur. Renal ischemia can lead to renal failure. Abdominal (mesenteric) ischemia can occur and cause abdominal pain, decreased bowel sounds, altered bowel function, and bowel necrosis.

TABLE 41.6 Interprofessional Care

Aortic Dissection

Diagnostic Assessment
- Health history and physical assessment
- ECG
- Chest x-ray
- CT scan
- Transesophageal echocardiogram
- MRI

Management
- Bed rest
- Pain relief with opioids
- Blood transfusion (if needed)

Drug Therapy (see Table 36.6)
- IV β-blockers
- IV calcium channel blockers
- ACE inhibitors

Surgical Therapy
- Endovascular aortic dissection repair
- Open surgical repair

Diagnostic Studies

Diagnostic studies to detect aortic dissection are similar to those for suspected aneurysms (Table 41.6). An ECG can help rule out cardiac ischemia. A chest x-ray may show a widening of the mediastinum and pleural effusion. MRI, 3D CT scanning, and transesophageal echocardiography (TEE) are equally reliable for diagnosing acute aortic dissection. A CT scan or MRI can give detailed information on the severity of the dissection and related complications (e.g., pericardial effusions, carotid dissection). TEE is preferred in very unstable patients or those with contraindications to CT or MRI (e.g., those with metal implants, allergies to contrast material).

Interprofessional Care

Patients with acute aortic dissection are managed in the ICU. The initial goals of therapy for acute aortic dissection without complications are heart rate (HR) and BP control and pain management. Lowering HR and BP reduces aortic wall stress by decreasing SBP and myocardial contractility (Table 41.6). This limits extension of the dissection. An IV β-blocker (e.g., esmolol) is titrated to a target HR under 60 beats/min or SBP between 100 and 110 mm Hg. A calcium channel blocker (e.g.,

diltiazem) can be used to lower HR if a β-blocker is contraindicated. Morphine decreases sympathetic nervous system stimulation and relieves pain. Supportive treatment for an acute aortic dissection is a bridge to surgery.

Conservative Therapy

The patient with an acute or chronic Type B aortic dissection without complications can be treated conservatively. Treatment includes pain relief, HR and BP control, and CVD risk factor modification with close surveillance imaging with CT or MRI.

Endovascular Dissection Repair

Endovascular repair is a treatment option for acute type B aortic dissections with complications (e.g., hemodynamic instability) and chronic type B aortic dissection with complications (e.g., peripheral ischemia).[14] Thoracic endovascular aortic repair (TEVAR) is similar to EVAR. Fewer postsurgical complications occur with TEVAR. However, TEVAR does not prevent the risk for renal failure, paraplegia, or stroke.[14] If a lumbar spinal drain is inserted to help decrease or prevent neurologic complications, strict aseptic technique is used to prevent infection.

Surgical Therapy

An acute type A aortic dissection is a surgical emergency. Mortality rate is 50% within 48 hours of symptom onset. Otherwise, surgery is indicated when conservative therapy is ineffective or when complications (e.g., HF) occur. Open surgical repair is recommended for patients with a chronic dissection who have a connective tissue disorder or an aneurysm greater than 5.5 cm. [12,14]

The aorta is fragile after dissection. Surgery is delayed, when possible, to allow time for edema to decrease and to permit blood clotting in the false lumen. Surgery involves resection of the aortic segment with the intimal tear and replacement with a synthetic graft. Even with prompt surgical intervention, the in-hospital mortality is high.[14] Causes of death include aortic rupture, mesenteric ischemia, MI, sepsis, stroke, and multiorgan failure.

❖ NURSING MANAGEMENT: AORTIC DISSECTION

Preoperatively, keep the patient in bed in a semi-Fowler's position and maintain a quiet environment. Manage pain and anxiety, giving opioids and sedatives as prescribed. These measures help to keep the HR and SBP at the lowest possible level that maintains vital organ perfusion (typically HR less than 60 beats/min; SBP between 100 and 120 mm Hg).

Titrating IV antihypertensive agents requires careful supervision. Maintain continuous ECG and arterial BP monitoring. Monitor vital signs frequently, sometimes as often as every 2 to 3 minutes, until target HR and BP are reached. Look for changes in peripheral pulses and signs of increasing pain, restlessness, and anxiety.

Postoperative care is similar to that after OAR. In preparation for discharge, focus on patient and caregiver teaching. Help patients understand that they need to take antihypertensive drugs daily for the rest of their lives. β-Blockers are used to control HR and BP and decrease myocardial contractility. ACE inhibitors (e.g., lisinopril) are given if the patient cannot tolerate β-blockers. It is important that patients understand the drug regimen and side effects (e.g., dizziness, depression, fatigue, erectile dysfunction). Tell the patient to discuss any side effects with the HCP before stopping any medication.

Follow up with regularly scheduled MRIs or CTs is essential. The most common cause of death in long-term survivors is aortic rupture from redissection or aneurysm formation. Tell patients that if the pain or other symptoms return, they should activate the emergency response system (ERS) for immediate care.

ACUTE AND CHRONIC VENOUS DISORDERS

PHLEBITIS

Phlebitis is an acute inflammation of the walls of small, cannulated veins. Manifestations include pain, tenderness, warmth, redness, swelling, and a palpable cord. Risk factors are mechanical irritation from an IV catheter, infusion of irritating drugs, and IV catheter location in an area of flexion (e.g., wrist and antecubital area). Avoid IV catheter insertion in these areas whenever possible.

Phlebitis is rarely infectious. It usually resolves quickly after catheter removal. If edema is present, elevate the extremity to promote fluid reabsorption. Apply warm, moist heat and give oral NSAIDs (e.g., ibuprofen) or topical NSAIDs (e.g., diclofenac gel) to relieve pain and inflammation.

VENOUS THROMBOSIS

Venous thrombosis involves the formation of a *thrombus* (blood clot) with vein inflammation. It is the most common disorder of the veins. We classify it as either superficial vein thrombosis or deep vein thrombosis. **Superficial vein thrombosis** is the formation of a thrombus in a superficial vein, usually the greater or lesser saphenous vein. **Deep vein thrombosis (DVT)** involves a thrombus in a deep vein, most often the iliac and/or femoral veins. **Venous thromboembolism (VTE)** is the preferred terminology. It represents the spectrum from DVT to pulmonary embolism (PE) (Table 41.7). Chapter 30 discusses PE.

Superficial vein thrombosis is serious. Nearly 25% of patients with superficial vein thrombosis have a DVT or PE at the time of diagnosis.[15] These patients are at risk for developing recurrent VTE.

Etiology

The 3 key factors (called **Virchow triad**) that cause venous thrombosis are (1) venous stasis, (2) damage of the endothelium (inner lining of the vein), and (3) hypercoagulability (Fig. 41.9). The patient at risk for developing VTE usually has predisposing conditions to these 3 factors (Table 41.8).

Venous Stasis

Normal venous blood flow depends on the action of muscles in the extremities and the function of venous valves, which allow

flow in one direction. *Venous stasis* occurs when the valves are dysfunctional or the muscles of the extremities are inactive. Venous stasis occurs most often in people who are obese or pregnant, have chronic HF or atrial fibrillation, have been traveling on long trips without regular exercise, have a prolonged surgical procedure, or are immobile for long periods (e.g., spinal cord injury, fractured hip, limb paralysis).

TABLE 41.7 Comparison of Superficial Vein Thrombosis and Venous Thromboembolism

	Superficial Vein Thrombosis	Venous Thromboembolism (VTE)
Usual location	Typically, superficial leg veins (e.g., varicosities). Sometimes superficial arm veins.	Deep veins of arms (e.g., axillary, subclavian), legs (e.g., femoral), pelvis (e.g., iliac), vena cava, and pulmonary system.
Clinical findings	Tenderness, itchiness, redness, warmth, pain, inflammation, and induration along the course of superficial vein. Vein appears as a palpable cord. Edema rarely occurs.	Tenderness to pressure over involved vein, induration of overlying muscle, venous distention. Edema. May have mild to moderate pain, deep reddish color to area caused by venous congestion. Some have no obvious physical changes in the affected extremity.
Sequelae	If untreated, clot may extend to deeper veins and VTE may occur.	Embolization to lungs (PE) may occur and may result in death. Pulmonary hypertension and post-thrombotic syndrome with or without venous leg ulceration may develop.

Endothelial Damage

Damage to the endothelium may be caused by direct (e.g., surgery, intravascular catheterization, trauma, burns, prior VTE) or indirect (chemotherapy, diabetes, sepsis) injury. Damaged endothelium stimulates platelet activation and starts the coagulation cascade. This predisposes the patient to thrombus development.

Hypercoagulability of Blood

Blood hypercoagulability occurs with many problems. These include severe anemias, polycythemia, cancers (e.g., breast, brain, pancreas, GI tract); nephrotic syndrome; high homocysteine levels; and protein C, protein S, and antithrombin deficiency. A patient with sepsis is predisposed to hypercoagulability because of endotoxins released from bacteria. Some drugs (e.g., corticosteroids, estrogens) predispose a patient to thrombus formation.

Women who use tobacco, take estrogen-based oral contraceptives, are postmenopausal on oral hormone therapy, are over 35 years old, and have a family history of VTE have a very high risk for VTE.[15] Women who take oral contraceptives and use tobacco double their risk. Smoking causes hypercoagulability by increasing plasma fibrinogen and homocysteine levels and activating the intrinsic coagulation pathway.

Pathophysiology

Localized platelet aggregation and fibrin entrap RBCs, WBCs, and more platelets to form a thrombus. A frequent site of thrombus formation is the valve cusp of a vein, where venous stasis occurs. As a thrombus enlarges, increased numbers of blood cells and fibrin collect behind it. This makes a larger clot with a "tail" that eventually blocks the lumen of the vein.

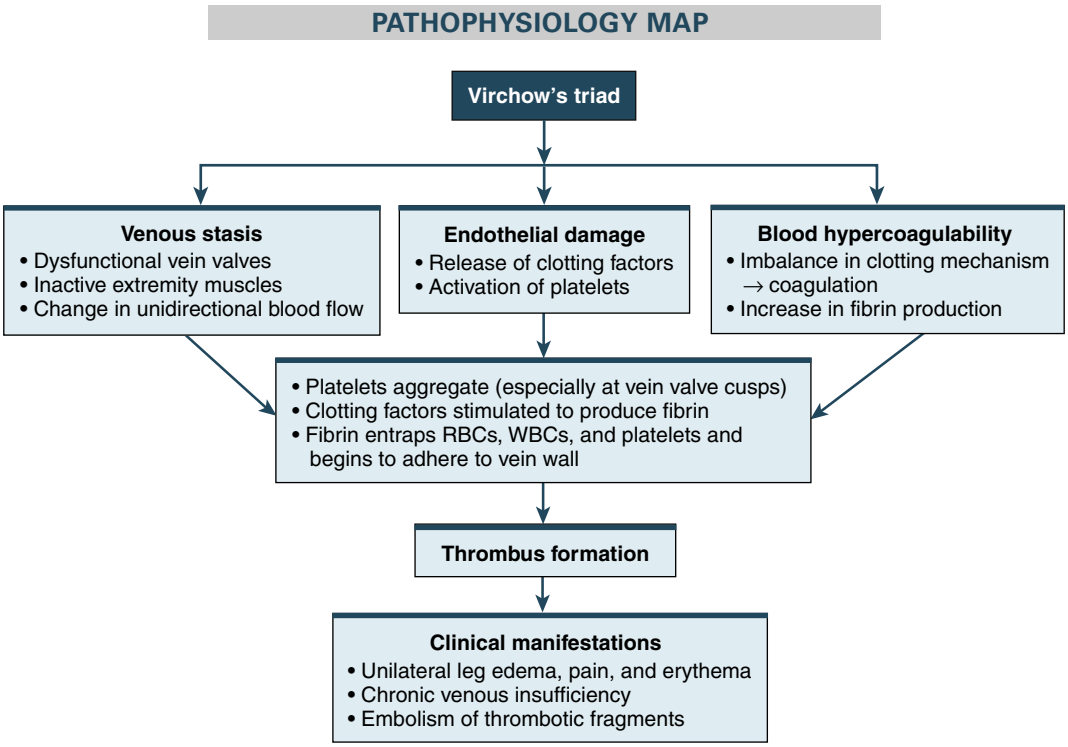

Fig. 41.9 Pathophysiology of VTE.

TABLE 41.8 Risk Factors for VTE

Endothelial Damage
- Abdominal and pelvic surgery (e.g., gynecologic, urologic surgery)
- Caustic or hypertonic IV drugs
- Pelvis, hip, or leg fractures
- History of VTE
- Indwelling, peripherally inserted central vein catheter
- IV drug use
- Trauma

Venous Stasis
- Advanced age
- Atrial fibrillation
- Bed rest
- Chronic heart failure
- Fractured leg or hip
- Long trips without adequate exercise
- Obesity
- Orthopedic surgery (especially hip or lower extremity)
- Pregnancy and postpartum period
- Prolonged immobility
- Spinal cord injury or limb paralysis
- Stroke
- Varicose veins

Hypercoagulability of Blood
- Antiphospholipid antibody syndrome
- Antithrombin III deficiency
- Cancer (especially breast, brain, hepatic, pancreatic, GI)
- Dehydration or malnutrition
- Elevated (clotting) factor VIII or lipoprotein (a)
- Erythropoiesis-stimulating drugs (e.g., epoetin alfa [Procrit])
- High altitudes
- Hormone therapy
- High homocysteine levels
- Nephrotic syndrome
- Oral contraceptives, especially in women older than 35 years who use tobacco
- Polycythemia vera
- Pregnancy and postpartum period
- Protein C deficiency
- Protein S deficiency
- Sepsis
- Severe anemias
- Tobacco use

If a thrombus only partially blocks the vein, endothelial cells cover the thrombus and stop the thrombotic process. If the thrombus does not become detached, it undergoes lysis or becomes firmly organized and adherent within 5 to 7 days. The organized thrombus may detach and result in an embolus. Turbulent blood flow is a major factor in embolization. The thrombus can become an embolus that flows through the venous circulation to the heart and lodges in the pulmonary circulation, becoming a PE.

Superficial Vein Thrombosis

Clinical Manifestations

The patient with superficial vein thrombosis may have a palpable, firm, subcutaneous cordlike vein (Table 41.7). The area surrounding the vein may be itchy, painful to the touch, reddened, and warm. A mild temperature elevation and leukocytosis may be present. Extremity edema may occur. Lower extremity superficial vein thrombosis often involves varicose veins.

Risk factors include increased age, pregnancy, obesity, cancer, recent fracture(s), estrogen therapy, recent sclerotherapy (e.g., treatment for varicose veins), recent surgery or long-distance travel, hypercoagulability, and a history of chronic venous insufficiency (CVI), superficial vein thrombosis, or VTE. It can occur in people with endothelial problems (e.g., Buerger disease).

Interprofessional Care

Ultrasound can confirm the diagnosis (clot 5 cm or larger) and rule out clot extension to a deep vein. If the superficial vein thrombosis affects a very short vein segment (less than 5 cm) and is not near the saphenofemoral junction, anticoagulants may not be needed. Oral NSAIDs can ease symptoms. Other interventions include telling the patient to wear graduated compression stockings or bandages, apply warm compresses, elevate the affected limb above the level of the heart, apply topical NSAIDS, and perform mild exercise, such as walking.

Venous Thromboembolism

Clinical Manifestations

The patient with lower extremity VTE may have unilateral leg edema, pain, tenderness with palpation, dilated superficial veins, a sense of fullness in the thigh or the calf, paresthesias, warm skin, redness, or a systemic temperature greater than 100.4°F (38°C) (Table 41.7). If the inferior vena cava is involved, both legs may be edematous and cyanotic. About 10% of VTEs involve the upper extremity veins. They may extend into the internal jugular vein or superior vena cava. If the superior vena cava is involved, similar symptoms may occur in the arms, neck, back, and face.

Complications

The most serious complications of VTE are PE, chronic thromboembolic pulmonary hypertension, post-thrombotic syndrome, and phlegmasia cerulea dolens. **Post-thrombotic syndrome (PTS)** occurs in 8% to 70% of patients. It results from chronic inflammation and chronic venous hypertension. Chronic venous hypertension is caused by vein wall and vein valve damage (from acute inflammation and thrombus reorganization), venous valve reflux, and persistent venous (outflow) obstruction.

Symptoms include pain, aching, fatigue, heaviness, sensation of swelling, cramps, pruritus, tingling, paresthesia, bursting pain with exercise, and venous claudication. Manifestations include persistent edema, spider veins (telangiectasia), venous dilation (ectasia), redness, cyanosis, increased pigmentation, eczema, pain during compression, atrophie blanche (white scar tissue), and *lipodermatosclerosis* (Fig. 41.10). Venous ulceration can occur with severe PTS. Signs of PTS typically begin within a few months to a few years of a VTE. Risk factors include persistent leg symptoms 1 month after VTE, proximal VTE location (e.g.,

Fig. 41.10 Lipodermatosclerosis. The leg becomes tapered like an "inverted bottle." Skin becomes scarred and leathery with brown discoloration and changes in pigmentation. (From Larocca C, Phillips TJ, et al: *Treatment of skin disease: comprehensive therapeutic strategies*, St Louis, 2018, Elsevier.)

near the iliofemoral junction), extensive VTE, recurrent VTE on the same side, asymptomatic VTE, and residual thrombus. Other factors include obesity, older age, poor INR control, daily tobacco use before pregnancy, increased D-dimer levels, elevated inflammatory markers, and varicose veins.

Phlegmasia cerulea dolens (swollen, blue, painful leg) is a rare complication of severe lower extremity VTE. It involves the major leg veins, causing near-total occlusion of venous outflow. Patients typically have sudden, massive swelling; deep pain; and intense cyanosis of the extremity. If untreated, the venous obstruction causes arterial occlusion and gangrene, requiring amputation.

Diagnostic Studies

Diagnosis of an initial VTE is based on the assessment combined with D-dimer testing and/or ultrasound. Table 41.9 presents the diagnostic studies used to determine the site or location and extent of a VTE.

Interprofessional Care

Prevention. All health care team members have important roles in VTE prevention. VTE prevention is a core measure of high-quality health care in high-risk hospitalized patients developed by The Joint Commission (TJC) and the National Quality Forum. TJC recommends that hospitals have a policy that addresses VTE prevention on admission of all adult patients. In patients at risk for VTE, interventions used are based on bleeding and thrombosis risk, medical history, current drugs, medical diagnoses, scheduled procedures, and patient preferences.

Early and aggressive mobilization is the easiest and most cost-effective method to decrease VTE risk. Patients on bed rest should change position at least every 2 hours. Unless contraindicated, teach patients to flex and extend their feet, knees, and hips at least every 2 to 4 hours while awake. Patients who are able should be out of bed in a chair for meals and walk at least 4 to 6 times per day. Teach the patient and caregiver about the importance of these measures. Early and frequent ambulation is sufficient prophylaxis for patients at very low risk for VTE who had minor surgical procedures. Anticoagulation and mechanical prophylaxis are not recommended for acutely ill medical patients at low risk for VTE.

Graduated compression stockings (e.g., thromboembolic deterrent [TED] hose) are a part of VTE prevention in hospitalized patients. VTE prevention is enhanced if the stockings are used along with anticoagulation. Proper stocking use means any toe hole is under the toes, the heel patch is over the heel, a thigh gusset is on the inner thigh (thigh length only), and there are no wrinkles. The stockings should not be rolled down, cut, or otherwise altered. Stockings that are not fitted and worn correctly impede venous return. This can cause arterial ischemia, edema, skin breakdown, and VTE. Stockings are not recommended if the patient already has a VTE.[15]

TABLE 41.9 Diagnostic Studies

VTE

Study	Description and Abnormal Findings
Blood Laboratory Studies	
ACT, aPTT, INR, bleeding time, Hgb, Hct, platelet count	Altered if patient has underlying blood dyscrasia (e.g., increased Hgb and Hct in patient with polycythemia).
D-dimer	Fragment of fibrin formed from fibrin degradation and clot lysis. High results suggest VTE. *Normal results:* <250 ng/mL (<250 mcg/L)
Fibrin monomer complex	Forms when concentration of thrombin exceeds that of antithrombin. Presence is evidence of thrombus formation and suggests VTE. *Normal results:* <6.1 mg/L
Noninvasive Venous Studies	
Duplex ultrasound	Combination of compression ultrasound with spectral and color flow Doppler. Veins examined for compressibility and intraluminal filling defects to help determine location and extent of thrombus (most widely used test to diagnose VTE).
Venous compression ultrasound	Evaluation of deep femoral, popliteal, and posterior tibial veins *Normal finding:* Veins collapse with application of external pressure. *Abnormal finding:* Veins do not collapse with application of external pressure. Failure to collapse suggests a thrombus.
Invasive Venous Studies	
Computed tomography venography (CTV)	Uses spiral CT to evaluate veins in the pelvis, thighs, and calves after injection of contrast material. May be done simultaneously with CT angiography of pulmonary vessels for patients being evaluated for VTE.
Contrast venography (phlebogram)	X-ray determination of location and extent of clot using contrast media to outline filling defects. Identifies the presence of collateral circulation. Once the gold standard, but now rarely done.
Magnetic resonance venography	Uses MRI with specialized software to evaluate blood flow through veins. Can be done with or without contrast. Highly accurate for pelvic and proximal veins. Less accurate for calf veins. Can distinguish acute and chronic thrombus.

ACT, Activated clotting time.

Intermittent pneumatic compression devices (IPCs) use inflatable sleeves or boots to compress the calf and thigh and/or foot and ankle to improve venous return. The sleeves apply external pressure through an electric pump. IPCs may be used with graduated compression stockings. Ensure correct fit of IPCs by accurately measuring the extremities. IPCs will not be effective if they are not applied correctly, if the fit is incorrect, or if the patient does not wear the device continuously while at rest. The IPCs can be removed for bathing, skin assessment, and ambulation. IPCs are not worn when a patient has an active VTE because of the risk for PE.

Drug therapy. Anticoagulants are used routinely for VTE prevention and treatment. The regimen depends on the patient's VTE risk. The goal of anticoagulant therapy for VTE prevention is to prevent clot formation. The goals for treatment of a confirmed VTE are to prevent new clot development, spread of the clot, and embolization.

The 3 major classes of anticoagulants available are (1) vitamin K antagonists (VKAs), (2) thrombin inhibitors (both indirect and direct), and (3) factor Xa inhibitors (Table 41.10).[15,16] Anticoagulant therapy does not dissolve the clot. Clot lysis

TABLE 41.10 Drug Therapy

Anticoagulant Therapy

Drug	Route of Administration	Considerations
Thrombin Inhibitors: Indirect		
Low-Molecular-Weight Heparin (LMWH)		
dalteparin (Fragmin) enoxaparin (Lovenox)	Subcutaneous	Routine coagulation tests typically not needed. Monitor CBC count at regular intervals. Do not expel air bubble from prefilled syringe. If giving subcutaneously, inject deep into subcutaneous tissue (preferably into the abdominal fatty tissue or above the iliac crest), inserting the entire length of the needle. Hold skinfold during injection but release before removing needle. Do not aspirate. Do not inject IM. Do not rub site after injection. Rotate sites. Reduced dosage needed in patients with renal problems. Use extreme caution in patients with a history of HIT. *Antidote:* Protamine reverses the effects of LMWH.
Unfractionated Heparin (UH)		
heparin sodium	Continuous IV Intermittent IV Subcutaneous	Therapeutic effects measured at regular intervals by the aPTT or ACT. Monitor CBC counts at regular intervals and titrate according to parameters. Follow administration guidelines for LMWH if giving subcutaneously. IV given as an adjunct for existing blood clots. SQ given prophylactically to prevent the development of clots. *Antidote:* Protamine reverses the effect of UH.
Factor Xa Inhibitors		
apixaban (Eliquis)	PO	All approved for VTE prevention and treatment.
betrixaban (Bevyxxa)	PO	Routine coagulation tests not needed. Monitor CBC and creatinine at regular intervals.
edoxaban (Savaysa)	PO	May cause thrombocytopenia.
fondaparinux (Arixtra)	Subcutaneous	Do not expel air bubble before giving fondaparinux. Follow administration guidelines as described for subcutaneous LMWHs.
rivaroxaban (Xarelto)	PO	*Antidote:* Andexanet alfa (Andexxa) reverses the effects of all Factor Xa inhibitors.
Thrombin Inhibitors: Direct		
Hirudin Derivatives		
bivalirudin (Angiomax)	IV	Therapeutic effect measured by ACT or aPTT. Used in patients with HIT who need anticoagulation.
desirudin (Iprivask)	Subcutaneous	*Antidote:* None.
Synthetic Thrombin Inhibitors		
argatroban (Acova)	IV	Argatroban therapeutic effect measured by aPTT. No routine coagulation tests needed for dabigatran.
dabigatran (Pradaxa)	PO	Used in patients at risk for or with HIT, for VTE prevention in joint replacement surgery, stroke prevention in nonvalvular atrial fibrillation. *Antidote:* Idarucizumab (Praxbind) reverses the effect of dabigatran only.
Vitamin K Antagonists (VKA)		
warfarin (Coumadin)	PO	INR used to monitor therapeutic levels. Give at the same time each day. Variations of certain genes (e.g., *CYP2CP, VKORC1*) may influence response to drug. *Antidote:* Vitamin K. For VKA-related bleeding, treatment with prothrombin complex concentrate (human) (Kcentra), IV vitamin K and/or fresh frozen plasma is recommended.

ACT, Activated clotting time; *HIT,* heparin-induced thrombocytopenia.

TABLE 41.11 Blood Coagulation Tests

Test and Drugs Monitored	Normal Value	Therapeutic Value
Activated Clotting Time (ACT)	70–120 sec*	>300 sec
• Hirudin derivatives (e.g., bivalirudin [Angiomax])		
• Synthetic thrombin inhibitors (e.g., argatroban [Acova])		
• Unfractionated heparin (e.g., heparin [Hep-Lock])		
Activated Partial Thromboplastin Time (aPTT)	30–40 sec	46–70 sec
• Hirudin derivatives		
• Synthetic thrombin inhibitors		
• Unfractionated heparin		
Anti-Factor Xa		
• Factor Xa inhibitors (e.g., fondaparinux [Arixtra], rivaroxaban [Xarelto])	0 units/mL 0 units/mL	0.6–1.0 units/mL 0.2
• Low-molecular-weight heparin (e.g., enoxaparin [Lovenox])		1.5 units/mL
International Normalized Ratio (INR)	0.75–1.25	2–3
• Vitamin K antagonists (e.g., warfarin [Coumadin])		

[a]Varies based on type of system and test reagent or activator used.

begins naturally through the body's intrinsic fibrinolytic system (see Chapter 33).

Vitamin K antagonists. The oral anticoagulant for long-term or extended anticoagulation is warfarin, a VKA. Warfarin inhibits activation of the vitamin K–dependent coagulation factors II, VII, IX, and X and the anticoagulant proteins C and S. See the list of clotting factors in Table 33.2. Fig. 33.4 shows the clotting pathways. Warfarin begins to take effect in 48 to 72 hours and achieves maximum effect several days later. Thus, an overlap of a parenteral anticoagulant (e.g., UH or low-molecular-weight heparin [LMWH]) and warfarin typically is required for 5 days. We monitor the level of anticoagulation daily using the INR. The INR is a standardized system of reporting prothrombin time (PT) (Table 41.11).

Take a careful history before starting warfarin. Do not give antiplatelet drugs or NSAIDs with warfarin as these increase bleeding risk.[16] Many other drugs, vitamins, minerals, and herbal supplements interact with warfarin. A diet that varies in vitamin K intake (e.g., green leafy vegetables) can make it hard to achieve and maintain a target INR level. Genetic variants in the genes *VKORC1* and cytochrome P450 2C9 *(CYP2C9)* may influence how some people respond to warfarin. See Table 13.5 and Fig. 13.7.

Thrombin inhibitors. There are 2 major classes of *indirect thrombin inhibitors*: UH and LMWHs. UH (e.g., heparin) affects both the intrinsic and common pathways of blood coagulation by way of the plasma antithrombin. Antithrombin inhibits thrombin-mediated conversion of fibrinogen to fibrin by affecting factors II (prothrombin), IX, X, XI, and XII (see Fig. 33.4).

Heparin can be given subcutaneously for VTE prevention or by continuous IV infusion for VTE treatment. IV heparin use requires frequent monitoring of clotting status by measuring activated partial thromboplastin time (aPTT) (Table 41.11).

One serious side effect of heparin is *heparin-induced thrombocytopenia* (HIT). An immune reaction to heparin causes a severe, sudden decrease in the platelet count along with a paradoxical increase in venous or arterial thrombosis. We diagnose HIT by measuring the presence of heparin antibodies in the blood. Treatment includes immediately stopping heparin therapy. If further anticoagulation is needed, we give a non-heparin anticoagulant (e.g., fondaparinux).[16] Another side effect of long-term heparin therapy is osteoporosis.

LMWHs (e.g., enoxaparin [Lovenox]) are derived from UH. They have more predictable dose responses, longer half-lives, and fewer bleeding complications than UH. LMWHs are less likely to cause HIT and osteoporosis. LMWHs typically do not require ongoing anticoagulant monitoring and dose adjustment. Their antiinflammatory properties may help prevent PTS and venous ulcer development. Protamine reverses the effect of LMWH.

Direct thrombin inhibitors are classified as hirudin derivatives or synthetic thrombin inhibitors. Hirudin is made using recombinant deoxyribonucleic acid (DNA) technology. It binds specifically with thrombin and directly inhibits its function without causing plasma protein and platelet interactions. Hirudin derivatives (e.g., bivalirudin [Angiomax]) are given by continuous IV infusion. Bivalirudin is given to patients with or at risk for HIT having a percutaneous coronary intervention. Anticoagulant activity is monitored using aPTT or activated clotting time (ACT) (Table 41.11). If bleeding occurs, there is no antidote for hirudin derivatives.

Argatroban—a synthetic direct thrombin inhibitor—hinders thrombin. Like bivalirudin, it is an alternative to heparin for the prevention and treatment of HIT and for patients with or at risk for HIT needing percutaneous coronary interventions. The effect of argatroban is not reversible. Its anticoagulant effect is monitored using aPTT or ACT.

Dabigatran (Pradaxa) is an oral direct thrombin inhibitor. It is used for VTE prevention after elective joint replacement, for stroke prevention in nonvalvular atrial fibrillation, and as a treatment for VTE. Dabigatran has 5 major advantages compared to warfarin: rapid onset, no need to monitor anticoagulation, few drug-food interactions, lower risk for major bleeding, and predictable dose response.

Factor Xa inhibitors. *Factor Xa inhibitors* inhibit factor Xa directly or indirectly, producing rapid anticoagulation. These include fondaparinux (Arixtra), rivaroxaban (Xarelto), apixaban (Eliquis), and edoxaban (Savaysa). All are used for both VTE prevention and treatment. Fondaparinux is contraindicated in patients with severe renal disease. Although coagulation monitoring or dose adjustment is not needed, anticoagulant activity can be measured using anti-Xa assays (Table 41.11).

Anticoagulant therapy for VTE prevention. For VTE prevention in the hospitalized medical patient at risk for thrombosis who is not bleeding, low-dose UH, LMWH, or fondaparinux is used. If the patient is at low VTE risk, drug prophylaxis is not needed. Patients with moderate VTE risk (e.g., general, gynecologic, urologic surgery) should receive either UH or LMWH. Patients with high VTE risk (e.g., trauma) should receive UH or LMWH until discharge. Patients having

abdominal or pelvic surgery for cancer or major orthopedic surgery (e.g., total knee or hip replacement) should receive VTE prophylaxis.[15]

Anticoagulant therapy for VTE treatment. Patients with confirmed VTE should receive initial treatment with either LMWH, UH, or an oral factor Xa drug. Oral VKA therapy may be an option. A therapeutic INR is maintained between 2.0 and 3.0 if VKA therapy is used. Active treatment of VTE should continue for at least 3 months.

Patients with multiple co-morbidities, complex medical issues, or a very large VTE usually are hospitalized for parenteral UH administration. Depending on the presentation and home situation, patients may be safely managed as outpatients.

Thrombolytic therapy for VTE treatment. Another treatment option for patients with a thrombus is catheter-directed administration of a thrombolytic drug (e.g., urokinase, tPA). It dissolves the clot(s), reduces the acute symptoms, improves deep venous flow, reduces valvular reflux, and may help to decrease the incidence of PTS. Catheter-directed thrombolysis is an option for patients who have a low risk of bleeding and present with an acute, extensive, symptomatic, proximal VTE. Systemic anticoagulation is needed before, during, and after catheter-directed thrombolysis. (Chapter 37 discusses thrombolytic therapy.)

CHECK YOUR PRACTICE

Your 55-year-old female patient is admitted with an extensive VTE in her right leg. She is receiving weight-based IV heparin per agency protocol: 18 units/kg/hr. You receive the following critical laboratory result: aPTT 122 s.

- Describe your next actions.

Surgical and interventional radiology therapies. A few patients with extensive, acute, proximal VTE who are not candidates for catheter-directed thrombolysis and/or interventional radiology therapies (due to bleeding risk) may have surgery.[3,15] Surgical options include open venous thrombectomy and inferior vena cava interruption. *Venous thrombectomy* involves the removal of a clot through a vein incision. Anticoagulant therapy is used after venous thrombectomy.

Vena cava interruption devices (e.g., Greenfield, Vena Tech, TrapEase filters) can be placed percutaneously through the right femoral or right internal jugular veins. The filter device is opened, and the spokes penetrate the vessel walls (Fig. 41.11). The filters act as a "sieve-type" device. They filter clots without interrupting blood flow. Complications after the insertion are rare but include air embolism, improper placement, migration of the filter, and perforation of the vena cava with retroperitoneal bleeding. Over time, clots can clog the filter and completely block the vena cava, requiring filter removal and replacement. A filter device is recommended with acute PE or proximal VTE of the leg in patients with active bleeding or if anticoagulant therapy is contraindicated or ineffective.

Percutaneous endovascular interventional radiology procedures can be used along with catheter-directed thrombolytic therapy, especially for severely symptomatic patients with iliocaval or iliofemoral obstruction. The procedures are like those used in the treatment of lower extremity PAD. The difference is accessing an occluded vein instead of an artery. Options include mechanical thrombectomy, pharmacomechanical devices, post-thrombus extraction, angioplasty, and/or stenting.[15] Anticoagulation therapy is recommended after an iliofemoral interventional radiology procedure. Post procedure nursing care focuses on (1) maintaining catheter systems (if continuous infusions); (2) monitoring for bleeding, embolization, and impaired perfusion; and (3) VTE prevention teaching.

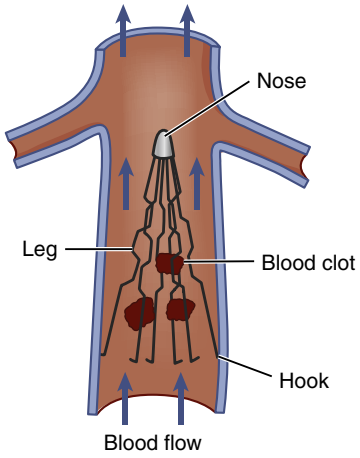

Fig. 41.11 Inferior vena cava interruption technique using Greenfield stainless-steel filter to prevent pulmonary embolism. As blood travels up the vena cava, clots are trapped in the filter.

NURSING MANAGEMENT: VENOUS THROMBOEMBOLISM

Assessment

Table 41.12 presents the subjective and objective data to obtain from a patient with VTE.

Clinical Problems

Clinical problems for the patient with VTE include:

- Inadequate tissue perfusion
- Pain
- Impaired tissue integrity
- Impaired respiratory function
- Musculoskeletal problem

Planning

The overall goals for the patient with VTE include (1) pain relief, (2) decreased edema, (3) increased knowledge of disorder and treatment plan, (4) no skin ulceration, (5) no bleeding complications, and (6) no evidence of PE.

Nursing Implementation

Acute Care

Focus your nursing care for the patient with VTE on preventing thrombi and reducing inflammation (Table 41.13). Review with the patient any drugs, vitamins, minerals, and herbal supplements that may interfere with anticoagulant therapy. Depending on the anticoagulant ordered, monitor INR, aPTT, ACT, anti-factor Xa levels, complete blood count (CBC), creatinine, factor X levels, hemoglobin, hematocrit, platelet levels, and/or liver enzymes. Monitor platelet counts for patients getting UH

TABLE 41.12 NURSING ASSESSMENT

VTE

Subjective Data

Important Health Information (Table 41.8)

Health history: Trauma to vein, intravascular catheter (e.g., peripherally inserted central catheter), varicose veins, pregnancy or recent childbirth, bacteremia, obesity, prolonged bed rest, irregular heartbeat (e.g., atrial fibrillation), COPD, HF, cancer, coagulation disorders and hypercoagulable states, systemic lupus erythematosus, MI, spinal cord injury, stroke, prolonged travel, recent bone fracture, dehydration

Medications: Use of estrogens (including oral contraceptives, hormone therapy), tamoxifen, raloxifene (Evista), corticosteroids, excessive amounts of vitamin E, erythropoiesis-stimulating drugs

Surgery or other treatments: Any recent surgery, especially orthopedic, gynecologic, GI, or urologic. Previous surgery involving veins. Central venous catheter

Functional Health Patterns

Health perception–health management: IV drug abuse, tobacco use, obesity

Activity-exercise: Inactivity

Cognitive-perceptual: Pain in area on palpation or ambulation

Objective Data

Cardiovascular

Distention and warmth of superficial veins in affected area. Edema and cyanosis of extremities, neck, back, and face (if superior vena cava involvement)

General

Fever, anxiety, pain

Skin

Increased size of extremity when compared with other side. Taut, shiny, warm skin, redness, tender to palpation. No physical changes in the affected extremity in some patients

Possible Diagnostic Findings

Leukocytosis, abnormal coagulation, anemia or ↑ hematocrit and RBC count, ↑ D-dimer level, positive venous compression on duplex ultrasound study; positive CT venogram, magnetic resonance venogram, or contrast venogram study

TABLE 41.13 NURSING MANAGEMENT

Caring for the Patient With VTE

- Assess patients for VTE risk and monitor for VTE in at-risk patients (see Table 41.8).
- Teach patients at risk for VTE about preventive measures, including leg exercise and ambulation, using graduated compression stockings and intermittent pneumatic compression devices (IPCs), avoiding nicotine, and taking anticoagulant drugs.
- Measure patients for graduated compression stockings and/or IPCs.
- Assess for the use of medications and substances that may affect the coagulation status.
- Give prescribed oral, subcutaneous, and IV anticoagulants.
- Evaluate the effect of anticoagulant drugs by monitoring appropriate laboratory results and side effects of therapy (Table 41.11).
- Titrate doses of unfractionated heparin (UH), warfarin, and direct thrombin inhibitors based on results of blood studies and agency protocols.
- Assess for complications of VTE, including PE and chronic venous insufficiency.
- Teach the patient and caregiver the manifestations of PE and the need to contact the emergency response system if these occur.
- Provide discharge teaching about use of graduated compression stockings, diet, laboratory testing, and anticoagulant therapy (Table 41.15).
- Supervise the AP:
  - Reposition patients who are on bed rest at least every 2 hr.
  - Remind patients about the need to flex and extend the legs and feet at least every 2 hr while in bed.
  - Help ambulatory patients to walk at least 4 to 6 times daily.
  - Help patients with putting on graduated compression stockings.
  - Apply IPCs.
- Collaborate with the physical therapist:
  - Assess patient's mobility status.
  - Develop exercise/muscle strengthening program as needed.
- Collaborate with the dietitian:
  - Assess patient's diet and nutrition status.
  - Provide diet teaching as needed.

DRUG ALERT

Anticoagulant Therapy

- Observe closely for any signs of bleeding: hypotension, tachycardia, hematuria, melena, hematemesis, petechiae, bruising, oozing or visible bleeding from trauma site or surgical incision.
- Tell patients to report bleeding: black or bloody stools, bleeding gums, bloody urine or sputum, coffee-ground or bloody vomit, excessive bruising, nosebleeds, excessive menstrual bleeding.
- Assess for mental status changes, especially in the older patient, since this may indicate cerebral bleeding.
- Tell patients to avoid taking aspirin, NSAIDs, fish oil supplements, garlic supplements, ginkgo biloba, and certain antibiotics (e.g., sulfamethoxazole and trimethoprim [Bactrim]).

or LMWH to assess for HIT. Direct thrombin inhibitors may need adjustment for patients with renal or liver disease. Check the results of pertinent tests before starting, giving, or changing anticoagulant therapy.

Monitor for and reduce the risk for bleeding with anticoagulant therapy (Table 41.14). Bleeding risk is greater in people receiving LMWH or UH with an active gastroduodenal ulcer, prior bleeding history, low platelet count, hepatic or renal failure, rheumatic disease, cancer, or age greater than 85 years. Patients receiving warfarin with an INR of 5.0 or more have a higher risk for bleeding. In case of anticoagulation above target goals, give reversal agents (e.g., protamine, vitamin K) or make dosage adjustments as prescribed.

Early ambulation does not increase the short-term risk of a PE in patients with VTE. In addition, early ambulation after acute VTE results in a more rapid decrease in edema and limb pain, fewer PTS symptoms, and better quality of life. Teach the patient and caregiver the importance of physical activity. Help the patient ambulate several times a day. For patients with acute VTE with severe edema and limb pain, bed rest with limb elevation may initially be prescribed.

Ambulatory Care

Focus discharge teaching on modifying VTE risk factors, monitoring laboratory values, diet and drug instructions, and

TABLE 41.14 NURSING MANAGEMENT

Patient Receiving Anticoagulants

Assessment

- Monitor vital signs as indicated.
- Examine urine and stool for overt and occult signs of blood.
- Inspect skin often, especially under any splinting devices.
- Evaluate platelet count for signs of heparin-induced thrombocytopenia.
- Evaluate appropriate laboratory coagulation tests for target therapeutic levels.
- Evaluate lower extremity for bruising or hematoma development if intermittent pneumatic compression device used.
- Perform assessments frequently for signs and symptoms of bleeding (e.g., hypotension, tachycardia) or clotting.
- Notify the HCP of any abnormalities in assessments, vital signs, or laboratory values.

Injections

- Avoid IM injections.
- Minimize venipunctures.
- Use small-gauge needles for venipunctures, unless therapy requires a larger gauge.
- Apply manual pressure for at least 10 min (or longer if needed) on venipuncture sites.

Patient Care

- Avoid restrictive clothing.
- Humidify any supplemental O_2.
- Apply moisturizing lotion to skin.
- Use electric razors, not straight razors.
- Perform physical care in a gentle manner.
- Tell patient not to forcefully blow nose.
- Avoid removing or disrupting established clots.
- Use soft toothbrushes or foam swabs for oral care.
- Reposition the patient carefully at regular intervals.
- Limit tape application. Use paper tape as appropriate.
- Give stool softeners to avoid hard stools and straining.
- Use support pads, mattresses, bed cradles, and therapeutic beds as indicated.
- Apply graduated compression stockings or intermittent pneumatic compression devices (if ordered) with attention to proper size, application, and use.
- Perform risk for fall and skin breakdown assessments per agency policy and implement safety and preventive measures as needed.

TABLE 41.15 PATIENT & CAREGIVER TEACHING

Anticoagulant Therapy

Include the following information in the teaching plan for a patient receiving anticoagulant therapy and the patient's caregiver:

1. Give reasons for and action of anticoagulant drug and how long therapy will last.
2. Take drug at the same time each day (preferably in afternoon or evening).
3. Depending on drug prescribed, obtain blood tests to assess therapeutic effect and whether change in dosage is needed.
4. Contact emergency response system immediately for any of the following adverse side effects of drug therapy:
   - Blood in urine or stool; or black, tarry stools
   - Vomiting blood, coffee-grounds emesis
   - Unusual bleeding from gums, skin, or nose, or heavy menstrual bleeding
   - Severe headaches or stomach pain
   - Chest pain, shortness of breath, palpitations (heart racing)
   - Weakness, dizziness, mental status changes
   - Cold, blue, or painful feet
5. Avoid activities with a high risk for injury that may cause bleeding (e.g., vigorous brushing of teeth, contact sports, rollerblading, use of straight razor).
6. Avoid all aspirin-containing drugs and NSAIDs.
7. Limit alcohol intake to small to moderate amounts (12 oz beer, 4 oz wine, 1 oz hard liquor/day).
8. Wear a Medic Alert device saying the anticoagulant drug being taken.
9. If taking warfarin (Coumadin), avoid frequent or dramatic changes in eating foods high in vitamin K (e.g., broccoli, spinach, kale, greens). Do not take supplemental vitamin K.
10. Consult with HCP before beginning or stopping any drug, vitamin, mineral, or dietary or herbal supplement.
11. Inform all HCPs, including dentist, of anticoagulant therapy.
12. Correct dosing is essential. Provide supervision if patient has confusion or cognitive problems.
13. Implement safety precautions to prevent falls (e.g., avoid use of throw rugs).
14. Apply pressure for 10 to 15 min if bleeding occurs (e.g., nosebleed).

guidelines for follow-up. Recommend the patient stop smoking and avoid all nicotine products. Teach the patient to avoid constrictive clothing. Tell women with a history of VTE to stop oral contraceptives or hormone therapy. Teach patients to limit standing or sitting in a motionless, leg-dependent position.

When traveling long distances, tell patients to frequently exercise the calf muscles, take short walks, and maintain hydration with nonalcoholic, noncaffeinated beverages. For those at high risk for VTE who are planning a long trip, recommend properly fitted, knee-high graduated compression stockings during travel to decrease edema and VTE risk. Aspirin or anticoagulant use is not suggested for long-distance travelers. Teach the patient and caregiver to contact ERS for signs and symptoms of PE, such as sudden onset of dyspnea, tachypnea, and pleuritic chest pain.

Review drug dosage, actions, and side effects, the need for routine blood tests, and what symptoms need immediate medical attention (Table 41.15). Devices are available for home monitoring of INR. Teach patients taking LMWH or fondaparinux and their caregivers how to give the drug subcutaneously. A well-balanced diet is important. Teach patients taking warfarin to follow a consistent diet of foods containing vitamin K. They should avoid any supplements containing vitamin K (e.g., vitamins, green tea). Tell the patient to avoid excess amounts of vitamin E and alcohol. Encourage proper hydration to prevent hypercoagulability of the blood, which may occur with dehydration.

The overweight patient needs implement a diet plan and increase physical activity to achieve and maintain desired weight. Exercise may help patients with VTE and PTS and improves the patient's quality of life. Help the patient develop an exercise program with an emphasis on leg strength training and aerobic activity.

Graduated compression stockings reduce swelling in patients with a proximal VTE.[15] Alternatively, IPCs may be used for patients with significant edema and moderate to severe PTS.

The long-term use of graduated compression stockings may not prevent PTS development.

Evaluation

The expected outcomes are that the patient with VTE will have:

- Minimal to no pain
- Intact skin
- Increased knowledge of disorder and treatment plan
- No signs of hemorrhage or occult bleeding

VARICOSE VEINS

Varicose veins, or *varicosities,* are dilated (3 mm or larger in diameter), tortuous superficial veins. They are often found in the saphenous vein system. Varicosities may be small and harmless or large and bulging. *Primary varicose veins* (idiopathic) due to a weakness of the vein walls are more common in women. *Secondary varicose veins* result from direct injury, a previous VTE, or excessive vein distention. Secondary varicose veins may occur in the esophagus (esophageal varices), vulva, spermatic cords (varicoceles), and anorectal area (hemorrhoids), and as abnormal arteriovenous (AV) connections.

Congenital varicose veins result from chromosomal defects that cause abnormal development of the venous system. *Reticular veins* are smaller varicose veins that appear flat, less tortuous, and blue-green in color. *Telangiectasias* (often called spider veins) are small visible vessels (generally less than 1 mm in diameter) that appear bluish black, purple, or red.

Etiology and Pathophysiology

Superficial veins in the lower extremities become dilated and tortuous in response to backward (retrograde) blood flow and increased venous pressure. Risk factors include family history of chronic venous disease, weak vein structure, female gender, tobacco use, increasing age, obesity, multiparity, history of VTE, venous obstruction resulting from extrinsic pressure by tumors, thrombophilia, phlebitis, previous leg injury, and occupations that require prolonged standing or sitting.

In primary varicose veins, weak vein walls allow the vein valve ring to enlarge, so the leaflets no longer fit together properly (incompetent). Incompetent vein valves allow backward blood flow, particularly when the patient is standing. This results in increased venous pressure and further venous distention. High pressure in the superficial veins can be caused by vein valve dysfunction in the deep veins or perforator veins (veins that perforate the deep fascia of muscles to connect the superficial veins to the deep veins).

Clinical Manifestations and Complications

Discomfort from varicose veins varies among people. It tends to be worse after episodes of superficial vein thrombosis. Symptoms affect women more often than men. The most common symptoms include a heavy, achy feeling or pain after prolonged standing or sitting. Walking or limb elevation relieves pain. Some patients feel pressure or an itchy, burning, tingling, throbbing, or cramp-like leg sensation. Swelling, restless or tired legs, fatigue, and nocturnal leg cramps may occur.

Superficial venous thrombosis is the most frequent complication of varicose veins. It may occur spontaneously or after trauma, surgery, or pregnancy. Rare complications include rupture of the varicose veins resulting in external bleeding and skin ulcerations.

Diagnostic Studies and Interprofessional Care

Superficial varicose veins often can be diagnosed by physical assessment. Duplex ultrasound imaging is the gold standard to evaluate venous anatomy, valvular competence, and venous obstruction.[17] Conservative treatment involves rest with limb elevation; graduated compression stockings; leg strengthening exercise, such as walking; and weight loss, if indicated.

Drug Therapy

Venoactive drugs work by stimulating release of chemicals within the vein walls to strengthen the circulation and reduce inflammation and edema. Several natural and synthetic venoactive agents have been used to treat varicose veins and advanced chronic venous disease. These include micronized purified flavonoid fraction, rutosides (e.g., horse chestnut seed extract [*Aesculus hippocastanum*]), proanthocyanidins (from grapes and apples), and *Ruscus* (butcher's broom).[16]

Therapeutic benefits of venoactive drugs include pain relief, edema reduction, and decreased leg cramping and restless legs. These drugs are widely used in Europe. They are not approved by the FDA. However, many are available over the counter as diet or herbal supplements.

DRUG ALERT

***Horse Chestnut Seed Extract* (Aesculus hippocastanum)**

- May interact with lithium and antidiabetic, antiplatelet, and anticoagulant drugs.
- Should not be taken by persons with liver or kidney disease or with a latex allergy.

Interventional and Surgical Therapies

Sclerotherapy involves the direct IV injection of a liquid or foam sclerosing substance (e.g., hypertonic saline, polidocanol, glycerin) that chemically ablates (destroys) the treated veins. Sclerotherapy can be used on telangiectasias, perforator veins, reticular veins, smaller varicose veins, and venous malformations (Fig. 41.12). This procedure is done in an office setting and causes minimal discomfort.

The most common complications of sclerotherapy are residual pigmentation, matting (new telangiectasias develop in the area), thrombophlebitis, and ulcers.[17] After injection, a graduated compression stocking or bandage is worn. Patients should not travel long distances during the first week after sclerotherapy to minimize the risk for a VTE.

Fig. 41.12 (A) Lateral aspect of varicose veins before treatment. (B) Lateral aspect of varicose veins 2 years after initial treatment with sclerotherapy. (From Goldman MP, Guex JJ, Weiss RA: *Sclerotherapy: treatment of varicose and telangiectatic leg veins,* ed 5, Philadelphia, 2011, Mosby.)

Other noninvasive options include transcutaneous laser therapy for telangiectasias and high-intensity pulsed-light therapy for reticular veins. Transcutaneous laser or light therapy is used for patients in whom sclerotherapy is contraindicated or has been ineffective. Vascular lasers work by heating the hemoglobin in the vessels, resulting in vessel sclerosis. Complications of these therapies include pain, blistering, hyperpigmentation, and superficial erosions.

A minimally invasive treatment option for saphenous vein reflux is endovenous ablation using thermal energy from radiofrequency or laser therapy. The HCP inserts a catheter into the vein to heat the vein wall, which then causes the vein to collapse. Complications include bruising, skin burns, hyperpigmentation, infection, paresthesia, superficial or deep vein thrombosis, and PE. Graduated compression stockings or bandages are worn afterwards. Endovenous thermal ablation may be done in combination with surgical ligation or phlebectomy.

Surgical intervention is needed for recurrent superficial venous thrombosis or when symptoms cannot be controlled with other therapy. The traditional surgical intervention involves ligation of the entire vein (usually the greater saphenous vein) and removal of its incompetent branches. An alternative but time-consuming technique is *ambulatory phlebectomy*. This involves pulling the varicosity through a "stab" incision followed by excision of the vein. *Transilluminated powered phlebectomy* involves the use of a tissue resector to destroy clusters of varicosities and removes the pieces via aspiration. Complications include bleeding, bruising, and infection.

❖ NURSING MANAGEMENT: VARICOSE VEINS

Prevention is a key factor related to varicose veins. Tell the patient to avoid sitting or standing for long periods, maintain ideal body weight, take precautions against injury to the extremities, avoid wearing constrictive clothing, and walk daily.

After vein ligation surgery, encourage the patient to deep breathe, which promotes venous return. Check the extremities regularly for color, movement, sensation, temperature, edema, and quality of pedal pulses. Some bruising and discoloration are normal. Elevate the legs 15 degrees to limit edema. Remove graduated compression stockings or bandages every 8 hours for short periods and then reapply them.

Long-term management is directed toward improving circulation and appearance, relieving discomfort, and avoiding complications. Varicosities can recur in other veins after surgery. Teach the patient the proper use and care of custom-fitted graduated compression stockings. The patient should apply stockings in bed before rising in the morning.

Emphasize the importance of periodic positioning of the legs above the heart. The overweight patient may need help with weight loss. The patient with a job that requires long periods of standing or sitting needs to frequently flex and extend the hips, legs, and ankles and change positions.

CHRONIC VENOUS INSUFFICIENCY AND VENOUS LEG ULCERS

Chronic venous insufficiency (CVI) describes abnormalities of the venous system that result in advanced signs and symptoms, such as edema, skin changes, and/or venous leg ulcers.[17] CVI can lead to *venous leg ulcers* (also called *venous stasis ulcers* or *varicose ulcers*). Although CVI and venous leg ulcers are not life-threatening diseases, they are painful, slow to heal, debilitating, and costly conditions that adversely affect patients' quality of life. They are a common problem in older adults.

Etiology and Pathophysiology

Both long-standing primary varicose veins and PTS can progress to CVI. *Ambulatory venous hypertension* causes serous fluid and RBCs to leak from the capillaries and venules into the tissue. This causes edema and chronic inflammatory changes. Enzymes in the tissue eventually break down RBCs. This releases *hemosiderin,* which causes a brownish skin discoloration. Over time, fibrous tissue replaces the skin and subcutaneous tissue around the ankle. This results in thick, hardened, contracted skin. Although the causes of CVI are known, the exact pathophysiology of venous leg ulcers is unknown.

Clinical Manifestations and Complications

In patients with CVI, the skin of the lower leg is leathery, with a characteristic brownish or "brawny" appearance from the hemosiderin deposition. Edema usually has been persistent for a prolonged period. Eczema with itching and scratching is often present (see Table 41.1).

Venous ulcers classically occur above the medial malleolus (Fig. 41.13). The ulcer is often quite painful, particularly when edema or infection is present. Pain may be worse when the leg is in a dependent position. If the venous ulcer is untreated, the wound becomes wider and deeper, increasing the risk for infection.

Interprofessional and Nursing Care

Compression is essential for venous ulcer healing and preventing venous ulcer recurrence. A variety of options are available for compression therapy. These include custom-fitted graduated compression stockings, elastic tubular support bandages, a Velcro wrap (CircAid), IPCs, and multilayer (3 or 4) bandage systems (e.g., Profore). Evaluate the patient when choosing a compression method. Before starting compression therapy, assess the arterial status to make sure that PAD is not present. An ABI of 0.4 or less suggests severe PAD, and the patient should not have any type of compression therapy.[3] Show how to correctly apply the compression therapy and have the patient "show back" the skill. Stockings should be worn daily to prevent recurrent leg ulcers. Tell the patient to replace stockings every 4 to 6 months.

Discuss activity guidelines and proper limb positioning. Tell patients with CVI to avoid standing or sitting for long periods, which decreases blood return from the lower extremities. Teach patients to frequently elevate their legs above the level of the heart to reduce edema. Encourage patients to begin a daily walking program once an ulcer heals. Tell the patient and caregiver to avoid trauma to the limbs. Teach proper foot and leg care to avoid more skin trauma.

Moist environment dressings are the basis of wound care. A variety of dressings are available. These include transparent film dressings, hydrocolloids, hydrogels, foams, alginates, gauze, and combination dressings. Dressing decisions should be based on wound characteristics, cost, best evidence, and clinician judgment. Chapter 12 and Table 12.14 discuss dressings.

Evaluate the patient's nutrition status. A balanced diet with adequate protein, calories, and nutrients is essential. Foods high in protein (e.g., meat, beans, cheese, tofu), vitamin A (green leafy vegetables), vitamin C (citrus fruits, tomatoes, cantaloupe), and zinc (meat, seafood) are most important for healing. For patients with diabetes, maintaining normal blood glucose levels aids the healing process.

Fig. 41.13 Venous leg ulcer. (From Quick C, Biers SM: *Essential surgery: problems, diagnosis, and management*, St Louis, 2020, Elsevier.)

Though venous leg ulcers are colonized by bacteria, routine use of antibiotics is not indicated. Signs of infection include change in quantity, color, or odor of the drainage; pus; redness of the wound edges; change in sensation around the wound; and warmth around the wound. There may be increased local pain, edema, or both; dark-colored granulation tissue; induration around the wound; delayed healing; and cellulitis. If signs of infection occur, obtain a wound culture. Culture results guide antibiotic therapy. The usual treatment for infection is wound debridement, wound excision, and systemic antibiotics.

If the ulcer does not heal with conservative therapy, drug therapy should be considered. Pentoxifylline is recommended with compression therapy to improve healing. Pentoxifylline minimizes WBC activation and adhesion to capillary endothelium and decreases oxidative stress.

Other treatments are considered for large venous leg ulcers that do not respond to standard therapy after 4 to 6 weeks. These include coverage with a skin replacement or substitute, such as split-thickness skin grafts or artificial bioengineered skin. Chapter 26 discusses skin grafting. Although grafts help with healing, they do not replace the need for lifelong compression therapy.

Patients with CVI have dry, flaky, itchy skin. Daily moisturizing decreases itching and prevents skin cracking. Contact dermatitis may result from contact with sensitizing products. These include such as topical antimicrobial agents (e.g., gentamicin); additives in bandages or dressings (e.g., adhesives); ointments containing lanolin, alcohols, or benzocaine; and over-the-counter creams or lotions with fragrance or preservatives. Assess wounds for signs of infection with each dressing change (Table 41.16).

TABLE 41.16 NURSING MANAGEMENT

Caring for the Patient With Chronic Venous Insufficiency

- Assess the patient for increases in edema, eczema, and venous leg ulcers.
- Assess diet and nutrition status and make referrals as needed.
- Assess for the use of venoactive diet supplements or herbs that may adversely affect co-morbid conditions and/or prescription drugs.
- Choose best options for compression therapy and wound care.
- Give prescribed analgesics, antibiotics, or other drugs.
- Apply compression therapy.
- Provide wound care for venous leg ulcers.
- Evaluate for the effectiveness of therapies and need for alternative approaches.
- Teach patient and caregiver about the manifestations, complications, and treatment of venous insufficiency.
- Supervise the AP:
  - Aid patients in elevating legs to reduce edema and pain.
  - Apply graduated compression stockings.
- Collaborate with the dietitian:
  - Assess diet and nutrition status.
  - Provide diet education as needed.

Case Study

Peripheral Artery Disease

(© IPGGutenbergUKLtd/iStock/Thinkstock.)

Patient Profile

S.J., a 73-year-old man, is admitted to the hospital with rest pain in both legs and a nonhealing ulcer of the big toe on the right foot.

Subjective Data

- History of a MI, stroke, hypertension, HF, type 1 diabetes
- Underwent a left femoral-popliteal bypass 5 years ago
- Has a 45-pack-year history of tobacco use
- Has been using insulin for 30 years
- Reports sudden, intense increase in right foot pain for past 2 hr
- Has slept in recliner with right leg in dependent position for several months to decrease leg pain

Current Medications

- Furosemide (Lasix) 40 mg/day PO
- Isosorbide dinitrate/hydralazine hydrochloride (BiDil) 1 tablet every 8 hr
- Aspart (NovoLog) insulin with meals (sliding scale)
- Glargine insulin 50 units/day subcutaneously
- Diltiazem sustained release (Cardizem LA) 240 mg/day PO
- Aspirin 325 mg/day PO
- Fish oil daily (self-prescribed)

Objective Data

Physical Assessment

- BP 148/92 mm Hg, irregular apical HR 90/min, respiratory rate 22/min, temp 97.9°F (36.6°C)
- Alert and oriented, anxious, with no apparent physical or mental deficits from stroke
- Has 1+ right femoral pulse, popliteal pulse by Doppler only, posterior tibial pulse by Doppler only, and dorsalis pedis pulse absent (not palpable or present by Doppler). Left leg pulses are 1+
- Right leg ABI: 0.20. Left leg ABI: 0.68
- Has a 2-cm necrotic ulcer on tip of right big toe
- Has thickened toenails. Shiny, thin skin on legs. No hair on both lower legs
- Right foot is very cool, pale, and mottled in color with decreased sensation
- No peripheral edema
- Bedside glucose measurement 298 mg/dL (last meal 4 hr before admission)

Discussion Questions

1. ***Recognize***: What risk factors do you identify that led to S.J. having PAD?
2. ***Analyze***: What are the important findings from S.J.'s assessment?
3. ***Plan***: What treatment options are possible?
4. ***Prioritize***: What is the important thing the team can do for S.J.?
5. ***Act***: What role do APs have in providing care?
6. ***Evaluate***: What do you need to continually monitor?
7. ***Safety***: What safety precautions should we consider?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A 50-year-old woman who weighs 95 kg has a history of high blood pressure, high sodium intake, tobacco use, and sedentary lifestyle. Which is the *most important* risk factor for peripheral artery disease (PAD) to address in the nursing plan of care?
   - **a.** Salt intake
   - **b.** Tobacco use
   - **c.** Excess weight
   - **d.** Sedentary lifestyle
2. Which information would the nurse include when explaining the cause of rest pain with PAD?
   - **a.** Vasospasm of cutaneous arteries in the feet
   - **b.** Decrease in blood flow to the nerves of the feet
   - **c.** Increase in retrograde venous perfusion to the lower legs
   - **d.** Constriction in blood flow to leg muscles during exercise
3. A patient with infective endocarditis develops sudden left leg pain with pallor, paresthesia, and a loss of peripheral pulses. Which action would the nurse take *first*?
   - **a.** Notify the HCP of the change in perfusion.
   - **b.** Start anticoagulant therapy with IV heparin.
   - **c.** Elevate the leg to improve the venous return.
   - **d.** Position the patient in reverse Trendelenburg.
4. Which clinical manifestations can the nurse expect to see in both patients with Buerger disease and patients with Raynaud phenomenon? *(select all that apply)*
   - **a.** Intermittent low-grade fevers
   - **b.** Sensitivity to cold temperatures
   - **c.** Gangrenous ulcers on fingertips
   - **d.** Color changes of fingers and toes
   - **e.** Episodes of superficial vein thrombosis
5. A patient is admitted to the hospital with a diagnosis of abdominal aortic aneurysm. Which signs and symptoms would suggest that the aneurysm has ruptured?
   - **a.** Rapid onset of shortness of breath and hemoptysis
   - **b.** Sudden low back pain and bruising along the flank
   - **c.** Patchy blue mottling on feet and toes and rest pain
   - **d.** Gradually increasing substernal chest pain and diaphoresis
6. Which nursing interventions are the *priority* 8 hours after an abdominal aortic aneurysm repair?
   - **a.** Assessing nutrition status and diet preferences
   - **b.** Starting IV heparin and monitoring anticoagulation
   - **c.** Administering IV fluids and watching kidney function
   - **d.** Elevating the legs and applying compression stockings
7. Which goal is the *first* priority of interprofessional care for a patient with a suspected acute aortic dissection?
   - **a.** Reduce anxiety
   - **b.** Monitor chest pain
   - **c.** Control blood pressure
   - **d.** Increase myocardial contractility

8. Which patient is at *highest* risk for venous thromboembolism (VTE)?
   - **a.** a. A 62-year-old man with spider veins who is having arthroscopic knee surgery
   - **b.** b. A 32-year-old woman who smokes, takes oral contraceptives, and is planning a long flight
   - **c.** A 26-year-old woman who is 3 days postpartum and received maintenance IV fluids for 12 hours during her labor
   - **d.** d. An active 72-year-old man at home recovering from transurethral resection of the prostate for benign prostatic hyperplasia
9. Which clinical findings would the nurse expect in a person with an acute lower extremity VTE? *(select all that apply)*
   - **a.** Pallor and coolness of foot and calf
   - **b.** Mild to moderate calf pain and tenderness
   - **c.** Grossly decreased or absent pedal pulses
   - **d.** Unilateral edema and induration of the thigh
   - **e.** Palpable cord along a superficial varicose vein
10. Which treatment would the nurse anticipate for an otherwise healthy person with an initial VTE?
    - **a.** IV argatroban as an inpatient
    - **b.** IV unfractionated heparin as an inpatient
    - **c.** Subcutaneous unfractionated heparin as an outpatient
    - **d.** Subcutaneous low-molecular-weight heparin as an outpatient
11. Which instruction is a *key* aspect of teaching for the patient on anticoagulant therapy?
    - **a.** Monitor for and report any signs of bleeding.
    - **b.** Do not take acetaminophen (Tylenol) for a headache.
    - **c.** Decrease your dietary intake of foods containing vitamin K.
    - **d.** Arrange to have blood drawn twice a week to check drug effects.
12. The nurse is planning care and teaching for a patient with venous leg ulcers. Which patient action is the *most* important in healing and control of this condition?
    - **a.** Following activity guidelines.
    - **b.** Using moist environment dressings.
    - **c.** Taking horse chestnut seed extract daily.
    - **d.** Applying graduated compression stockings.

1. b; 2. b; 3. a; 4. b, c, d; 5. b; 6. c; 7. c; 8. b; 9. b, d; 10. d; 11. a; 12. d.

Shock, Sepsis, and Multiple Organ Dysfunction Syndrome

Helen Miley

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Fluid and Electrolytes
Gas Exchange
Inflammation
Perfusion

LEARNING OUTCOMES

1. Relate the pathophysiology to the clinical manifestations of the different types of shock.
2. Compare the effects of shock, sepsis, systemic inflammatory response syndrome, and multiple organ dysfunction syndrome (MODS) on the major body systems.
3. Compare the interprofessional care, drug therapy, and nursing management of patients with different types of shock.
4. Describe the interprofessional care and nursing management of a patient with MODS.

KEY TERMS

cardiogenic shock
hypovolemic shock
multiple organ dysfunction syndrome (MODS)
neurogenic shock
obstructive shock
sepsis
septic shock
shock
systemic inflammatory response syndrome (SIRS)

Shock, systemic inflammatory response syndrome (SIRS), sepsis, and multiple organ dysfunction syndrome (MODS) are serious and interrelated problems (Fig. 42.1). **Shock** is a syndrome characterized by decreased tissue perfusion and impaired cellular metabolism. This results in an imbalance between the supply of and demand for O_2 and nutrients. The exchange of O_2 and nutrients at the cellular level is essential to life. When cells are hypoperfused, the demand for O_2 and nutrients exceeds the supply at the microcirculatory level. Ischemia can occur, leading to cell injury and death. Thus shock is life-threatening. This chapter gives an overview of the different types of shock, SIRS, sepsis, and MODS and their related management.

SHOCK

Classification of Shock

The 4 main categories of shock are cardiogenic, hypovolemic, distributive, and obstructive (Table 42.1). Although the cause, initial presentation, and management vary for each type, the physiologic responses of cells to hypoperfusion are similar.

Cardiogenic Shock

Cardiogenic shock occurs when either systolic or diastolic dysfunction of the heart's pumping action results in reduced cardiac output (CO), stroke volume (SV), and BP. These changes compromise myocardial perfusion, further depress myocardial function, and decrease CO and perfusion. Causes of cardiogenic shock are shown in Table 42.1. It is the leading cause of death from acute myocardial infarction (MI). Although the in-hospital mortality has improved due to aggressive intervention, the 6- to 12-month mortality remains 50%.[1]

Fig. 42.2 shows the pathophysiology of cardiogenic shock. The heart's inability to pump the blood forward is called *systolic dysfunction.* This inability results in a low CO (less than 4 L/min) and *cardiac index* (less than 2.5 L/min/m^2). Systolic dysfunction primarily affects the left ventricle because systolic pressure is greater on the left side of the heart. The most common cause of systolic dysfunction is acute MI. When systolic dysfunction affects the right side of the heart, blood flow through the pulmonary circulation is reduced. Decreased filling of the heart results in decreased SV. Table 42.1 lists causes of diastolic dysfunction.

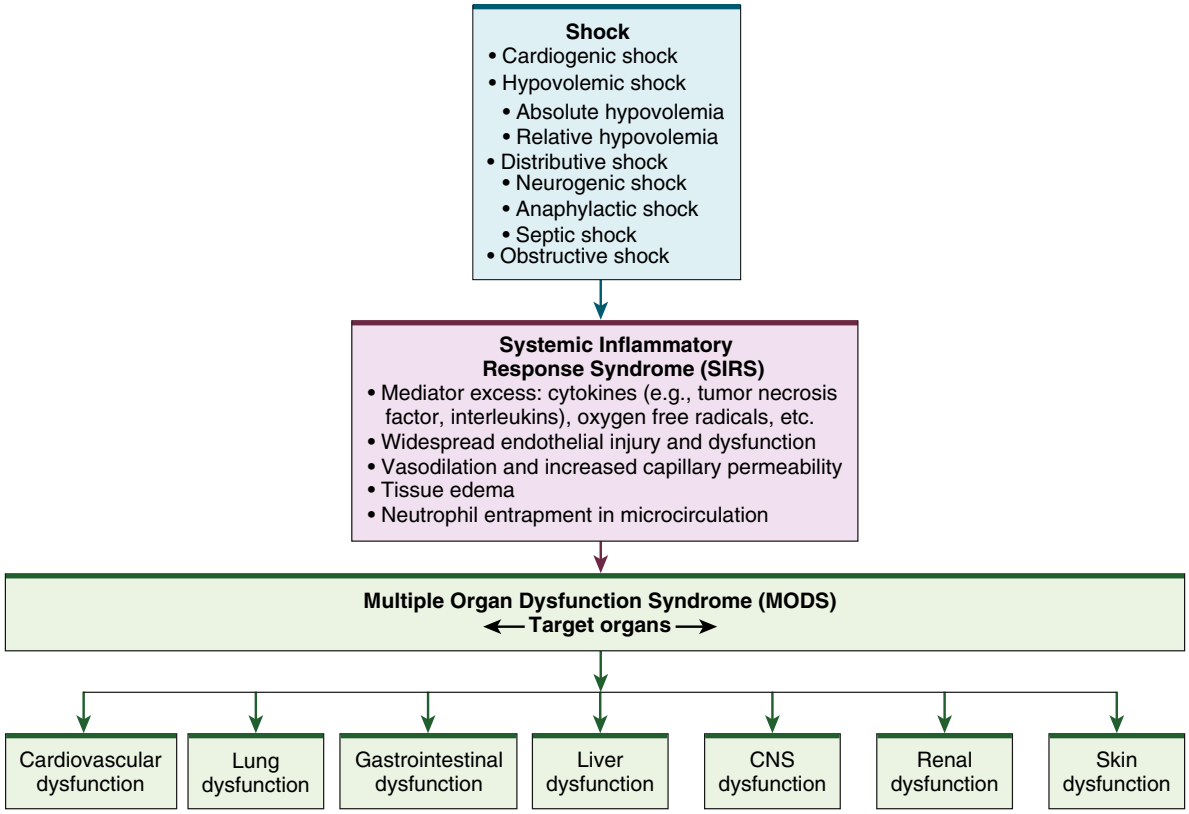

Fig. 42.1 Relationship of shock, systemic inflammatory response syndrome, and multiple organ dysfunction syndrome.

TABLE 42.1 Classification of Shock States

Types and Causes	Associated Conditions
Cardiogenic Shock	
• Diastolic dysfunction: inability of the heart to fill	Cardiac tamponade, ventricular hypertrophy, cardiomyopathy
• Dysrhythmias	Bradydysrhythmias, tachydysrhythmias
• Structural factors	Valvular stenosis or regurgitation, ventricular septal rupture, tension pneumothorax
• Systolic dysfunction: inability of the heart to pump blood forward	MI, cardiomyopathy, blunt cardiac injury, severe systemic or pulmonary hypertension, myocardial depression from metabolic problems
Hypovolemic Shock	
Absolute Hypovolemia	
• External loss of whole blood	Hemorrhage from trauma, surgery, GI bleeding
• Loss of other body fluids	Vomiting, diarrhea, excessive diuresis, diabetes insipidus, diabetes
Relative Hypovolemia	
• Fluid shifts	Burn injuries, ascites
• Internal bleeding	Fracture of long bones, ruptured spleen, hemothorax, severe pancreatitis
• Massive vasodilation	Sepsis
• Pooling of blood or fluids	Bowel obstruction

Types and Causes	Associated Conditions
Distributive Shock	
Anaphylactic Shock	
• Hypersensitivity (allergic) reaction to a sensitizing substance	Contrast media, blood or blood products, drugs, insect bites, anesthetic agents, food or food additives, vaccines, environmental agents, latex
Neurogenic Shock	
• Hemodynamic consequence of spinal cord injury and/or disease at or above T5	Severe pain, drugs, hypoglycemia, injury
• Spinal anesthesia	
• Vasomotor center depression	
Septic Shock	
• At-risk patients	Older adults, patients with chronic diseases (e.g., diabetes, chronic kidney disease, HF), patients receiving immunosuppressive therapy or who are malnourished or debilitated
• Infection	Pneumonia, peritonitis, urinary tract, invasive procedures, indwelling lines and catheters
Obstructive Shock	
• Physical obstruction impeding the filling or outflow of blood resulting in reduced CO	Cardiac tamponade, tension pneumothorax, superior vena cava syndrome, abdominal compartment syndrome, pulmonary embolism

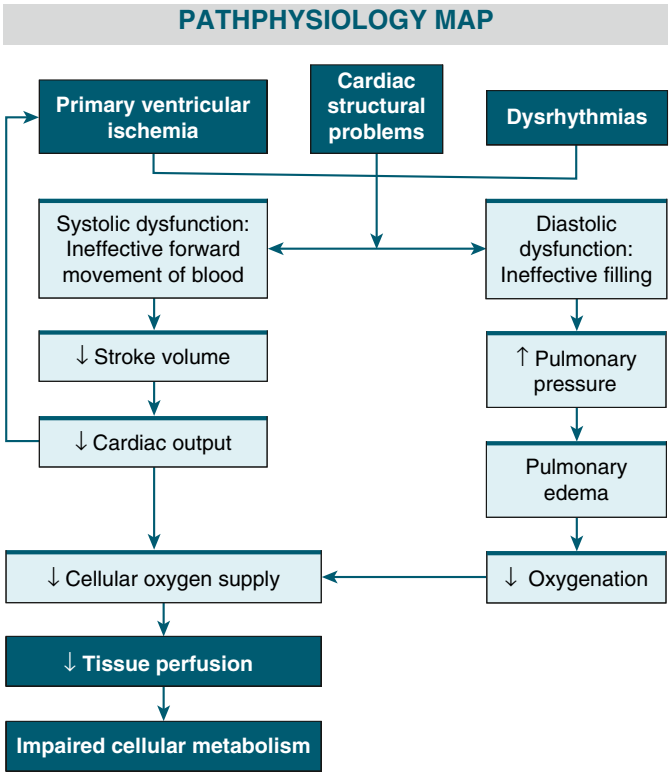

Fig. 42.2 The pathophysiology of cardiogenic shock.

The early presentation of a patient with cardiogenic shock is similar to that of a patient with acute decompensated heart failure (HF) (see Chapter 38). The patient may have tachycardia and hypotension. Pulse pressure may be narrowed due to the heart's inability to pump blood forward during systole and increased volume during diastole. An increase in systemic vascular resistance (SVR) increases the workload of the heart. This increases myocardial O_2 consumption.

On assessment, the patient is tachypneic. There are crackles on auscultation of breath sounds because of pulmonary congestion. The hemodynamic profile shows an increase in the pulmonary artery (PA) wedge pressure (PAWP), stroke volume variation (SVV), and pulmonary vascular resistance.

Signs of peripheral hypoperfusion (e.g., cyanosis, pallor, weak peripheral pulses, cool and clammy skin, delayed capillary refill) occur. Decreased renal blood flow results in sodium and water retention and decreased urine output. Anxiety, confusion, and agitation may develop with impaired cerebral perfusion. Tables 42.2 and 42.3 describe the laboratory findings and clinical presentation of a patient with cardiogenic shock.

Hypovolemic Shock

Hypovolemic shock occurs from inadequate fluid volume in the intravascular space to support adequate perfusion (Table 42.1).[2] The volume loss may be either an absolute or a relative volume loss. *Absolute hypovolemia* results when fluid is lost through hemorrhage, gastrointestinal (GI) loss (e.g., vomiting, diarrhea), fistula drainage, diabetes insipidus, or diuresis. In *relative hypovolemia,* fluid volume moves out of the vascular space into the extravascular space (e.g., intracavitary space). We call this type of fluid shift *third spacing.* One example of relative volume loss is fluid leaking from the vascular space to the interstitial space from increased capillary permeability, as seen in burns (see Chapter 26).

Whether the intravascular volume loss is absolute or relative, the consequences are similar. The reduced intravascular volume results in a decreased venous return to the heart, decreased preload, decreased SV, and decreased CO. A cascade of events results in decreased tissue perfusion and impaired cellular metabolism, the hallmarks of shock (Fig. 42.3).

The patient's response to acute volume loss depends on several factors, including extent of injury, age, and general state of health. The clinical presentation of hypovolemic shock is consistent (Table 42.3). An overall assessment of physiologic reserves may indicate the patient's ability to compensate. A patient may compensate for a loss of up to 15% of the total blood volume (approximately 750 mL). Further loss of volume (15% to 30%) results in a sympathetic nervous system (SNS)-mediated response.[2] This response results in an increase in heart rate, CO, and respiratory rate and depth. The decreased circulating blood volume causes decreases in SV, central venous pressure (CVP), and PAWP.

The patient may appear anxious. Urine output begins to decrease. If hypovolemia is quickly corrected by crystalloid fluid replacement, tissue dysfunction is generally reversible. If volume loss is greater than 30%, compensatory mechanisms may fail and immediate replacement with blood products should be started. Loss of autoregulation in the microcirculation and irreversible tissue destruction occur with loss of more than 40% of the total blood volume. Common laboratory studies and assessments that are done include serial measurements of hemoglobin and hematocrit levels, electrolytes, lactate, blood gases, mixed central venous O_2 saturation (SvO_2), and hourly urine outputs (Table 42.2).

Distributive Shock

Distributive shock has many causes. It is a condition of relative hypovolemia due to intravascular volume redistribution from loss of vascular tone or disordered permeability. The 3 subsets are neurogenic, anaphylactic, and septic.[3]

Neurogenic shock. **Neurogenic shock** is a hemodynamic phenomenon that can occur within 30 minutes of a spinal cord injury and last up to 6 weeks. Neurogenic shock related to spinal cord injuries is generally associated with a cervical or high thoracic injury. The injury results in a massive vasodilation without compensation because of the loss of SNS vasoconstrictor tone.[4] This massive vasodilation leads to a pooling of blood in the blood vessels, tissue hypoperfusion, and impaired cellular metabolism (Fig. 42.4).

In addition to spinal cord injury, spinal anesthesia can block transmission of impulses from the SNS. Depression of the vasomotor center of the medulla from drugs (e.g., opioids, benzodiazepines) can decrease vasoconstrictor tone of the peripheral blood vessels, resulting in neurogenic shock (Table 42.1).

The classic manifestations are hypotension (from the massive vasodilation) and bradycardia (from unopposed parasympathetic stimulation).[4] The patient may not be able to regulate

TABLE 42.2 Diagnostic Studies

Shock

Study	Finding	Significance of Finding
Arterial blood gases	Respiratory alkalosis	Found in early shock due to hyperventilation
	Metabolic acidosis	Occurs later in shock when lactate accumulates in blood from anaerobic metabolism
Base deficit	>–6	Acid production due to hypoxia
Blood cultures	Growth of organisms	May grow organisms in patients who are in septic shock
BUN	↑	Impaired kidney function caused by hypoperfusion from severe vasoconstriction, or occurs due to cell catabolism (e.g., trauma, infection)
Creatine kinase	↑	Trauma, MI in response to cellular damage and/or hypoxia
Creatinine	↑	Impaired kidney function caused by hypoperfusion because of severe vasoconstriction
DIC screen		Acute DIC can develop within hours to days after an initial assault on the body (e.g., shock)
• D-dimer	↑	
• Fibrin split products (FSPs)	↑	
• Fibrinogen level	↓	
• INR	↑	
• Platelet count	↓	
• PTT and PT	↑	
• Thrombin time	↑	
Glucose	↑	Found in early shock because of release of liver glycogen stores in response to sympathetic nervous system stimulation and cortisol. Insulin insensitivity develops
	↓	Depleted glycogen stores with liver dysfunction possible as shock progresses
Electrolytes (serum)		
• Sodium	↑	Found in early shock because of ↑ secretion of aldosterone, causing renal retention of sodium
	↓	May be iatrogenic if excess hypotonic fluid is given after fluid loss
• Potassium	↑	Results when dead cells release potassium. Occurs in acute kidney injury and acidosis
	↓	Found in early shock because of ↑ secretion of aldosterone, causing renal excretion of potassium
Lactate level	↑	Usually ↑ once significant hypoperfusion and impaired O_2 use at the cellular level have occurred. By-product of anaerobic metabolism
Liver enzymes (ALT, AST, GGT)	↑	Liver cell destruction in progressive stage of shock
Procalcitonin (PCT)	↑	Biomarker released in response to bacterial infections
RBC count, hematocrit, hemoglobin	Normal	Remains within normal limits in shock because of relative hypovolemia and pump failure and in hemorrhagic shock before fluid resuscitation
	↓	Hemorrhagic shock after fluid resuscitation when fluids other than blood are used
	↑	Nonhemorrhagic shock caused by actual hypovolemia and hemoconcentration
Troponin	↑	MI
White blood cell count	↑, ↓	Infection, septic shock

body temperature. Combined with massive vasodilation, the inability to regulate temperature promotes heat loss. At first, the patient's skin is warm due to the massive vasodilation. As the heat disperses, the patient is at risk for hypothermia. Later, the patient's skin may be cool or warm depending on the ambient temperature (*poikilothermia,* taking on the temperature of the environment). The skin is usually dry. Tables 42.2 and 42.3 further describe the laboratory findings and clinical presentation of a patient with neurogenic shock.

Although spinal shock and neurogenic shock often occur in the same patient, they are not the same disorder. *Spinal shock* is a transient condition that is present after an acute spinal cord injury (see Chapter 65). The patient with spinal shock has an absence of all voluntary and reflex neurologic activity below the level of the injury.

Anaphylactic shock. *Anaphylactic shock* is an acute, life-threatening hypersensitivity (allergic) reaction to a sensitizing substance (e.g., drug, chemical, vaccine, food, insect venom).[5] The reaction quickly causes massive vasodilation, release of vasoactive mediators, and an increase in capillary permeability. As capillary permeability increases, fluid leaks from the vascular space into the interstitial space.

Anaphylactic shock can lead to respiratory distress due to laryngeal edema or severe bronchospasm and circulatory failure from the massive vasodilation. The patient has a sudden onset of symptoms, including dizziness, chest pain, incontinence, swelling of the lips and tongue, wheezing, and stridor. Skin changes include flushing, pruritus, urticaria, and angioedema. The patient may be anxious and confused and have a sense of impending doom.

A patient can have a severe allergic reaction, leading to anaphylactic shock, after contact, inhalation, ingestion, or injection with an antigen (allergen) to which the person has previously been sensitized (Table 42.1). IV administration of the antigen (allergen) is the route most likely to cause anaphylaxis. However, oral, topical, and inhalation routes can cause

PATHPHYSIOLOGY MAP

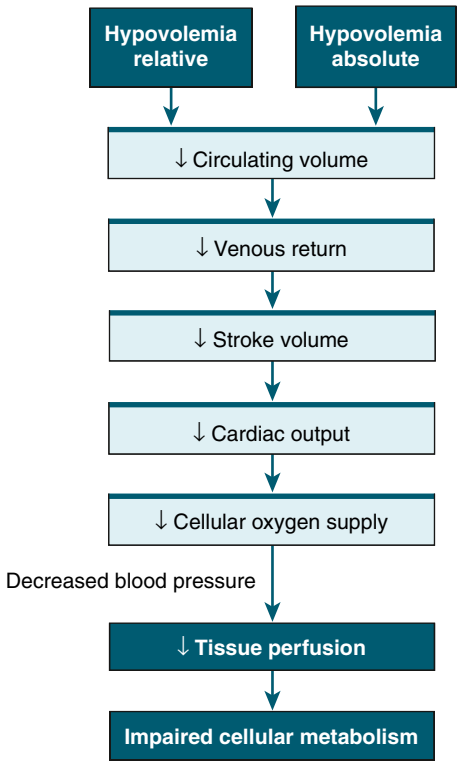

Fig. 42.3 The pathophysiology of hypovolemic shock.

PATHOPHYSIOLOGY MAP

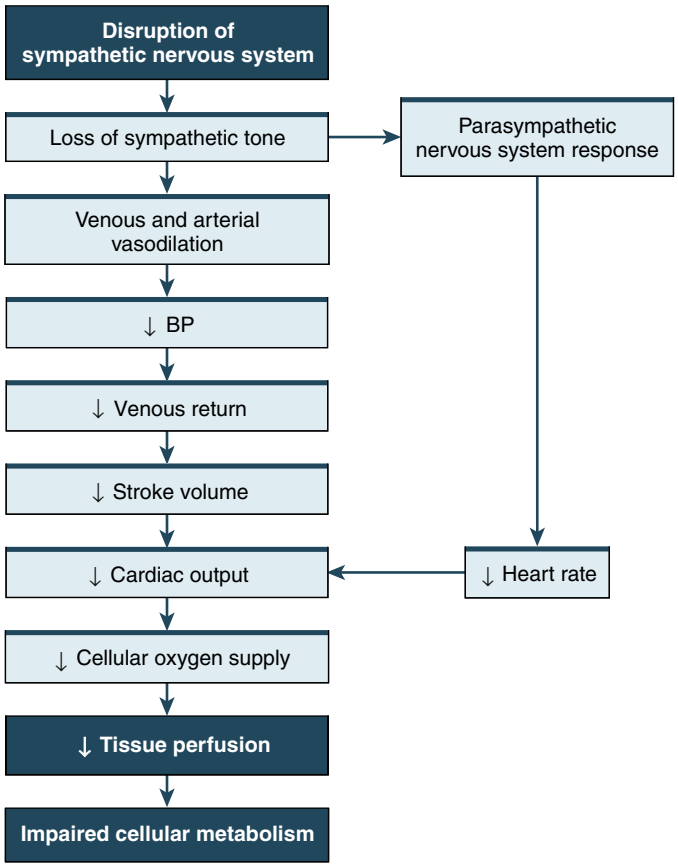

Fig. 42.4 The pathophysiology of neurogenic shock.

TABLE 42.4 Diagnostic Criteria

Sepsis

Infection, documented or suspected, and some of the following:

General Variables
- Altered mental status
- Fever (temperature >100.9°F [38.3°C])
- Heart rate >90 beats/min
- Hyperglycemia (blood glucose >140 mg/dL) in the absence of diabetes
- Hypothermia (core temperature <97.0°F [36°C])
- SBP ≤100 mm Hg
- Significant edema or positive fluid balance (>20 mL/kg over 24 hr)
- Tachypnea (respiratory rate ≥22/min)

Inflammatory Variables
- ↑ C-reactive protein
- Leukocytosis (WBC count >12,000/μL)
- Leukopenia (WBC count <4000/μL)
- Normal WBC count with >10% immature forms (bands)
- ↑ Procalcitonin

Hemodynamic Variables
- Arterial hypotension (SBP <90 mm Hg, MAP <70 mm Hg, or a decrease in SBP >40 mm Hg)

Organ Dysfunction Variables
- Acute oliguria (urine output <0.5 mL/kg/hr for at least 2 hr despite adequate fluid resuscitation)
- Arterial hypoxemia (PaO_2/FIO_2 <300)
- Coagulation abnormalities (INR >1.5 or PTT >60 s)
- Hyperbilirubinemia (total bilirubin >4 mg/dL)
- Ileus (absent bowel sounds)
- Serum creatinine increase >0.5 mg/dL
- Thrombocytopenia (platelet count <100,000/μL)

Tissue Perfusion Variables
- Hyperlactatemia (>1 mmol/L)
- Mottling, ↓ capillary refill

FIO_2, Fraction of inspired O_2; *INR,* international normalized ratio; *PaO_2,* partial pressure of arterial O_2; *PTT,* partial thromboplastin time.

anaphylactic reactions. Tables 42.2 and 42.3 describe the laboratory findings and clinical presentation of a patient in anaphylactic shock. Quick action is critical to prevent an allergic reaction from progressing to anaphylactic shock. Anaphylaxis is discussed in Chapter 14.

Septic shock. **Sepsis** is a life-threatening syndrome in response to infection. It is characterized by a dysregulated patient response along with new organ dysfunction related to the infection (Table 42.4).[6] In as many as 30% of patients with sepsis, we never identify the causative agent. Sepsis and septic shock have a high incidence worldwide, with a mortality rate of 25% or higher.[7]

Septic shock is a subset of sepsis. It has an increased mortality risk due to profound circulatory, cellular, and metabolic abnormalities. Septic shock is characterized by persistent hypotension, despite adequate fluid resuscitation, and inadequate tissue perfusion that results in tissue hypoxia.[8] The main organisms that cause sepsis are gram-negative and gram-positive bacteria. Parasites,

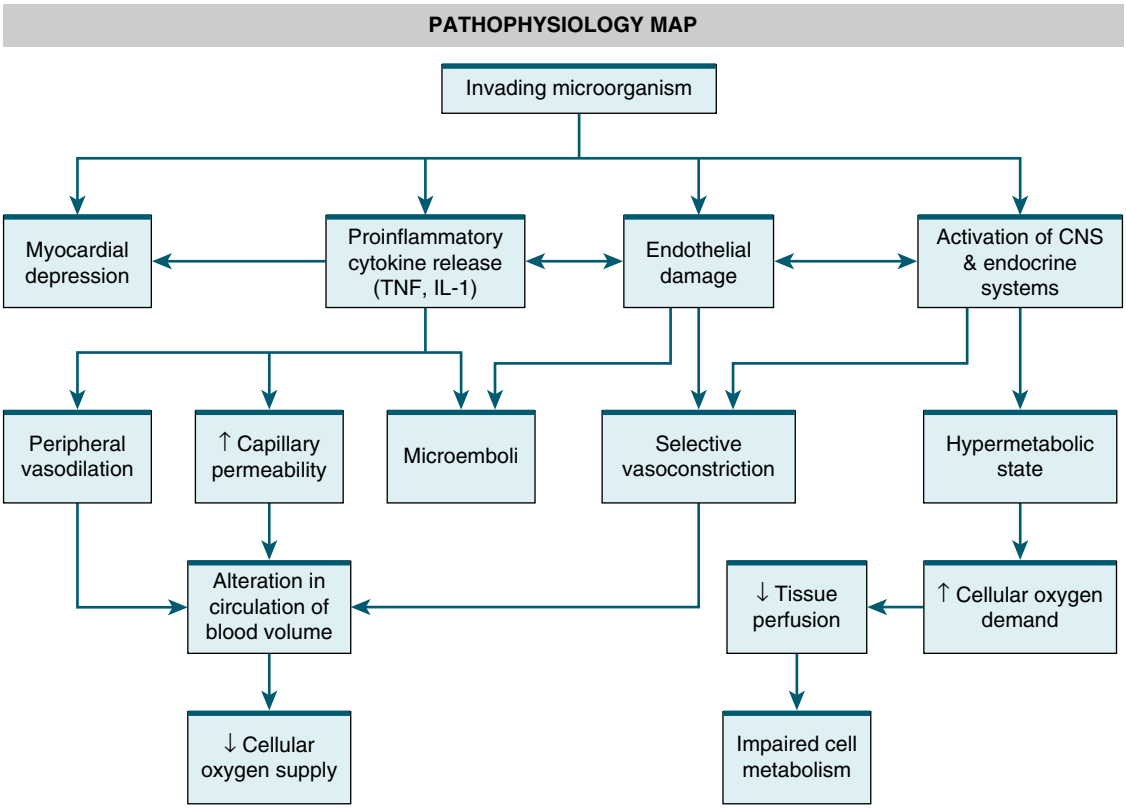

Fig. 42.5 The pathophysiology of septic shock. *IL,* Interleukin; *TNF,* tumor necrosis factor.

fungi, and viruses can also cause sepsis and septic shock.[8] Fig. 42.5 presents the pathophysiology of septic shock.

When a microorganism enters the body, this triggers normal immune and inflammatory responses. However, in sepsis and septic shock, the body's response to the microorganism is exaggerated. Both proinflammatory and antiinflammatory responses are activated. Coagulation increases, and fibrinolysis decreases.[6] Endotoxins from the microorganism cell wall stimulate the release of cytokines. These include tumor necrosis factor (TNF), interleukin-1 (IL-1), and other proinflammatory mediators that act through secondary mediators, such as platelet-activating factor, IL-6, and IL-8.[9] (See Chapter 12 for more about the inflammatory response.) The release of platelet-activating factor results in the formation of microthrombi and microvasculature obstruction. The combined effects of the mediators result in endothelial damage, vasodilation, increased capillary permeability, and neutrophil and platelet aggregation and adhesion to the endothelium.

Septic shock has 3 major pathophysiologic effects: vasodilation, maldistribution of blood flow, and myocardial depression. Patients may be euvolemic, but because of acute vasodilation and shifting of fluids out of the intravascular space, relative hypovolemia and hypotension occur. Blood flow in the microcirculation is decreased, causing poor O_2 delivery and tissue hypoxia. We think the combination of TNF and IL-1 has a role in sepsis-induced myocardial dysfunction. The ejection fraction (EF) is decreased for the first few days after the initial insult. Because of a decreased EF, the ventricles dilate to maintain the SV. The EF typically improves, and ventricular dilation resolves over 7 to 10 days. Persistent high CO and a low SVR beyond 24 hours is an ominous finding. It is often associated with hypotension and MODS. Coronary artery perfusion and myocardial O_2 metabolism are not primarily altered in septic shock.

Respiratory failure is common. The patient initially hyperventilates as a compensatory mechanism, causing respiratory alkalosis. Once the patient can no longer compensate, respiratory acidosis develops. Respiratory failure develops in 85% of patients with sepsis; 40% develop acute respiratory distress syndrome (ARDS) (see Chapter 32). These patients may need intubation with mechanical ventilation.

Other signs include changes in neurologic status, decreased urine output, and GI dysfunction, such as GI bleeding and paralytic ileus. Table 42.3 gives the clinical presentation of a patient with septic shock.

Obstructive Shock

Obstructive shock develops when a physical obstruction to blood flow occurs with a decreased CO (Fig. 42.6). This can be caused by restricted diastolic filling of the right ventricle from compression (e.g., cardiac tamponade, tension pneumothorax, superior vena cava syndrome).[10] Other causes include *abdominal compartment syndrome,* in which increased abdominal pressures compress the inferior vena cava. This decreases venous return to the heart. Pulmonary embolism and right ventricular thrombi cause an outflow obstruction as blood leaves the right ventricle through the PA. This leads to decreased blood flow to the lungs and decreased blood return to the left atrium.

Patients have a decreased CO, increased afterload, and variable left ventricular filling pressures depending on the obstruction. Other signs include jugular venous distention and pulsus paradoxus. Rapid assessment and treatment are important to

PATHOPHYSIOLOGY MAP

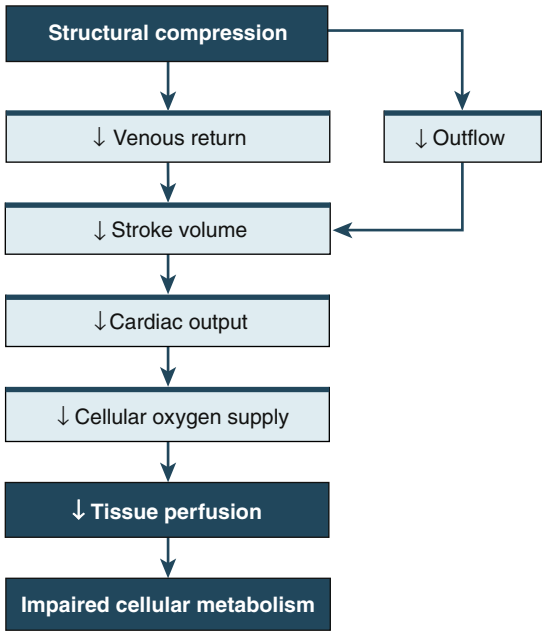

Fig. 42.6 The pathophysiology of obstructive shock.

prevent further hemodynamic compromise and possible cardiac arrest (Fig. 42.6).

Stages of Shock

In addition to understanding the underlying pathogenesis of the type of shock the patient has, management is guided by knowing where the patient is on the shock "continuum." We categorize shock into 4 overlapping stages: (1) initial stage, (2) compensatory stage, (3) progressive stage, and (4) refractory stage.[5]

Initial Stage

The *initial stage* of shock occurs at a cellular level. This stage is usually not clinically apparent. Metabolism changes at the cellular level from aerobic to anaerobic, causing lactic acid buildup. Lactic acid is a waste product that is removed by the liver.[7] However, this process requires O_2, which is unavailable because of the decrease in tissue perfusion.

Compensatory Stage

In the *compensatory stage* the body activates neural, hormonal, and biochemical compensatory mechanisms to try to overcome the increasing consequences of anaerobic metabolism and maintain homeostasis. The patient's clinical presentation begins to reflect the body's responses to the imbalance in O_2 supply and demand (Table 42.5).

A classic sign of shock is a drop in BP. This occurs because of a decrease in CO and a narrowing of the pulse pressure. The baroreceptors in the carotid and aortic bodies immediately respond by activating the SNS. The SNS stimulates vasoconstriction and the release of the potent vasoconstrictors epinephrine and norepinephrine. Blood flow to the heart and brain is maintained. Blood flow to the nonvital organs, such as kidneys, GI tract, skin, and lungs, is diverted or shunted.

The myocardium responds to the SNS stimulation and the increased O_2 demand by increasing the heart rate and contractility. Increased contractility increases myocardial O_2 consumption. The coronary arteries dilate to try to meet the increased O_2 demands of the myocardium.

Shunting blood away from the lungs has an important clinical effect. Decreased blood flow to the lungs increases the patient's physiologic dead space. *Physiologic dead space* is the anatomic dead space (the amount of air that will not reach gas-exchanging units) and any inspired air that cannot take part in gas exchange. The clinical result of an increase in dead space ventilation is a *ventilation-perfusion mismatch.* Some areas of the lungs that are being ventilated will not be perfused because of the decreased blood flow to the lungs. Arterial O_2 levels will decrease, and the patient will have a compensatory increase in the rate and depth of respirations (see Chapter 32).

The shunting of blood from other organ systems results in clinically important changes. The decrease in blood flow to the GI tract results in impaired motility and a slowing of peristalsis. This increases the risk for a paralytic ileus.

Decreased blood flow to the skin results in the patient feeling cool and clammy. The exception is the patient in early septic shock who may feel warm and flushed because of a hyperdynamic state. Decreased renal blood flow activates the renin-angiotensin system. Renin stimulates angiotensinogen to make angiotensin I, which is then converted to angiotensin II. Angiotensin II is a potent vasoconstrictor that causes both arterial and venous vasoconstriction. The net result is an increase in venous return to the heart and an increase in BP. Angiotensin II stimulates the adrenal cortex to release aldosterone. This results in sodium and water reabsorption and potassium excretion by the kidneys. The increase in sodium reabsorption raises the serum osmolality and stimulates the release of antidiuretic hormone (ADH). ADH increases water reabsorption by the kidneys, further increasing blood volume. The increase in total circulating volume results in an increase in CO and BP.

A multisystem response to decreasing tissue perfusion starts during the compensatory stage of shock. At this stage, the body can compensate for the changes in tissue perfusion. If the cause of the shock is corrected, the patient will recover with little or no residual effects. If the cause of the shock is not corrected and the body is unable to compensate, the patient enters the progressive stage of shock.

Progressive Stage

The *progressive stage* of shock begins as compensatory mechanisms fail. Changes in the patient's mental status are important findings in this stage. Patients must be moved to the intensive care unit (ICU), if not already there, for advanced monitoring and treatment.

The cardiovascular system is now profoundly affected. CO begins to fall, causing a decrease in BP and coronary artery, cerebral, and peripheral perfusion. Decreased cellular perfusion continues. Altered capillary permeability occurs, allowing fluid and protein to leak out of the vascular space into the surrounding interstitial space. Circulating volume decreases with an increase in systemic interstitial edema. The patient may have *anasarca* (diffuse profound edema). Fluid leakage from the vascular space affects the solid organs (e.g., liver, GI tract, lungs) and peripheral tissues by further decreasing perfusion.

TABLE 42.5 Manifestations of Stages of Shock

Compensatory Stage	Progressive Stage	Refractory Stage
Cardiovascular System		
Sympathetic nervous system response: • Epinephrine/norepinephrine (vasoconstriction) release • ↑ Myocardial O_2 consumption • ↑ Contractility • ↑ HR • Coronary artery dilation • Narrowed pulse pressure • ↓ BP	↑ Capillary permeability → systemic interstitial edema ↓ CO → ↓ BP and ↑ HR MAP <60 mm Hg (or 40 mm Hg drop in BP from baseline) ↓ Coronary perfusion → dysrhythmias, myocardial ischemia, MI ↓ Peripheral perfusion → ischemia of distal extremities, ↓ pulses, ↓ capillary refill	Profound hypotension ↓ CO Bradycardia, irregular rhythm ↓ BP inadequate to perfuse vital organs
Gastrointestinal System		
↓ Blood supply ↓ GI motility Hypoactive bowel sounds ↑ Risk for paralytic ileus	Vasoconstriction and ↓ perfusion → ischemic gut (e.g., stomach, intestines, gallbladder, pancreas): • Erosive ulcers • GI bleeding • Translocation of GI bacteria • Impaired absorption of nutrients	Ischemic gut
Hepatic System		
	Failure to metabolize drugs and waste products Cell death (↑ liver enzymes) Jaundice (↓ clearance of bilirubin) ↑ NH_3 (ammonia) and lactate	Metabolic changes from accumulation of waste products (e.g., NH_3, lactate, CO_2)
Hematologic System		
	DIC: • Thrombin clots in microcirculation • Consumption of platelets and clotting factors	DIC progresses
Neurologic System		
Oriented to person, place, time Restless, apprehensive, confused Change in level of consciousness	↓ Cerebral perfusion pressure ↓ Cerebral blood flow ↓ Responsiveness to stimuli Delirium	Unresponsive Areflexia (loss of reflexes) Pupils nonreactive and dilated
Renal System		
↓ Renal blood flow ↑ Renin resulting in release of angiotensin (vasoconstrictor) ↑ Aldosterone causing Na^+ and H_2O reabsorption ↑ Antidiuretic hormone causing H_2O reabsorption	Renal tubules become ischemic → acute tubular necrosis ↓ Urine output ↑ BUN-to-creatinine ratio ↑ Urine sodium ↓ Urine osmolality and specific gravity ↓ Urine potassium Metabolic acidosis	Anuria
Respiratory System		
• ↓ Blood flow to the lungs: • ↑ Physiologic dead space • ↑ Ventilation-perfusion mismatch • Hyperventilation • ↑ Minute ventilation (V_E) • Tachypnea	ARDS: • ↑ Capillary permeability • Pulmonary vasoconstriction • Pulmonary interstitial edema • Alveolar edema • Diffuse infiltrates • Tachypnea • ↓ Compliance • Moist crackles	Severe refractory hypoxemia Respiratory failure
Skin		
Pale and cool Warm and flushed	Cold and clammy	Mottled, cyanotic
Temperature		
Normal or abnormal	Hypothermia or hyperthermia	Hypothermia

Sustained hypoperfusion results in weak peripheral pulses. Ischemia of the distal extremities eventually occurs. Myocardial dysfunction from decreased perfusion results in dysrhythmias, myocardial ischemia, and possibly MI. The result is complete deterioration of the cardiovascular system.

The pulmonary system is often the first system to show signs of critical dysfunction. Blood flow to the lungs is reduced. In response to the decreased blood flow and SNS stimulation, the pulmonary arterioles constrict. This increases PA pressure. As the pressure within the pulmonary vasculature increases, blood flow to the pulmonary capillaries decreases and ventilation-perfusion mismatch worsens.

Another key response in the lungs is fluid movement from the pulmonary vasculature into the interstitial space. As capillary permeability increases, fluid moving into the interstitial spaces results in interstitial edema, bronchoconstriction, and decreased functional residual capacity. With further increases in capillary permeability, fluid moves into the alveoli, causing alveolar edema and a decrease in surfactant production. The combined effects of pulmonary vasoconstriction and bronchoconstriction are impaired gas exchange, decreased compliance, and worsening ventilation-perfusion mismatch. Clinically, the patient has tachypnea, crackles, and an overall increased work of breathing.

The GI system is affected by prolonged decreased tissue perfusion. As the blood supply to the GI tract is decreased, the normally protective mucosal barrier becomes ischemic. This ischemia predisposes the patient to ulcers and GI bleeding (see Chapter 46). It increases the risk for bacterial migration from the GI tract to the blood and lungs. There is a decreased ability to absorb nutrients.

The loss of the liver's functional ability leads to a failure of the liver to metabolize drugs and waste products (e.g., lactate, ammonia). Jaundice results from the accumulation of bilirubin. As the liver cells die, liver enzymes increase. The liver loses its ability to function as an immune organ. Kupffer cells no longer destroy bacteria from the GI tract. Instead, they are released into the bloodstream, increasing the risk of bacteremia.

Prolonged hypoperfusion on the kidneys causes renal tubular ischemia. The resulting acute tubular necrosis may lead to acute kidney injury (AKI). This can be worsened by nephrotoxic drugs (e.g., certain antibiotics, anesthetics, diuretics) (see Chapter 51). The patient has decreased urine output and increased blood urea nitrogen (BUN) and serum creatinine. Metabolic acidosis occurs from the kidneys' inability to excrete acids (especially lactic acid) and reabsorb bicarbonate.

Hematologic dysfunction adds to the complexity of the clinical picture. The patient is at risk for disseminated intravascular coagulation (DIC). The consumption of platelets and clotting factors with secondary fibrinolysis results in clinically significant bleeding from many orifices. These include the GI tract, lungs, and puncture sites (see Chapter 34). Table 42.3 shows laboratory values in DIC.

In this stage, aggressive interventions are needed to prevent the development of MODS.

Refractory Stage

In this last stage of shock, decreased perfusion from peripheral vasoconstriction and decreased CO worsen anaerobic metabolism. Lactic acid accumulation contributes to increased capillary permeability and dilation. Increased capillary permeability allows fluid and plasma proteins to leave the vascular space and move to the interstitial space. Blood pools in the capillary beds due to the constricted venules and dilated arterioles. The loss of intravascular volume worsens hypotension and tachycardia and decreases coronary blood flow. Decreased coronary blood flow leads to worsening myocardial depression and a further decline in CO. Cerebral blood flow cannot be maintained and cerebral ischemia results.

The patient now has profound hypotension and hypoxemia. The failure of the liver, lungs, and kidneys results in an accumulation of waste products, such as lactate, urea, ammonia, and CO_2. The failure of an organ system affects several other organ systems. Recovery is unlikely in this stage. The organs are in failure, and the body's compensatory mechanisms are overwhelmed (Table 42.5).

Diagnostic Studies

There is no single diagnostic study to determine whether a patient is in shock. The diagnosis starts with a history and physical assessment. A thorough medical and surgical history and a history of recent events (e.g., surgery, chest pain, trauma) give valuable data.

Decreased tissue perfusion in shock leads to an increased lactate with a base deficit (the amount needed to bring the pH back to normal). These laboratory changes reflect an increase in anaerobic metabolism.[7] Table 42.2 outlines laboratory findings seen in shock.

Other diagnostic studies include a 12-lead electrocardiogram (ECG), continuous ECG monitoring, chest x-ray, continuous pulse oximetry, and hemodynamic monitoring. Chapter 35 discusses hemodynamic monitoring.

Interprofessional Care

Successful management of a patient in shock depends on the early recognition and treatment of shock. Prompt intervention in the early stages of shock may prevent the decline to the progressive or irreversible stage. Successful management includes (1) identifying patients at risk for developing shock; (2) integrating the patient's history, physical assessment, and clinical findings to establish a diagnosis; (3) interventions to control or eliminate the cause; (4) protecting target and distal organs from dysfunction; and (5) providing multisystem supportive care.

Table 42.6 provides an overview of the initial assessment findings and interventions for the emergency care of patients in shock. General management strategies begin with ensuring that the patient is responsive and has a patent airway. Once the airway is established, either naturally or with an endotracheal tube, O_2 delivery must be optimized. Supplemental O_2 and mechanical ventilation may be needed to maintain an arterial O_2 saturation of 90% or more (PaO_2 greater than 60 mm Hg) to avoid hypoxemia (see Chapter 28). The mean arterial pressure (MAP) and circulating blood volume are optimized with fluid replacement and drug therapy.

TABLE 42.6 EMERGENCY MANAGEMENT

Shock

Common Causes	Assessment Findings	Interventions
Medical • Addisonian crisis • Dehydration • Diabetes • Diabetes insipidus • MI • Pulmonary embolus • Sepsis **Surgical** • Aortic dissection • GI bleeding • Postoperative bleeding • Ruptured ectopic pregnancy or ovarian cyst • Ruptured organ or vessel • Vaginal bleeding **Trauma** • Fractures, spinal injury • Multiorgan injury • Ruptured or lacerated vessel or organ (e.g., spleen)	• Anxiety • Chills • Confusion • Cool, clammy skin (warm skin in early onset of septic and neurogenic shock) • Cyanosis • Dysrhythmias • Extreme thirst • Feeling of impending doom • Hypotension • ↓ Level of consciousness • Narrowed pulse pressure • Nausea and vomiting • Obvious hemorrhage or injury • ↓ O_2 saturation • Pallor • Rapid, weak, thready pulses • Restlessness • Tachypnea, dyspnea, or shallow, irregular respirations • Temperature dysregulation • Weakness	**Initial** • If unresponsive, assess circulation, airway, and breathing (CAB). • If responsive, monitor airway, breathing, and circulation (ABC). • Stabilize cervical spine as appropriate. • Control any external bleeding with direct pressure or pressure dressing. • Give high-flow O_2 (100%) by nonrebreather mask or bag-valve-mask. • Anticipate need for intubation and mechanical ventilation. • Establish IV access with 2 large-bore catheters (14- to 16-gauge) or an intraosseous access device; aid with central line insertion. • Begin fluid resuscitation with crystalloids (e.g., 30 mL/kg repeated until hemodynamic improvement is seen). • Draw blood for laboratory studies (e.g., blood cultures, lactate, WBC). • Assess for life-threatening injuries (e.g., cardiac tamponade, liver laceration, tension pneumothorax). • Consider vasopressor therapy if hypotension persists after fluid resuscitation. • Insert an indwelling urinary catheter and nasogastric tube. • Start antibiotic therapy after blood cultures if sepsis is suspected. • Obtain 12-lead ECG and treat dysrhythmias. **Ongoing Monitoring** • ABCs • Level of consciousness • Vital signs, including pulse oximetry; peripheral pulses, capillary refill, skin color and temperature • Respiratory status • Heart rate and rhythm • Urine output

Oxygen and Ventilation

O_2 delivery depends on CO, available hemoglobin, and arterial O_2 saturation (SaO_2). Methods to optimize O_2 delivery are directed at increasing supply and decreasing demand. Supply is increased by (1) optimizing the CO with fluid replacement and/or drug therapy, (2) increasing the hemoglobin through blood transfusions, and/or (3) increasing the arterial O_2 saturation with supplemental O_2 and mechanical ventilation.

Plan care to avoid disrupting the balance of O_2 supply and demand. Space activities that increase O_2 consumption (e.g., endotracheal suctioning, position changes) appropriately for O_2 conservation. Intermittent or continuous monitoring of $ScvO_2$ by a central venous catheter or mixed venous O_2 saturation (SvO_2) may be helpful. Both reflect the dynamic balance between O_2 supply and demand. Assess these values along with related hemodynamic measures (e.g., arterial pressure–based cardiac output [APCO], O_2 consumption, hemoglobin) to evaluate the patient's response to treatments and activities (see Chapters 28 and 35).

Fluid Resuscitation

The cornerstone of therapy for septic, hypovolemic, and anaphylactic shock is volume expansion with fluid administration (Table 42.7).[8] The goal for fluid resuscitation is to restore tissue perfusion. Fluid resuscitation should start using 1 or 2 large-bore (e.g., 14- to 16-gauge) IV catheters, an intraosseous (IO) access device, or a central venous catheter.

! SAFETY ALERT

Intraosseous (IO) Access

- Use an IO access device for emergency resuscitation when IV access cannot be obtained.
- Insertion sites include the sternum, proximal and distal tibia, and proximal and distal humerus.
- Remove IO devices within 24 hr of insertion or as soon as possible after peripheral or central IV access is obtained.
- Monitor for complications: extravasation of drugs and fluids into the soft tissue, fractures caused during insertion, and osteomyelitis.

The choice of fluid is based on the type and volume of fluid lost and the patient's clinical status. The ideal choice of fluid is controversial.[11–13] Currently, normal saline is most often used in the initial resuscitation of shock. Large-volume resuscitation with normal saline can lead to hyperchloremic metabolic acidosis. Lactated Ringer solution can cause serum lactate levels to increase because the failing liver cannot convert lactate to bicarbonate.[13] Transfusions of RBCs may be given to treat hypovolemic shock due to bleeding. Colloids (4% to 5%) have not been shown to improve patient outcomes.[12,13]

Fluid responsiveness is determined by clinical assessment. Although BP helps to determine whether the patient's CO is adequate, an assessment of end-organ perfusion (e.g., urine output, neurologic function, peripheral pulses) provides more

TABLE 42.7 Fluid Therapy in Shock

Fluid Type	Mechanism of Action	Type of Shock	Nursing Implications
Crystalloids			
Isotonic			
• 0.9% NaCl, normal saline solution (NSS) • Lactated Ringer (LR) solution	Fluid primarily stays in the intravascular space, ↑ intravascular volume.	Used for initial volume replacement in most types of shock.	Monitor patient closely for circulatory overload. Do not use LR in patients with liver failure. LR may be used if hyperchloremic acidosis develops from use of NSS in fluid resuscitation.
Hypertonic			
• 1.8%, 3%, 5% NaCl	Fluid stays in the intravascular space, increases serum osmolarity, shifts fluid volume from intracellular space to extracellular space to intravascular space.	May be used for initial volume expansion in hypovolemic shock.	Monitor patient closely for signs of hypernatremia (e.g., disorientation, seizures). Central line preferred for infusing saline solutions ≥3%, since these may damage veins.
Blood or Blood Products			
Packed red blood cells Fresh frozen plasma Platelets	Replaces blood loss, increases O_2-carrying capability. Replaces coagulation factors. Helps control bleeding caused by thrombocytopenia.	All types.	Same precautions as any blood administration (see Chapter 34).
Colloids			
Human serum albumin (5% or 25%)	Can increase plasma colloid osmotic pressure. Rapid volume expansion.	All types except cardiogenic and neurogenic shock.	Use 5% solution in hypovolemic patients. Use 25% solution in patients with fluid and sodium restrictions. Monitor for circulatory overload. Mild side effects of chills, fever, and urticaria may develop. More expensive than crystalloids.
dextran (dextran 40)	Hyperosmotic glucose polymer.	Limited use because of side effects, including reducing platelet adhesion, diluting clotting factors.	Increases risk for bleeding. Monitor patient for allergic reactions and acute kidney injury. Has maximum volume recommendations per manufacturer.

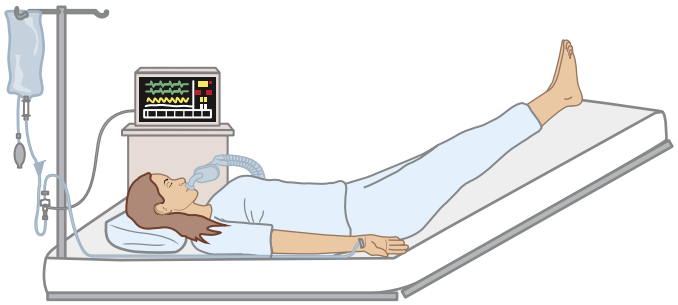

Fig. 42.7 Passive leg raise challenge in a patient with septic shock.

relevant data. Monitor vital signs, cerebral and abdominal perfusion pressures, capillary refill, neurologic status, and skin temperature. Evaluate trends in BP with an automatic BP cuff or an arterial catheter. Use an indwelling urinary catheter to monitor urine output during resuscitation. Hemodynamic parameters, such as SVV or CO, are also used.

Other interventions we use to monitor fluid response include a passive leg raise (PLR) challenge and inferior vena cava evaluation.[14,15] A PLR challenge provides a transient increase in fluid volume of 150 to 500 mL by placing the patient supine and raising the legs to 45 degrees (Fig. 42.7). Response is monitored within 1 to 2 minutes by measuring CO, CI, SV, SVV, or other parameters for improvement. If the response is positive, the patient is fluid responsive and should receive more fluids.

! SAFETY ALERT

Complications of Fluid Resuscitation

- Warm crystalloid and colloid solutions during massive fluid resuscitation to prevent hypothermia.
- When giving large volumes of packed RBCs, remember that they do not contain clotting factors.
- Assess for hypocalcemia and disseminated intravascular coagulation (DIC).
- Replace clotting factors based on the clinical status and laboratory studies.

Drug Therapy

The goal of drug therapy is to correct decreased tissue perfusion. Decisions on which drug to use should be based on the physiologic goal. We give IV drugs used to improve perfusion via an infusion pump and central venous line. Many of these drugs have vasoconstrictor properties that are harmful if the drug leaks into the tissues while being infused peripherally (Table 42.8).

Sympathomimetic drugs. Drugs that mimic the action of the SNS are called *sympathomimetic*. Their effects are mediated through their binding to α- or β-adrenergic receptors. They differ in their relative α- and β-adrenergic effects.[16]

Many of these drugs cause peripheral vasoconstriction and are called *vasopressor drugs* (e.g., norepinephrine, dopamine, phenylephrine). These drugs can cause severe peripheral vasoconstriction and an increase in SVR, further risking

TABLE 42.8 Drug Therapy

Shock

Drug[a]	Mechanism of Action	Type of Shock	Nursing Implications
angiotensin II (Giapreza)	↑ BP, ↑ MAP ↑ SVR	Septic and other distributive shock	Give via central line. Monitor for thromboembolic events. Provide VTE prophylaxis.
dobutamine	↑ Myocardial contractility ↓ Ventricular filling pressures ↓ SVR, PAWP ↑ CO, SV, CVP ↑/↓ HR	Used in cardiogenic shock with severe systolic dysfunction Used in septic shock to increase O_2 delivery and raise $ScvO_2$ or SvO_2 to 70% if Hgb >7 g/dL or Hct ≥30%	Give via central line (infiltration leads to tissue sloughing). Do not give in same line with $NaHCO_3$. Monitor HR, BP (hypotension may worsen, requiring addition of a vasopressor). Stop infusion if tachydysrhythmias develop.
dopamine	Positive inotropic effects: ↑ Myocardial contractility ↑ Automaticity ↑ Atrioventricular conduction ↑ HR, CO ↑ BP, ↑ MAP ↑ MVO_2 Can cause progressive vasoconstriction at high doses	Cardiogenic shock	Give via central line (infiltration leads to tissue sloughing). Do not give in same line with $NaHCO_3$. Monitor for tachydysrhythmias. Monitor for peripheral vasoconstriction (e.g., paresthesias, coldness in extremities) at moderate to high doses.
epinephrine (Adrenalin)	*Low doses:* β-Adrenergic agonist (cardiac stimulation, bronchodilation, peripheral vasodilation) ↑ HR, contractility, CO ↓ SVR *High doses:* α-Adrenergic agonist (peripheral vasoconstriction) ↑ SV, SVR ↑ Systolic/↓ diastolic BP, widened pulse pressure ↑ CVP, PAWP	Cardiogenic shock Anaphylactic shock Septic shock, if 2nd agent needed after norepinephrine Cardiac arrest, pulseless ventricular tachycardia, ventricular fibrillation, asystole	Monitor for HR >110 beats/min. Monitor for dyspnea, pulmonary edema. Monitor for chest pain, dysrhythmias from ↑ MVO_2. Monitor for renal failure due to ischemia.
hydrocortisone (Solu-Cortef)	↓ Inflammation, reverses ↑ capillary permeability ↑ BP, HR	Septic shock requiring vasopressor therapy (despite fluid resuscitation) to maintain adequate BP Anaphylactic shock if hypotension persists after initial therapy	Monitor for hypokalemia, hyperglycemia. Consider use as continuous infusion.
nitroglycerin	Venous dilation Dilates coronary arteries ↓ Preload, MVO_2, SVR, BP	Cardiogenic shock	Continuously monitor BP and HR, since reflex tachycardia may occur. Glass bottle recommended for infusion.
norepinephrine (Levophed)	β_1-Adrenergic agonist (cardiac stimulation) α-Adrenergic agonist (peripheral vasoconstriction) Renal and splanchnic vasoconstriction ↑ BP, MAP, CVP, PAWP, SVR ↑/↓ CO	Cardiogenic shock after MI Septic shock—first drug of choice for BP unresponsive to adequate fluid resuscitation	Give via central line (infiltration leads to tissue sloughing). Monitor for dysrhythmias due to ↑ MVO_2 requirements.
phenylephrine	α-Adrenergic agonist (peripheral vasoconstriction) Renal, mesenteric, splanchnic, cutaneous, and pulmonary blood vessel constriction ↑ HR, BP, SVR ↑/↓ CO	Neurogenic shock	Monitor for reflex bradycardia, headache, restlessness. Monitor for renal failure from ↓ renal blood flow. Give via central line (infiltration leads to tissue sloughing).
sodium nitroprusside	Arterial and venous vasodilation ↓ Preload, afterload ↓ CVP, PAWP ↑/↓ CO ↓ BP	Cardiogenic shock with ↑ SVR	Continuously monitor BP. Protect solution from light. Wrap infusion bottle with opaque covering. Give with D_5W only. Monitor serum cyanide levels and for signs of cyanide toxicity (e.g., metabolic acidosis, tachycardia, altered level of consciousness, seizures, coma, almond smell on breath).
vasopressin	Antidiuretic hormone Nonadrenergic vasoconstrictor ↑ MAP ↑ Urine output	Shock states (most often septic shock) refractory to other vasopressors	Given with norepinephrine and in low doses. Infusions are not titrated. Monitor hemodynamic pressures and urine output.

[a]Consult agency guidelines, pharmacist, pharmacology references, and drug manufacturer's materials for more information and dosing recommendations.

CVP, Central venous pressure; *MVO_2,* myocardial O_2 consumption; *PAWP,* pulmonary artery wedge pressure; *SVR,* systemic vascular resistance.

tissue perfusion. The increased SVR increases the workload of the heart and myocardial O_2 demand. It can harm a patient in cardiogenic shock by causing further myocardial damage and increasing the risk for dysrhythmias.[17] Use of vasopressor drugs is limited to patients who do not respond to fluid resuscitation. Adequate fluid resuscitation must be achieved before starting vasopressors because the vasoconstrictor effects in patients with low blood volume will further reduce tissue perfusion. Typically, if hypotension persists after adequate fluid resuscitation, we then give a vasopressor (e.g., norepinephrine, dopamine) and/or an inotrope (e.g., dobutamine).

The goal of vasopressor therapy is to achieve and maintain a MAP of greater than 65 mm Hg.[16] Continuously monitor end-organ perfusion (e.g., urine output, level of consciousness) and serum lactate levels (e.g., every 3 hours for the first 6 hours) to ensure that tissue perfusion is adequate.

Vasodilator drugs. Patients in cardiogenic shock have decreased myocardial contractility. Vasodilators may be needed to decrease afterload. This reduces myocardial workload and O_2 requirements. Although generalized sympathetic vasoconstriction is a useful compensatory mechanism for maintaining BP, excessive constriction can reduce tissue blood flow and increase the workload of the heart. The reason for using vasodilator therapy is to break the harmful cycle of widespread vasoconstriction causing a decrease in CO and BP, resulting in further sympathetic-induced vasoconstriction.

The goal of vasodilator therapy, as in vasopressor therapy, is to maintain the MAP greater than 65 mm Hg. Monitor hemodynamic parameters (e.g., CVP, CO, $ScvO_2$/SvO_2, SV, PA pressures) and assessment findings so that fluids can be increased, or vasodilator therapy decreased if a serious fall in CO or BP occurs. The vasodilator agent most often used for the patient in cardiogenic shock is nitroglycerin. Vasodilation may be enhanced with nitroprusside or nitroglycerin in noncardiogenic shock.

Nutrition Therapy

Protein-calorie malnutrition is common because of hypermetabolism. Nutrition is vital to reducing mortality.[18] Enteral nutrition (EN) should be started within the first 24 hours. However, full calorie replacement is not recommended for previously well-nourished adults early in a critical illness.[18] Start the patient on a *trophic feeding*. This is a small amount of EN (e.g., 10 mL/hr). Early EN enhances perfusion of the GI tract and helps maintain the integrity of the gut mucosa. Advance feedings as tolerated and as prescribed. We use parenteral nutrition (PN) only if EN is contraindicated. Chapter 44 discusses EN and PN.

Weigh the patient daily on the same scale at the same time of day. If the patient has a significant weight loss, rule out dehydration before adding more calories. Large weight gains are common because of third spacing of fluids. Monitor serum protein, total albumin, prealbumin, BUN, serum glucose, and serum electrolytes to assess nutrition status.

Measures Specific to Type of Shock

Cardiogenic Shock

For a patient in cardiogenic shock, the overall goal is to restore heart function and the balance between O_2 supply and demand in the myocardium. Cardiac catheterization is done as soon as possible after the initial insult.[1] Specific measures to restore blood flow include angioplasty with stenting, emergency revascularization, and valve replacement. Until these interventions are done, we must support the heart to optimize SV and CO to achieve optimal perfusion (Tables 42.8 and 42.9).[12]

Hemodynamic management aims to reduce the workload of the heart through drug therapy and/or mechanical interventions. Drug choice is based on the clinical goal. Drugs can decrease the workload of the heart by dilating coronary arteries (e.g., nitrates) and reducing preload (e.g., diuretics), afterload (e.g., vasodilators), and heart rate and contractility (e.g., β-adrenergic blockers).

The patient may benefit from a circulatory assist device (e.g., intraaortic balloon pump, ventricular assist device [VAD]) (see Chapter 39). The goals are to decrease SVR and left ventricular workload so that the heart can heal. A VAD may be used as a temporary measure for the patient in cardiogenic shock who is awaiting heart transplantation. Heart transplantation is an option for a small, select group of patients with cardiogenic shock.

Hypovolemic Shock

The underlying principles of managing hypovolemic shock focus on stopping the fluid loss and restoring circulating volume. We often calculate the initial fluid resuscitation using a 3:1 rule (3 mL of isotonic crystalloid for every 1 mL of estimated blood loss). Table 42.7 describes fluids used for volume resuscitation, their mechanism of action, and specific nursing implications.

Septic Shock

Patients in septic shock need large amounts of fluid replacement (Fig. 42.8). The overall goal of fluid resuscitation is to restore the intravascular volume and organ perfusion. We achieve initial volume resuscitation by giving 30 mL/kg of an isotonic crystalloid solution. Albumin 4% to 5% is an option when patients need substantial volume.

A fluid challenge technique (e.g., a minimum of 30 mL/kg of crystalloids) may be done and repeated until hemodynamic improvement (e.g., increase in MAP and/or CVP) is seen. To optimize and evaluate large-volume fluid resuscitation, hemodynamic monitoring is needed. Table 42.9 shows predetermined end points of fluid resuscitation along with methods to reassess volume status.

If the patient is hypotensive after initial volume resuscitation and no longer fluid responsive, we may add vasopressors. The first drug of choice is norepinephrine.[16] Vasodilation and low CO, or vasodilation alone, can cause low BP despite adequate fluid resuscitation. Vasopressin may be added for those who are refractory to initial vasopressor therapy.[17] Exogenous vasopressin can replace the stores of physiologic vasopressin that are often depleted in septic shock.

DRUG ALERT

Vasopressin

- Given along with norepinephrine.
- Infuse at low doses (e.g., 0.03 units/min) using an IV pump.
- Do not titrate infusion.
- Use cautiously in patients with coronary artery disease.

TABLE 42.9 Interprofessional Care

Shock

Oxygenation	Circulation	Drug Therapies	Supportive Therapies
Cardiogenic Shock			
• Provide supplemental O_2 (e.g., nasal cannula, nonrebreather mask) • Intubation and mechanical ventilation, if needed • Monitor $ScvO_2$ or SvO_2	• Restore blood flow with angioplasty with stenting, emergent coronary revascularization • Reduce workload of heart with circulatory assist devices: IABP, VAD	• Nitrates (e.g., nitroglycerin) • Inotropes (e.g., dobutamine) • Diuretics (e.g., furosemide) • β-Adrenergic blockers (contraindicated with ↓ ejection fraction)	• Treat dysrhythmias
Hypovolemic Shock			
• Provide supplemental O_2 • Monitor $ScvO_2$ or $ScvO_2$	• Rapid fluid replacement using 2 large-bore (14–16 gauge) peripheral IV lines, an intraosseous access device, or central venous catheter • Restore fluid volume (e.g., blood or blood products, crystalloids) • End points of fluid resuscitation: • CVP 15 mm Hg • PAWP 10–12 mm Hg	• No specific drug therapy	• Correct the cause (e.g., stop bleeding, GI losses) • Use warmed IV fluids, including blood products (if appropriate)
Septic Shock			
• Provide supplemental O_2 • Intubation and mechanical ventilation, if needed • Monitor $ScvO_2$ or SvO_2	• Aggressive fluid resuscitation (e.g., 30 mL/kg of crystalloids repeated if hemodynamic improvement is noted) • End points of fluid resuscitation are based on: • Focused physical assessment including vital signs, cardiopulmonary assessment, capillary refill, peripheral pulses, and skin or any 2 of the following: • $ScvO_2$ >70 or SvO_2 >65 • CVP 8–12 mm Hg • Cardiovascular ultrasound • Fluid responsiveness with passive leg raise or fluid challenge	• Antibiotics as ordered • Vasopressors (e.g., norepinephrine) • Inotropes (e.g., dobutamine) • Anticoagulants (e.g., low-molecular-weight heparin)	• Obtain cultures (e.g., blood, wound) before beginning antibiotics • Monitor temperature • Control blood glucose • Stress ulcer prophylaxis
Neurogenic Shock			
• Maintain patent airway • Provide supplemental O_2 • Intubation and mechanical ventilation (if needed)	• Cautious administration of fluids	• Vasopressors (e.g., phenylephrine) • Atropine (for bradycardia)	• Minimize spinal cord trauma with stabilization • Monitor temperature
Anaphylactic Shock			
• Maintain patent airway • Optimize oxygenation with supplemental O_2 • Intubation and mechanical ventilation, if needed	• Aggressive fluid resuscitation with colloids	• Epinephrine (IM or IV) • Antihistamines (e.g., diphenhydramine) • Histamine (H_2)-receptor blockers • Bronchodilators: nebulized (e.g., albuterol) • Corticosteroids (if hypotension persists)	• Identify and remove offending cause • Prevent via avoidance of known allergens • Premedicate with history of prior sensitivity (e.g., contrast media)
Obstructive Shock			
• Maintain patent airway • Provide supplemental O_2 • Intubation and mechanical ventilation, if needed	• Restore circulation by treating cause of obstruction • Fluid resuscitation may provide temporary improvement in CO and BP	• No specific drug therapy	• Treat cause of obstruction (e.g., pericardiocentesis for cardiac tamponade, needle decompression or chest tube insertion for tension pneumothorax, embolectomy for pulmonary embolism)

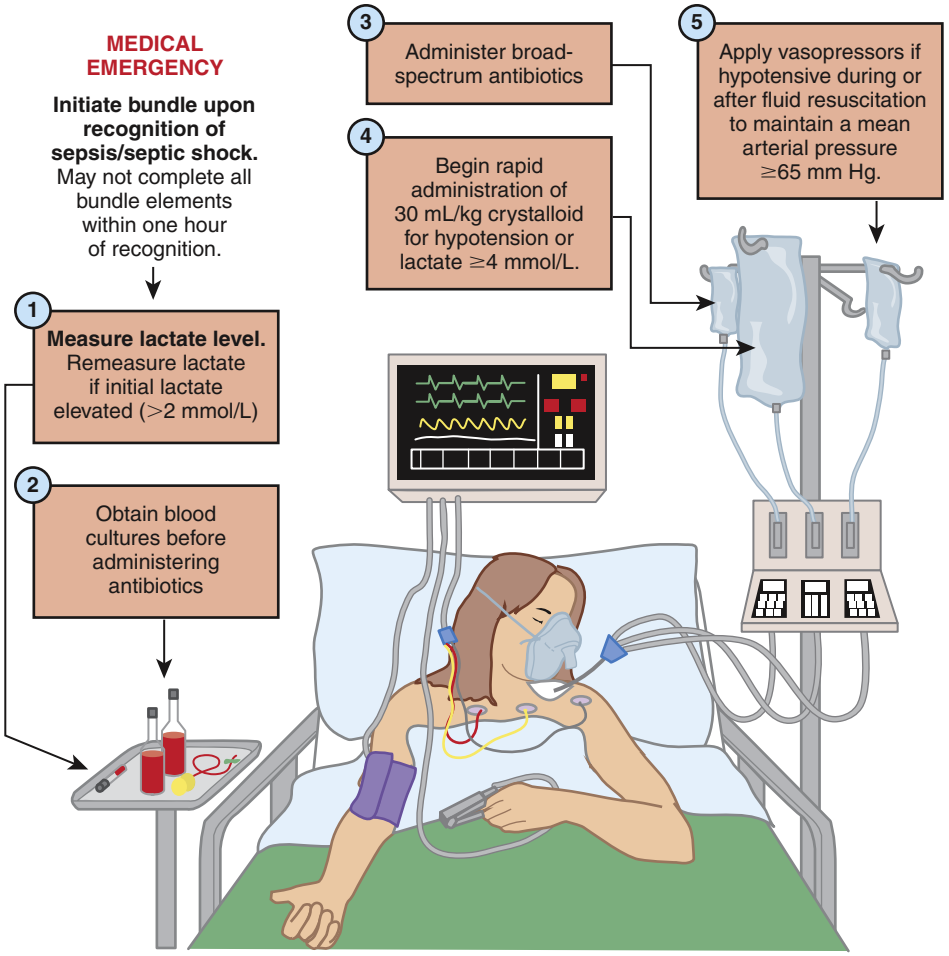

Fig. 42.8 Hour-1 bundle for sepsis and septic shock. (From Institute for Healthcare Improvement: Surviving Sepsis campaign.)

Vasopressor drugs may increase BP but can decrease SV. Giving an inotropic agent (e.g., dobutamine) can offset the decrease in SV and increase tissue perfusion (Table 42.8). IV corticosteroids may be considered for patients in septic shock who cannot maintain an adequate BP despite vasopressor therapy and fluid resuscitation.

To try to meet the increasing tissue demands coupled with a low SVR, the patient initially has a normal or high CO. If the patient is unable to achieve and maintain an adequate CO and has unmet tissue O_2 demands, CO may have to be increased using drug therapy (e.g., dopamine). $ScvO_2$ or SvO_2 monitoring is used to assess the balance between O_2 delivery and consumption, and adequacy of the CO (see Chapter 35). If balance is maintained, tissue demands will be met.

Broad-spectrum antibiotics are an important and early part of therapy. They should be started within the first hour of sepsis or septic shock.[19] Obtain cultures (e.g., blood, wound, urine, stool, sputum) before starting antibiotics. However, this should not delay the start of antibiotics within the first hour. Specific antibiotics may be ordered after we identify the organism.

Glucose levels should be maintained below 180 mg/dL (10.0 mmol/L) for patients in shock.[7] Monitor glucose levels according to agency policy. Stress ulcer prophylaxis with proton pump inhibitors (e.g., pantoprazole) and VTE prophylaxis (e.g., heparin, enoxaparin [Lovenox]) are recommended.[7]

Neurogenic Shock

The specific treatment of neurogenic shock is based on the cause. If the cause is spinal cord injury, we use general measures to promote spinal stability (e.g., spinal precautions, cervical stabilization with a collar). Once the spine is stabilized, treating hypotension and bradycardia are essential to prevent further spinal cord damage. Treatment involves vasopressors (e.g., phenylephrine) to maintain BP and organ perfusion (Table 42.8). Bradycardia may be treated with atropine. Infuse fluids cautiously because hypotension is not related to fluid loss. The patient with a spinal cord injury is monitored for hypothermia caused by hypothalamic dysfunction (Table 42.9).

Anaphylactic Shock

The first strategy in managing patients at risk for anaphylactic shock is prevention. A thorough history is key to avoiding risk factors for anaphylaxis (Table 42.1). The clinical presentation of anaphylactic shock is dramatic. Immediate intervention is required. Epinephrine is the drug of choice to treat anaphylactic

shock.[6] It causes peripheral vasoconstriction and bronchodilation and opposes the effect of histamine. Diphenhydramine and histamine receptor blockers (e.g., famotidine) are given as adjunctive therapies to block the ongoing release of histamine from the allergic reaction.

Maintaining a patent airway is important. The patient can quickly develop airway compromise from laryngeal edema or bronchoconstriction. Nebulized bronchodilators are highly effective. Aerosolized epinephrine can reduce treat laryngeal edema. Endotracheal intubation may be needed to secure and maintain a patent airway.

Hypotension results from fluid leaking out of the intravascular space into the interstitial space due to increased vascular permeability and vasodilation. Aggressive fluid resuscitation, usually with crystalloids, is needed. IV corticosteroids may be helpful in anaphylactic shock if significant hypotension persists after 1 to 2 hours of aggressive therapy (Tables 42.8 and 42.9).

Obstructive Shock

The main strategy in treating obstructive shock is early recognition and treatment to relieve or manage the obstruction (Table 42.1). Mechanical decompression for pericardial tamponade, tension pneumothorax, and hemopneumothorax may be done by needle or tube insertion. A pulmonary embolism requires immediate anticoagulation therapy, thrombolytic therapy, or pulmonary embolectomy. Superior vena cava syndrome, a compression or obstruction of the outflow tract of the mediastinum, may be treated by radiation, debulking, or removal of the mass or cause. A decompressive laparotomy may be done for abdominal compartment syndrome for patients with high intraabdominal pressures and hemodynamic instability.

NURSING MANAGEMENT: SHOCK

Assessment

Focus your assessment on the ABCs: airway, breathing, and circulation. Next, assess for tissue perfusion. This includes evaluating vital signs, level of consciousness, peripheral pulses, capillary refill, skin (e.g., temperature, color, moisture), and urine output. As shock progresses, the patient's neurologic status declines, urine output decreases, skin becomes cooler and mottled, and peripheral pulses decrease.

To understand the complexity of the patient's clinical status, integrate all the assessment data. Obtain a brief history from the patient or caregiver. Include a description of the events leading to the shock state, time of onset and duration of symptoms, and health history (e.g., medications, allergies). Obtain details about any care the patient received before hospitalization.

Clinical Problems

Clinical problems for the patient in shock may include:

- Impaired cardiac function
- Impaired respiratory function
- Altered BP

More information on nursing diagnoses and interventions for the patient with shock is presented in eNursing Care Plan 42.1 (available on the website for this chapter).

Planning

The overall goals for a patient in shock include (1) adequate tissue perfusion, (2) restoration of normal or baseline BP, (3) recovery of organ function, (4) avoiding complications from prolonged states of hypoperfusion, and (5) preventing health care–associated complications.

Implementation

Health Promotion

You play a key role in the prevention of shock by identifying patients at risk. In general, patients who are older, are immunocompromised, or have chronic illnesses are at an increased risk. Any person who has surgery or trauma is at risk for shock from hemorrhage, spinal cord injury, sepsis, and other problems (Table 42.1).

Planning is essential to help prevent shock after you identify an at-risk patient. For example, a patient with an acute anterior wall MI is at high risk for cardiogenic shock.[1] The main goal for this patient is to limit the infarct size. This is done by restoring coronary blood flow. Rest, analgesics, and sedation can reduce the myocardial demand for O_2. Modify the ICU environment to provide care at intervals that will not increase the patient's O_2 demand. For example, if the patient becomes tired with bathing, perform this care at a time that does not interfere with tests or other activities that may increase O_2 demand.

A person with certain severe allergies, such as to drugs, shellfish, insect bites, and latex, is at increased risk for anaphylactic shock. This risk can be decreased by carefully assessing the patient for allergies.

! SAFETY ALERT

Preventing Allergic Reactions

- Always confirm the patient's allergies before giving drugs or starting diagnostic procedures (e.g., CT scan with contrast media).
- Premedicate (e.g., diphenhydramine, methylprednisolone) patients who need a drug to which they are at high risk for an allergic reaction (e.g., contrast media).
- Encourage patients with allergies to obtain and wear a medical alert device and report all allergies to their HCPs.
- Teach patients about kits that contain equipment and drugs (e.g., epinephrine) for the treatment of acute allergic reactions.

Careful monitoring of fluid balance can help prevent hypovolemic shock. Ongoing monitoring of intake and output and daily weights is important. Identifying trends in the patient's condition is more meaningful than any single piece of clinical information.

Carefully monitor all patients for infection. Progression from an infection to sepsis and septic shock depends on the patient's defense mechanisms. Patients who are immunocompromised are at high risk for opportunistic infections. Strategies to decrease the risk for health care–associated

infections (HAIs) include decreasing the number of invasive catheters (e.g., central lines, bladder catheters), using aseptic technique during invasive procedures, and paying strict attention to hand washing. Change equipment per agency policy. Thoroughly sanitize or discard (if disposable) equipment between patient use.

Evidence-based guidelines are available to reduce the risk for HAIs (e.g., ventilator-associated pneumonia, central line infections, catheter-associated urinary tract infections). These guidelines, called *care bundles,* outline key interventions aimed at reducing infections.[18]

Acute Care

Your role in shock involves (1) monitoring the patient's ongoing status, (2) identifying trends to detect changes in the patient's condition, (3) planning and implementing nursing interventions and therapy, (4) evaluating the patient's response to therapy, (5) providing emotional support to the patient and caregiver, and (6) collaborating with other health care team members to coordinate care.

Neurologic status. Assess the patient's neurologic status, including orientation and level of consciousness using a valid tool, at least every 1 to 2 hours. Neurologic status is the best indicator of cerebral blood flow. Be aware of the manifestations of neurologic involvement (e.g., changes in behavior, restlessness, blurred vision, confusion, paresthesias). Note any subtle changes in the patient's mental status (e.g., mild agitation) and report them to the HCP.

Orient the patient to person, place, time, and events on a regular basis. Orientation to the ICU environment is especially important. Reduce noise and light levels to control sensory input. Keep a day-night cycle of activity, and rest as much as possible. Sensory overload and disruption of the patient's diurnal cycle may contribute to delirium (see Chapter 64).

Cardiovascular status. We base most of the therapy for shock on information about cardiovascular status. If the patient is unstable, continuously assess heart rate and rhythm, BP, CVP, and PA pressures, including CO, SVR, SV, and SVV (if available). Monitoring trends in hemodynamic parameters provides more important information than single values. Integrating hemodynamic with physical assessment data is essential in planning strategies to manage the patient with shock. Chapter 35 discusses cardiovascular monitoring.

Continuously monitor the patient's ECG. Dysrhythmias may result from the cardiovascular and metabolic problems. Assess heart sounds for an S_3 or S_4 sound or new murmurs. An S_3 sound usually indicates HF. Monitor the patient's skin for signs of adequate perfusion. Changes in temperature, pallor, flushing, cyanosis, diaphoresis, and piloerection may indicate hypoperfusion.

Give the prescribed therapy to correct cardiovascular problems. Assess the patient's response to fluid and drug administration as often as every 5 to 10 minutes. Make adjustments (e.g., drug titration) as needed. Once tissue perfusion is restored and the patient is stabilized, you can decrease the frequency of monitoring and slowly wean the patient off drugs to support BP and tissue perfusion.

CHECK YOUR PRACTICE

You are admitting a 69-year-old male patient to the ICU with a diagnosis of sepsis. Your findings show that he is confused, with weak peripheral pulses and a BP of 84/50.

- What fluids would you expect to be ordered?
- How much fluid would you expect to infuse to improve his BP?
- Despite aggressive fluid resuscitation, the patient is still hypotensive. What drug would you expect to give to improve tissue perfusion?

Respiratory status. Frequently assess respiratory status to ensure adequate oxygenation, detect complications, and provide data about acid-base status. At first, monitor the rate, depth, and rhythm of respirations as often as every 15 to 30 minutes. Increased rate and depth provide information about the patient's attempts to correct metabolic acidosis. Assess breath sounds every 1 to 2 hours and as needed for any changes that may indicate fluid overload or accumulation of secretions.

Use pulse oximetry to continuously monitor O_2 saturation. Pulse oximetry using a patient's finger may not be accurate in a shock state because of poor peripheral circulation. Instead, attach the probe to the ear, nose, or forehead (according to the manufacturer's guidelines). Arterial blood gases (ABGs) give definitive information on ventilation and oxygenation status and acid-base balance. Initial interpretation of ABGs is often your responsibility. A PaO_2 less than 60 mm Hg (in the absence of chronic lung disease) indicates hypoxemia and the need for higher O_2 concentrations or for a different mode of O_2 administration. Low $PaCO_2$ with a low pH and low bicarbonate level may mean that the patient is trying to compensate for metabolic acidosis from increasing lactate levels.

A rising $PaCO_2$ with a persistently low pH and PaO_2 indicates the need for advanced pulmonary management. Many patients in shock are intubated and on mechanical ventilation. Maintaining a patent airway and monitoring for ventilator-related complications are critical. Chapter 28 discusses mechanical ventilation.

Renal status. At first, measure urine output every 1 to 2 hours to assess the adequacy of renal perfusion. Inserting an indwelling urinary catheter helps to measure during resuscitation. Urine output less than 0.5 mL/kg/hr may indicate inadequate renal perfusion. Use trends in serum creatinine values to assess renal function. Serum creatinine is a better indicator of renal function than BUN levels because the patient's catabolic state affects BUN levels.

Body temperature. Monitor temperature every 4 hours if normal. In the presence of a high or subnormal temperature, obtain hourly core temperatures (e.g., urinary, esophageal, PA catheter). Use light covers and control the room temperature to keep the patient comfortably warm. If the patient's temperature increases to greater than 101.5°F (38.6°C) and the patient becomes uncomfortable or shows cardiovascular compromise, treat the fever with antipyretic drugs (e.g., ibuprofen) and remove some of the patient's covers. Consider a cooling device if fever persists despite treatment (see Table 12.5).

Gastrointestinal status. Auscultate bowel sounds at least every 4 hours. Monitor for abdominal distention. If a nasogastric

tube is present, measure drainage and check for occult blood. Check all stools for occult blood.

Skin integrity. Hygiene is especially important because impaired tissue perfusion predisposes the patient to skin breakdown and infection. Perform bathing and other nursing measures carefully because a patient in shock has problems with O_2 delivery to tissues. Use clinical judgment in determining priorities of care to limit the demands for increased O_2. Monitor trends in O_2 consumption (e.g., SpO_2, $ScvO_2/SvO_2$) during all interventions to assess the patient's tolerance of activity.

The increased O_2 demand that occurs with repositioning those with limited O_2 reserves makes preventing pressure injuries challenging. Turn the patient at least every 1 to 2 hours. Maintain good body alignment. Use a pressure-relieving or pressure-reducing mattress or a specialty bed as needed. Perform passive range of motion 3 or 4 times a day to maintain joint mobility and help to prevent breakdown.

Oral care is essential because mucous membranes may become dry and fragile in the volume-depleted patient. The intubated patient usually has difficulty swallowing, causing pooled secretions in the mouth. Apply a water-soluble lubricant to the lips to prevent drying and cracking. Brush the patient's teeth or gums with a soft toothbrush every 12 hours. Swab the lips and oral mucosa with a moisturizing solution every 2 to 4 hours.

Emotional support. Do not underestimate the effects of fear and anxiety when the patient and caregiver are faced with a life-threatening situation. Fear, anxiety, and pain may worsen respiratory distress and increase catecholamine release. When implementing care, monitor the patient's mental state and pain level. Give drugs to decrease anxiety and pain as needed. Continuous infusions of a benzodiazepine (e.g., lorazepam) and an opioid or sedative (e.g., morphine, propofol) are helpful in decreasing anxiety and pain.[20]

Do not overlook the patient's spiritual needs. Patients may want a visit from a spiritual or religious leader. One way to provide support is to offer to call the leader rather than wait for the patient or caregiver to express a wish for counseling.

CHECK YOUR PRACTICE

Your patient is a 74-year-old man recovering from septic shock after a perforated diverticulum. He has been in the ICU for 7 days. His condition has finally stabilized. His wife has been at his bedside for his entire ICU stay. While caring for him, you suggest that she take a brief walk and get some coffee. She bursts out with tears, "I can't leave him. You know that he almost died."

- How can you support this caregiver?

Caregivers need to be informed of the patient's condition. Give the patient and caregiver simple explanations of all procedures before you carry them out and information about the plan of care. If they ask questions about progress and prognosis, give simple and honest answers.

If possible, the same nurses should care for the patient. This decreases anxiety, limits conflicting information, and increases trust. If the prognosis becomes grave, support the caregiver when making tough decisions, such as withdrawing life support. The health care team must promote realistic expectations and outcomes. Remember, compassion is as essential as scientific and technical expertise in providing care.

Ensure that the caregiver can spend time with the patient, provided the patient perceives this time as comforting.[20] Explain in simple terms the purpose of any tubes and equipment attached to or surrounding the patient. Tell them what they may and may not touch. If possible, place the patient's hands and arms outside the sheets to encourage therapeutic touch. Encourage caregivers to perform simple comfort measures if desired. Provide privacy as much as possible while assuring them that help is readily available should it be needed. Always position the call light in reach of the patient or caregiver.

Ambulatory Care

Rehabilitation of the patient who had a critical illness requires prevention or early treatment of complications and teaching focused on disease management or prevention of recurrence based on the initial cause of shock. Continue to monitor the patient for complications throughout the recovery period. These may include decreased range of motion, muscle weakness, decreased physical endurance, AKI (see Chapter 51), and fibrotic lung disease (from ARDS) (see Chapter 32). Patients recovering from shock often need diverse services after discharge. These can include admission to transitional care units (e.g., for mechanical ventilation weaning), rehabilitation centers (inpatient or outpatient), or home health care agencies. Start planning for a safe transition from hospital to home as soon as the patient is admitted to the hospital.

Evaluation

The expected outcomes are that the patient who has shock will have:

- Adequate tissue perfusion with restoration of normal or baseline BP
- Normal organ function with no complications from hypoperfusion
- Decreased fear and anxiety

SYSTEMIC INFLAMMATORY RESPONSE SYNDROME AND MULTIPLE ORGAN DYSFUNCTION SYNDROME

Etiology and Pathophysiology

Systemic inflammatory response syndrome (SIRS) is a systemic inflammatory response to a variety of insults, including infection (sepsis), ischemia, infarction, and injury.[20] Generalized inflammation in organs remote from the initial insult characterizes SIRS. Many different mechanisms can trigger SIRS. These include:

- Mechanical tissue trauma: burns, crush injuries, surgery
- Abscess formation: intraabdominal, extremities
- Ischemic or necrotic tissue: pancreatitis, vascular disease, MI
- Microbial invasion: bacteria, viruses, fungi, parasites
- Endotoxin release: gram-negative and gram-positive bacteria
- Global perfusion deficits: postcardiac resuscitation, shock states
- Regional perfusion deficits: distal perfusion deficits

Multiple organ dysfunction syndrome (MODS) is the failure of 2 or more organ systems in an acutely ill patient such that homeostasis cannot be maintained without intervention.[21] MODS results from SIRS. These 2 syndromes represent the ends of a continuum. Transition from SIRS to MODS does not occur in a clear-cut manner (Fig. 42.1).

Organ and Metabolic Dysfunction

When the inflammatory response is activated, consequences include the release of mediators, direct damage to the endothelium, and hypermetabolism. Vascular permeability increases. This allows mediators and protein to leak out of the endothelium and into the interstitial space. White blood cells begin to digest the foreign debris, and the coagulation cascade is activated (see Chapter 33). Hypotension, decreased perfusion, microemboli, and redistributed or shunted blood flow eventually compromise organ perfusion.

The respiratory system is often the first system to show signs of dysfunction in SIRS and MODS.[21] Inflammatory mediators have a direct effect on the pulmonary vasculature. The endothelial damage from the release of inflammatory mediators causes increased capillary permeability. This causes movement of fluid from the pulmonary vasculature into the pulmonary interstitial spaces. The fluid then moves to the alveoli, causing alveolar edema. Type I pneumocytes (alveolar cells) are destroyed. Type II pneumocytes are damaged. Surfactant production is decreased. The alveoli collapse. This creates an increase in *shunt* (blood flow to the lungs that does not take part in gas exchange) and worsening ventilation-perfusion mismatch. The result is ARDS. Patients with ARDS need aggressive pulmonary management with mechanical ventilation. See Chapter 32 for a discussion of ARDS.

Cardiovascular changes include myocardial depression and massive vasodilation in response to increasing tissue demands. Vasodilation results in decreased SVR and BP. The baroreceptor reflex causes release of *inotropic* (increasing force of contraction) and *chronotropic* (increasing heart rate) factors that enhance CO. To compensate for hypotension, CO increases by an increase in heart rate and SV. Increases in capillary permeability cause a shift of albumin and fluid out of the vascular space. This further reduces venous return and thus preload. The patient becomes warm and tachycardic with a high CO and a low SVR. Other signs include decreased capillary refill, skin mottling, increased CVP and PAWP, and dysrhythmias. $ScvO_2$ or SvO_2 may be abnormally high because the patient is perfusing areas not consuming much O_2 (e.g., skin, nonworking muscle). Other areas may have blood shunted away from them. Eventually, either perfusion of vital organs becomes insufficient or the cells are unable to use O_2 and their function is further compromised.

Neurologic dysfunction in SIRS and MODS often presents as mental status changes. These acute changes can be an early sign of SIRS or MODS. The patient may be confused and agitated, combative, disoriented, lethargic, or comatose. These changes are due to hypoxemia, the effects of inflammatory mediators, and impaired perfusion.

AKI from hypoperfusion and the effects of the mediators are common. Decreased renal perfusion activates the SNS and the renin-angiotensin system. Stimulating the renin-angiotensin system causes systemic vasoconstriction and aldosterone-mediated sodium and water reabsorption. Another risk factor for AKI is the use of nephrotoxic drugs. Many antibiotics used to treat gram-negative bacteria (e.g., aminoglycosides) can be nephrotoxic. Careful monitoring of drug levels is essential to avoid nephrotoxic effects.

The GI tract plays a key role in the development of MODS. GI motility is often decreased in critical illness, causing abdominal distention and paralytic ileus. In the early stages of SIRS and MODS, blood is shunted away from the GI mucosa. This makes it highly vulnerable to ischemic injury. Decreased perfusion leads to a breakdown of the normally protective mucosal barrier. This increases the risk for ulceration, GI bleeding, and bacterial movement from the GI tract into circulation.

Metabolic changes are pronounced. Both SIRS and MODS trigger a hypermetabolic response. Glycogen stores are rapidly converted to glucose (glycogenolysis). Once glycogen is depleted, amino acids are converted to glucose (gluconeogenesis), reducing protein stores. Fatty acids are mobilized for fuel. Catecholamines and glucocorticoids are released and cause hyperglycemia and insulin resistance. The net result is a catabolic state with a loss of lean body mass (muscle).

Hypermetabolism may last for several days and cause liver dysfunction. Liver dysfunction in MODS may begin long before clinical evidence of it is present. Protein synthesis is impaired. The liver cannot make albumin, a key protein in maintaining plasma oncotic pressure. This changes plasma oncotic pressure, causing fluid and protein to leak from the vascular spaces to the interstitial space. At this point, giving albumin does not normalize oncotic pressure.

As hypermetabolism persists, the patient cannot convert lactate to glucose and lactate accumulates (lactic acidosis). Despite increases in glycogenolysis and gluconeogenesis, eventually the liver cannot maintain an adequate glucose level and the patient becomes hypoglycemic. Hypoglycemia can also develop due to acute adrenal insufficiency.

DIC may result from dysfunction of the coagulation system. DIC causes microvascular clotting and bleeding at the same time because of the depletion of clotting factors and excessive fibrinolysis. Chapter 34 discusses DIC.

Electrolyte imbalances are common. They result from the hormonal and metabolic changes and fluid shifts. These changes worsen mental status changes, neuromuscular problems, and dysrhythmias. ADH and aldosterone release results in sodium and water retention. Aldosterone increases urinary potassium loss. Catecholamines cause potassium to move into the cell, causing hypokalemia. Hypokalemia can cause dysrhythmias and muscle weakness. Metabolic acidosis results from impaired tissue perfusion, hypoxia, and the shift to anaerobic metabolism. This increases lactate levels. Progressive renal dysfunction contributes to metabolic acidosis. Hypocalcemia, hypomagnesemia, and hypophosphatemia are common.

Clinical Manifestations of SIRS and MODS

The clinical manifestations of SIRS and MODS are described in Table 42.10.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: SIRS AND MODS

The prognosis for the patient with MODS is poor, with mortality rates of 40% to 60%.[21] Mortality increases as more organ systems fail. The most common cause of death is sepsis. Survival improves with early, goal-directed therapy. So, the most important goal is to prevent SIRS from progressing to MODS.

Your key role is vigilant assessment and ongoing monitoring to detect early signs of deterioration or organ dysfunction. Interprofessional care for patients with SIRS and MODS focuses on (1) preventing and treating infection, (2) maintaining tissue oxygenation, (3) nutrition and metabolic support, and (4) appropriate support of individual failing organs. Table 42.10 outlines the management for patients with SIRS and MODS.

TABLE 42.10 Manifestations and Management of SIRS and MODS

Manifestations	Management
Cardiovascular System	
Biventricular failure	Volume management to ↑ preload
↓ BP, MAP, SVR	Hemodynamic monitoring
↑ HR, CO, SV	Arterial pressure monitoring to maintain MAP >65 mm Hg
Massive vasodilation	Vasopressors
Myocardial depression	Intermittent or continuous $ScvO_2$ or SvO_2 monitoring
Systolic, diastolic dysfunction	Balance O_2 supply and demand
	Continuous ECG monitoring
	Circulatory assist devices
	VTE prophylaxis
Central Nervous System	
Acute change in neurologic status	Evaluate for hepatic or metabolic encephalopathy
Confusion, disorientation, delirium	Optimize cerebral blood flow
Fever	↓ Cerebral O_2 requirements
Hepatic encephalopathy	Prevent secondary tissue ischemia
Seizures	Calcium channel blockers (reduce cerebral vasospasm)
Endocrine System	
Hyperglycemia → hypoglycemia	Provide continuous insulin infusion and glucose to maintain blood glucose 140–180 mg/dL (7.77–10.0 mmol/L)
Gastrointestinal System	
GI bleeding	Stress ulcer prophylaxis
Hypoperfusion → ↓ peristalsis, paralytic ileus	• Antacids (e.g., Maalox) • Proton pump inhibitors (e.g., omeprazole) • sucralfate (Carafate)
Mucosal ischemia • ↓ Intramucosal pH • Potential translocation of gut bacteria • Potential abdominal compartment syndrome	Monitor abdominal distention, intraabdominal pressures Dietitian consult Enteral nutrition Stimulate mucosal activity Provide essential nutrients and optimal calories
Mucosal ulceration on endoscopy	

Manifestations	Management
Hepatic System	
Bilirubin >2 mg/dL (34 μmol/L)	Maintain adequate tissue perfusion
Hepatic encephalopathy	Provide nutrition support (e.g., enteral nutrition)
Jaundice	Careful use of drugs metabolized by liver
↑ Liver enzymes (ALT, AST, GGT)	
↓ Serum albumin, prealbumin, transferrin	
↑ Serum NH_3 (ammonia)	
Hematologic System	
↑ Bleeding times, ↑ PT, ↑ PTT	Observe for bleeding from obvious and/or occult sites
↑ D-dimer	Replace factors being lost (e.g., platelets)
↑ Fibrin split products	Minimize traumatic interventions (e.g., IM injections, multiple venipunctures)
↓ Platelet count (thrombocytopenia)	
Renal System	
Prerenal: renal hypoperfusion • BUN/creatinine ratio >20:1 • ↓ Urine Na^+ <20 mEq/L • ↑ Urine osmolality • Urine specific gravity >1.020	Diuretics • Loop diuretics (e.g., furosemide) • May need to ↑ dosage due to ↓ glomerular filtration rate
Intrarenal: acute tubular necrosis • BUN/creatinine ratio <10:1–15:1 • ↑ Urine Na^+ >20 mEq/L • ↓ Urine osmolality • Urine specific gravity ~1.010	Continuous renal replacement therapy (see Chapter 51)
Respiratory System	
• Development of ARDS (see Chapter 32): • Bilateral fluffy infiltrates on chest x-ray • ↓ Compliance • Dyspnea (severe)	Optimize O_2 delivery and minimize O_2 consumption Mechanical ventilation (see Chapter 28) • Positive end-expiratory pressure • Lung protective modes (e.g., pressure-control inverse ratio ventilation, low tidal volumes) • Permissive hypercapnia • Positioning (e.g., continuous lateral rotation therapy, prone positioning)
• ↑ C-reactive protein • Minute ventilation • PaO_2/FIO_2 ratio <200 • PAWP <18 mm Hg • Pulmonary hypertension • Refractory hypoxemia • Tachypnea • Ventilation-perfusion (V/Q) mismatch	

ALT, Alanine aminotransferase; *AST,* aspartate aminotransferase; *GGT,* γ-glutamyl transferase; *PA,* pulmonary artery; *PAWP,* pulmonary artery wedge pressure; *PT,* prothrombin time; *PTT,* partial thromboplastin time; *$ScvO_2$,* O_2 saturation in venous blood; *SvO_2,* O_2 saturation in mixed venous blood; *SVR,* systemic vascular resistance.

Preventing and Treating Infection

Aggressive infection control strategies are essential to decrease the risk for HAIs. Early, aggressive surgery is recommended to remove necrotic tissue (e.g., early debridement of burn tissue) that can provide a culture medium for microorganisms. Aggressive pulmonary management, including early mobilization, can reduce the risk for infection. Strict asepsis can decrease infections related to intraarterial lines, endotracheal tubes, indwelling urinary catheters, IV lines, and other invasive devices or procedures. Daily assessment of the ongoing need for invasive lines and other devices is an important strategy to prevent or limit HAIs.

Despite aggressive strategies, infection may develop. Once an infection is suspected, begin interventions to treat the cause. Send appropriate cultures and start broad-spectrum antibiotic therapy, as ordered. Adjust therapy based on the culture results, if needed.

Maintaining Tissue Oxygenation

Hypoxemia often occurs because patients have greater O_2 needs and decreased O_2 supply to the tissues. Interventions that decrease O_2 demand and increase O_2 delivery are essential. Sedation, mechanical ventilation, analgesia, and rest may decrease O_2 demand and should be considered. Treating fever, chills, and pain decreases O_2 demand. O_2 delivery may be optimized by individualizing tidal volumes with positive end-expiratory pressure, increasing preload (e.g., fluids) or myocardial contractility to enhance CO, or reducing afterload to increase CO.

Nutrition and Metabolic Needs

Hypermetabolism can result in profound weight loss, cachexia, and further organ failure. Protein-calorie malnutrition is a key sign of hypermetabolism. Total energy expenditure is often increased 1.5 to 2.0 times the normal metabolic rate. Because of their short half-life, monitor plasma transferrin and prealbumin levels to assess hepatic protein synthesis.

The goal of nutrition support is to preserve organ function. Providing early and optimal nutrition decreases morbidity and mortality rates. EN is preferred. If we cannot use EN, then consider PN (see Chapter 44). Provide glycemic control with insulin with a goal of 180 mg/dL or less.[6]

Support of Failing Organs

Support of any failing organ is a goal of therapy. For example, the patient with ARDS requires aggressive O_2 therapy and mechanical ventilation (see Chapter 28). DIC should be treated appropriately (e.g., blood products) (see Chapter 34). Renal failure may require dialysis. Continuous renal replacement therapy is better tolerated than hemodialysis, especially in a patient with hemodynamic instability (see Chapter 51).

A final consideration may be that further interventions are futile. It is important to maintain communication between the health care team and the patient's caregiver about realistic goals and outcomes for the patient with MODS. Withdrawing life support and starting end-of-life care may be the best options for the patient.

Case Study

Shock

Patient Profile

K.L., a 25-year-old Korean American male, was not wearing his seat belt when he was driving a motor vehicle involved in a crash. K.L. was ejected through the windshield and found 10 ft from his car. He was face down, conscious, and moaning. His wife and daughter were in the car with their seat belts on. They sustained minor injuries and are very frightened and upset. All passengers were taken to the ED. This information pertains to K.L.

Subjective Data

- States, "I can't breathe"
- Cries out when abdomen is palpated

Objective Data

Physical Assessment

- *Cardiovascular:* BP 80/56 mm Hg; apical pulse 138 but no palpable radial or pedal pulses; carotid pulse 1+. ECG shows:

- *Respiratory:* respiratory rate 35 breaths/min; labored breathing with shallow respirations; asymmetric chest wall movement; absence of breath sounds on left side. Trachea deviated slightly to the right
- *Abdomen:* slightly distended and left upper quadrant painful on palpation
- *Musculoskeletal:* open compound fracture of the lower left leg

Diagnostic Studies

- Chest x-ray: hemothorax with 6 rib fractures
- Hematocrit: 28%

Interprofessional Care (in the ED)

- Intraosseous access in right proximal tibia placed prehospital
- Left chest tube placed, draining bright red blood
- Fluid resuscitation started with crystalloids
- High-flow O_2 via nonrebreather mask

Emergency Surgical Procedures

- Splenectomy
- Repair of torn intercostal artery
- Repair of compound fracture

Discussion Questions

- ***Recognize***: What types of shock is K.L. experiencing? What clinical manifestations of this type does he display?
- ***Recognize***: What were the causes of K.L.'s shock states?
- ***Analyze***: What are his potential complications?
- ***Plan:*** What ongoing nursing assessment parameters are essential?
- ***Prioritize:*** Based on the assessment data presented, what are the priority clinical problems?
- ***Prioritize:*** What are the priority nursing responsibilities for K.L.?
- ***Act:*** K.L.'s parents arrive. English is their second language. They are very anxious and asking about their son. What can you do to provide culturally competent family-centered care?
- ***Act:*** Identify the tasks that could be delegated to assistive personnel (AP).

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient has a spinal cord injury at T4. Vital signs include falling blood pressure with bradycardia. The nurse recognizes that the patient is experiencing
   - **a.** a relative hypervolemia.
   - **b.** an absolute hypovolemia.
   - **c.** neurogenic shock from low blood flow.
   - **d.** neurogenic shock from massive vasodilation.
2. A 78-year-old man with a history of diabetes has confusion and temperature of 104°F (40°C). There is a wound on his right heel with purulent drainage. After an infusion of 3 L of normal saline solution, his assessment findings are BP 84/40 mm Hg; heart rate 110; respiratory rate 42 and shallow; CO 8 L/min; and PAWP 4 mm Hg. This patient's symptoms are *most* likely indicative of
   - **a.** sepsis.
   - **b.** septic shock.
   - **c.** multiple organ dysfunction syndrome.
   - **d.** systemic inflammatory response syndrome.
3. Treatment for cardiogenic shock includes *(select all that apply)*
   - **a.** dobutamine to increase myocardial contractility.
   - **b.** vasopressors to increase systemic vascular resistance.
   - **c.** circulatory assist devices such as an intraaortic balloon pump.
   - **d.** corticosteroids to stabilize the cell wall in the infarcted myocardium.
   - **e.** Trendelenburg positioning to facilitate venous return and increase preload.
4. The *most* accurate assessment parameters for the nurse to use to determine adequate tissue perfusion in the patient with MODS are
   - **a.** blood pressure, pulse, and respirations.
   - **b.** breath sounds, blood pressure, and body temperature.
   - **c.** pulse pressure, level of consciousness, and pupillary response.
   - **d.** level of consciousness, urine output, and skin color and temperature.

1. d; 2. b; 3. a, c; 4. d.

Case Study

Applying Clinical Judgment With Multiple Patients

You are working on the cardiovascular stepdown unit and have been assigned to care for the following 5 patients. You have 1 AP assigned to help you.

(© Jupiterimages/ Banana-Stock/ Thinkstock)	L.P. is a 63-year-old man who came to the ED with chest pain, dyspnea, and palpitations. Cardiac enzymes were normal. ECG showed atrial fibrillation with a rapid ventricular response. He has been on IV diltiazem and IV heparin for 24 hr. Although his heart rate has decreased, the atrial fibrillation persists. Vital signs: 124/72, 102, RR 18, O_2 saturation 98% on 2 L/min via nasal cannula.
(© iStockphoto/ Thinkstock.)	J.E. is a 70-year-old woman admitted with shortness of breath, fatigue, and weight gain. She has a systolic murmur and bilateral crackles. Her ejection fraction is 20%. She is receiving IV furosemide, PO potassium and enalapril, and IV nesiritide infusion. Cardiac enzymes are normal. Vital signs: 108/62, 92, RR 22, O_2 saturation 94% on 6 L/min via nasal cannula.
(© iStockphoto/ Thinkstock.)	D.M. is a 51-year-old man who was admitted 2 days ago with a suspected inferolateral wall MI. Cardiac catheterization showed a 90% blockage of his left anterior descending (LAD) artery. Angioplasty was done, and 2 stents inserted. During his admission, he has been diagnosed with diabetes and hypertension. He is now 2 days post-PTCA, has had no recurrence of his chest pain, and is to be discharged today.
(© iStockphoto/ Thinkstock.)	J.M. is a 68-year-old man admitted 5 days ago with acute decompensated HF. He had electrophysiology studies and implantation of an implantable cardiodefibrillator (ICD). He now is being treated for HF. Discharge is expected tomorrow.
(© iStockphoto/ Thinkstock.)	S.J. is a 73-year-old man admitted with rest pain in both legs and a nonhealing ulcer of the big toe on the right foot. He has history of MI, stroke, hypertension, and type 1 diabetes. He had a left femoral-popliteal bypass 5 years ago. Right foot is cool, pale, and mottled with decreased sensation. He has a 1+ right femoral pulse, right posterior tibial pulse only obtained by Doppler. Right dorsalis pedis pulse absent by Doppler. Left leg pulses are 1+. Vital signs: 148/92, 90 and irregular, RR 22.

1. Highlight all the findings above that require your follow-up.
2. After receiving report, which patient should you see first? Second?
3. Which tasks could you delegate to the AP? *(select all that apply)*
   a. Calculating intake for L.P.'s heparin infusion.
   b. Report changes in pain or sensation of S.J.'s legs.
   c. Teach D.M. about activity restriction after PTCA.
   d. Obtain vital signs and O_2 saturation for to L.P. and J.M.
   e. Hook up J.M. to 12-lead ECG and monitor for dysrhythmias.
4. As you are assessing L.P., the AP tells you that S.J. is diaphoretic and reports chest pain. Use an X for the nursing actions listed below that are Indicated (appropriate or necessary), Contraindicated (could be harmful), or Nonessential (makes no difference or not necessary) for S.J. at this time.

Nursing Action	Indicated	Contraindicated	Nonessential
Administer prescribed as-needed nitroglycerin.			
Change the right foot dressing and perform a peripheral vascular assessment.			
Obtain a 12-lead ECG and start continuous ECG monitoring per protocol.			
Call respiratory therapy to give him a breathing treatment.			
Perform focused heart and lung assessments.			
Apply O_2 per nasal cannula per protocol.			
Obtain vital signs with O_2 saturation.			

Case Study Progression

S.J. rates his chest pain as a 9/10. His blood pressure is 110/70, heart rate 110, respiratory rate 26, and O_2 saturation 93% on room air. You obtain a 12-lead ECG and administer 0.4 mg SL nitroglycerin with minimal pain relief after 5 minutes. The 12-lead ECG shows new ST elevation in leads II, III, and aVF.

5. Which interventions would you expect the HCP to order for S.J.? *(select all that apply)*
   a. Cardiac biomarkers
   b. IV morphine sulfate
   c. Emergent cardiac catheterization
   d. Furosemide 40 mg IV push STAT
   e. Increase the O_2 flow rate to 12 L/min
6. Choose the most *likely* option for the information missing from statement below by selecting from the lists of options provided.

Case Study—cont'd

Because J.E is receiving nesiritide, he is at risk for experiencing _____**1**_____. To detect this complication, you will need to monitor _____**2**_____.

Options for 1	Options for 2
Hypokalemia	Blood pressure
Hypotension	Respiratory rate
respiratory depression	Serum potassium levels

7. You are preparing to give morning medications. Which patient's medication should be given first?
   a. Oral potassium and enalapril to J.E.
   b. Oral metoprolol, aspirin, and clopidogrel to D.M.
   c. IV furosemide, oral enalapril and metoprolol to J.M.
   d. Subcut Novolog, oral diltiazem and furosemide to S.J.
8. What would you include in teaching about ICDs with J.M. and his family?
   a. Avoid air travel.
   b. Avoid driving for 6 weeks.
   c. Avoid any sexual activity in case the ICD discharges.
   d. Avoid standing near antitheft devices in stores and public buildings.
9. You are reviewing J.M.'s assessment findings in preparation for his discharge tomorrow. For each assessment finding, use an X to indicate whether the interventions were Effective (helped to meet expected outcomes), Ineffective (did not help to meet expected outcomes), or Unrelated (not related to the expected outcomes).

Assessment Finding	Effective	Ineffective	Unrelated
Peripheral edema is 3+ bilaterally			
Can walk to the bathroom and back without becoming fatigued and short of breath			
Heart rate 101/min, regular			
Restlessness, inattentive			
Weight has decreased by 12 lb in 5 days			
Normal bowel sounds			
Reports no chest pain after walking in hall			

10. You ask the AP to take D.M.'s vital signs before and after having him walk 300 feet. When reviewing the patient's chart, you note record of the patient's walk but not his vital signs. What is your initial action?
    a. Report the incident to the charge nurse for follow-up.
    b. Talk to the AP about why the vital signs were not recorded.
    c. Walk D.M. yourself again and take his vital signs pre- and post-activity.
    d. Ask the AP to ambulate D.M. again and obtain his vital signs before and after.

Assessment: Gastrointestinal System

Kara Ann Ventura

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Elimination
Fluids and Electrolytes
Nutrition

LEARNING OUTCOMES

1. Describe the structures and functions of the organs of the gastrointestinal tract.
2. Describe the structures and functions of the liver, gallbladder, biliary tract, and pancreas.
3. Distinguish the processes of ingestion, digestion, absorption, and elimination.
4. Explain the processes of biliary metabolism, bile production, and bile excretion.
5. Link the age-related changes of the gastrointestinal system to the differences in assessment findings.
6. Obtain significant subjective and objective assessment data related to the gastrointestinal system from a patient.
7. Perform a physical assessment of the gastrointestinal system using appropriate techniques.
8. Distinguish normal from abnormal findings of a physical assessment of the gastrointestinal system.
9. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the gastrointestinal system.

The gastrointestinal (GI) system, also called the *digestive system,* consists of the GI tract and its associated organs and glands. Included in the GI tract are the mouth, esophagus, stomach, small intestine, large intestine, rectum, and anus. The associated organs are the liver, pancreas, and gallbladder (Fig. 43.1). Problems that change physiologic processes or associated organs affect a person's ability to maintain nutrition status and eliminate waste.

STRUCTURES AND FUNCTIONS OF GASTROINTESTINAL SYSTEM

The GI tract extends around 30 ft (9 m) from the mouth to the anus. The GI tract is essentially a tube composed of 4 layers. From the inside to the outside, these layers are (1) mucosa lining; (2) submucosa connective tissue, which contains glands, blood vessels, and lymph nodes; (3) muscle; and (4) serosa.

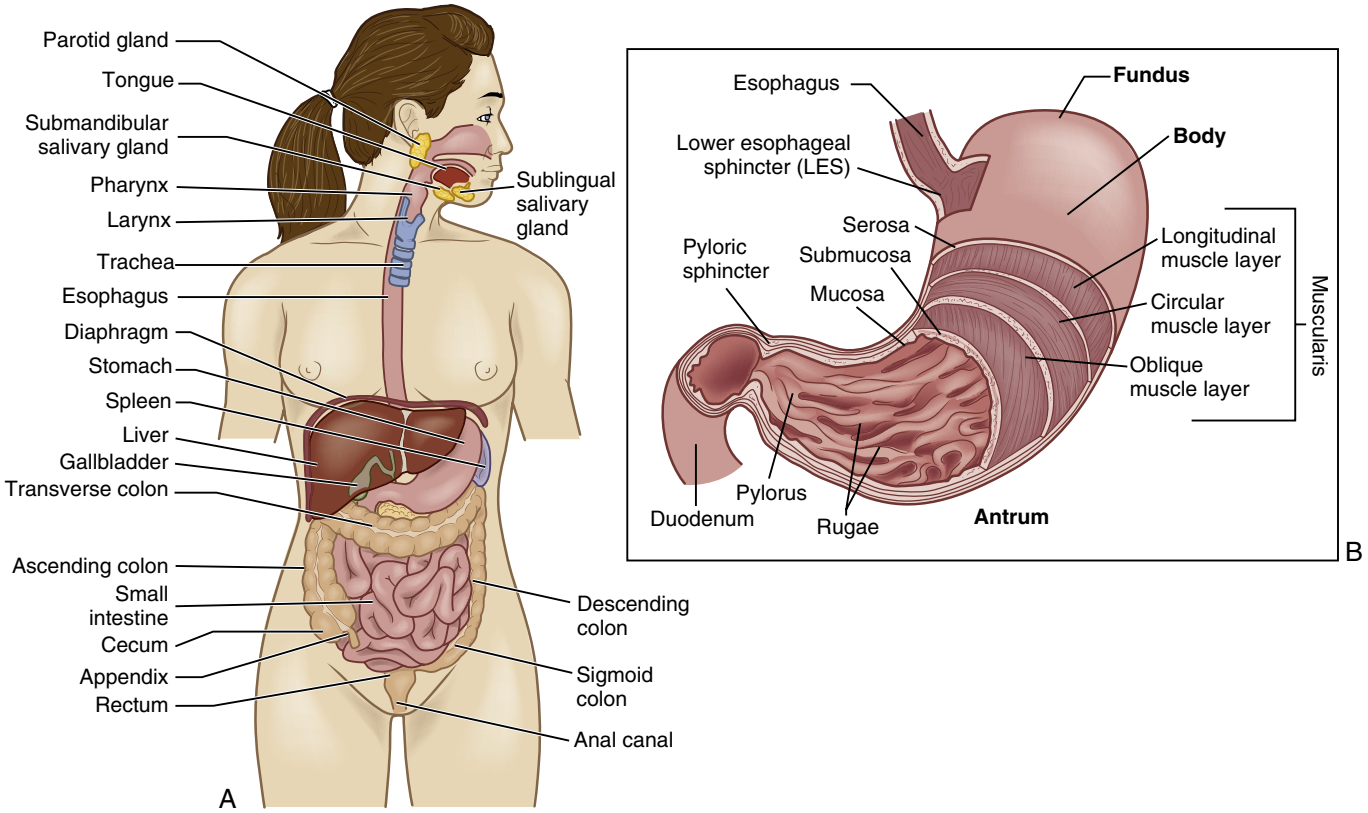

Fig. 43.1 (A) Location of organs of the GI system. (B) Parts of the stomach.

There are 3 smooth muscle layers: the oblique (inner) layer, circular (middle) layer, and longitudinal (outer) layer.

Parasympathetic and sympathetic branches of the autonomic nervous system (ANS) innervate the GI tract. The parasympathetic (cholinergic) system is mainly excitatory. The sympathetic (adrenergic) system is mainly inhibitory. For example, parasympathetic stimulation increases peristalsis, and sympathetic stimulation decreases it. Both sympathetic and parasympathetic afferent fibers relay sensory information.

The GI tract has its own nervous system: the enteric nervous system (ENS) or intrinsic nervous system. The ENS system regulates motility and secretion along the entire GI tract. The ENS is composed of 2 networks: (1) Meissner plexus in the submucosa and (2) Auerbach (myenteric) plexus between the muscle layers. The submucosal plexus controls secretion and is involved in many sensory functions. The myenteric plexus is the major nerve supply to the GI tract and controls GI movements. Although the ENS receives innervation from the ANS, it functions independently of the brain and spinal cord.

Circulation in the GI system is unique in that venous blood draining the GI tract organs empties into the portal vein, which then perfuses the liver. This allows the liver to clean the blood of bacteria and toxins from the GI tract. The celiac artery, superior mesenteric artery (SMA), and the inferior mesenteric artery (IMA) supply arterial blood to the GI tract. The stomach and duodenum receive their blood supply from the celiac axis. The distal small intestine to mid large intestine receives its blood supply from branches of the hepatic and SMA. The distal large intestine through the anus receives its blood supply from the IMA. The GI tract and accessory organs receive 25% to 30% of the cardiac output at rest and 35% or more after eating. Because such a large percent of the cardiac output perfuses these organs, the GI tract is a major source from which to divert blood flow during exercise, stress, or injury.

The peritoneum almost completely covers the abdominal organs. The 2 layers of the peritoneum are the *parietal layer,* which lines the abdominal cavity wall, and the *visceral layer*. It covers the abdominal organs. The peritoneal cavity is the potential space between the parietal and visceral layers. The 2 folds of the peritoneum are the mesentery and omentum. The mesentery attaches the small intestine and part of the large intestine to the posterior abdominal wall. It contains blood and lymph vessels. The omentum hangs like an apron from the stomach to the intestines. It contains fat and lymph nodes.

The main function of the GI system is to supply nutrients to body cells. This is accomplished through the processes of (1) *ingestion* (taking in food), (2) *digestion* (breaking down food), and (3) *absorption* (transferring food products into circulation). *Elimination* is the process of excreting the waste products of digestion.

Ingestion

Ingestion is the intake of food. *Appetite,* the desire to ingest food, influences how much food a person eats. We have an appetite center in the hypothalamus. Several factors, including hypoglycemia, an empty stomach, and a decrease in body temperature, stimulate appetite. The hormone *ghrelin* released from the stomach mucosa plays a role in appetite stimulation. Another hormone, *leptin,* is

involved in appetite suppression. See Chapter 48 for more about ghrelin and leptin. The sight, smell, and taste of food can stimulate appetite. Stomach distention, illness (especially accompanied by fever), hyperglycemia, nausea and vomiting, and certain drugs (e.g., amphetamines) inhibit appetite.

Deglutition, or swallowing, is the mechanical portion of ingestion. The organs involved in deglutition are the mouth, pharynx, and esophagus.

Mouth

The mouth consists of the lips and oral (buccal) cavity. The lips surround the opening of the mouth and function in speech. The hard and soft palates form the roof of the oral cavity. The oral cavity contains the teeth, used in *mastication* (chewing), and the tongue. The tongue is a solid muscle mass. It aids in chewing and moving food to the back of the throat for swallowing. The taste receptors (taste buds) are on the sides and tip of the tongue. The tongue is also important in speech.

Within the oral cavity are 3 pairs of salivary glands: parotid, submaxillary, and sublingual glands. These glands produce saliva. Saliva consists of water, protein, mucin, inorganic salts, and salivary amylase.

Pharynx

The pharynx is a muscular tube lined with mucous membrane. It has 3 divisions: nasopharynx, oropharynx, and laryngeal pharynx. The mucous membrane is continuous with the nasal cavity, mouth, auditory tubes, and larynx. During ingestion, the oropharynx is the route for food from the mouth to the esophagus. Food or liquid stimulates receptors in the oropharynx, initiating the swallowing reflex. During swallowing, the epiglottis closes over the opening to the larynx and prevents food from entering the respiratory tract. The tonsils and adenoids, composed of lymphoid tissue, help the body prevent infection.

Esophagus

The esophagus is a hollow, muscular tube that receives food from the pharynx and moves it to the stomach. It is 7 to 10 in (18 to 25 cm) long and 0.8 in (2 cm) in diameter. The esophagus is in the thoracic cavity. It is structurally composed of 4 layers: inner mucosa, submucosa, muscularis propria, and outermost adventitia. The upper third of the esophagus is composed of striated skeletal muscle. The distal two thirds are composed of smooth muscle.

Between swallows, the esophagus is collapsed and the *upper esophageal sphincter* (UES) closed. With swallowing, the UES relaxes, and a peristaltic wave moves the bolus into the esophagus. The muscular layers contract *(peristalsis)* and propel the food to the stomach. The *lower esophageal sphincter* (LES) at the distal end of the esophagus controls the opening of the esophagus into the stomach. It stays contracted except during swallowing, belching, or vomiting. The LES is an important barrier that normally prevents reflux of acidic gastric contents into the esophagus.

Digestion and Absorption

Stomach

The stomach's functions are to store food, mix food with gastric secretions, and empty contents in small boluses into the small intestine. The stomach absorbs only small amounts of water, alcohol, electrolytes, and certain drugs.

The stomach is usually J shaped and lies obliquely in the epigastric, umbilical, and left hypochondriac regions of the abdomen (Fig. 43.5, later in the chapter). It always contains gastric fluid and mucus. The 3 main parts of the stomach are the fundus (cardia), body, and antrum (Fig. 43.1). The pylorus is a small portion of the antrum proximal to the pyloric sphincter. The LES and pyloric sphincter guard the entrance to and exit from the stomach.

The stomach wall has 4 layers. The serous (outer) layer of the stomach is continuous with the peritoneum. The muscular layer consists of the longitudinal (outer) layer, circular (middle) layer, and oblique (inner) layer. The mucosal layer forms folds called rugae that have many small glands. In the fundus, the glands contain (1) chief cells, which secrete pepsinogen, and (2) parietal cells, which secrete hydrochloric (HCl) acid, water, and intrinsic factor. HCl acid makes gastric juice acidic. This acidic pH helps protect us against ingested organisms. Intrinsic factor promotes cobalamin (vitamin B_{12}) absorption in the small intestine.

Small Intestine

The primary functions of the small intestine are digestion and **absorption**, the uptake of nutrients from the gut lumen to the bloodstream. The small intestine is a coiled tube about 23 ft (7 m) in length and 1 to 1.1 in (2.5 to 2.8 cm) in diameter. It extends from the pylorus to the ileocecal valve. The small intestine is composed of the duodenum, jejunum, and ileum. The ileocecal valve prevents reflux of large intestine contents into the small intestine.

The mucosa of the small intestine is thick, vascular, and glandular. The functional units of the small intestine are *villi*. They are minute, fingerlike projections in the mucous membrane. Villi contain epithelial cells that produce the intestinal digestive enzymes. The epithelial cells on the villi also have *microvilli*. The circular folds in the mucous and submucous layers, along with the villi and microvilli, increase the surface area for digestion and absorption.

The digestive enzymes on the brush border of the microvilli chemically break down nutrients for absorption. Between the bases of the villi lie the crypts of Lieberkühn, which contain the multipotent stem cells. These are the precursors for the other epithelial cell types. Brunner's glands in the submucosa of the duodenum secrete an alkaline fluid containing bicarbonate that neutralizes acidic fluids and protects the mucosa. Intestinal goblet cells secrete mucus that protects the mucosa.

Physiology of Digestion

Digestion is the physical and chemical breakdown of food into absorbable substances. The timely movement of food through the GI tract and the secretion of specific enzymes promote digestion. These enzymes break down food to particles of appropriate size for absorption (Table 43.1).

The process of digestion begins in the mouth, where food is chewed, mechanically broken down, and mixed with saliva. Saliva helps us swallow by lubricating food. Saliva contains amylase, which breaks down starches to maltose. Chewing and the sight, smell, thought, and taste of food stimulate the release of saliva. A person makes about 1 L of saliva each day. After

TABLE 43.1 GI Secretions

Daily Amount (mL)	Secretions/ Enzymes	Action
Salivary Glands		
1000–1500	Salivary amylase	Initiates starch digestion
Stomach		
2500	HCl acid	Activation of pepsinogen to pepsin
	Intrinsic factor	Essential for cobalamin absorption in ileum
	Lipase	Fat digestion
	Pepsinogen	Protein digestion
Small Intestine		
3000	Aminopeptidases	Protein digestion
	Amylase	Carbohydrate digestion
	Enterokinase	Activation of trypsinogen to trypsin
	Lactase	Lactose to glucose and galactose
	Lipase	Fat digestion
	Maltase	Maltose to 2 glucose molecules
	Peptidases	Protein digestion
	Sucrase	Sucrose to glucose and fructose
Pancreas		
700	Amylase	Starch to disaccharides
	Chymotrypsin	Protein digestion
	Lipase	Fat digestion
	Trypsinogen	Protein digestion
Liver and Gallbladder		
1000	Bile	Emulsifies fats and aids in absorption of fatty acids and fat-soluble vitamins (A, D, E, K)

TABLE 43.2 Phases of Gastric Secretion

Stimulus to Secretion	Secretion
Cephalic (nervous)	
Sight, smell, taste of food (before food enters stomach). Initiated in the CNS and mediated by the vagus nerve.	HCl acid, pepsinogen, mucus
Gastric (hormonal and nervous)	
Food in antrum of stomach, vagal stimulation.	Release of gastrin from antrum into circulation to stimulate gastric secretions and motility
Intestinal (hormonal)	
Presence of chyme in small intestine.	*Acidic chyme* (pH <2): Release of secretin, gastric inhibitory polypeptide, cholecystokinin into circulation to decrease HCl acid secretion *Chyme* (pH >3): Release of gastrin from duodenum to increase acid secretion

swallowing, food moves through the esophagus to the stomach. No digestion or absorption occurs in the esophagus.

Both GI secretion and motility are under neural and hormonal control. Food entering the stomach and small intestine triggers the release of hormones into the bloodstream (Tables 43.2 and 43.3). These hormones play important roles in the control of HCl acid secretion, production and release of digestive enzymes, and motility.

In the stomach, muscle action mixes the food with gastric secretions to form *chyme,* which is now ready for absorption. Protein digestion begins with the release of pepsinogen from chief cells. The stomach's acidic environment results in the conversion of pepsinogen to its active form, pepsin. Pepsin begins the breakdown of proteins. There is minimal digestion of starches and fats. The stomach also serves as a reservoir for food, releasing it slowly into the small intestine. The length of time that food stays in the stomach depends on the composition of the food. The average meal stays in the stomach for 3 to 4 hours.

In the small intestine, the physical presence and chemical nature of chyme stimulates motility and secretion. Secretions involved in digestion include enzymes from the pancreas, bile from the liver, and enzymes from the small intestine (Table 43.1). Carbohydrates are broken down to monosaccharides, fats to glycerol and fatty acids, and proteins to amino acids. Enzymes on the brush border of the microvilli complete the digestion process. These enzymes break down disaccharides to monosaccharides and peptides to amino acids for absorption.

The absorption of most of the end products of digestion occurs in the small intestine. The movement of the villi enables these end products to come in contact with the absorbing membrane. Monosaccharides, fatty acids, amino acids, water, electrolytes, vitamins, and minerals are absorbed.

Elimination

Large Intestine

The large intestine is a hollow, muscular tube around 5 to 6 ft (1.5 to 1.8 m) long and 2 in (5 cm) in diameter. The 4 parts of the large intestine are shown in Fig. 43.2.

The most important functions of the large intestine are water and electrolyte absorption. The large intestine also forms feces and serves as a reservoir for the fecal mass until defecation occurs. Feces are composed of water (75%), bacteria, unabsorbed minerals, undigested foodstuffs, bile pigments, and desquamated (shed) epithelial cells. The large intestine secretes mucus, which acts as a lubricant and protects the mucosa.

Microorganisms in the colon contribute to digestion by (1) producing vitamin K and some B vitamins and (2) breaking down proteins that are not digested or absorbed in the small intestine into amino acids. Bacteria deaminate the amino acids, resulting in ammonia. Ammonia is carried to the liver, where it is converted to urea. Urea is excreted by the kidneys. Bacteria produce gas that escapes the colon through the anus as *flatulence* or *flatus*. If an infection or antibiotics alter the normal microbiome, an overgrowth of pathogenic bacteria can occur and cause disease.

The movements of the large intestine are usually slow. However, propulsive (mass movements) peristalsis does occur. Food entering the stomach and duodenum triggers gastrocolic and duodenocolic reflexes, resulting in peristalsis in the colon. These reflexes are more active after the first daily meal and often result in bowel evacuation.

TABLE 43.3 Hormones Controlling GI Secretion and Motility

Hormone	Source	Activating Stimuli	Function
Gastrin	Gastric and duodenal mucosa	Stomach distention, partially digested proteins in pylorus	Stimulates gastric acid secretion and motility. Maintains LES tone.
Cholecystokinin	Duodenal mucosa	Fatty acids and amino acids in small intestine	Contracts gallbladder and relaxes sphincter of Oddi. Allows increased flow of bile into duodenum. Release of pancreatic digestive enzymes.
Gastric inhibitory peptide	Duodenal mucosa	Fatty acids and lipids in small intestine	Inhibits gastric acid secretion and motility.
Secretin	Duodenal mucosa	Acid entering small intestine	Inhibits gastric motility and acid secretion. Stimulates pancreatic bicarbonate secretion.

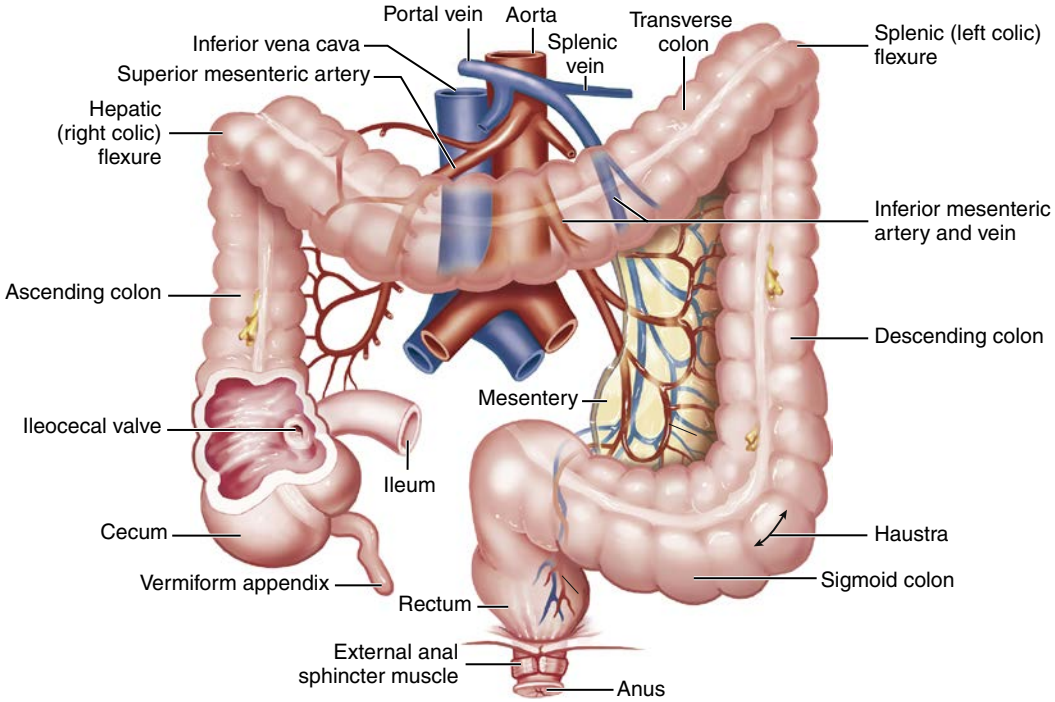

Fig. 43.2 Anatomic locations of the large intestine. (From Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2018, Mosby.)

Defecation is a reflex action involving voluntary and involuntary control. Feces in the rectum stimulate sensory nerve endings that produce the desire to defecate. The reflex center for defecation is in the parasympathetic nerve fibers in the sacral part of the spinal cord. These fibers produce contraction of the rectum and relaxation of the internal anal sphincter. When a person feels the desire to defecate, they can voluntarily relax the external anal sphincter. An acceptable environment for defecation is usually needed or the urge to defecate will be ignored. If you suppress defecation for long periods, problems can occur, such as constipation or fecal impaction.

The **Valsalva maneuver**, often referred to as "bearing down," can promote defecation. During this maneuver, the person inspires deeply and holds the breath, closing the airway, while contracting abdominal muscles and bearing down. This increases both intraabdominal and intrathoracic pressures and reduces venous return to the heart. The heart rate temporarily decreases along with a decrease in cardiac output. This results in a transient drop in BP. When the patient relaxes, thoracic pressure falls, resulting in a sudden flow of blood into the heart, increased heart rate, and an immediate rise in BP. The Valsalva maneuver may be contraindicated in the patient with a head injury, eye surgery, heart problems, hemorrhoids, abdominal surgery, or liver cirrhosis with portal hypertension.

Liver, Biliary Tract, and Pancreas

Liver

The liver is the largest internal organ in the body, weighing around 3 lb (1.36 kg). It lies in the right epigastric region (Fig. 43.5 later in the chapter). Most of the liver is enclosed in peritoneum. It has a fibrous capsule that divides it into right and left lobes (Fig. 43.3).

The functional units of the liver are lobules. A lobule consists of rows of hepatic cells *(hepatocytes)* arranged in cords that radiate out from a central vein. Capillaries called *sinusoids* lie between the rows of hepatocytes. Sinusoids are lined with **Kupffer cells**. They carry out phagocytic activity, removing bacteria and toxins from the blood. The hepatic cells secrete bile into tiny canals called *canaliculi.* These merge with other canals to form larger, interlobular bile ducts, which unite into the 2 main left and right hepatic ducts.

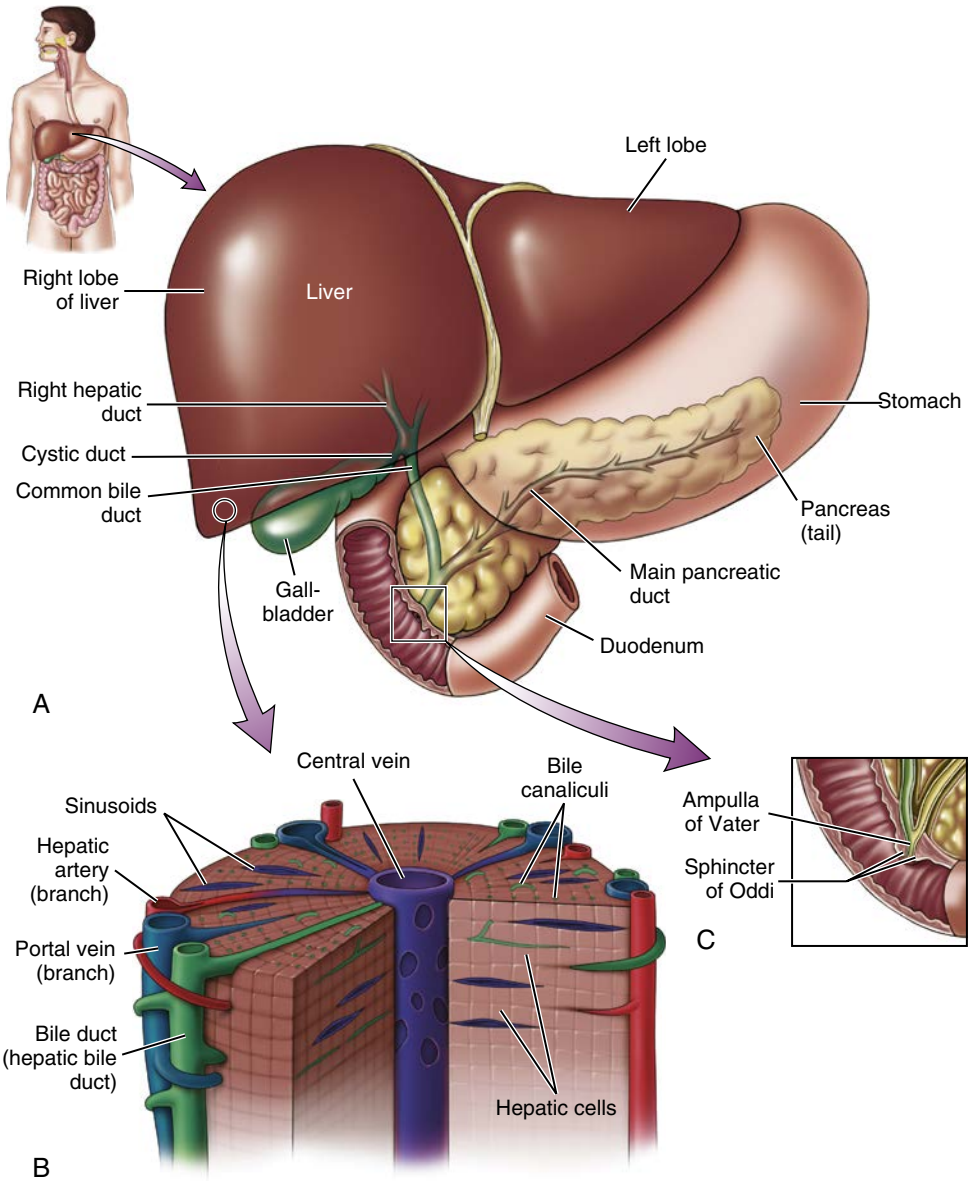

Fig. 43.3 (A) Gross structure of the liver, gallbladder, pancreas, and duct system. (B) Liver lobule. (C) Entrance of the common bile duct into the duodenum.

The liver has a rich blood supply. The portal circulatory system brings blood to the liver from the stomach, intestines, spleen, and pancreas. About 25% of the blood supply comes from the hepatic artery, a branch of the celiac artery. The other 75% comes from the portal vein. The portal vein carries absorbed products of digestion directly to the liver. Once in the liver, the portal vein branches and comes in contact with each lobule.

The liver performs many functions and is essential for life. It has metabolic, secretory, vascular, and storage functions (Table 43.4). The hepatic cells constantly make bile. Bile consists of water, cholesterol, bile salts, electrolytes, fatty acids, and bilirubin. It provides the alkaline medium needed for the action of pancreatic lipase. Bile salts are needed for fat emulsification and digestion.

Bilirubin metabolism. The liver constantly makes **bilirubin**, a pigment derived from the breakdown of hemoglobin (Fig. 43.4). When released into the bloodstream, it binds to albumin. This form of bilirubin is called *unconjugated*. It is insoluble in water and transported to the liver. In the liver, unconjugated bilirubin is conjugated with glucuronic acid and excreted in bile into the intestine. *Conjugated* bilirubin is soluble in water. In the intestines, bacterial action reduces bilirubin to stercobilinogen and urobilinogen. Stercobilinogen accounts for the brown color of stool. A small amount of urobilinogen is reabsorbed into the blood. It then is returned to the liver through the portal circulation. There, it is excreted again in the bile or entered into circulation and excreted by the kidneys.

Biliary Tract

The biliary tract consists of the gallbladder and ducts that connect the liver, gallbladder, and duodenum. The gallbladder is a pear-shaped sac found below the liver. Its function is to concentrate and store bile. It holds around 45 mL of bile. The presence of fat in the upper duodenum triggers the release of cholecystokinin, which causes the gallbladder to contract and release bile.

The hepatic ducts receive bile from the canaliculi in the liver lobules. The left and right hepatic ducts merge with the cystic

TABLE 43.4 Liver Functions

Function	Description
Metabolic Functions	
Blood clotting	Synthesis of prothrombin (factor I), fibrinogen (factor II) and factors V, VII, IX, and X.
Carbohydrate metabolism	Performs glycogenesis (conversion of glucose to glycogen), glycogenolysis (process of breaking down glycogen to glucose), gluconeogenesis (formation of glucose from amino acids and fatty acids).
Detoxification	Inactivates drugs and harmful substances and excretes their breakdown products.
Fat metabolism	Synthesis of lipoproteins, breakdown of triglycerides into fatty acids and glycerol, formation of ketone bodies, synthesis of fatty acids from amino acids and glucose, synthesis and breakdown of cholesterol.
Protein metabolism	Synthesis of nonessential amino acids, synthesis of plasma proteins (except gamma globulin), synthesis of clotting factors. Bacteria in colon deaminate amino acids to form ammonia (NH_3), which is then changed to urea (NH_4).
Secretory Functions	
Bile production	Formation of bile, which contains bile salts, bile pigments (mainly bilirubin), and cholesterol.
Bilirubin	Conjugation and secretion of bilirubin.
Vascular Functions	
Blood filtration	Breakdown of old RBCs, WBCs, bacteria, and other particles. Breakdown of hemoglobin from old RBCs to bilirubin and biliverdin.
Blood reservoir	Serves as temporary storage for blood within general circulation.
Storage Functions	
Storage	Stores glucose in form of glycogen; vitamins, including fat-soluble (A, D, E, K) and water-soluble (B_1, B_2, cobalamin, folic acid); fatty acids; minerals (iron, copper); and amino acids in form of albumin and β-globulins.

duct from the gallbladder to form the common bile duct. Bile moves down the common bile duct to enter the duodenum at the ampulla of Vater (Fig. 43.3). The pancreatic duct also enters the duodenum at this point.

Pancreas

The pancreas is a long, slender gland lying behind the stomach and in front of the first and second lumbar vertebrae. It consists of a head, body, and tail. The peritoneum covers the anterior surface of the pancreas. The pancreas has lobes and lobules. The pancreatic duct extends along the gland and enters the duodenum through the common bile duct at the ampulla of Vater (Fig. 43.3).

The pancreas has both exocrine and endocrine functions. The exocrine function contributes to digestion through the production and release of enzymes (Table 43.1). The endocrine function occurs in the islets of Langerhans, whose β cells secrete insulin and amylin; α cells secrete glucagon; δ cells secrete somatostatin; and F cells secrete pancreatic polypeptide.

Gerontologic Considerations: Effects of Aging on GI System

The process of aging changes the functional ability of the GI system. Diet, alcohol intake, and obesity affect organs of the GI

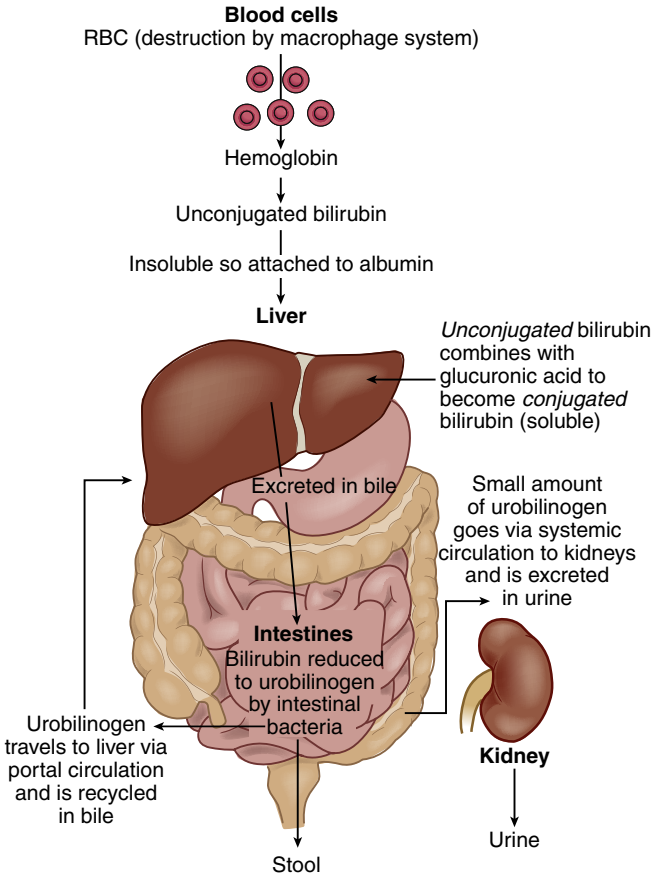

Fig. 43.4 Bilirubin metabolism and conjugation.

system, making it a challenge to separate the sole effects of aging from lifestyle. Many factors can lead to a decrease in appetite and make eating less pleasurable. Caries and periodontal disease can lead to loss of teeth. Taste buds decline in number and the sense of smell lessens, leading to decreased ability to taste. With less saliva, a very dry mouth *(xerostomia)* is common.[1]

Age-related changes in the esophagus include delayed emptying, resulting from smooth muscle weakness; reduced UES opening; and an incompetent LES. Although GI motility decreases with age, secretion and absorption are less affected. The older adult often has a decrease in intrinsic acid and HCl acid secretion *(hypochlorhydria)*.[2]

Chronic constipation affects 30% to 40% of adults over age 60.[3] Factors that may increase the risk for constipation include slower peristalsis, anorectal dysfunction, inactivity, decreased fiber intake, inadequate fluid intake, and constipating medications. Neurologic, cognitive, and metabolic problems may play a role. See Chapter 47 for more about constipation.

The liver size decreases after 50 years of age, but results of liver function tests (LFTs) stay within normal ranges. Age-related enzyme changes in the liver decrease the liver's ability to metabolize drugs and hormones. The size of the pancreas is unaffected by aging. It does undergo structural changes, such as fibrosis, fatty acid deposits, and atrophy. Gallbladder diseases increase with age.[4]

Older adults, especially those over 85, are at risk for decreased food intake. The inability to obtain food affects nutrition intake. Economic constraints may reduce the number of fresh fruits and vegetables consumed and, thus, the amount of

fiber. Immobility limits the ability to prepare meals. Age-related changes in the GI system and differences in assessment findings are outlined in Table 43.5.

ASSESSMENT OF GASTROINTESTINAL SYSTEM

Subjective Data

Important Health Information

Health history. Obtain information from the patient about the history or presence of the problems related to GI functioning and fully explore any symptoms. Ask about any abdominal pain, nausea, vomiting, abdominal distention, jaundice, heartburn, dyspepsia, changes in appetite, hematemesis, indigestion, bloating, and trouble swallowing. Review the patient's bowel habits. Ask about diarrhea, constipation, melena, rectal bleeding, and excessive gas. Assess for related conditions, such as food intolerance or allergies, lactose intolerance, and anemia. Ask the patient about a history or presence of problems, such as reflux, gastritis, hepatitis, colitis, gallstones, hemorrhoids, peptic ulcer, cancer, diverticuli, or hernias.

Ask the patient about weight history. Explore in detail any unexplained or unplanned weight loss or gain within the past 6 to 12 months. Discuss any history of chronic dieting and repeated weight loss and gain.

Medications. Assess the patient's past and current use of medications. Ask about the reason for taking the medication, the dose and frequency, length of time taken, route, its effect, and any side effects. Include information about probiotics and nutrition supplements. Many medications cause side effects in the GI system. GI problems can affect drug absorption and effectiveness. Antacids and laxatives may affect medication absorption. Ask the patient about laxative or antacid use, including the kind and frequency.

Many chemicals, herbal supplements, and drugs may be hepatotoxic (see *livertox.nih.gov*). They can result in significant harm unless monitored closely. Examples include chronic high doses of acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs). NSAIDs may also cause upper GI bleeding, with an increasing risk as the person ages. Other medications, such as antibiotics, may change the normal bacterial composition in the GI tract, resulting in diarrhea.

Surgery or other treatments. Obtain information about hospitalizations for any problems related to the GI system. Record any abdominal or rectal surgery, including the year,

TABLE 43.5 GERONTOLOGIC ASSESSMENT DIFFERENCES

GI System

Expected Aging Changes	Differences in Assessment Findings
Mouth	
Atrophy of gingival tissue	Poor-fitting dentures
↓ Number of taste buds, ↓ sense of smell	↓ Sense of taste (especially salty and sweet)
↓ Volume of saliva	Dry oral mucosa
Gingival retraction	Loss of teeth, dental implants, dentures, difficulty chewing
Esophagus	
↓ LES pressure, ↓ motility	Epigastric distress, dysphagia, potential for hiatal hernia and aspiration
Abdominal Wall	
↓ Number and sensitivity of sensory receptors	Less sensitivity to surface pain
Thinner and less taut	More visible peristalsis, easier palpation of organs
Stomach	
Atrophy of gastric mucosa, ↓ blood flow	Food intolerances, signs of anemia from cobalamin malabsorption, slower gastric emptying
Small Intestines	
Slightly ↓ motility and secretion of most digestive enzymes	Indigestion, slowed intestinal transit, delayed absorption of fat-soluble vitamins
Liver	
↓ Protein synthesis, ↓ ability to regenerate	↓ Drug and hormone metabolism
↓ Size and lowered position	Easier palpation because of lower border extending past costal margin
Large Intestine, Anus, Rectum	
↓ Anal sphincter tone and nerve supply to rectal area	Fecal incontinence
↓ Muscular tone, ↓ motility	Flatulence, abdominal distention, relaxed perineal musculature
↓ Transit time, ↓ sensation to defecation	Constipation, fecal impaction
Pancreas	
Pancreatic ducts distended, ↓ lipase production, ↓ pancreatic reserve	Impaired fat absorption, ↓ glucose tolerance

Case Study

Patient Introduction

(© iStockphoto/Thinkstock.)

Patient Profile

L.C. is a 58-year-old Native American man from a Pueblo tribe in northern New Mexico. L.C.'s wife and family drove 50 miles to take him to the Indian Health Service hospital. He comes into the emergency department (ED) doubled over with abdominal pain. He is grimacing and holding his abdomen with both arms. You are working as the triage nurse that morning.

Discussion Questions

1. What are the possible causes for L.C.'s acute abdominal pain?
2. Is his condition stable or is it an emergency?
3. What type of assessment should you do: comprehensive, focused, or emergency?
4. What assessment questions will you ask him?
5. How will you individualize the assessment based on his ethnic/cultural background?

You will learn more about L.C. and his condition as you read this assessment chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

reason for surgery, postoperative course, and blood transfusions. Terms related to common GI surgeries are listed in Table 43.6.

Functional Health Patterns

Key questions to ask a patient with a GI problem are outlined in Table 43.7.

Health perception–health management pattern. Ask about the patient's health practices related to the GI system. This includes maintaining normal body weight, proper dental care, adequate nutrition, and effective elimination habits.

Ask about recent foreign travel with possible exposure to hepatitis or parasitic infestation. Explore any sexual and drug use behaviors that may increase risk for hepatitis exposure. Determine whether the patient has received hepatitis A and B vaccination.

Assess the patient for habits that directly affect GI functioning. High rates of binge drinking alcohol and the intake of alcohol in large quantities or for long periods have harmful effects on the stomach mucosa.[5] Chronic alcohol exposure causes fatty infiltration of the liver and can cause damage, leading to cirrhosis and hepatocellular cancer. Obtain a history of cigarette smoking. Nicotine is irritating to the GI tract mucosa. Cigarette

TABLE 43.6 GI Surgeries

Procedure	Description
Appendectomy	Removal of appendix
Cholecystectomy	Removal of gallbladder
Choledochojejunostomy	Opening between common bile duct and jejunum
Choledocholithotomy	Opening into common bile duct for removal of stones
Colectomy	Removal of colon
Colostomy	Opening into colon
Esophagoenterostomy	Removal of part of esophagus with segment of colon attached to remaining part
Esophagogastrostomy	Removal of esophagus and anastomosis of remaining part to stomach
Gastrectomy	Removal of stomach
Gastrostomy	Opening into stomach
Glossectomy	Removal of tongue
Hemiglossectomy	Removal of half of tongue
Herniorrhaphy	Repair of a hernia
Ileostomy	Opening into ileum
Mandibulectomy	Removal of mandible
Pyloroplasty	Enlargement and repair of pyloric sphincter area
Vagotomy	Resection of branch of vagus nerve

TABLE 43.7 HEALTH HISTORY

GI System

Health Perception–Health Management

- Describe any measures used to treat GI symptoms such as diarrhea or constipation.
- Do you smoke?[a] Do you drink alcohol?[a]
- Are you exposed to any chemicals on a regular basis?[a] Have you been exposed in the past?[a]
- Have you recently traveled outside the United States?[a]

Nutritional-Metabolic

- Describe your usual daily food and fluid intake.
- Do you take any supplemental vitamins or minerals?[a]
- Have you had any changes in appetite or food tolerance?[a]
- Has there been any weight change in the past 6–12 months?[a]
- Are you allergic to any foods?[a]

Elimination

- Describe the frequency and time of day you have bowel movements. What is the consistency of the bowel movement?
- Do you use laxatives or enemas?[a] If so, how often?
- Have there been any recent changes in your bowel pattern?[a]
- Do you have any pain with bowel movements or pain relieved by bowel movements?
- Describe any skin problems caused by GI problems.
- Do you need any assistive equipment, such as ostomy equipment, raised toilet seat, commode?

Activity-Exercise

- Do you have limitations in mobility that make it hard for you to obtain and prepare food?[a]
- Sleep-Rest
- Do you have any problem sleeping because of a GI problem?[a]
- Are you awakened by symptoms such as gas, abdominal pain, diarrhea, or heartburn?[a]

Cognitive-Perceptual

- Have you had any change in taste or smell that have affected your appetite?[a]
- Do you have any heat or cold sensitivity that affects eating?[a]
- Does pain interfere with food preparation, appetite, or chewing?[a]
- Do pain medications cause constipation, diarrhea, or appetite suppression?[a]

Self-Perception–Self-Concept

- Describe any changes in your weight that have affected how you feel about yourself.
- Have you had any changes in normal elimination that have affected how you feel about yourself?[a]
- Do you have any symptoms of GI disease caused physical changes that are a problem for you?[a]

Role-Relationship

- Describe the impact of any GI problem on your usual roles and relationships.
- Have any changes in elimination affected your relationships?[a]
- Do you live alone? Describe how your family or others assist you with your GI problems.

Sexuality-Reproductive

- Describe the effect of your GI problem on your sexual activity.
- Coping–Stress Tolerance
- Do you have GI symptoms in response to stressful or emotional situations?[a]
- Describe how you deal with any GI symptoms that result.

Value-Belief

- Describe any cultural or religious beliefs about food and food preparation that may influence the treatment of your GI problem.

[a]If yes, describe.

BOX 43.1 GENETIC RISK ALERT

Colorectal Cancer (CRC)

- CRC may run in families if first-degree relatives (parents, siblings) or many other family members (grandparents, aunts, uncles) had CRC. This is especially true when family members are diagnosed with CRC before age 50
- Genetic conditions associated with an increased risk for CRC include:
  - Hereditary nonpolyposis colorectal cancer (HNPCC). It is caused by mutations in several different genes.
  - Familial adenomatous polyposis (FAP). FAP is characterized by multiple polyps that are noncancerous at first but eventually develop into cancer if not treated. Most cases of FAP are due to mutations of the adenomatous polyposis coli *(APC)* gene.

Inflammatory Bowel Disease (IBD)

- People with IBD have a genetic predisposition or susceptibility to the disease.
- First-degree relatives have a 5- to 20-fold increased risk for developing IBD.

smoking is related to GI cancers (especially mouth and esophageal cancers), esophagitis, and ulcers. Smoking delays the healing of ulcers.

Family history is an important part of this health pattern. About one third of cases of colorectal cancer (CRC) occur in patients with a family history. Because of the relationship between CRC and breast cancer, ask about a history of either type of cancer in the family (Box 43.1).

Nutritional-metabolic pattern. A thorough nutrition assessment is essential. Take a diet history and ask about both content and amount or portion size. Food preferences and preparation may vary by culture and religion. Open-ended questions allow the patient to express beliefs and feelings about the diet. For example, you can say, "Please tell me about your food and beverage intake over the past 24 hours." You can use a 24-hour diet recall to analyze the adequacy of the diet. Help the patient recall the preceding day's food intake, including early morning and nighttime intake, snacks, and liquids. Then evaluate the diet in relation to recommended servings for diet intake using a guide such as MyPlate *(*www.choosemyplate.gov*)*. A 1-week recall may provide more information on usual diet patterns. Compare weekday and weekend diet intake patterns in relation to both the quality and quantity of food.

Ask the patient about the use of sugar and salt substitutes, caffeine intake, and amount of fluid and fiber intake. Note any changes in appetite, food tolerance, and weight. Anorexia and weight loss may indicate cancer or inflammation. Decreased food intake can be the consequence of economic problems or depression.

Ask about food allergies and intolerances, including lactose and gluten. Have the patient describe the allergic response and any GI symptoms.

Elimination pattern. Elicit a detailed account of the patient's bowel elimination pattern. Note the frequency, time of day, and usual stool consistency. Ask about the presence of pain with bowel movements, if bowel movements relieve pain, and any recent changes in bowel patterns. Explore the use of laxatives and enemas, including type, frequency, and results.

Document the amount and type of fluid and fiber intake. These influence the frequency and consistency of stools. Inadequate fiber intake can be associated with constipation. Look for any association between a skin and GI problem. Food allergies can cause skin lesions, pruritus, and edema. Diarrhea can result in redness, irritation, and pain in the perianal area. External drainage systems, such as an ileostomy or ileal conduit, may cause local skin irritation.

Activity-exercise pattern. Activity and exercise affect GI motility. Immobility is a risk factor for constipation. Assess ambulatory status to determine if the patient can secure and prepare food. If the patient is unable to do these tasks, see if a family member or an outside agency is meeting this need. Note any limitation in the ability to feed oneself. Assess for access to a toilet. Identify the use of and access to supplies such as a commode or ostomy supplies.

Sleep-rest pattern. GI symptoms can interfere with the quality of sleep. Nausea, vomiting, diarrhea, indigestion, and bloating can produce sleep problems. Ask the patient if GI symptoms affect sleep or rest. For example, a patient with gastroesophageal reflux disease (GERD) may wake with burning epigastric pain.

A patient may have a bedtime ritual that involves a specific food or beverage. Herbal teas may be sleep inducing. Document individual routines and comply with these whenever possible to avoid sleeplessness. Hunger can prevent sleep. A light, easily digested snack may be helpful.

Cognitive-perceptual pattern. Sensory changes can result in problems related to acquiring, preparing, and ingesting food. Changes in taste or smell can affect appetite and eating pleasure. Vertigo can make shopping or standing at a stove difficult and dangerous. Heat or cold sensitivity can make some foods painful to eat. Problems in expressive communication limit the patient's ability to state personal food preferences.

Both acute and chronic pain influence intake. Behaviors associated with pain include avoiding activity, fatigue, and disrupted eating patterns. For patients receiving opioid medications, assess for decreased appetite, constipation, nausea, and sedation.

Self-perception–self-concept pattern. Many GI and nutrition problems affect the patient's self-perception. Overweight and underweight persons may have problems related to self-esteem and body image. Repeated attempts to achieve a personally acceptable weight can be discouraging and depressing for some people. The way a person recounts a weight history can alert you to potential problems in this area.

The need for external devices to manage elimination, such as a colostomy or an ileostomy, may be challenging for some patients. The patient's willingness to engage in self-care and to discuss this situation provides you with valuable information related to body image and self-esteem.

The altered physical changes from advanced liver disease can be disturbing for the patient. Jaundice, muscle wasting, and ascites cause significant changes in external appearance. Assess the patient's attitude about these changes.

Role-relationship pattern. Problems related to the GI system, such as cirrhosis, hepatitis, ostomies, obesity, and cancer, may affect the patient's ability to maintain usual roles and relationships. A person may need to leave a job or reduce work hours. Changes in body image and self-esteem can affect relationships.

Sexuality-reproductive pattern. Changes related to sexuality and reproductive status can result from problems of the GI system. For example, obesity, jaundice, and ascites could decrease the acceptance of a potential sexual partner. An ostomy can affect the patient's confidence related to sexual activity. Your sensitive questioning can identify potential problems.

Anorexia can affect the reproductive status of a female patient. Obesity leads to reduced fertility and increased miscarriage rates in women.

Coping–stress tolerance pattern. Determine what is stressful for the patient and what coping mechanisms the patient uses. Factors outside the GI tract can influence its functioning. Both psychologic and emotional factors, such as stress and anxiety, influence GI functioning in many people. Stress can manifest as anorexia, nausea, epigastric and abdominal pain, or diarrhea. It can worsen some GI problems, such as peptic ulcer disease, irritable bowel syndrome, and IBD. However, never attribute GI symptoms solely to psychologic factors.

Value-belief pattern. Assess the patient's spiritual, religious, and cultural beliefs about food and food preparation. Whenever possible, respect these preferences. Determine if any value or belief could interfere with planned interventions. For example, if the patient with anemia is a vegetarian, you will need to consider how to increase their intake of iron-rich foods other than meat. Thoughtful assessment and consideration of the patient's beliefs and values usually increase adherence and satisfaction.

Case Study

Subjective Data

(© iStockphoto/Thinkstock.)

A focused subjective assessment of L.C. revealed the following information:

- ***Health History:*** Negative history for medical or surgical problems.
- ***Medications:*** None.
- ***Health Perception–Health Management:*** L.C. states he has not been feeling well for the past several weeks. He feels weak and fatigues easily. Denies exposure to chemicals. No recent travel outside of the United States. Smokes 1 pack of cigarettes per day for 20 years. Drinks 3–4 bottles of beer per day.
- ***Nutritional-Metabolic:*** L.C. is 5 ft, 9 in tall and weighs 140 lb (BMI: 20.7 kg/m^2). States has been losing weight over the past several months and does not have an appetite. No food allergies.
- ***Elimination:*** Reports alternating episodes of constipation and diarrhea. He noticed some bright red blood in stools. Has not had a bowel movement for 4 days.
- ***Cognitive-Perceptual:*** Rates pain as a 9 on a scale of 0 to 10. States pain comes and goes in waves. Prefers to lie still with knees flexed and drawn into his abdomen.

Discussion Questions

1. Which subjective assessment findings concern you most?
2. Based on these subjective assessment findings, what should you include in the physical assessment? What would you be looking for?
3. What would be your priority assessment?

You will learn more about physical assessment of the GI system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Objective Data

Physical Assessment

Mouth

Inspection. Inspect the mouth for symmetry, color, and size. Observe for abnormalities, such as pallor or cyanosis, cracking, ulcers, or fissures. The dorsum (top) of the tongue should have a thin white coating. The undersurface should be smooth. Observe for any lesions. Using a tongue blade, inspect the buccal mucosa. Note the color, any areas of pigmentation, and any lesions. Dark-skinned persons normally have patchy areas of pigmentation. In assessing the teeth and gums, look for caries, loose teeth, abnormal shape and position of teeth, and swelling, bleeding, discoloration, or gingival inflammation. Note any distinctive breath odor.

Inspect the pharynx by tilting the patient's head back and depressing the tongue with a tongue blade. Observe the tonsils, uvula, soft palate, and anterior and posterior pillars. Tell the patient to say "ah." The uvula and soft palate should rise and remain in the midline.

Palpation. Palpate any suspicious areas in the mouth. Note ulcers, nodules, indurations, and areas of tenderness. The mouth of the older adult needs careful assessment. Pay attention to dentures (e.g., fit, condition), the ability to swallow, and the tongue. Note any lesions. Ask the patient with dentures to remove them during an oral exam to allow for good visualization and palpation of the area.

Abdomen. We use 2 systems to anatomically describe the surface of the abdomen. One system divides the abdomen into 4 quadrants by a perpendicular line from the sternum to the pubic bone and a horizontal line across the abdomen at the umbilicus (Fig. 43.5A and Table 43.8). The other system divides the abdomen into 9 regions (Fig. 43.5B). We often assess only the epigastric, umbilical, and suprapubic or hypogastric regions.

For the abdominal assessment, good lighting should shine across the abdomen. The patient should be in the supine position and as relaxed as possible. To help relax the abdominal muscles, have the patient slightly flex the knees and raise the head of the bed slightly. The patient should have an empty bladder. Use warm hands when doing the abdominal assessment to avoid eliciting muscle guarding. Ask the patient to breathe slowly through the mouth.

The standard approach for examining the abdomen is appropriate for an older adult. The abdomen may be thinner and laxer unless the patient is obese.

Inspection. Assess the abdomen for skin changes (color, texture, scars, striae, dilated veins, rashes, lesions), umbilicus (location and contour), symmetry, and contour (flat, rounded [convex], concave, protuberant, distended). Note observable hernias or masses. Is there any movement (pulsations, peristalsis)? A normal aortic pulsation may be seen in the epigastric area. Look across the abdomen tangentially (across the abdomen in a line) for peristalsis. Peristalsis is not normally visible in an adult but may be visible in a thin person.

Auscultation. When you examine the abdomen, auscultate before percussion and palpation because these latter procedures may alter the bowel sounds. Use the diaphragm of the stethoscope to auscultate bowel sounds because they are high pitched. Use the bell of the stethoscope to detect lower pitched sounds. Warm the stethoscope in your hands before auscultating to help prevent abdominal muscle contraction. Listen in the epigastrium and in all 4 quadrants. Start in the right lower quadrant because bowel sounds are normally present there. Listen for bowel sounds for at least 2 minutes. Do not count bowel sounds. Determine if they are normal, hypoactive, or hyperactive.

The frequency and intensity of bowel sounds vary depending on the phase of digestion. Normal sounds are high pitched and gurgling. Stomach growling or loud gurgles *(borborygmi)* indicate hyperperistalsis. The bowel sounds are high pitched (rushes and tinkling) when the intestines are under tension, as in intestinal obstruction. Listen for decreased or absent bowel sounds. If you are patient and listen for several minutes, you will often find the bowel sounds are not absent but are hypoactive. If you do not hear bowel sounds, note the amount of time you listened in each quadrant without hearing bowel sounds.

Listen for vascular sounds. A *bruit,* best heard with the bell of the stethoscope, is a swishing or buzzing sound and indicates turbulent blood flow. Normally, you should not hear aortic bruits.

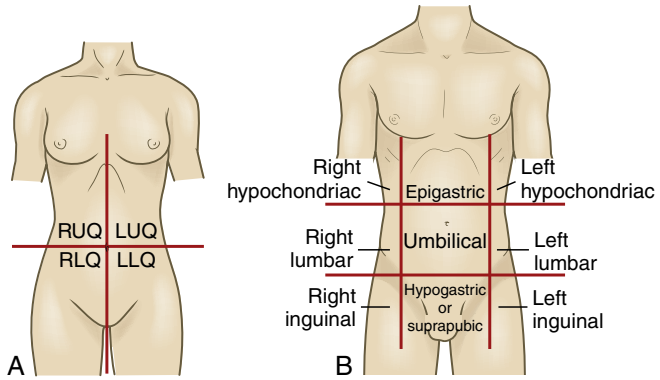

Fig. 43.5 (A) Abdominal quadrants. (B) Abdominal regions. *LLQ,* Left lower quadrant; *LUQ,* left upper quadrant; *RLQ,* right lower quadrant; *RUQ,* right upper quadrant.

Percussion. The purpose of percussing the abdomen is to estimate the size of the liver and spleen and determine the presence of fluid, distention, and masses. Sound waves vary according to the density of underlying tissues. Air produces a higher pitched, hollow sound termed *tympany.* Fluid or masses produce a short, high-pitched sound with little resonance termed *dullness.* Lightly percuss all 4 quadrants of the abdomen and assess the distribution of tympany and dullness (Fig. 43.6). Tympany is the predominant percussion sound of the abdomen.

To percuss the liver, start below the umbilicus in the right midclavicular line and percuss lightly upward until you hear dullness. This is the lower border of the liver. Next, start at the nipple line in the right midclavicular line and percuss downward between ribs to the area of dullness indicating the upper border of the liver. Measure the height or vertical space between the 2 borders to determine the size of the liver. The normal range of liver height in the right midclavicular line is 2.4 to 5 in (6 to 12.7 cm).

Palpation. Use palpation to assess the abdominal organs and detect any tenderness, distention, masses, or fluid. Palpation is important because it may reveal a tumor. Begin with light palpation. Palpate any areas in which the patient reports tenderness last.

Use *light palpation* to detect tenderness or cutaneous hypersensitivity, muscular resistance, masses, and swelling. Help the patient relax for deeper palpation. Keep your fingers together and press gently with the pads of the fingertips, depressing the abdominal wall about 0.4 in (1 cm). Use smooth movements and palpate all quadrants (Fig. 43.7A).

Use *deep palpation* to delineate abdominal organs and masses (Fig. 43.7B). Use the palmar surfaces of your fingers to press more deeply. Again, palpate all quadrants. Note the location, size, and shape of masses, as well as the presence of tenderness. During these maneuvers, observe the patient's facial expression because it will provide nonverbal cues of discomfort or pain.

TABLE 43.8 Structures Located in Abdominal Regions

Right Upper Quadrant	Left Upper Quadrant	Right Lower Quadrant	Left Lower Quadrant
• Liver and gallbladder • Pylorus • Duodenum • Head of pancreas • Right adrenal gland • Portion of right kidney • Hepatic flexure of colon • Portion of ascending and transverse colon	• Left lobe of liver • Spleen • Stomach • Body of pancreas • Left adrenal gland • Portion of left kidney • Splenic flexure of colon • Portion of transverse and descending colon	• Lower pole of right kidney • Cecum and appendix • Portion of ascending colon • Bladder (if distended) • Right ovary and fallopian tube • Uterus (if enlarged) • Right spermatic cord • Right ureter	• Lower pole of left kidney • Sigmoid flexure • Part of descending colon • Bladder (if distended) • Left ovary and fallopian tube • Uterus (if enlarged) • Left spermatic cord • Left ureter

Another method for deep abdominal palpation is the 2-hand method. Place one hand on top of the other and apply pressure to the bottom hand with the fingers of the top hand. With the fingers of the bottom hand, feel for organs and masses. Practice both methods of palpation to determine which is most effective.

Check a problem area on the abdomen for rebound tenderness by pressing in slowly and firmly over the painful site. Withdraw the palpating fingers quickly. Pain on withdrawal of the fingers indicates peritoneal inflammation. Because assessing for rebound tenderness may produce pain and severe muscle spasm, it should be done at the end of the assessment and only by an experienced practitioner.

To palpate the liver, place your left hand behind the patient to support the right eleventh and twelfth ribs (Fig. 43.8). The patient may relax on your hand. Press the left hand forward and place the right hand on the patient's right abdomen lateral to the rectus muscle. The fingertips should be below the lower border of liver dullness and pointed toward the right costal margin. Gently press in and up. The patient should take a deep breath with the abdomen so that the liver drops and is in a better position for palpation. Try to feel the liver edge as it comes down to the fingertips. During inspiration, the liver edge should feel firm, sharp, and smooth. Describe the surface and contour and any tenderness. If the patient has chronic obstructive pulmonary disease, large lungs, or a low diaphragm, the liver may be palpated 0.4 to 0.8 in (1 to 2 cm) below the right costal margin.

To palpate the spleen, move to the patient's left side. Place your right hand under the patient, and support and press the patient's left lower rib cage forward. Place your left hand below the left costal margin and press it in toward the spleen. Ask the patient to breathe deeply. The fingertips can feel the tip or edge of an enlarged spleen. The normal spleen size range is about 5 in long (12.7 cm), 3 in wide (7.6 cm), and 1.5 in (3.8 cm) thick. It is normally not palpable. If it is palpable, do not continue, because manual compression of an enlarged spleen may cause it to rupture.

Rectum and anus. Inspect perianal and anal areas for color, texture, masses, rashes, scars, erythema, fissures, and external hemorrhoids. Palpate any masses or unusual areas with a gloved hand.

For the digital examination of the rectum, place a gloved, lubricated index finger against the anus while having the patient gently bear down (Valsalva maneuver). Then, as the sphincter relaxes, insert the finger. Point the finger toward the umbilicus. Try to get the patient to relax. Insert the finger into the rectum as far as possible and palpate all surfaces. Assess any nodules, tenderness, or irregularities. Use the gloved finger to remove a stool sample and check it for occult blood. However, a single

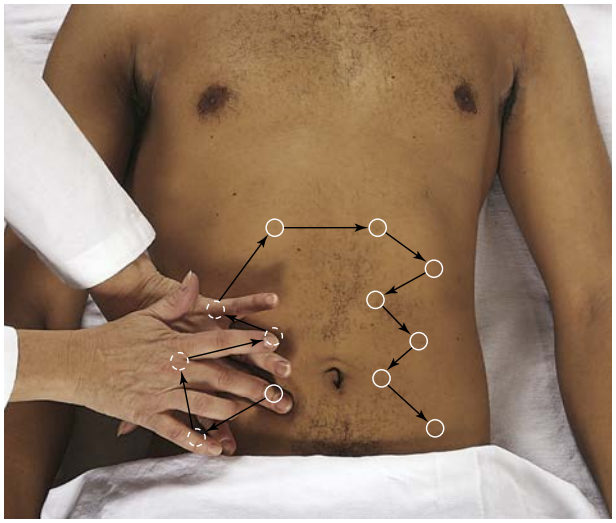

Fig. 43.6 Technique for percussion of the abdomen. Moving clockwise, percuss lightly in all 4 quadrants. (From Jarvis C: *Physical examination and health assessment,* ed 8, St Louis, 2020, Saunders.)

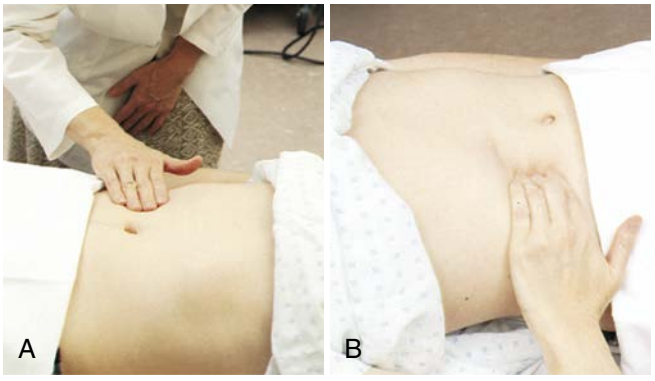

Fig. 43.7 (A) Technique for light palpation of the abdomen. (B) Technique for deep palpation.

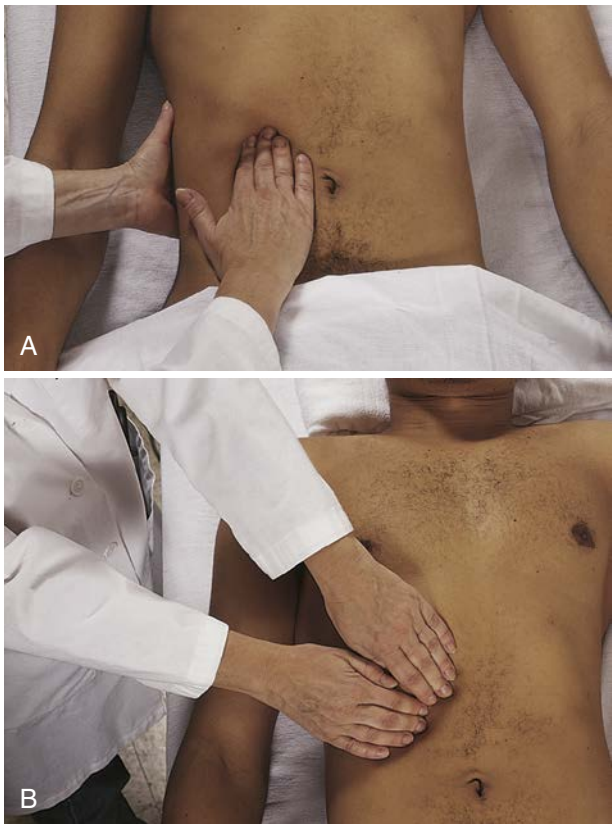

Fig. 43.8 (A) Technique for liver palpation. (B) Alternative technique to palpate liver with fingers hooked over the costal region. (From Jarvis C: *Physical examination and health assessment,* ed 8, St Louis, 2020, Saunders.)

guaiac-based fecal occult blood test has limited sensitivity in detecting CRC.

Findings of a normal physical assessment of the GI system are shown in Table 43.9. Table 43.10 outlines assessment abnormalities. Gerontologic differences in the GI system and differences in assessment findings are described in Table 43.5. A *focused assessment* (Box 43.2) evaluates the status of previously identified GI problems and monitors for signs of new problems.

TABLE 43.9 Normal Physical Assessment of GI System

Mouth
- Moist and pink lips
- Pink and moist buccal mucosa and gingivae without plaques or lesions
- Teeth in good repair
- Protrusion of tongue in midline without deviation or twitches
- Pink uvula (in midline), soft palate, tonsils, and posterior pharynx
- Swallows smoothly without coughing or gagging

Abdomen
- Flat without masses or scars. No bruises
- Bowel sounds in all quadrants
- No abdominal tenderness; nonpalpable liver and spleen
- Liver 10 cm in right midclavicular line
- Generalized tympany

Anus
- Absence of lesions, fissures, and hemorrhoids
- Good sphincter tone
- Rectal walls smooth and soft
- No masses
- Stool soft, brown, and heme negative

Case Study

Objective Data: Physical Assessment

(© iStockphoto/Thinkstock.)

A focused assessment of L.C. reveals the following: BP 120/74, heart rate 110, respiratory rate 24, temperature 100.4°F (43°C). Abdomen firm and slightly distended. High-pitched bowel sounds in upper quadrants. No bowel sounds auscultated in left lower quadrant. Mild abdominal palpation elicits pain.

Discussion Questions

1. Which physical assessment findings concern you most?
2. Based upon the assessment data presented so far, what would be 3 priority clinical problems?
3. What diagnostic studies do you think may be ordered for L.C.?

You will learn more about diagnostic studies related to the GI system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

DIAGNOSTIC STUDIES OF GASTROINTESTINAL SYSTEM

Tables 43.11 and 43.12 present common diagnostic studies of the GI system. Selected diagnostic studies are described in more detail here.

For most diagnostic studies, make sure the signed consent form for the procedure is in the medical record. The HCP doing the procedure is responsible for explaining the procedure and

TABLE 43.10 ASSESSMENT ABNORMALITIES

GI System

Finding	Description	Possible Etiology and Significance
Mouth		
Acute marginal gingivitis	Friable, edematous, painful, bleeding gingivae	Irritation from ill-fitting dentures or orthodontic appliances, calcium deposits on teeth, food impaction
Candidiasis	White, curdlike lesions surrounded by erythematous mucosa	*Candida albicans*
Cheilitis	Inflammation of lips (usually lower) with fissuring, scaling, crusting	Often unknown
Cheilosis	Softening, fissuring, and cracking of lips at angles of mouth	Riboflavin deficiency
Geographic tongue	Scattered red, smooth (loss of papillae) areas on dorsum of tongue	Unknown
Glossitis	Reddened, ulcerated, swollen tongue	Exposure to streptococci, irritation, injury, vitamin B deficiencies, anemia
Herpes simplex	Vesicular lesion	Herpesvirus
Leukoplakia	Thickened white patches	Premalignant lesion
Pyorrhea	Recessed gingivae, purulent pockets	Periodontitis
Smooth tongue	Red, slick appearance	Cobalamin deficiency
Ulcer, plaque on lips or in mouth	Sore or lesion	Cancer, viral infections
Esophagus and Stomach		
Dyspepsia	Burning or indigestion	Peptic ulcer disease, gallbladder disease
Dysphagia	Difficulty swallowing, sensation of food sticking in esophagus	Esophageal problems, cancer of esophagus
Eructation	Belching	Various GI problems, GERD, dyspepsia, rumination
Hematemesis	Vomiting of blood	Esophageal varices, bleeding peptic ulcer
Nausea and vomiting	Feeling of impending vomiting, expulsion of gastric contents through mouth	GI infections, common manifestation of many GI problems, stress, fear, and pathologic conditions

TABLE 43.10 ASSESSMENT ABNORMALITIES—cont'd

GI System

Finding	Description	Possible Etiology and Significance
Odynophagia	Painful swallowing	Cancer of esophagus, esophagitis
Pyrosis	Heartburn, burning in epigastric or substernal area	Hiatal hernia, esophagitis, incompetent LES
Abdomen		
Absence of liver dullness	Tympany on percussion	Air from viscus (e.g., perforated ulcer)
Absent bowel sounds	No bowel sounds on auscultation	Peritonitis, paralytic ileus, obstruction
Ascites	Accumulated fluid within abdominal cavity, eversion of umbilicus (usually)	Peritoneal inflammation, heart failure, metastatic cancer, cirrhosis
Borborygmi	Waves of loud, gurgling sounds	Hyperactive bowel from eating
Bruit	Humming or swishing sound heard through stethoscope over vessel	Partial arterial obstruction (narrowing of vessel), turbulent flow (aneurysm)
Distention	Excessive gas accumulation, enlarged abdomen, generalized tympany	Obstruction, paralytic ileus
Hepatomegaly	Enlargement of liver, liver edge >1–2 cm below costal margin	Metastatic cancer, hepatitis, venous congestion, cardiac congestion
Hernia	Bulge or nodule in abdomen, usually appearing on straining	Inguinal (in inguinal canal), femoral (in femoral canal), umbilical (herniation of umbilicus), diastasis rectus (deformity) or incisional (defect in muscles after surgery)
Hyperresonance	Loud, tinkling rushes	Intestinal obstruction
Masses	Lump on palpation	Tumors, cysts
Nodular liver	Enlarged, hard liver with irregular edge or surface	Cirrhosis, focal nodular hyperplasia, cancer
Rebound tenderness	Sudden pain when fingers withdrawn quickly	Peritoneal inflammation, appendicitis
Splenomegaly	Enlarged spleen	Chronic leukemia, hemolytic states, portal hypertension, some infections
Rectum and Anus		
Fissure	Ulceration in anal canal	Straining, irritation
Hemorrhoids	Thrombosed veins in rectum and anus (internal or external)	Portal hypertension, chronic constipation, prolonged sitting or standing, pregnancy
Mass	Firm, nodular edge	Tumor, cancer
Melena	Abnormal, black, tarry stool containing digested blood	Cancer, bleeding in upper GI tract from ulcers, varices
Pilonidal cyst	Opening of sinus tract, cyst in midline just above coccyx	Probably congenital
Steatorrhea	Fatty, frothy, foul-smelling stool	Chronic pancreatitis, biliary obstruction, malabsorption problems
Tenesmus	Painful and ineffective straining, Sense of incomplete evacuation	Inflammatory bowel disease, irritable bowel syndrome, diarrhea from GI infection (e.g., food poisoning)

obtaining written consent. You have a key role in teaching patients about the procedures. When preparing the patient, it is important to ask about any known allergies to drugs, iodine, shellfish, or contrast media.

Many GI system diagnostic procedures require (1) measures to cleanse the GI tract and (2) ingestion or injection of a contrast medium or a radiopaque tracer. Often, the patient has a series of GI diagnostic tests done. Monitor the patient closely to ensure adequate hydration and nutrition during the testing period.

Some diagnostic studies are especially difficult and uncomfortable for the older adult. Adjustments may be needed during the preparation, especially for those with certain health conditions (e.g., diabetes).[6] Consider any physical limitations and pressure points when positioning the older patient during testing. Monitor the patient closely to avoid problems, such as dehydration from prolonged fluid restriction and diarrhea from bowel-cleansing procedures.

Radiologic Studies

Upper GI Series

An upper GI series with small bowel follow-through provides visualization of the oropharyngeal area, esophagus, stomach, and small intestine. The procedure consists of the patient swallowing contrast medium (a thick barium solution or gastrografin) and then assuming different positions on the x-ray table. The movement of the contrast medium is observed with fluoroscopy, and a series of x-rays are taken. An upper GI series is useful in identifying esophageal strictures, polyps, tumors, hiatal hernias, foreign bodies, and ulcers.

Lower GI Series

The purpose of a lower GI series, or a barium enema, is to observe (using fluoroscopy) the colon filling with contrast medium and to observe (by x-ray) the filled colon. The patient receives an enema of contrast medium. This procedure identifies polyps,

BOX 43.2 FOCUSED ASSESSMENT

GI System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Loss of appetite	Y	N
Abdominal pain	Y	N
Changes in stools (color, blood, consistency, frequency, pain)	Y	N
Nausea, vomiting	Y	N
Painful swallowing	Y	N

Objective: Diagnostic

Check the following results for critical values.

Endoscopy: colonoscopy, sigmoidoscopy, esophagogastroduodenoscopy	✓
CT scan	✓
Radiologic series: upper GI, lower GI	✓
Stool for occult blood or ova and parasites	✓
Liver function tests	✓

Objective: Physical Assessment

Inspect

Skin for color, scars, petechiae, and other lesions.	✓
Abdominal contour for symmetry and distention	✓
Perianal area for intact skin, hemorrhoids	✓

Auscultate

Bowel sounds	✓

Palpate

Abdominal quadrants using light touch	✓
Abdominal quadrants using a deep technique	✓

tumors, and other lesions in the colon. Adding air contrast after the barium provides better visualization (Fig. 43.9). Because the patient must retain the barium, an older or immobile patient may not tolerate it very well.

Virtual Colonoscopy

Virtual colonoscopy combines CT scanning or MRI to produce images of the colon and rectum less invasively. It requires radiation and prior cleansing of the colon but no sedation.

Compared to conventional colonoscopy, virtual colonoscopy provides a better view inside the colon that is narrow from inflammation or a growth.[7] If a polyp is found, it will have to be removed by conventional colonoscopy. Virtual colonoscopy may be less sensitive in obtaining information on the details and color of the mucosa and in detecting small (less than 10 mm) or flat polyps.

Endoscopy

Endoscopy refers to the direct visualization of a body structure through an endoscope. An endoscope is a fiberoptic instrument with a light and camera attached, allowing the ability to take video and still pictures (Fig. 43.10). Some endoscopes have a channel through which to pass instruments, such as biopsy forceps and cytology brushes.

Endoscopy can examine the esophagus, stomach, duodenum, and colon. *Endoscopic retrograde cholangiopancreatography* (ERCP) visualizes the pancreatic, hepatic, and common bile ducts. Endoscopy is often combined with diagnostic procedures, including biopsy, cytologic studies, invasive, and therapeutic procedures. Examples include polypectomy, sclerosis or banding of varices, cauterization of bleeding sites, common bile duct stone removal, and balloon dilation.

TABLE 43.11 Diagnostic Studies

GI System

Study	Description and Purpose	Nursing Responsibility
Endoscopy		
Colonoscopy	Directly visualizes entire colon up to ileocecal valve with flexible fiberoptic scope. Patient's position is changed frequently during procedure to assist with advancement of scope to cecum. Used to diagnose or detect inflammatory bowel disease, polyps, tumors, and diverticulosis and dilate strictures. Procedure allows for biopsy and removal of polyps without laparotomy	*Before:* Bowel preparation prior varies depending on HCP. Patient should avoid fiber for up to 72 hr prior, then either a clear or full liquid diet 24 hr before. Bowel cleansing should follow a split-dose regimen. The evening before the procedure, the patient should use a cleansing solution. The second dose should begin 4–6 hr before the procedure. A split-dose regimen started early morning the day of a procedure provides better cleansing for patients scheduled in the afternoon. Encourage the patient to drink all the solution. Stools will be clear or clear yellow liquid when the colon is clean. Bisacodyl tablets or suppositories may be given before the cleansing solution to remove the bulk of the stool. Explain to patient that a flexible scope will be inserted while patient in side-lying position and sedation will be given. *After:* Patient may have abdominal cramps caused by stimulation of peristalsis because the bowel is constantly inflated with air during procedure. Teach patients about pain post-colonoscopy and the characteristics of this pain. Tell patients if pain lasts longer than 24 hr to notify HCP. Check vital signs. Observe for rectal bleeding and manifestations of perforation (e.g., malaise, abdominal distention, tenesmus)

TABLE 43.11 Diagnostic Studies—cont'd

GI System

Study	Description and Purpose	Nursing Responsibility
Endoscopic retrograde cholangiopancreatography (ERCP)	Fiberoptic endoscope (using fluoroscopy) is orally inserted into descending duodenum. Then common bile and pancreatic ducts are cannulated. Contrast medium is injected into ducts to allow for direct visualization of structures. Can be used to retrieve a gallstone from distal common bile duct, dilate strictures, biopsy, and diagnose pseudocysts	*Before:* Explain procedure. Keep patient NPO 8 hr before. Ensure consent form is signed. Give sedation immediately before and during procedure. Give antibiotics if ordered. *After:* Check vital signs. Assess for perforation or infection. Pancreatitis is most common complication. Check for return of gag reflex
Esophagogastroduodenoscopy (EGD)	Directly visualizes mucosal lining of esophagus, stomach, and duodenum with flexible endoscope. Test may use video imaging to visualize stomach motility. Detects inflammation, ulcerations, tumors, varices, or Mallory-Weiss tears. Biopsies may be taken. Varices can be treated with band ligation or sclerotherapy	*Before:* Keep patient NPO for 8 hr. Ensure consent form is signed. Give preoperative medication if ordered. Explain to patient that local anesthesia may be sprayed on throat before insertion of scope and that patient will be sedated during procedure. *After:* Keep patient NPO until gag reflex returns. Gently tickle back of throat to determine reflex. Use warm saline gargles for relief of sore throat. Check temperature q15–30 min for 1–2 hr (sudden temperature spike is sign of perforation). Asses for pain which may be a sign of perforation
Laparoscopy (peritoneoscopy)	Visualize peritoneal cavity and contents with laparoscope. Double-puncture peritoneoscopy permits better visualization of abdominal cavity, especially liver. Done in operating room. Can obtain biopsy specimen	*Before:* Ensure consent form is signed. Keep patient NPO 8 hr. Give preoperative sedative medication. Ensure bladder and bowels are emptied. *After:* Observe for complications of bleeding and bowel perforation after the procedure
Sigmoidoscopy	Directly visualizes rectum and sigmoid colon with lighted flexible endoscope. Sometimes a special table is used to tilt patient into knee-chest position. Used to detect tumors, polyps, inflammatory and infectious diseases, fissures, hemorrhoids	*Before:* Bowel preparation similar to colonoscopy. Explain to patient knee-chest position, need to take deep breaths during insertion of scope, and possible urge to defecate as scope is passed. Encourage patient to relax and let abdomen go limp. *After:* Observe for rectal bleeding after polypectomy or biopsy
Video capsule endoscopy	Patient swallows a vitamin-sized capsule with camera, which provides endoscopic visualization of GI tract (Fig. 43.11). Camera takes >50,000 images during test, relaying them to monitoring device that patient wears on a belt. Images then downloaded to computer. Used to look at areas of GI tract not accessible by upper and lower endoscopy	*Before:* Keep patient NPO for 8 hr. May have bowel preparation similar to colonoscopy. After swallowing capsule, clear liquids resumed in 2 hr and food in 4 hr. *After:* 8 hr after swallowing device, patient returns to have monitoring device removed. Tell patient that capsule is disposable and will be present in a bowel movement
Radiology		
Cholangiography		
• Magnetic resonance cholangiopancreatography (MRCP)	Use of MRI technology to obtain images of biliary and pancreatic ducts	Same as MRI
• Percutaneous transhepatic catheter (PTC)	Under local anesthesia and monitored anesthesia care, a long needle is passed into liver (under fluoroscopy) and into bile duct. Bile is removed. Radiopaque contrast medium directly injected into biliary system. Used to determine filling of hepatic and biliary ducts	*Before:* Assess patient's medications for contraindications, precautions, or complications with use of contrast medium. Keep patient NPO for 8–12 hr before test. Start prophylactic IV antibiotics 1 hr prior *After:* Observe patient for signs of hemorrhage, bile leakage, and infection. Observe safety precautions until sedation wears off. Maintain bed rest for 6 hr
• Surgical cholangiogram	Contrast medium is injected into common bile duct during surgery on biliary structures	*Before:* Explain that anesthetic will be used. Assess patient's medications for contraindications or precautions with use of contrast medium
Computed tomography (CT) scan	Noninvasive radiologic examination allows for exposures at different depths. Using oral and IV contrast medium accentuates density differences. Detects biliary tract, liver, and pancreatic disorders	*Before:* Before contrast medium used, evaluate renal function. Assess if patient is allergic to shellfish since the contrast is iodine based. Patient may need to be NPO prior. *During:* Warn patient that contrast injection may cause a feeling of being warm and flushed. Patient must lie completely still during scan. *After:* Encourage patient to drink fluids to avoid renal problems with any contrast
Defecography	Uses fluoroscopy or MRI to assess the shape and position of the rectum during defecation. Using a lubricated small plastic tip, fill rectum and anus with barium. Oral barium allows small bowel to be visualized. The person then sits on a toilet-like seat attached to the x-ray table and is asked to push and empty the rectum. Images are taken while person is sitting at rest, straining, squeezing, and during defecation. Detects pelvic floor abnormalities	*Before:* Keep patient NPO for 2 hr. 2 enemas are given 2 hr before, 15 min apart. Oral barium is given 1 hr before.

Continued

TABLE 43.11 Diagnostic Studies—cont'd

GI System

Study	Description and Purpose	Nursing Responsibility
Gastric emptying breath test (GEBT)	Noninvasive test that measures CO_2 in a patient's breath. Used to diagnose delayed gastric emptying. Baseline breath test done. Then patient eats a special test meal that includes a scrambled egg mix and *Spirulina platensis,* a protein enriched with carbon-13. It is measured in breath samples collected at multiple time points after the meal	*Before:* Teach patient to be NPO after midnight and that the test takes 4 hr. *During:* Can be done in any clinical setting. It does not require special training or special precautions related to radiation
Lower GI or barium enema	Fluoroscopic x-ray examination of colon using contrast medium given rectally (enema) (Fig. 43.9). Double-contrast or air-contrast barium enema is test of choice. Air is infused after the barium flows through transverse colon. Used to detect the presence of tumors, diverticula, and polyps	*Before:* Give laxatives and enemas until colon is clear of stool evening before. Follow clear liquid diet evening before. Keep patient NPO for 8 hr before test. Teach patient that cramping and urge to defecate may occur during procedure and patient may be placed in various positions on tilt table. *After:* Give fluids, laxatives, or suppositories to help in expelling barium. Observe stool for passage of contrast medium. Tell patient that stool may be white for up to 72 hr.
Magnetic resonance imaging (MRI)	Noninvasive procedure using radiofrequency waves and a magnetic field. IV contrast medium (gadolinium) may be used. Used to detect hepatobiliary disease, hepatic lesions, and sources of GI bleeding and stage colorectal and other cancers	*Before:* Check for pregnancy, allergies, and renal function. Have patient remove all metal objects. Ask about any staples, plates, dental bridges, or other metal appliances. Remove metallic foil patches. Patient may need to be fasting. Assess for claustrophobia and the need for antianxiety medication. *During*: Patient must lie completely still during scan
Nuclear imaging scans (scintigraphy)	Tracer doses of a radioactive isotope are injected IV, and a scanning device picks up radioactive emission, which is recorded on paper. Shows size, shape, and position of organ. Identifies functional disorders and structural defects	*Before:* Tell patient that the substance used contains only traces of radioactivity and poses little to no danger. Schedule no more than 1 radionuclide test a day. Explain to patient need to lie flat during scanning
• Gastric emptying studies	Assesses ability of stomach to empty solids. Patient eats cooked egg containing ^{99m}Tc and toast with water. Images are obtained at 0, 1, 2, and 4 hr later. Used to study gastric emptying disorders caused by ulcers, ulcer surgery, diabetes, cancer, or functional disorders	Same as above
• Hepatobiliary scintigraphy (HIDA)	Patient is given IV injection of ^{99m}Tc and positioned under camera to record distribution of tracer dose in liver, biliary tree, gallbladder, and proximal small intestine. Used to identify obstructions of bile ducts (gallstones, tumors), gallbladder disease, and bile leaks	Same as above
• Scintigraphy of GI bleeding	^{99m}Tc–labeled sulfur colloid or ^{99m}Tc labeling of the patient's own RBCs to determine the site of active GI blood loss. Sulfur colloid or patient's RBCs are injected, then images of abdomen taken at intermittent intervals	Same as above
Small bowel series	Contrast medium is ingested, and films taken every 30 min until medium reaches terminal ileum	*Before:* Explain procedure, including the need to drink contrast medium and assume various positions on x-ray table. Keep patient NPO for at least 8 hr. Tell patient to avoid smoking after midnight. *After:* Take measures to prevent contrast medium impaction (fluids, laxatives). Tell patient that stool may be white for up to 72 hr.
Upper GI or barium swallow	Fluoroscopic x-ray study using contrast medium. Used to diagnose structural abnormalities of esophagus, stomach, and duodenum	Same as for small bowel series
Ultrasound	Noninvasive procedure. High-frequency ultrasound waves are passed into body structures and recorded as they are reflected. Used to show size and shape of an organ	

TABLE 43.11 Diagnostic Studies—cont'd

GI System

Study	Description and Purpose	Nursing Responsibility
• Abdominal ultrasound	A conductive gel is applied to skin, and a transducer is placed on the area. Detects abdominal masses (tumors, cysts), gallstones, biliary and liver disease, ascites	*Before:* Teach patient to be NPO for 8–12 hr. Air or gas can reduce quality of images. Food intake can cause gallbladder contraction, resulting in suboptimal study
• Endoscopic ultrasound (EUS)	Small ultrasound transducer is installed on tip of endoscope. Because EUS transducer gets close to the organ(s) being examined, images obtained are more accurate and detailed than those provided by traditional ultrasound. Detects and stages esophageal, gastric, rectal, biliary, and pancreatic tumors and abnormalities	Same as EGD
• Ultrasound elastography (Fibroscan)	Transient elastography uses an ultrasound transducer to assess level of liver fibrosis. Used to monitor patients with chronic liver disease	*Before:* Explain the need to lie in dorsal decubitus position with right arm in extreme abduction
Virtual colonoscopy	Combines CT scanning or MRI with computer virtual reality software. Air is introduced via a tube placed in rectum to enlarge colon to enhance visualization. Images obtained while patient is on back and abdomen. Computer combines images to form 2D and 3D pictures that are viewed on monitor. Detects intestine and colon diseases, including polyps, cancer, diverticulosis, and lower GI bleeding	*Before:* Bowel preparation similar to colonoscopy

TABLE 43.12 Laboratory Studies

GI System

Test	Reference Interval	Description and Purpose
Blood Studies		
Amylase	60–120 U/L (30–220 U/L)	Enzyme secreted by pancreas. Important in diagnosing acute pancreatitis. Level peaks in 24 hr and then returns to normal in 48–72 hr
Gastrin	25–100 pg/mL when fasting	Hormone secreted by cells of the antrum of the stomach, the duodenum, and the pancreatic islets of Langerhans
Lipase	0–160 U/L	Enzyme secreted by pancreas. Important in diagnosing pancreatitis. Level stays higher longer than serum amylase in acute pancreatitis
Fecal Tests		
Fecal analysis	Note form, consistency, and color. Specimen examined for mucus, blood, pus, parasites, and fat content	Teach patient to keep diet free of red meat for 24–48 hr before occult blood test
Fecal DNA testing	Negative	Detects shredded cell debris from polyps, adenomas, and cancers
Fecal occult blood	Negative	Detects blood in stool related to the presence of inflammatory bowel disease, diverticulosis, ulcers, cancer, and other GI problems
Stool culture	Normal intestinal flora	Tests for the presence of bacteria, including *Clostridium difficile*

The major complication of GI endoscopy is perforation through the structure being studied. Many endoscopic procedures require short-acting IV sedation. All endoscopic procedures require informed, written consent. Specific endoscopy procedures are discussed in Table 43.11.

Capsule endoscopy is a noninvasive approach to visualize the GI tract (Fig. 43.11). Colon capsule endoscopy is useful in diagnosing small bowel disease and monitoring inflammation in patients with IBD. Its sensitivity in detecting small lesions, colonic polyps, and CRC is being researched.[7]

Liver Function Studies

LFTs are serologic (blood) studies that reflect hepatic disease. Table 43.13 describes the most common LFTs.

Liver Biopsy

The purpose of a liver biopsy is to obtain hepatic tissue. The tissue is used to establish a diagnosis of cancer or liver disease or assess and stage fibrosis and cirrhosis. It may be done to follow the progression of liver disease.

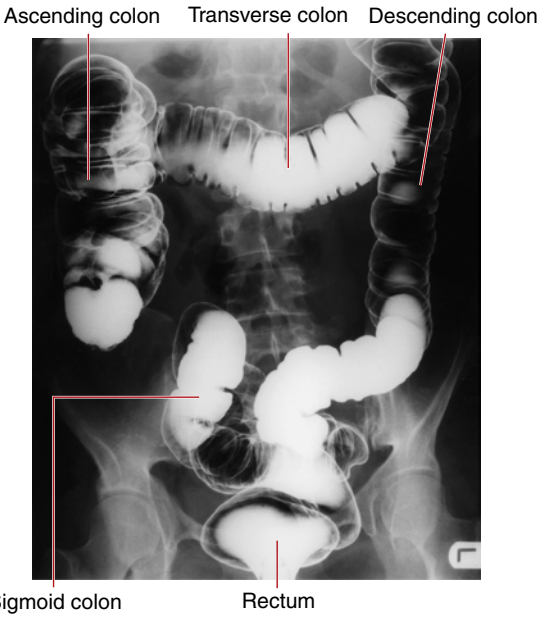

Fig. 43.9 Barium enema x-ray showing the large intestine. (From Drake RL, Vogl W, Mitchell AWM: *Gray's anatomy for students,* ed 4, St Louis, 2020, Elsevier.)

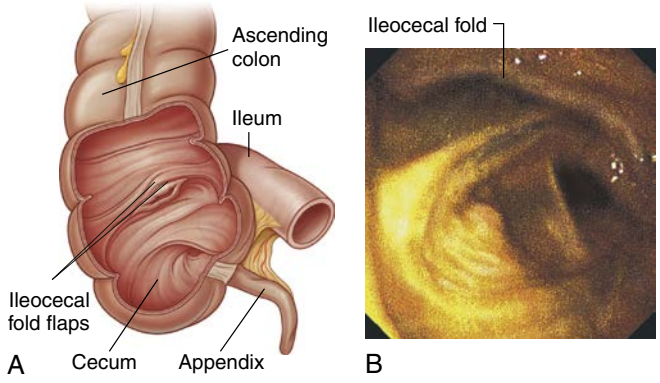

Fig. 43.10 (A) Illustration showing the ileocecal junction and the ileocecal fold. (B) Endoscopic image of the ileocecal fold. (From Drake RL, Vogl W, Mitchell AWM: *Gray's anatomy for students,* ed 4, 2020, Elsevier.)

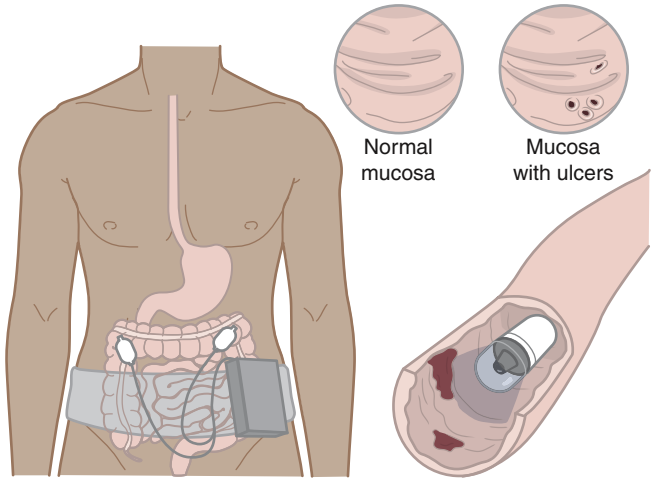

Fig. 43.11 Capsule endoscopy. The pill-sized video capsule has its own camera and light source. As it travels through the GI tract, it sends messages through sensing electrodes placed on the chest and abdomen to a data recorder worn on a waist belt. After the test, the images are viewed on a computer.

TABLE 43.13 Liver Function Tests

Test	Reference Interval	Description and Purpose
Bile Formation and Excretion		
Serum bilirubin		Measures liver's ability to conjugate and excrete bilirubin, distinguishing between unconjugated (indirect) and conjugated (direct) bilirubin in plasma
• Total	0.3–1.0 mg/dL (5.1–17 μmol/L)	Measures direct and indirect total bilirubin
• Direct	0.1–0.3 mg/dL (1.7–5.1 μmol/L)	Measures conjugated bilirubin. High in obstructive jaundice
• Indirect	0.2–0.8 mg/dL (3.4–12 μmol/L)	Measures unconjugated bilirubin. High in hepatocellular and hemolytic conditions
Urinary bilirubin	0 or negative	Measures urinary excretion of conjugated bilirubin
Hemostatic Function		
Prothrombin time (PT)	11–12.5 s	Determination of prothrombin activity
Vitamin K	0.1–2.2 ng/mL (0.22–4.88 nmol/L)	Essential cofactor for many clotting factors
Lipid Metabolism		
Cholesterol (serum)	200 mg/dL (<5.2 mmol/L), varying with age	Synthesized and excreted by liver. High in biliary obstruction. Low in cirrhosis and malnutrition
Protein Metabolism		
α-Fetoprotein	<10 ng/mL (<10 mcg/L)	Sign of hepatocellular cancer
Ammonia	10–80 mcg/dL (6–47 μmol N/L)	Conversion of ammonia to urea normally occurs in liver. Increase can result in hepatic encephalopathy due to liver cirrhosis
Protein (serum)	Albumin: 3.5–5.0 g/dL (35–50 g/L) Globulin: 2.3–3.4 g/dL (23–34 g/L) Total protein: 6.4–8.3 g/dL (64–83 g/L)	Measures serum proteins made by liver
Serum Enzymes		
Alanine aminotransferase (ALT)	4–36 U/L	High in liver damage and inflammation
Alkaline phosphatase (ALP)	30–120 U/L (0.5–2.0 μkat/L)	Originates from bone and liver. Serum levels rise when excretion is impaired because of biliary tract obstruction
γ-Glutamyl transpeptidase (GGT)	Male and Female >45: 8–38 U/L Female <45: 5–27 U/L	Present in biliary tract, not in skeletal or heart muscle. High in hepatitis, cholestatic liver diseases and alcoholic liver diseases. More sensitive for liver dysfunction than ALP
Aspartate aminotransferase (AST)	0–35 U/L (0.0–0.58 μkat/L)	High in liver damage and inflammation

TABLE 43.14 NURSING MANAGEMENT

Care of the Patient Undergoing Closed Liver Biopsy

Preprocedure

- Perform baseline assessment, including vital signs, pulse oximetry.
- Withhold food and fluids for 8–12 hr before.
- Check patient's coagulation status (prothrombin time, clotting or bleeding time).
- Give sedative and other drugs, as ordered.
- Obtain type and crossmatch (In event patient bleeds and requires blood).
- Teach patient and caregiver about procedure and postprocedure care. Explain need to hold breath after expiration when needle is inserted.
- Ensure informed consent has been signed.

Postprocedure

- Check vital signs to detect internal bleeding q15min × 2, q30min × 4, q1hr × 4.
- Notify HCP of dyspnea, cyanosis, and restlessness, which may occur with pneumothorax.
- Keep patient lying on right side for minimum of 2 hr to splint puncture site. Then maintain bed rest for 12–14 hr, as ordered.
- Apply a small dressing over the needle insertion site.
- Teach patient and caregiver about discharge care, including signs and symptoms to report to HCP (e.g., site complications) and any activity restrictions. Tell patient to avoid straining or coughing, which increase intraabdominal pressure.

A liver biopsy can be open and closed. The *open method* involves making an incision and removing a wedge of tissue. It is done in the operating room with the patient under general anesthesia, often with another surgical procedure. The *closed,* or *needle, biopsy* can be done 2 ways. A percutaneous procedure is often done with ultrasound or CT guidance. The HCP administers a local anesthetic, then inserts a needle between 6th and 7th or 8th and 9th intercostal spaces on the right side to obtain specimen of hepatic tissue. Table 43.14 outlines the nursing management of a patient undergoing a liver biopsy. A liver biopsy done in interventional radiology can be obtained through a transjugular approach. The HCP enters the jugular vein and advances a small sheath into the hepatic vein. A biopsy needle is passed through the sheath, into the vein wall, then into the liver tissue.

Case Study

Objective Data: Diagnostic Studies

(© iStockphoto/Thinkstock.)

The ED physician performs a rectal examination and finds a palpable mass. The following diagnostic tests are ordered:

- CBC
- Electrolytes
- Liver function tests
- Urinalysis
- CT scan of the abdomen
- Colonoscopy

The CBC reveals an Hgb of 6.8 g/dL and Hct of 20%. The WBC count is normal. The electrolytes, liver function tests, and urinalysis are within normal limits. The CT scan reveals pockets of gas and fluid in the ascending colon and 2 medium-sized tumors in the transverse colon.

Discussion Questions

1. Which diagnostic study results concern you most?
2. With this information, what other diagnostic studies would you expect to be ordered for L.C.?
3. What are the interprofessional team's priorities for L.C. at this time?

Case study continued in Chapter 47.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient is admitted to the hospital with diarrhea and dehydration. The nurse recognizes that increased peristalsis resulting in diarrhea can be related to
   - **a.** sympathetic inhibition.
   - **b.** mixing and propulsion.
   - **c.** sympathetic stimulation.
   - **d.** parasympathetic stimulation.
2. A patient has a high blood level of indirect (unconjugated) bilirubin. One cause of this finding is that
   - **a.** the gallbladder is unable to contract to release stored bile.
   - **b.** bilirubin is not being conjugated and excreted into the bile by the liver.
   - **c.** the Kupffer cells in the liver are unable to remove bilirubin from the blood.
   - **d.** there is an obstruction in the biliary tract preventing flow of bile into the small intestine.
3. As gastric contents move into the small intestine, the bowel is normally protected from the acidity of gastric contents by the
   - **a.** inhibition of secretin release.
   - **b.** secretion of mucus by goblet cells.
   - **c.** release of pancreatic digestive enzymes.
   - **d.** release of gastrin by the duodenal mucosa.
4. A patient has jaundice with pale colored stools. This is *most* likely related to
   - **a.** decreased bile flow into the intestine.
   - **b.** increased production of urobilinogen.
   - **c.** increased bile and bilirubin in the blood.
   - **d.** increased production of cholecystokinin.
5. An 80-year-old man states that, although he adds a lot of salt to his food, it still does not have much taste. The nurse's response is based on the knowledge that the older adult
   - **a.** should not have any changes in taste.
   - **b.** has a loss of taste buds, especially for sweet and salt.
   - **c.** has some loss of taste but no problems chewing food.
   - **d.** loses some sense of taste related to the increased ability to smell.
6. When the nurse is assessing the health perception–health maintenance pattern as related to gastrointestinal function, an appropriate question to ask is

a. "What is your usual bowel elimination pattern?"
b. "What percentage of your income is spent on food?"
c. "Have you traveled to a foreign country in the last year?"
d. "Do you have diarrhea when you are under a lot of stress?"

7. When assessing the abdomen, the nurse should
a. position the patient in the supine position with the bed flat and knees straight.
b. listen for bowel sounds in the epigastrium and all 4 quadrants for 2 minutes.
c. describe bowel sounds as absent if no sound is heard in a quadrant after 2 minutes.
d. use the following order of techniques: inspection, palpation, percussion, auscultation.

8. Normal physical assessment findings of the gastrointestinal system are *(select all that apply)*
a. nonpalpable spleen.
b. borborygmi in upper right quadrant.
c. tympany on percussion of the abdomen.
d. liver edge 2 to 4 cm below the costal margin.
e. finding of a firm, nodular edge on the rectal examination.

9. In preparing a patient for a colonoscopy, the nurse explains that
a. a signed permit is not needed.
b. sedation will be used during the procedure.
c. one cleansing enema part of the required preparation.
d. light meals should be eaten for 3 days before the procedure.

1. d; 2. b; 3. b; 4. a; 5. b; 6. c; 7. b; 8. a, c; 9. b.

Nutrition Problems

Mariann M. Harding

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Functional Ability
Health Promotion
Nutrition

LEARNING OUTCOMES

1. Relate the components of a well-balanced diet to their impact on health outcomes.
2. Describe the etiology, clinical manifestations, and interprofessional and nursing management of malnutrition.
3. Describe the components of a nutrition assessment.
4. Explain the indications, complications, and nursing management related to the use of enteral nutrition.
5. Explain the indications, complications, and nursing management related to the use of parenteral nutrition.
6. Compare the etiology, clinical manifestations, and nursing management of eating disorders.

KEY TERMS

anorexia nervosa (AN)
bulimia nervosa (BN)
enteral nutrition (EN)
malabsorption syndrome
malnutrition
parenteral nutrition (PN)
refeeding syndrome
tube feeding

This chapter focuses on problems related to nutrition. A review of normal nutrition provides a basis for evaluating nutrition status. We need sufficient energy, protein, and other nutrients to maintain health. Many problems affect nutrition by changing the way we ingest, absorb, digest, and metabolize nutrients. These changes can lead to malnutrition and health problems that affect functional status and quality of life. This makes assessment and interventions aimed at promoting optimal nutrition important nursing roles.

NUTRITION PROBLEMS

Nutrition is the sum of processes by which one takes in and uses nutrients. We view nutrition status on a continuum from undernutrition to normal nutrition to overnutrition. Any change in nutrient intake or use can cause nutrition problems. Nutrition problems occur in all ages, cultures, ethnic groups, and socioeconomic classes and across all educational levels.

Many factors influence nutrition. We establish our attitudes toward food and eating habits early. Diet intake often reflects cultural or religious practices. Financial status and community resources affect the food someone can buy.

NORMAL NUTRITION

Nutrition is important for energy, growth, and maintaining and repairing body tissues. Optimal nutrition, in the absence of any underlying disease process, results from eating a balanced diet (Box 44.1). The major components of the basic food groups are macronutrients (carbohydrates, fats, proteins), micronutrients (vitamins, minerals, electrolytes), and water. Optimal nutrition and daily physical activity are essential for health.

Body type, age, gender, medications, physical activity, and the presence of disease influence a person's daily caloric requirements. Adjustments in caloric intake are necessary depending on changes in health status and daily activity level. There are several ways to estimate caloric needs. The Mifflin–St. Jeor equation calculates daily adult energy (calorie) requirements based on resting metabolic rate (Table 44.1).[1] A simple way to estimate daily calories needed is by kilocalories per kilogram (kcal/kg). An average adult should consume 20 to 25 cal/kg body weight to

BOX 44.1 PROMOTING POPULATION HEALTH

Health Impact of a Well-Balanced Diet

- Reduces risk for anemia
- Maintains normal body weight and prevents obesity
- Maintains good bone health and reduces risk for osteoporosis
- Lowers the risk for developing high cholesterol and type 2 diabetes
- Decreases the risk for heart disease, hypertension, and some cancers

TABLE 44.1 Estimating Daily Energy (Calorie) Requirements

Mifflin–St. Jeor Equation

For each gender, use the formula below to calculate energy expenditure:
Men: 10 × weight (kg) + 6.25 × height (cm) – 5 × age (year) + 5
Women: 10 × weight (kg) + 6.25 × height (cm) – 5 × age (year) – 161
To determine total daily calorie needs, the energy expenditure is multiplied by the appropriate activity factor, as follows:
1.200 = sedentary (little or no exercise)
1.375 = lightly active (light exercise/sports 1–3 days/week)
1.550 = moderately active (moderate exercise/sports 3–5 days/week)
1.725 = very active (hard exercise/sports 6–7 days a week)
1.900 = extra active (very hard exercise/sports and physical job)

Example

Man: Weight 180 lb (82 kg); height 5 ft, 10 in (178 cm); age 50, very active
Energy expenditure = 10 (82) + 6.25 (178) – 5 (50) + 5 × 1.725 = 2911
Woman: Weight 150 lb (68 kg); height 5 ft, 6 in (168 cm); age 60; lightly active
Energy expenditure = 10 (68) + 6.25 (168) – 5 (60) –161 × 1.375 = 1745

lose weight and 25 to 30 cal/kg to maintain weight. Those with injury or illness may need at least 30 to 35 cal/kg.

Carbohydrates, the body's main source of energy, yield about 4 cal/g. We classify them as either simple or complex depending on the number of sugars they have. Simple carbohydrates come in 2 forms: monosaccharides, such as glucose and fructose, which are found in fruits and honey, and disaccharides, such as sucrose, maltose, and lactose. They are found in foods such as table sugar, malted cereal, and milk. Complex carbohydrates (polysaccharides) include starches, such as cereal grains, potatoes, and legumes.

Carbohydrates are the chief protein-sparing ingredient in a nutritionally sound diet. The Dietary Reference Intake (DRI) recommendations are that 45% to 65% of total calories should come from carbohydrates.[2] A person should take around 14 g of fiber per 1000 calories eaten per day from fruits, vegetables, and whole grains. This equals roughly 28 to 30 g for a typical 2000-calorie diet. We should choose food and beverages with little added sugar or caloric sweeteners.

Fats are a major source of energy for the body. One gram of fat yields 9 calories. Fats are stored in adipose tissue and the abdominal cavity. They act as carriers of essential fatty acids and fat-soluble vitamins. Fats give us a feeling of satiety after eating. Fat intake should be no more than 20% to 35% of total calories.[2]

Fats can be divided into (1) potentially harmful (saturated fat and *trans* fat) and (2) healthier diet fat (monounsaturated and polyunsaturated fat). One type of polyunsaturated fat, omega-3 fatty acids, may be especially beneficial to your heart. Omega-3 fatty acids (found in some types of fatty fish) may decrease the risk for coronary artery disease.[3]

TABLE 44.2 NUTRITION THERAPY

Foods High in Protein

Complete Proteins
- Eggs
- Fish
- Meats
- Milk and milk products (e.g., cheese)
- Poultry

Incomplete Proteins
- Grains (e.g., corn)
- Legumes (e.g., navy beans, soybeans, peas)
- Nuts (e.g., peanuts)
- Seeds (e.g., sesame seeds, sunflower seeds)

Diets high in excess calories, usually in the form of fats, contribute to obesity. We should consume less than 10% of calories from saturated fatty acids (about 20 g of saturated fat per day in a 2000-calorie diet) and choose foods with no *trans*-fatty acids.[2]

Proteins are an essential part of a well-balanced diet. They are needed for tissue growth, repair, and maintenance; body regulatory functions; and energy production. Ideally, 10% to 35% of daily caloric needs should come from protein.[2] The recommended daily protein intake is 0.8 to 1 g/kg of body weight. For the normal healthy person of average body size, this equals about 45 to 65 g of protein daily. One gram of protein yields 4 calories. Amino acids are the basic units of protein structure. We classify the 22 amino acids as essential or nonessential. The body can make nonessential amino acids if an adequate supply of protein is available. The body cannot make the 9 essential amino acids. Their availability depends totally on one's diet. We obtain them from both animal and plant sources. *Complete proteins* contain all the essential amino acids. Proteins that lack one or more of the essential amino acids are *incomplete proteins.* Table 44.2 lists foods high in protein.

Vitamins are organic compounds needed in small amounts for normal metabolism. Vitamins function in enzyme reactions that facilitate amino acid, fat, and carbohydrate metabolism. A diet consisting of foods from the 5 basic food groups is essential for obtaining the recommended intake of essential vitamins. Vitamins are divided into 2 categories: *water-soluble* vitamins (vitamin C and the B-complex vitamins) and *fat-soluble* vitamins (vitamins A, D, E, and K). Since the body stores excess fat-soluble vitamins, consuming too much can result in toxicity. There are upper limits for vitamins A, D, and E.

Mineral salts (e.g., magnesium, iron, calcium) make up about 4% of the total body weight. The body needs minerals to build and repair tissues, regulate body fluids, and assist in various functions. Minerals needed in amounts greater than 100 mg/day are *major minerals*. Minerals present in minute amounts are *trace elements.* Table 44.3 lists the major minerals and trace elements. Some minerals are stored and can be toxic if taken in excess amounts. The amount of minerals needed daily varies

TABLE 44.3 Major Minerals and Trace Elements

Major Minerals
- Calcium
- Chloride
- Magnesium
- Phosphorus
- Potassium
- Sodium
- Sulfur

Trace Elements
- Chromium
- Copper
- Fluoride
- Iodine
- Iron
- Manganese
- Molybdenum
- Selenium
- Zinc

from a few micrograms of trace minerals to 1 g or more of the major minerals, such as calcium, phosphorus, and sodium. A well-balanced diet usually meets the daily requirements of minerals. However, deficiency and excess states can occur.

VEGETARIAN DIET

There are many types of vegetarians and no strict definition of the word "vegetarian." The common element among all vegetarians is the exclusion of red meat from the diet. Many vegetarians are *vegans,* who are pure or total vegetarians and eat only plants, or *lacto-ovo-vegetarians*. They eat plants, dairy products, and eggs.

Without a well-planned diet, vegetarians can have vitamin or protein deficiencies. Plant protein, although of lesser quality than animal protein, fulfills most protein requirements. Combinations of vegetable protein foods (e.g., cornmeal, kidney beans) can increase the nutritional value. Milk made from soybeans or almonds is an excellent protein source and should be calcium fortified. Vegans and lacto-ovo-vegetarians are also at risk for iron deficiency. Table 44.4 lists examples of foods high in iron.

The main deficiency for a strict vegan is a lack of cobalamin (vitamin B_{12}).[2] We obtain cobalamin from animal protein, special supplements, or foods fortified with the vitamin. Vegans not using cobalamin supplements can develop megaloblastic anemia and the neurologic signs of cobalamin deficiency. Other deficiencies that may be present include calcium, zinc, and vitamins A and D.

Culturally Competent Care: Nutrition

People have unique cultural heritages that may affect eating customs and nutrition status. Each culture has its own beliefs and behaviors related to food and the role that food plays in the cause and treatment of disease. Culture and religion can influence which foods are considered edible, how they are prepared, when they are eaten, and how and who prepares them. Some religions, such as Judaism and Islam, have specific laws about food.

Assess the patient's diet history and the extent to which they adhere to diet practices. Avoid cultural stereotyping. Do not make assumptions or generalizations about diet based on a person's cultural background. Diet habits differ within and among ethnic groups. Acculturation, the process by which a person adopts the lifestyle of a new culture, can affect diet practices.

Implement needed changes to ensure that we serve proper meals. A Jewish patient who eats only Kosher food may find comfort in knowing that an enteral feeding formula is Kosher. Another example is adjusting meal plans for the Muslim patient observing Ramadan (the Islamic month of *fasting,* in which Muslims refrain from eating and drinking during daylight hours).

TABLE 44.4 NUTRITION THERAPY

Foods High in Iron

These foods provide 25%–39% of the Dietary Reference Intake (DRI) of iron.

Food	Selected Serving Size
Breads, Cereals, and Grain Products	
Farina, regular or quick cooked (enriched)	⅔ cup
Oatmeal, instant, fortified, prepared (enriched)	⅔ cup
Ready-to-eat cereals, fortified (enriched)	1 oz
Meat, Poultry, Fish, and Alternatives	
Beef liver, braised	3 oz
Chicken or turkey liver, braised	½ cup diced
Clams: steamed, boiled, or canned (drained)	3 oz
Oysters: baked, broiled, steamed, or canned (undrained)	3 oz
Pork liver, braised	3 oz
Soybeans, cooked	½ cup

MALNUTRITION

Malnutrition is a deficit, excess, or imbalance in a person's intake of energy and/or nutrients.[4] It may occur with or without inflammation. Malnutrition affects body composition and functional status. Other terms we use to describe malnutrition are *undernutrition* and *overnutrition.*

Overnutrition refers to the ingestion of more food than is required for body needs, as in obesity. See Chapter 45 for information about obesity. *Undernutrition* occurs when nutrition reserves are depleted and nutrient and energy intake are not sufficient to meet daily needs or added metabolic stress. Most use the term malnutrition to refer to undernutrition. We use the terms interchangeably here.

Malnutrition is a problem worldwide across the care continuum (community, hospital, long-term care). Rates for malnutrition in the hospital setting range from 30% to 50%.[5] The prevalence of malnutrition in older adults ranges from about 6% (community-dwelling older adults) to 50% (rehabilitation settings).[6]

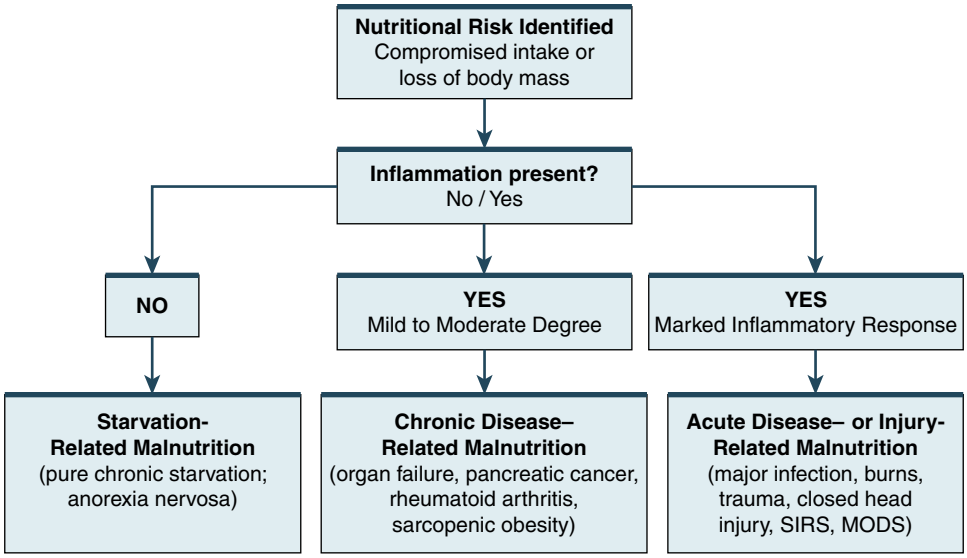

Fig. 44.1 Definitions of malnutrition. *MODS,* Multiple organ dysfunction syndrome; *SIRS,* systemic inflammatory response syndrome. (From Nix S: *Williams' basic nutrition and diet therapy,* ed 15, St Louis, 2018, Elsevier.)

Etiology

Several terms describe the types and causes of adult malnutrition. There are 3 cause-based terms used in clinical settings. They stress the interaction and importance of inflammation on nutrition status (Fig. 44.1).[7]

- *Starvation-related malnutrition,* or primary PCM, occurs when nutrition needs are not met. In primary PCM, there is chronic starvation without inflammation (e.g., anorexia nervosa).
- *Chronic disease-related malnutrition,* or secondary PCM, occurs when diet intake does not meet tissue needs, although it would under normal conditions. It is related to conditions that have sustained mild to moderate inflammation. Examples of conditions associated with secondary PCM include organ failure, cancer, rheumatoid arthritis, and obesity.
- *Acute disease-related or injury-related malnutrition* is related to acute disease or injury states with marked inflammatory response (e.g., major infection, burns, trauma, surgery).

Contributing Factors

Many factors contribute to malnutrition. These include socioeconomic factors, physical illnesses, incomplete diets, and drug-nutrient interactions. Table 44.5 lists conditions that increase the risk for malnutrition.

TABLE 44.5 Conditions That Increase the Risk for Malnutrition

- Chronic alcohol use
- Decreased mobility that limits access to food or its preparation
- Dementia
- Depression
- Drugs with antinutrient or catabolic properties (e.g., corticosteroids, antibiotics)
- Excess dieting to lose weight
- Need for increased nutrients because of hypermetabolism or stress (e.g., infection, trauma, fever)
- No oral intake and/or receiving standard IV solutions for 10 days (adults) or for 5 days (older adults)
- Nutrient losses from malabsorption, dialysis, diarrhea, or wounds
- Swallowing problems (e.g., head and neck cancer, stroke)

Socioeconomic Factors

Those with limited financial resources may have *food insecurity* (inadequate access). Food insecurity is a major public health problem. It affects the overall quality of food that is available in both quantity and nutritional value. Those with food insecurity usually choose less expensive "filling" foods. They tend to be more energy dense (high fat) and lack nutritional value. This type of diet increases the risk for nutrition problems.

To help obtain food, people may use "safety net programs." These include food assistance programs; housing and energy subsidies; and in-kind contributions from relatives, friends, food pantries, or charitable organizations. Consult with social workers to help patients gain access to government and local programs, such as Meals on Wheels, that deliver nutritious meals to homebound people.

The "heat or eat" phenomenon is problematic. Those with limited economic resources may struggle to pay bills or put food on the table. Older adults on a fixed income have an added burden of deciding on whether to pay for medications or food. You and the dietitian can help patients in making food choices that meet nutrition requirements while staying within their limited resources.

Physical Illnesses

Malnutrition is a common consequence of illness, surgery, injury, or hospitalization. The hospitalized patient, especially the older adult, is at risk for becoming malnourished. Prolonged illness, major surgery, sepsis, draining wounds, burns, hemorrhage, fractures, and immobilization can contribute to malnutrition. Undernutrition can worsen a pathologic condition. An

TABLE 44.6 Recommended Daily Vitamin Intake and Manifestations of Deficiencies

Vitamin	Dietary Reference Intake	Manifestations of Deficiencies
Fat Soluble		
A (retinol)	*Men:* 900 mcg/retinol equivalents[a] *Women:* 700 mcg/retinol equivalents	Dry, scaly skin. Increased susceptibility to infection, night blindness, anorexia, eye irritation, keratinization of respiratory and GI mucosa, bladder stones, anemia, retarded growth
D	*Adults ages 19–70:* 600 IU *Adults age >70:* 800 IU	Muscular weakness, excessive sweating, diarrhea and other GI problems, bone pain, active or healed rickets, osteomalacia
E	*Adults:* 15 mg	Neurologic deficits
K	*Men:* 120 mcg *Women:* 90 mcg	Blood coagulation problems
Water Soluble		
B_1 (thiamine)	*Men:* 1.2 mg *Women:* 1.1 mg	Anorexia, fatigue, nervous irritability, constipation, paresthesias, insomnia
B_6 (pyridoxine)	*Men ages 19–50:* 1.3–1.7 mg *Men age >51:* 1.7 mg *Women ages 19–50:* 1.3–1.5 mg *Women age >51:* 1.5 mg	Seizures, dermatitis, anemia, neuropathy with motor weakness, anorexia
B_{12} (cobalamin)	*Adults:* 2.4 mcg	Megaloblastic anemia, anorexia, glossitis, sore mouth and tongue, pallor, neurologic problems (e.g., depression, dizziness), weight loss, nausea, constipation
C	*Men:* 90 mg *Women:* 75 mg	Bleeding gums, loose teeth, easy bruising, poor wound healing, scurvy, dry, itchy skin
Folate (folic acid)	*Adults:* 400 mcg	Impaired cell division and protein synthesis, megaloblastic anemia, anorexia, fatigue, sore tongue, diarrhea, forgetfulness

[a]1 retinol equivalent = 10 international units vitamin A activity from β-carotene or 3.33 international units vitamin A activity from retinol.

existing deficiency state is likely to become more severe during illness.

Anorexia, nausea, vomiting, diarrhea, abdominal distention, and abdominal cramping may accompany gastrointestinal (GI) disease. Any combination of these symptoms interferes with normal food intake and metabolism. In addition, a patient may restrict intake to a few foods or fluids that may not be nutritious out of fear of worsening an existing GI problem.

Malabsorption syndrome is the impaired absorption of nutrients from the GI tract. Decreases in digestive enzymes or in bowel surface area can quickly lead to a deficiency state. Many drugs have GI side effects and alter normal digestive and absorptive processes. For example, antibiotics can change the normal flora of the intestines. This decreases the body's ability to make biotin, a B-complex vitamin whose production depends on that gut flora.

Fever, which accompanies many illnesses, injuries, and infections, increases basal metabolic rate (BMR) and nitrogen loss. Each degree of temperature increase on the Fahrenheit scale raises the BMR by about 7%. Without an increase in caloric intake, the body uses protein stores to supply calories and protein depletion develops. After the body temperature returns to normal, the rate of protein breakdown and resynthesis may stay increased for several weeks.

Consider the nutrition requirements of a patient who is not overtly ill but having diagnostic studies. This patient may be nutritionally fit on entering the hospital but can become malnourished because of diet restrictions imposed by multiple diagnostic studies.

Incomplete Diets

Vitamin deficiencies are rare in most developed countries. When vitamin imbalances do occur, they usually involve several vitamins rather than a single one. This may happen with a person with a pattern of alcohol and drug use, those who are chronically ill, and those who follow poor diet practices. Persons who had surgery on the GI tract may be at risk for vitamin deficiencies. For example, resection of the terminal ileum poses a risk for deficiencies of fat-soluble vitamins. After a gastrectomy, patients need cobalamin supplements. Because intrinsic factor (normally made in the stomach) is not available to bind with cobalamin, cobalamin cannot be absorbed in the ileum. Followers of fad diets or poorly planned vegetarian diets are at risk.

Manifestations of vitamin imbalances range from skin problems to neurologic signs. The recommended dietary allowances for essential vitamins and manifestations of imbalances are outlined in Table 44.6.

Drug-Nutrient Interactions

A *drug-nutrient interaction* occurs when a drug affects the use of nutrients in the body. Many drug and food or beverage interactions may occur. Potential adverse interactions include incompatibilities, altered drug effectiveness, and impaired nutrition. Many drugs have side effects, such as changes in taste, appetite, and nausea. Grapefruit juice can increase the absorption of some drugs, enhancing their effect. Drug-nutrient interactions can occur with the use of herbs and diet supplements. Monitor and prevent these potential interactions for patients in the hospital and at home.

Pathophysiology of Starvation

Knowing the pathophysiology of the starvation process will help you understand the physiologic changes that occur in

malnutrition. Initially, the body selectively uses carbohydrates (glycogen) rather than fat and protein to meet metabolic needs. These carbohydrate stores, found in the liver and muscles, are minimal. They may be totally depleted within 18 hours. During the early phase of starvation, the body uses protein only in its normal role in cellular metabolism.

Once carbohydrate stores are depleted, the body converts skeletal protein to glucose for energy. Alanine and glutamine are the first amino acids used in *gluconeogenesis,* the process by which the liver forms glucose. The resulting plasma glucose allows metabolic processes to continue. When these amino acids are used as energy sources, the person may be in negative nitrogen balance (nitrogen excretion exceeds nitrogen intake).

Within 5 to 9 days, the body uses fat to supply much of the needed energy. In prolonged starvation, fat provides up to 97% of calories, conserving protein. Depletion of fat stores depends on the amount available. Fat stores are generally used up in 4 to 6 weeks. Once fat stores are gone, the body uses visceral and body proteins, including those in internal organs and plasma. They rapidly decrease because they are the only remaining body source of energy available.

If a malnourished patient has surgery, physical trauma, or an infection, the stress response is superimposed on the starvation response. The body uses protein stores for energy to meet the increased metabolic energy expenditure.

As protein depletion continues, liver function becomes impaired and protein synthesis decreases. The decrease in protein synthesis lowers plasma oncotic pressure. A major function of plasma proteins, primarily albumin, is to maintain the osmotic pressure of blood. When the oncotic pressure decreases, body fluids shift from the vascular space into the interstitial compartment. Eventually, albumin leaks into the interstitial space along with the fluid. Edema becomes observable. Edema in the patient's face and legs can mask underlying muscle wasting.

As the total blood volume decreases, the skin appears dry and wrinkled. As fluids shift to the interstitial space, ions also move. Sodium (the main extracellular ion) concentration increases in the cell. Potassium (the main intracellular ion) and magnesium shift to the extracellular space. The sodium-potassium exchange pump has high-energy needs, using 20% to 50% of all calories ingested. When the diet is extremely deficient in calories and essential proteins, the pump will fail. This leaves sodium inside the cell (along with water), and the cell expands.

The liver is the body organ that loses the most mass during protein deprivation. Fat gradually infiltrates the liver due to decreased synthesis of lipoproteins. Death will rapidly ensue if the person does not receive protein and necessary nutrients.

Impact of Inflammation

Inflammation affects nutrient metabolism and is an important part of nutrition status. During the starvation process, there is a decreased BMR, sparing of skeletal muscle, and decreased protein breakdown. In inflammatory states, there are changes in the expression of proinflammatory (e.g., interleukin-6 [IL-6]) and antiinflammatory cytokines (e.g., IL-10). Cytokine changes result in increased protein and skeletal muscle breakdown, increased BMR, decreased insulin secretion, decreased negative acute phase protein (albumin, prealbumin) production, and increased positive acute phase protein (e.g., C-reactive protein [CRP]) production.

Fig. 44.2 Severe malnutrition with muscle wasting and loss subcutaneous tissue. (From Carlson GL, Fearon K: *Principles and practice of surgery*, ed 7, St Louis, 2018, Elsevier.)

Clinical Manifestations and Diagnostic Studies

The manifestations of malnutrition range from mild to emaciation and death (Fig. 44.2). The most obvious signs are seen in the skin (dry and scaly skin, brittle nails, rashes, hair loss), mouth (crusting and ulceration, changes in tongue), muscles (decreased mass, weakness), and CNS (mental changes, such as confusion, irritability). The speed at which malnutrition develops depends on the quantity and quality of the protein intake, caloric value, illness, and person's age.

The manifestations result from numerous interactions at the cellular level. As protein intake declines, the muscles (the largest store of protein in the body) become wasted and flabby. This leads to weakness and fatigability. Decreased protein is available for tissue repair, causing delayed wound healing. The person is more susceptible to infections. Both humoral and cell-mediated immunity are deficient. Leukocytes decrease in the peripheral blood. Impaired phagocytosis occurs because of the lack of energy needed to drive the process. The lack of iron and folic acid (necessary building blocks for red blood cells [RBCs]) causes anemia.

The diagnosis of malnutrition is best determined by nutrient intake, functional status, and body composition, including a thorough history of weight loss. Obtain vital signs, height, and weight. Perform a complete physical assessment. Table 44.7 outlines the assessment and findings of the patient with malnutrition.

There are no specific laboratory tests for malnutrition. Serum electrolyte levels reflect changes taking place between the intracellular and extracellular spaces. The serum potassium level often increases. The RBC count and hemoglobin level indicate the presence and degree of anemia. The total lymphocyte count decreases with malnutrition. Calculate it by multiplying the percent of lymphocytes times the total white blood cell (WBC)

TABLE 44.7 NURSING ASSESSMENT

Malnutrition

Subjective Data

Important Health Information

Health history: Severe burns, major trauma, hemorrhage, draining wounds, bone fractures with prolonged immobility, chronic renal or liver disease, cancer, malabsorption syndromes, GI obstruction, infectious diseases, acute (e.g., trauma, sepsis) or chronic inflammatory condition (e.g., rheumatoid arthritis)

Medications: Corticosteroids, chemotherapy, diet pills, diet supplements, herbs

Surgery or other treatments: Recent surgery, radiation

Functional Health Patterns

Health perception–health management: Alcohol or drug use. Malaise, apathy

Nutritional-metabolic: Increase or decrease in weight, weight problems. Increase or decrease in appetite, typical diet intake, food preferences and aversions, food allergies or intolerance. Ill-fitting or absent dentures. Dry mouth, problems chewing or swallowing, bloating, or gas. ↑ Sensitivity to cold, delayed wound healing

Elimination: Constipation, diarrhea, nocturia, decreased urine output

Activity-exercise: Increase or decrease in activity. Weakness, fatigue, decreased endurance

Cognitive-perceptual: Pain in mouth. Paresthesias, loss of position, and vibratory sense

Role-relationship: Change in family (e.g., loss of a spouse), financial resources, food availability

Sexual-reproductive: Amenorrhea, impotence, decreased libido

Objective Data

General

Listless, cachectic, underweight for height

Cardiovascular

↑ or ↓ heart rate, ↓ BP, dysrhythmias, peripheral edema

Eyes

Pale or red conjunctivae, gray keratinized epithelium on conjunctiva (Bitot spots). Dryness and dull appearance of conjunctivae and cornea, soft cornea. Blood vessel growth in cornea. Redness and fissuring of eyelid corners

GI

Swollen, smooth, raw, beefy red tongue (glossitis), hypertrophic or atrophic papillae. Dental cavities, absent or loose teeth, discolored tooth enamel. Spongy, pale, receded gums with a tendency to bleed easily, periodontal disease. Ulcerations, white patches, or plaques. Redness, swelling of oral mucosa. Distended, tympanic abdomen. Ascites, hepatomegaly, decreased bowel sounds, steatorrhea

Musculoskeletal

Decreased muscle mass with poor tone, "wasted" appearance, bowlegs, knock-knees, beaded ribs, chest deformity, prominent bony structures

Neurologic

Decreased or loss of reflexes, tremor; irritability, confusion, syncope, peripheral neuropathy

Respiratory

↓ Respiratory rate, ↓ vital capacity, crackles, weak cough, slight cyanosis

Skin

Dry, brittle, sparse hair with color changes and lack of luster, alopecia. Dry, scaly lips. Fever blisters, angular crusts, and lesions at corners of mouth (cheilosis). Brittle, ridged nails. Decreased tone and elasticity of skin. Cool, rough, dry, scaly skin with brown-gray pigment changes. Reddened, scaly dermatitis, scrotal dermatitis.

Possible Diagnostic Findings

↓ Hemoglobin and hematocrit, ↓ mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), or mean corpuscular hemoglobin concentration (MCHC). Altered serum electrolyte levels, especially hyperkalemia. ↓ BUN and creatinine, ↓ serum albumin, transferrin, and prealbumin. ↑ C-reactive protein, ↓ lymphocytes, ↑ liver enzymes, ↓ serum vitamin levels

count. Liver enzyme levels may increase. Serum levels of both fat-soluble and water-soluble vitamins usually decrease. Low serum levels of fat-soluble vitamins correlate with the presence of *steatorrhea* (fatty stools).

Albumin and prealbumin are *negative acute phase proteins.* This means that during an inflammatory response, the liver decreases synthesis of these proteins. Low or below normal levels indicate the presence of inflammation. Because of the strong relationship between inflammation and malnutrition, they are useful in identifying patients at risk for poor outcomes.[8]

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: MALNUTRITION

◆ Assessment

As a nurse, you are responsible for nutrition screening across care settings. Nutrition screening identifies those who are malnourished or at risk for malnutrition. The Joint Commission requires nutrition screening for all patients within 24 hours of admission with a detailed nutrition assessment if a patient is at risk. Following a standard approach to nutrition screening using valid and reliable tools will accurately identify those at risk. Many screening and assessment tools are available. Hospital-specific screening tools review common admission assessment data, including a history of weight loss, intake before admission, use of nutrition support, chewing or swallowing issues, and skin breakdown.

The Malnutrition Universal Screening Tool (Fig. 44.3) and Nutrition Risk Screening are common tools used with adults in acute care. The MNA assesses nutrition status in older adults. In long-term care, we use the Minimum Data Set (MDS) form to obtain nutrition information. In home care settings, the Outcome and Assessment Information Set (OASIS) is used to collect information on diet, oral intake, dental health, swallowing problems, and any need for meal assistance.

If screening identifies a person at risk, perform a full nutrition assessment. A nutrition assessment is a comprehensive approach that includes medical, nutrition, and medication histories; physical assessment; anthropometric measurements; and

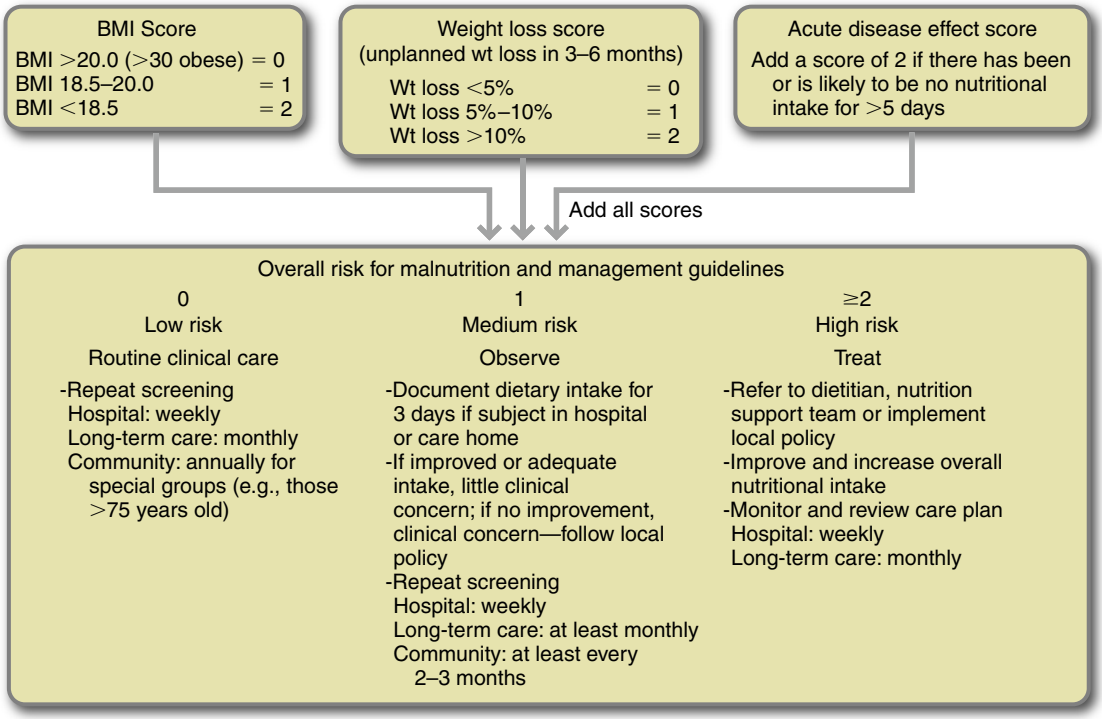

Fig. 44.3 The Malnutrition Universal Screening Tool (MUST) for adults. (Adapted from Mahan LK, Raymond JL: *Krause's food & the nutrition care process,* ed 14, St Louis, 2016, Saunders.)

TABLE 44.8 Nutrition Physical Assessment

Anthropometric Measurements
- Height and weight
- Body mass index (BMI)
- Rate of weight change
- Amount of weight loss

Physical Assessment
- Physical appearance
- Muscle mass and strength
- Dental and oral health

Laboratory Data
- Glucose
- Electrolytes
- Lipid profile
- Blood urea nitrogen (BUN)
- Albumin, prealbumin, C-reactive protein

Functional Status
- Ability to perform basic and instrumental activities of daily living
- Handgrip strength
- Performance tests (e.g., timed walk tests)

laboratory data (Table 44.8). A nutrition assessment provides the basis for nutrition intervention.

Obtain a complete diet history from the patient or caregiver. Assessing the foods eaten over the past week reveals a great deal about the patient's diet habits and knowledge of good nutrition. Often, the patient's nutrition state is not the reason for seeking medical care. However, it may be a contributing factor to the problem and have an impact on management and recovery.

◆ Anthropometric Measurements

Obtain height, weight, and girth measurements. Calculate the body mass index (BMI). We often use waist circumference and hip-to-waist ratio to assess nutrition status (see Chapter 45). Obtaining accurate measures of weight and height are critical. When possible, measure the patient's actual height rather than using the patient's self-report. Alternatives to standing height (stature) measurements include arm demi-span and knee-height measurements. The *arm demi-span* is the distance from a point on the midline at the suprasternal notch to the web between the middle and ring fingers with the arm horizontally outstretched. For persons confined to bed, using a Luft ruler is an alternative to standing height.

When assessing weight, obtain a detailed weight history, noting weight loss. Ask whether the weight loss was intentional and the period over which it took place. A loss of more than 5% of usual body weight over 6 months (whether intentional or unintentional) is a critical indicator for further assessment, especially in the older adult.[9] If an involuntary weight loss exceeds 10% of the usual weight, determine the reason. Unintentional weight loss is important to consider in the obese person. Malnutrition can be present despite excess body weight. Determine the patient's current weight in relation to ideal body weight.

Body mass index is a measure of weight for height (see Fig. 45.7). A BMI of less than 18.5 kg/m^2 is considered underweight, normal weight is a BMI between 18.5 and 24.9 kg/m^2, and overweight is a BMI between 25 and 29.9 kg/m^2. A BMI of 30 kg/m^2

or greater is obese. BMIs outside the normal weight range are associated with increased mortality.

Measure skinfold thickness at various sites (indicators of subcutaneous fat stores) and midarm muscle circumference (indicator of protein stores). The sites most reflective of body fat are those over the biceps and triceps, below the scapula, above the iliac crest, and over the upper thigh. Compare the measures obtained with standards for healthy persons of the same age and gender. Both skinfold thickness and midarm circumference may decrease in malnutrition. Shifts in hydration status influence these measurements. These measurements are most beneficial when done serially and by persons trained in anthropometry.

Functional Measurements

Functional assessment focuses on performance of activities of daily living (ADLs) tools. The tools used most often are the Katz Index and Lawton Scale. Measuring muscle strength can assess physical functional status, an important outcome of nutrition status.[9] We can measure handgrip strength with a hand dynamometer. Timed gait and chair stands are markers of lower extremity strength.

Clinical Problems

Clinical problems for the patient with malnutrition include:

- Nutritionally compromised
- Body weight problem
- Risk for impaired tissue integrity
- Inadequate community resources

Planning

The overall goals are that the patient with malnutrition will (1) achieve an appropriate weight, (2) consume a specified number of calories per day on an individualized diet, and (3) have no adverse consequences related to malnutrition or nutrition therapies.

Implementation

Health Promotion

It is part of your role to teach and reinforce healthy eating habits. Use MyPlate, the Dietary Guidelines for Americans, and Nutrition Facts food labels to promote healthy nutrition. The MyPlate approach is a visual guide for sensible meal planning. It helps Americans eat healthfully and make good food choices. MyPlate focuses on the proportions of 5 food groups (grains, protein, fruits, vegetables, and dairy) that you should eat at each meal (Fig. 44.4 and Table 44.9). At the health professionals' link at www.myplate.gov, you can download daily food plans, sample menus, and tips for how to be physically active. These materials are valuable to use in patient teaching. MyPlate materials for older adults are available at https://hnrca.tufts.edu/myplate/.

There are many resources to help people eat a nutritious diet and maintain a healthy weight. Electronic and print sources are available for determining nutrition information in commonly consumed foods. Many food products have Nutrition Facts labels (Fig. 44.5). Consumer and health professional education materials on Nutrition Facts labels are available on the US Food and Drug Administration (FDA) website (www.fda.gov/Food/LabelingNutrition/ucm20026097.htm).

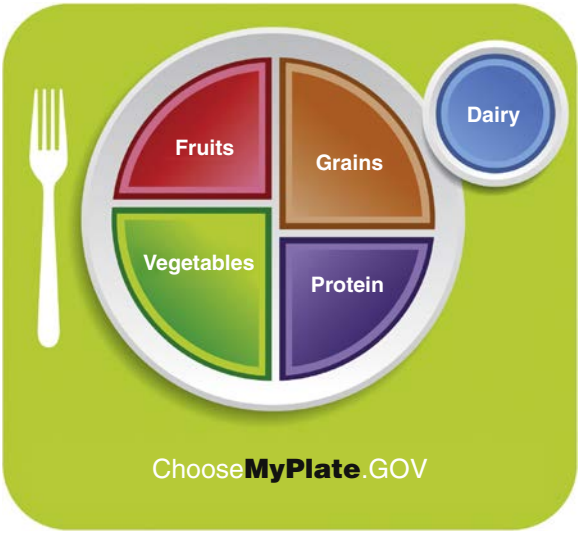

Fig. 44.4 MyPlate is the primary food group symbol that serves as a reminder to make healthy food choices and to build a healthy plate at mealtimes. It is a visual cue that shows the 5 food groups from which to select healthy foods. The plate is divided into 4 slightly different-sized quadrants. Fruits and vegetables take up half the space. Grains and protein make up the other half. The vegetables and grains portions are the largest portion. Next to the plate is a blue circle for dairy, which could be a glass of milk or food, such as cheese or yogurt. For more information, see www.myplate.gov. (From US Department of Agriculture, Center for Nutrition Policy and Promotion: *Guidance on use of USDA's MyPlate and statements about amounts of food groups contributed by foods on food product labels*, Washington, DC.)

Help the patient find reliable Internet sources that provide evidence-based food and nutrition recommendations. Interactive web-based programs and mobile device applications are available to track physical activity, calories, nutrients, and foods eaten. Mobile device applications help with making healthy eating choices easier. Some use built-in barcode scanners to scan foods quickly and give their nutrition facts. Users can compare items for their nutrition benefit and cost. Other applications give information on portion sizes and adjustments needed to reduce calories, sodium, or fat in the diet based on the user's height, weight, and activity level.

Acute Care

Collaborate with the HCP and dietitian to identify patients with malnutrition and implement appropriate interventions to meet the patient's nutrition needs. Assess nutrition during your assessment of the patient's other physical problems. Identify risk factors for malnutrition and why they exist. With increased stress, such as surgery, severe trauma, and sepsis, the patient needs more calories and protein. Wound healing requires increased protein synthesis. The patient having major surgery who is malnourished or is at risk for malnutrition needs several weeks of increased protein and calorie intake preoperatively to promote healing after surgery.

Teach the patient and caregiver the importance of good nutrition. Discuss the reason for daily weights, intake, and output. Measure weight and height on admission. Daily weights give an

TABLE 44.9 NUTRITION THERAPY

MyPlate Tips for a Healthy Lifestyle

Making food choices for a healthy lifestyle can be as simple as using these 10 tips. Use the ideas in this list to (1) balance your calories, (2) choose foods to eat more often, and (3) cut back on foods to eat less often.

1. Balance calories	• Find out how many calories you need for a day as a first step in managing your weight. Go to www.myplate.gov to find your calorie level. • Being physically active also helps you balance calories.
2. Enjoy your food, but eat less	• Take the time to enjoy your food as you eat it. • Eating too fast or when your attention is elsewhere may lead to eating too many calories. • Pay attention to hunger and fullness cues before, during, and after meals. Use them to recognize when to eat and when you have had enough.
3. Avoid oversized portions	• Use a smaller plate, bowl, and glass. • Portion out foods before you eat. • When eating out, choose a smaller size portion, share a dish, or take home part of your meal.
4. Foods to eat more often	• Eat more vegetables, fruits, whole grains, and fat-free or 1% milk and dairy products. • These foods have the nutrients you need for health, including potassium, calcium, vitamin D, and fiber. • Make them the basis for meals and snacks.
5. Make half your plate fruits and vegetables	• Choose red, orange, and dark-green vegetables such as tomatoes, sweet potatoes, and broccoli, along with other vegetables, for your meals. • Add fruit to meals as part of main or side dishes or as dessert.
6. Switch to fat-free or low-fat (1%) milk	• They have the same amount of calcium and other essential nutrients as whole milk. • They have fewer calories and less saturated fat.
7. Make half your grains whole grains	• To eat more whole grains, substitute a whole-grain product for a refined product. • For example, eat whole-wheat bread instead of white bread, or brown rice instead of white rice.
8. Foods to eat less often	• Cut back on foods high in solid fats, added sugars, and salt. • Limit cakes, cookies, ice cream, candies, sweetened drinks, pizza, and fatty meats such as ribs, sausages, bacon, and hot dogs. • Use these foods as occasional treats, not everyday foods.
9. Compare sodium in foods	• Use the Nutrition Facts label (Fig. 44.4) to choose lower sodium versions of foods, such as soup, bread, and frozen meals. • Select foods labeled "low sodium," "reduced sodium," or "no salt added."
10. Drink water instead of sugary drinks	• Cut calories by drinking water or unsweetened beverages. • Soda, energy drinks, and sports drinks are a major source of added sugar and calories in American diets.

For educational purposes only. This label does not meet the labeling requirements described in 21 CFR 101.9.

Fig. 44.5 Sample of a Nutrition Facts label. (From US Department of Health and Human Services, *Nutrition facts label,* Silver Spring, MD.)

ongoing record of body weight gain or loss. Rapid gains and losses are usually the result of shifts in fluid balance. In conjunction with accurate recording of food and fluid intake, body weight gives a clear picture of the patient's fluid and nutrition state.

If the patient can take food by mouth, obtain a daily calorie count and diet diary to give an accurate record of food intake. Help the patient and caregiver select high-calorie and high-protein foods (unless medically contraindicated). Table 44.10 gives examples of high-calorie, high-protein foods. Offering foods preferred by the patient enhances intake. You may have caregivers bring the patient's favorite foods from home.

Make sure the environment is conducive to eating. Provide a quiet environment. Offer oral hygiene and hand hygiene. Help the patient to a comfortable position and place the bedside table at the right height. Clear the bedside table of clutter. Place urinals, bedpans, and emesis basins out of sight. If needed, open cartons and packages. Protect mealtime from unnecessary interruptions by performing nonurgent care before or after mealtime.

The undernourished patient usually needs to have between-meal supplements. These may consist of items prepared in the dietary department or commercially prepared products. Eating these items provides extra calories, proteins, fluids, and nutrients. If the patient is unable to consume enough nutrition with a high-calorie, high-protein diet, consider adding oral liquid supplements.

Oral liquid supplements are widely used as an adjunct to meals and fluid intake in the patient whose intake is deficient.

TABLE 44.10 NUTRITION THERAPY

High-Calorie, High-Protein Diet

Suggestions for foods for a high calorie, high protein diet include:

Breads and Cereals
- Buttermilk biscuits, muffins, banana bread, zucchini bread
- Granola and other cereals with dried fruit
- Hot cereals (oatmeal, cream of wheat) prepared with milk, added fat (butter or margarine), and sugar
- Potatoes prepared with added fat (butter and whole milk)

Vegetables
- Fried vegetables
- Vegetables prepared with added fat (margarine, butter)

Fruits
- Canned fruit in heavy syrup
- Dried fruit

Meat
- Casseroles
- Fried meats
- Meats covered in cream sauces or gravy
- Peanut butter

Milk and Milk Products
- Ice cream
- Milkshakes
- Whipping cream, heavy cream
- Whole milk and milk products (yogurt, ice cream, cheese)
- Whole milk with added nutrition supplements

They provide advanced nutrition and calories and are inexpensive. These include milkshakes, puddings, or commercially available products (e.g., Carnation Instant Breakfast, Ensure, Boost). In long-term care, using these instead of water for oral medication administration increases caloric intake.

Some patients may benefit from appetite stimulants, such as megestrol acetate or dronabinol (Marinol), to improve intake. Enteral nutrition (EN) may be an option in the patient who is still unable to take in enough calories (Fig. 44.6). If EN is not possible, consider starting parenteral nutrition (PN).

Refeeding Syndrome

Refeeding syndrome is the body's response to the switch from starvation to a fed state in the initial phase of nutrition therapy in patients who are severely malnourished.[10] Conditions that predispose patients to refeeding syndrome include chronic alcohol use, cancer, trauma, inflammatory bowel disease, and major surgery. Hypophosphatemia is the hallmark of refeeding syndrome. Other manifestations include hyperglycemia, fluid retention, hypokalemia, and hypomagnesemia. Serious outcomes include dysrhythmias and respiratory arrest.

In the at-risk patient, we should start feeding rates at no more than 50% of their usual energy requirements and gradually increase. Monitor electrolyte values and maintain ECG monitoring. Many receive phosphate, potassium, magnesium, and B vitamin supplements.

Ambulatory Care

Many patients are discharged on a therapeutic diet. Discharge preparation for both the patient and caregiver is essential. Teach them about the cause of the undernourished state and ways to avoid the problem in the future. They need to be aware that undernourishment, whatever the cause, can recur and that adhering to their diet for a few weeks cannot fully restore a normal nutrition state. It may take many months to reach this goal.

Assess their ability to follow the diet instructions considering past eating habits, religious and ethnic preferences, age, income, resources, and state of health. Emphasize the need for continual follow-up care to achieve and maintain rehabilitation. In your discharge planning, ensure proper follow-up, such as visits by the home health nurse and outpatient dietitian referrals.

Determine the need for nutritious meals and snacks after discharge from the hospital. If access to a dietitian is limited, you may be the main source of nutrition information. In your assessment, consider the availability and acceptability of community resources that provide meals, such as Meals on Wheels, senior congregate feeding sites, and the Supplemental Nutrition Assistance Program (SNAP). SNAP allows low-income households, regardless of age, to buy more food of a greater variety.

Keeping a diet diary for 3 days at a time is one way to analyze and reinforce healthful eating patterns. These records are helpful in follow-up care. Encourage self-assessment of progress by having the patient weigh themselves once or twice a week and keep a weight record.

Evaluation

The expected outcomes are that the patient who is malnourished will:
- Achieve and maintain optimal body weight
- Consume a well-balanced diet
- Have no adverse outcomes related to malnutrition
- Maintain optimal physical functioning

Gerontologic Considerations: Malnutrition

Nutrition affects quality of life, functional status, and health in older adults. They are particularly vulnerable to malnutrition across care settings. Older hospitalized adults with malnutrition are more likely to have poor wound healing, pressure injuries, infections, decreased muscle strength, postoperative complications, and increased mortality. They are less able to regain body weight lost after illness or surgery.

You play a key role in performing a complete assessment of factors related to their nutrition risk. Older adults may report little or no appetite, problems with eating or swallowing, inadequate servings of nutrients, and fewer than 2 meals per day. Limited incomes may cause them to restrict the number of meals or the nutrient quality of meals eaten. Social isolation is a problem in older adults. Those who live alone may lose their desire to cook and report decreased appetite. Functional limitations may affect the ability to feed oneself, buy food, or cook and prepare meals. Some may lack transportation to buy food.[6]

Chronic illnesses associated with aging can affect nutrition status. For example, depression and dysphagia (from a stroke) can affect intake. Poor oral health from gum disease, missing

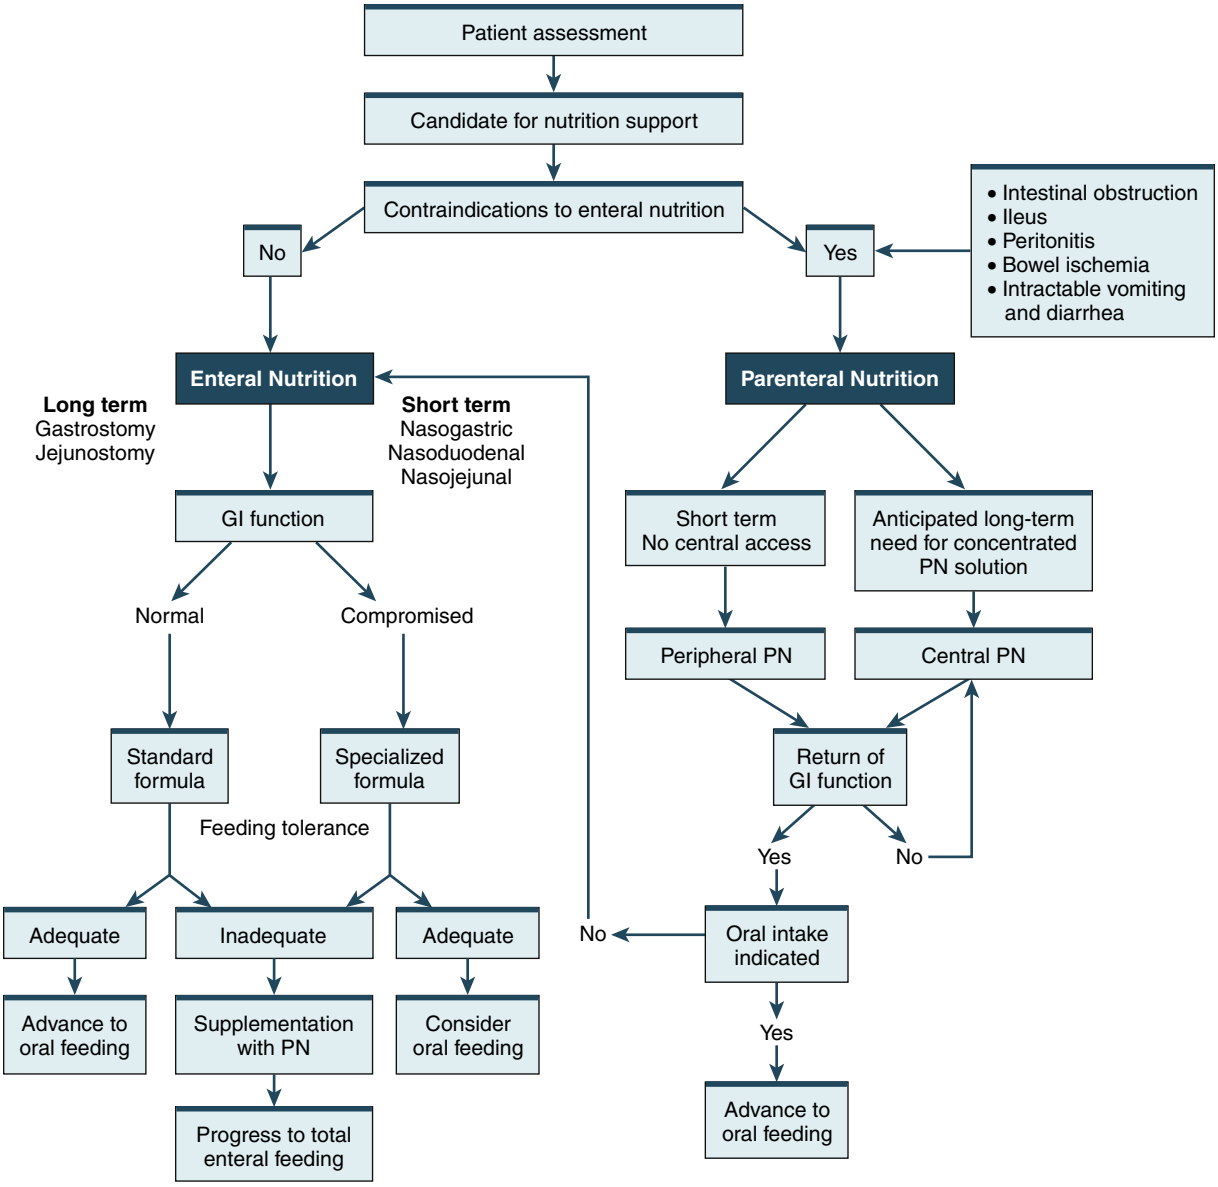

Fig. 44.6 Nutrition support algorithm. (Adapted from Ukleja A, Freeman KL, Gilbert K, ASPEN Board of Directors: Standards for nutrition support: adult hospitalized patients, *Nutr Clin Pract* 25:403, 2010.)

teeth, or dry mouth can impair the ability to chew and swallow food.[6] Medications can cause dry mouth, change the taste of food, or decrease appetite. Older adults with dementia (see Chapter 64) or a stroke (see Chapter 62) present unique challenges regarding eating and feeding.

Physiologic changes associated with aging include a decrease in lean body mass and redistribution of fat around internal organs, which can decrease caloric requirements. Sarcopenia (loss of lean body mass with aging) affects muscle strength and function. Older adults on bed rest or prolonged inactivity lose more lean body mass than younger adults. Changes in smell and taste (from medications, nutrient deficiencies, taste-bud atrophy) affect appetite.

General nutrition guidelines apply to older adults. Their requirements may vary depending on the degree of malnutrition and physiologic stress. To prevent loss of muscle mass and maintain function, older adults may need to increase their protein intake and ingest a moderate amount of high-quality protein at each meal.[11] Daily vitamin D requirements are higher for older adults (Table 44.6).[2]

Focus your initial care strategies on improving oral intake and providing a pleasant, social environment for meals. Special strategies, such as using adaptive devices and proper positioning, may be needed to help increase intake.[11] Some older adults may need nutrition support therapies until their strength and general health improve. Before starting any nutrition support therapy (e.g., EN, PN) for an older patient unable to give consent, review their advance directives about artificial nutrition and hydration.

Malnourished or nutritionally at-risk older adults are vulnerable when discharged from the hospital to the home. They may not be able to shop for or prepare foods during their initial recovery period. Consult with the social worker and dietitian to ensure there is access to food on discharge. Home-delivered

meals or groceries or senior congregate feeding programs are an appropriate referral. Community nutrition programs can make mealtime a pleasant, social event. Improving the social setting of a meal often improves intake.

SPECIALIZED NUTRITION SUPPORT

If patients are unable to maintain or achieve adequate nutrition status, nutrition support may be needed. Fig. 44.6 shows a decision-making tree for nutrition support.

Some agencies have nutrition support teams. The team's function is to manage the nutrition support of select patients. The nutrition support nurse on that team is a key resource for issues about patients' nutrition and nutrition access. Other team members often include the HCP, dietitian, and pharmacist.

Enteral Nutrition

Enteral nutrition (EN), also known as **tube feeding**, is nutrition (e.g., a nutritionally balanced liquefied food or formula) delivered through a tube, catheter, or stoma directly into the GI tract. EN is used with the patient who has a functioning GI tract but is unable to take any or enough oral nourishment or when it is unsafe to do so.

Indications for EN include persons with anorexia, orofacial fractures, head and neck cancer, neurologic or psychiatric conditions that prevent oral intake, extensive burns, or critical illness (especially if mechanical ventilation is needed), and those receiving chemotherapy or radiation therapy. Contraindications for EN include GI obstruction, prolonged ileus, severe diarrhea or vomiting, and enterocutaneous fistula. EN is easily administered, safer, more physiologically efficient, and less expensive than PN.

There is a wide variety of EN formulas. Their concentration, flavor, osmolality, and amounts of protein, sodium, and fat vary. There are special formulas for patients with diabetes and liver, kidney, or lung disease. Most are lactose free. Concentrations range from 1 to 2 cal/mL. Most standard formulas provide between 1 and 1.5 cal/mL. The more calorically dense the formula, the less water it has. The number and size of particles in the formula determine its osmolality. The more hydrolyzed or broken down the nutrients, the greater the osmolality.

A formula with a high sodium content is contraindicated in the patient with cardiovascular problems, such as heart failure. Those with short bowel syndrome or ileocecal resection should not receive one with a high fat content because of impaired fat absorption.

Common delivery options are continuous infusion or intermittent (bolus) feedings by infusion pump, bolus feedings by gravity, and bolus feedings by syringe. Critically ill patients often receive EN by continuous infusion. Bolus feeding may be an option if the patient improves or is receiving EN at home.

The type of EN access depends on the (1) anticipated length of time EN will be needed, (2) risk for aspiration, (3) patient's clinical status, (4) adequacy of digestion and absorption, and (5) patient's anatomy (e.g., extreme obesity). Fig. 44.7 shows the locations of commonly used enteral feeding tubes.

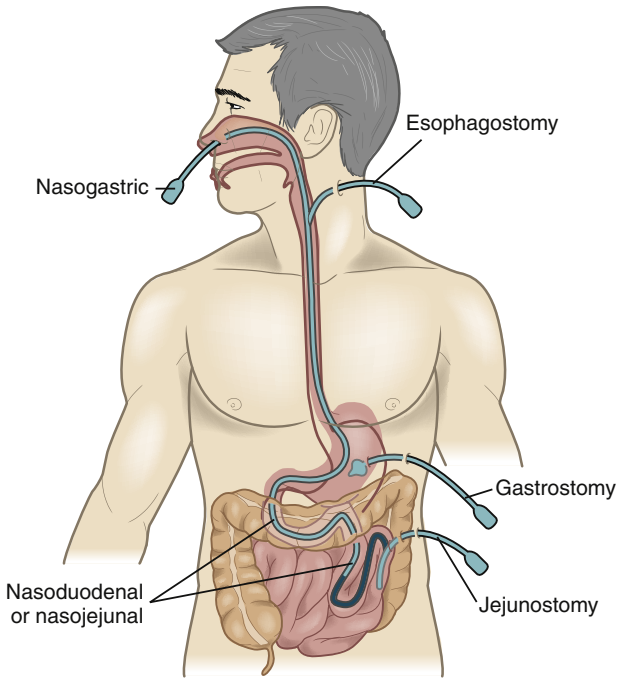

Fig. 44.7 Common enteral feeding tube placement locations.

Orogastric, Nasogastric, and Nasointestinal Tubes

Nasally and orally placed tubes (orogastric, nasogastric [NG], nasoduodenal, nasojejunal) are appropriate for short-term feeding (less than 4 weeks). Nasoduodenal and nasojejunal tubes are transpyloric tubes. They are used when pathophysiologic conditions call for feeding the patient below the pyloric sphincter. Placement into the small intestine decreases the chance of regurgitating gastric contents into the esophagus and aspiration. However, the patient can still aspirate gastric secretions if the stomach is not emptying properly.

Polyurethane or silicone feeding tubes are long, small in diameter, soft, and flexible. This design decreases the risk for mucosal damage from prolonged placement. These tubes are radiopaque, making their position readily identified by x-ray. A stylet is used for tube placement in a comatose patient because the ability to swallow is not essential during insertion. A complication that can result from using a stylet is perforation.

While smaller feeding tubes have many advantages over tubes with wider lumens, such as the standard NG tube, there are some disadvantages. Because of the small diameter and length, these tubes clog easily. They are harder to use for checking residual volume (RV). They are particularly prone to occlusion if you do not thoroughly crush and dissolve oral drugs before administration. Failure to flush the tubing before and after giving drugs or checking RV can cause tube occlusion. Vomiting or coughing can dislodge the tube. They can become knotted or kinked. Problems with a tube may require removal and insertion of a new tube, adding to cost and patient discomfort.

Gastrostomy and Jejunostomy Tubes

If feedings are needed for an extended time, tubes can be placed in the stomach (gastrostomy) or small bowel (jejunostomy). A gastrostomy tube can be placed surgically, radiologically,

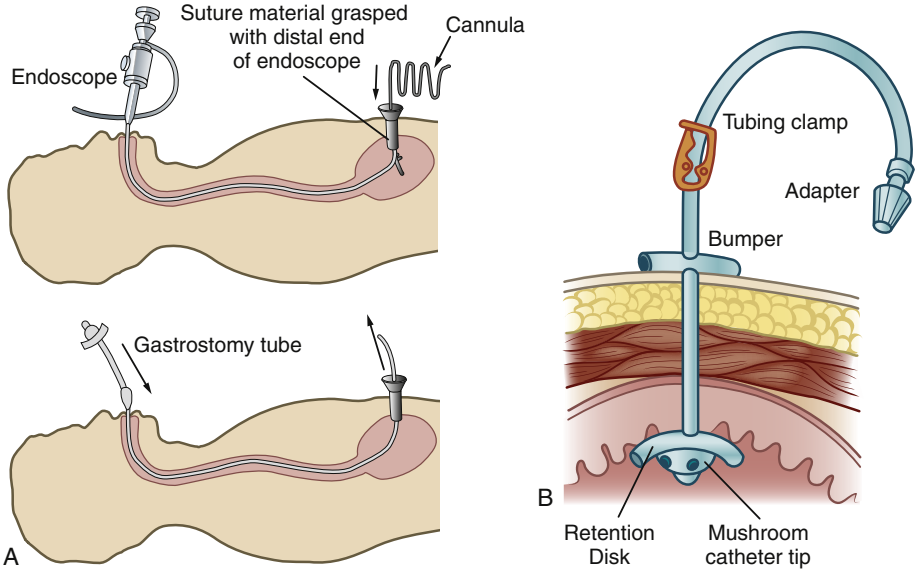

Fig. 44.8 Percutaneous endoscopic gastrostomy. (A) Gastrostomy tube placement via percutaneous endoscopy. With use of endoscopy, a gastrostomy tube is inserted through the esophagus into the stomach and then pulled through a stab wound made in the abdominal wall. (B) A retention disk and bumper secure the tube.

or endoscopically (Fig. 44.7). The patient must have an intact, unobstructed GI tract. The esophageal lumen must be wide enough to pass the endoscope for percutaneous endoscopic gastrostomy (PEG) tube placement (Fig. 44.8). PEG tube and radiologically placed gastrostomy tube procedures have fewer risks than surgical placement. The procedure requires IV sedation and local anesthesia. IV antibiotics are given before the procedure.

For the patient with chronic reflux, feeding through a jejunostomy (J-tube) may be necessary to reduce the risk for aspiration. Jejunostomy tubes are placed either endoscopically or with open or laparoscopic surgery. Combination gastrojejunostomy (G-J) tubes allow for simultaneous gastric decompression and small bowel feeding. When a patient has a G-J tube, it is important to know which port is the gastric and which is the jejunal.

The tube is either premarked or marked at the skin insertion site. Feedings can start within 24 hours after a surgically placed gastrostomy or jejunostomy tube without waiting for flatus or a bowel movement. Most other PEG tube feedings can start within 4 hours of insertion, although agency policies may vary.

EN and Safety

You have a critical role in ensuring that EN is administered safely. Aspiration and dislodged tubes are important safety concerns. Nursing management of EN is addressed in Table 44.11.

Accidental tube removal can result in delayed feedings and potential discomfort with tube replacement. The management of common problems in patients receiving EN is outlined in Table 44.12. A nursing care plan for the patient receiving EN (eNursing Care Plan 44.1) is available on the website for this chapter.

Specific care and teaching related to feeding tubes and EN are discussed in the following section. Remember it is important to teach the patient and caregiver how to care for the feeding tube and properly administer EN.

Tube position. Obtain x-ray confirmation of newly inserted nasal or orogastric tubes to confirm proper position before starting feedings or medications.[12] Smaller feeding tubes can pass directly into the bronchus on insertion without any obvious respiratory manifestations. Do not use the auscultation method to determine tube placement. Placing a tube under electromagnetic guidance reduces the risk for misplacement during blind insertion. Capnography, a direct monitor of breath-to-breath CO_2 level, can help determine tube placement in the respiratory tract.[12]

Maintain proper placement of the tube after starting feedings. To determine if a tube is still in the proper position, mark the exit site of the tube at the time of the initial x-ray and check the tube external length at regular intervals.[13] Consider applying a nasal bridle in patients who try to pull out a tube or for whom taping the nose is difficult.

A small bowel tube may dislocate upward into the stomach, or the tube's tip can dislocate upward into the esophagus. If you see a significant increase in the external length, use other bedside tests to help determine whether the tube has become dislocated. These measures include assessing aspirate color and pH. Because each measure has limitations, confirm placement with more than one test. If you are checking VR, watch for unexpected changes in volume. An increase in VR may indicate displacement of a small intestine tube into the stomach.

Aspiration risk. Evaluate all enterally fed patients for risk for aspiration. Before starting feedings, ensure the tube is in the right position. Proper patient positioning decreases the risk for aspiration. To prevent aspiration, always keep the head of the bed elevated 30 to 45 degrees. If the patient does not tolerate a backrest elevation, use a reverse Trendelenburg position to elevate the head of the bed, unless contraindicated. If you need

TABLE 44.11 NURSING MANAGEMENT

EN

Maintaining EN Infusions

- Check tube placement before feeding and before each medication administration.
- Assess for bowel sounds before feeding.
- Flush NG or gastrostomy tube as needed.
- Evaluate nutrition status of patient receiving enteral feedings.

Ensuring Patient Safety

- Give medications in the safest form possible.
  - Dilute viscous liquid medications.
  - Use liquid medications only if they are designated safe for enteral use.
  - Do not add medications to enteral feeding formula.
  - If using tablets, only use immediate-release forms.
  - Crush drugs to a fine powder and dissolve in 30–60 mL of purified water.
- Employ measures to decrease aspiration risk.
- Keep head of bed elevated to 30- to 45-degree angle.
- Check for RV per agency policy.
- Assess regularly for complications related to tubes and enteral feedings (e.g., aspiration, diarrhea, abdominal distention, hyperglycemia, fecal impaction).
- Teach patient and caregiver about home EN and tube care.

Delegate to Licensed Practical/Vocational Nurse (LPN/VN)

- Insert NG tube for stable patient.
- Flush NG and gastrostomy tubes.
- Give bolus or continuous enteral feeding for stable patient.
- Remove NG tube.
- Give medications through NG or gastrostomy tube to stable patient.
- Provide skin care around gastrostomy or jejunostomy tubes.

Supervise Assistive Personnel (AP)

- Provide oral care to patient with NG, gastrostomy, or jejunostomy tube.
- Weigh patient who is receiving EN.
- Keep the head of bed elevated 30–45 degrees.
- Report patient symptoms (e.g., nausea, diarrhea) that may indicate problems with EN to RN or LPN.
- Alert RN or LPN about infusion pump alarms.
- Empty drainage devices and measure output.

Collaborate With Dietitian

- Evaluate nutrition status of patient receiving EN.
- Select appropriate EN formula.
- Monitor for and manage complications related to EN.
- Teach patient and caregiver about home EN.

Collaborate With Pharmacist

- Select appropriate form of each medication being given enterally.
- Determine if medication must be given separately.

TABLE 44.12 NURSING MANAGEMENT

EN Problems

Problems and Causes	Management
Constipation	
Decreased fluid intake	• Increase fluid intake if not contraindicated. • Give total fluid intake of 30 mL/kg body weight.
Formula	• Change formula to one with more fiber content. • Give as-needed laxative.
Inactivity	• Encourage ambulation unless contraindicated. • Collaborate with physical therapy to promote activity.
Dehydration	
Diarrhea, vomiting	• Decrease rate or change formula. • Check drugs that patient is receiving, especially antibiotics. • Avoid bacterial contamination of formula and equipment.
Fluid intake	• Increase intake and check amount and number of feedings. • Administer supplemental tube, oral, or IV fluid intake if appropriate.
High-protein formula	• Change formula to one with less protein.
Hyperosmotic diuresis	• Check blood glucose levels often. • Change formula to one with less glucose.
Diarrhea	
Contaminated formula	• Refrigerate unused formula and record date opened. • Discard outdated formula. • Discard formula left standing for longer than manufacturer's guidelines. • 8 hr for ready-to-feed formulas (cans). • 4 hr for reconstituted formula. • 24 hr for closed-system enteral formulas. • Use a closed system.
Feeding too fast	• Dilute or decrease rate of feeding. • Change to continuous feedings. • Stop excess water boluses.
Formula	• Change to a formula that has more fiber or is less hypertonic. • Change to continuous feedings.
Infection	• Obtain stool culture for fecal leukocyte determination, *C. difficile,* and/or toxin assay.
Medications	• Check for drugs that may cause diarrhea (e.g., sorbitol in liquid medications, antibiotics).
Tube moving distally	• Properly secure tube before beginning feeding. • Check placement before each bolus feeding or at least every 4 hr if continuous feedings.
Vomiting	
Delayed gastric emptying	• Consult with HCP about a prokinetic drug. • Follow agency policy to manage RV.
Improper tube placement	• Replace tube in proper position. • Check tube position before each bolus feeding and every 4 hr if continuous feedings.

to lower the head of the bed for a procedure, quickly returning the patient to at least 30 degrees is critical. Follow agency policy for stopping feeding while the patient is supine. With bolus feedings, keep the head elevated for 30 to 60 minutes after feeding.

There is much disagreement about whether to check RV when giving feedings into the stomach. Some think an increased RV increases the risk for aspiration. Other research does not support the practice. Follow your agency policy for checking RV. Common protocols call for checking RV every 6 to 8 hours in non-critically ill patients and before each bolus feeding.

Other measures to decrease aspiration risk include giving feedings continuously, minimizing the use of sedation, and performing frequent oral suctioning, if needed. Promotility drugs, such as erythromycin or metoclopramide, improve gastric emptying and may reduce aspiration risk.

Site care. Skin care around gastrostomy and jejunostomy tube sites is important because the action of digestive juices irritates the skin. Assess the skin around the feeding tube daily for signs of redness and maceration. Monitor bumper tension and routinely check for pressure injury.

To keep the skin clean and dry, initially rinse it with sterile water and dry it. Apply a dressing until the site is healed. After that, wash with mild soap and water. A protective ointment (zinc oxide, petroleum gauze) or a skin barrier (Karaya, Stomahesive) may be used on the skin around the tube. If the skin is irritated, consider using other types of drain or tube pouches. Consult a wound, ostomy, and continence nurse (WOCN) if problems occur.

Tube patency. All enteral feedings require routine flushing. Flush feeding tubes in adults with 30 mL of warm tap water every 4 hours during continuous feedings or before and after each bolus feeding. Use sterile water in immunocompromised and critically ill patients. Always flush tubes between each medication and after all medications are given. Flush clogged tubes with warm water, using a back-and-forth motion. If that does not work, a pancreatic enzyme solution, an enzymatic declogging kit, or mechanical devices for clearing feeding tubes are options.[13]

Misconnection. An *enteral feeding misconnection* is an inadvertent connection between an enteral feeding system and a nonenteral system, such as an IV line, a peritoneal dialysis catheter, or a tracheostomy tube cuff. With an enteral feeding misconnection, EN formula intended for the GI tract is given IV or into the respiratory tract. Severe patient injury and death can result from tubing misconnection. Table 44.13 gives tips to decrease the risk for enteral feeding misconnections.

TABLE 44.13 NURSING MANAGEMENT

Decreasing Enteral Feeding Misconnections

The following are tips to help you decrease your risk for making an enteral feeding misconnection:

1. Teach visitors, LPN/VNs, and AP to notify the nurse if an enteral feeding line becomes disconnected and not to reconnect any line.
2. Do not change or adapt IV or feeding devices because it may compromise the safety features that are part of the design.
3. Do not use an IV pump or IV tubing to deliver an enteral feeding.
4. When making a reconnection or connecting any new device or infusion, trace lines back to their origins and ensure connections are secure.
5. When patient arrives on a new unit or setting or during shift handoff, recheck connections and trace all tubes.
6. Route tubes and catheters that have different purposes in unique and standardized directions (e.g., route IV lines toward the patient's head and enteral lines toward the feet).
7. Label or color-code feeding tubes and connectors.
8. When there are multiple access points and/or several bags hanging, place proximal and distal labels on all tubings.
9. Check the patient's vital signs after making any connection.
10. Identify and confirm a solution's label, since a 3-in-1 PN solution can look like an enteral nutrition formulation bag. Label the bags with large, bold statements such as "WARNING! For Enteral Use Only—NOT for IV Use."
11. Make all connections under proper lighting conditions.

Gerontologic Considerations: Enteral Nutrition

EN can improve nutrition status in the older patient. Because of physiologic changes, the older adult is more vulnerable to complications from EN, especially fluid and electrolyte imbalances. Complications such as diarrhea can leave the patient dehydrated. Decreased thirst perception or impaired cognitive function decreases the patient's ability to seek needed fluids.

With aging, there is an increased risk for glucose intolerance. As a result, the older patient may be more susceptible to hyperglycemia from the high carbohydrate load of some EN formulas. The older adult with compromised cardiovascular function (e.g., heart failure) will have a decreased ability to handle large volumes of formula. If this happens, the patient may need a more concentrated formula (2.0 cal/mL). The older adult has an increased risk for aspiration caused by gastroesophageal reflux disease (GERD), delayed gastric emptying, hiatal hernia, or decreased gag reflex. Physical mobility, fine motor movement, and visual changes may contribute to problems managing EN in the home setting.

TABLE 44.14 Common Indications for PN

- Chronic severe diarrhea and vomiting
- Complicated surgery or trauma
- GI obstruction
- GI tract anomalies and fistulae
- Intractable diarrhea
- Severe anorexia nervosa
- Severe malabsorption
- Short bowel syndrome

Parenteral Nutrition

Parenteral nutrition (PN) is the administration of nutrients directly into the bloodstream. PN is used when the GI tract cannot be used for the ingestion, digestion, and absorption of essential nutrients. Table 44.14 lists common reasons for PN.

Composition

PN is customized to meet the needs of each patient. The composition is reformulated as the patient's condition changes. This requires you to collaborate with the health care team in delivering PN to the patient.

Different commercially prepared PN base solutions are available. Some contain dextrose and protein in the form of amino acids. A 3-in-1 or total nutrient admixture containing an IV fat emulsion, dextrose, and amino acids is widely used.[14] Standard electrolytes (sodium, potassium, chloride, calcium, magnesium, phosphate) are available in some premixed solutions or added by pharmacy. The pharmacy also adds prescribed vitamins and trace elements (zinc, copper, chromium, selenium, manganese) to meet the patient's needs.

Calories

Calories in PN mainly come from carbohydrates in the form of dextrose and fat in the form of fat emulsion. Dextrose 100 to 150 g/day (1 g provides about 3.4 calories, as opposed to oral carbohydrates, which provide 4 calories) has a protein-sparing effect. Providing adequate nonprotein calories in the form of glucose and fat allows the use of amino acids for wound healing and not for energy. However, overfeeding can lead to metabolic complications. To minimize these problems, the recommended energy intake is 20 to 30 cal/kg/day in a nonobese patient.[15]

Fat-emulsion solutions of 10%, 20%, and 30% are available. Fat emulsions supply about 1 cal/mL (10% solution) or 2 cal/mL (20% solution). Fat emulsions primarily contain soybean or safflower triglycerides with egg phospholipids added as an emulsifier.[16] They supply a large number of calories in a small amount of fluid. This is beneficial when the patient is at risk for fluid overload.

IV fat emulsions should provide up to 20% to 30% of total calories of PN.[15,16] Most stable patients receive 1 g/kg/day. Critically ill patients may not tolerate this dose and may receive less than 1 g/kg/day. Serum triglyceride levels are done at the beginning of PN and then closely monitored. Give IV fat emulsions administered separately over a minimum of 12 hours. The initial infusion rate should not exceed 0.5 mL/kg/hr. If no reactions occur, the rate can increase to 1 mL/hr.

Fat emulsions are contraindicated in the patient with a problem with fat metabolism, such as hyperlipidemia. They are used cautiously in the patient at risk for fat embolism (e.g., fractured femur) and the patient with an allergy to eggs or soybeans.

Protein

Protein is provided at the rate of 0.8 to 1.5 g/kg/day depending on the patient's needs. Protein requirements can exceed 150 g/day (2 g/kg/day) to ensure a positive nitrogen balance in septic, critically ill, burn, or multiple trauma patients.[14] Protein needs may be lower than 1 g/kg in those with acute kidney injury or end-stage renal disease who are not on dialysis.

Electrolytes

The exact amount of electrolytes needed depends on the patient's health problem and on serum electrolyte levels. Assess individual requirements daily at the beginning of therapy and then several times a week as the treatment progresses. The following are ranges for average daily electrolyte requirements for adult patients without renal or liver impairment:

- Sodium: 1 to 2 mEq/kg
- Potassium: 1 to 2 mEq/kg
- Magnesium: 8 to 20 mEq
- Calcium: 10 to 15 mEq
- Phosphate: 20 to 40 mmol

Trace Elements and Vitamins

Zinc, copper, manganese, selenium, and chromium are added according to the patient's condition and needs. Monitor levels of these elements. The daily addition of a multivitamin preparation to the PN generally meets the vitamin requirements. The HCP may order additional amounts.

Methods of Administration

PN is given as central PN or peripheral parenteral nutrition (PPN). Central PN and PPN differ in nutrient content and tonicity, which is measured in milliosmoles (mOsm; the concentration of particles in a fluid).

Central parenteral nutrition. *Central PN* is indicated when long-term support is needed or when the patient has high protein and caloric requirements. We give central PN through a central venous catheter or a peripherally inserted central catheter (PICC) whose tip lies in the superior vena cava (see Chapter 17). Central PN solutions are hypertonic, measuring at least 1600 mOsm/L. The high glucose content ranges from 20% to 50%. Central PN must be infused in a large central vein so that rapid dilution can occur. The use of a peripheral vein for hypertonic, central PN solutions would cause irritation and thrombophlebitis.

Peripheral parenteral nutrition. PPN is given through a peripherally inserted catheter or vascular access device into a large vein. PPN is used when (1) nutrition support is needed for only a short time, (2) protein and caloric requirements are not high, (3) the risk for a central catheter is too great, or (4) to supplement inadequate oral intake.

Compared with central PN, PPN has fewer nutrients. While this makes PPN less hypertonic, it still has an osmolality of up to 800 mOsm/L. This increases the risk for phlebitis. Another potential complication is fluid overload. PPN requires large volumes of fluid, which many patients cannot tolerate.

❖ NURSING MANAGEMENT: PARENTERAL NUTRITION

Nursing management of patients receiving PN is outlined in Table 44.15 and eNursing Care Plan 44.2, available on the website for this chapter. Complications from PN are related to either the catheter or the PN infusion itself (Table 44.16).

◆ Home Nutrition Support

Home PN or EN is an accepted mode of nutrition therapy for patients who are at risk for or are malnourished and need continued nutrition support. Some patients receive home therapy for many months, even years. It is important to teach the patient and caregiver about catheter or tube care, proper technique in mixing and handling of the solutions and tubing, and side effects and complications.

Home nutrition therapies are expensive. Specific criteria must be met for expenses to be reimbursed. The discharge planning team must be involved early to help plan for such issues. Home nutrition support may be a burden for the patient and caregivers and affect the quality of life. Tell the family about support groups, such as the Oley Foundation *(*www.oley.org*)*, that provide peer support and advocacy.

EATING DISORDERS

Eating disorders are psychiatric conditions associated with physiologic alterations and risk for death. The manifestations of eating disorders vary across gender, age, socioeconomic status, and race and ethnicity. Patients with eating disorders may be

TABLE 44.15 NURSING MANAGEMENT

PN Infusions

Preparation of PN Solutions

- All PN solutions must be prepared by a pharmacist or trained technician using strict aseptic techniques under a laminar flow hood.
- Add nothing to PN solutions after they are prepared in the pharmacy.
- Limit number of people involved in preparing and administering PN to reduce risk for infection.
- PN solutions are ordered daily to adjust to the patient's current needs.
- PN solution label shows the nutrient content, all additives, time mixed, and expiration date and time.
- Solutions must be refrigerated until 30 min before use and are good for 24 hr at room temperature.

Maintaining PN Infusions

- Follow proper aseptic techniques to reduce infection risk.
- Use a 0.22-micron filter with parenteral solutions not containing fat emulsion and a 1.2-micron filter with solutions containing fat emulsion.
- Change filters and IV tubing with each new PN container or every 24 hr.
- Label tubing and filter with date and time they are put into use.
- If a multilumen catheter is present, use a dedicated line for PN.
- Do not draw blood from a line dedicated for PN unless absolutely necessary.
- Control the infusion rate. Give PN using an infusion pump.
- Set an alarm to alert for tubing obstruction.
- Periodically check the volume infused because pump malfunctions can change the rate.

Ensuring Patient Safety

- Before starting PN, check label and ingredients in solution to make sure they match what the HCP ordered.
- A second RN should verify infusion pump settings before beginning PN.
- Trace the administration tubing to the point of origin in the body at the start of the infusion and at all handoffs.
- Check the solution for leaks, color changes, particulate matter, clarity, and fat emulsions separating. If present, promptly return it to the pharmacy for replacement.
- Discontinue a PN solution and replace it with a new solution if bag is not empty at the end of 24 hr. At room temperature, the solution (especially when containing fat emulsion) is a good medium for microorganism growth.
- If fat emulsions are infused separately from the PN solution, the preferred delivery method is a continuous low volume delivered over 12 hr.

Hyperglycemia

- Check glucose levels at bedside q4–6hr.
- Maintain a glucose range of 140–180 mg/dL. Give sliding scale doses of insulin to keep the glucose level in the normal range.

Hypoglycemia

- If a PN formula bag should empty before the next solution is available, a 10% or 20% dextrose solution (based on the amount of dextrose in the central PN solution) or 5% dextrose solution (based on the amount of dextrose in the peripheral PN solution) can be given to prevent hypoglycemia.

Catheter-Related Infections

- Carefully assess the catheter site for signs of inflammation and infection. Phlebitis can readily occur because of the hypertonic infusion. Catheter-related infection and septicemia can occur:
  - Local manifestations: redness, tenderness, and exudate at the catheter insertion site
  - Systemic manifestations: fever, chills, nausea, vomiting, and malaise
- Immunosuppressed patients are at high risk for infection. Note subtle signs in patients receiving chemotherapy, corticosteroids, or antibiotics, which can mask signs of infection.
- To reduce the risk for infection, catheters with antibiotic or antiseptic surfaces may be used.
- Follow agency policy for changing catheter dressings and other central line infection prevention measures (see Chapter 17).
- If you suspect an infection during a dressing change, send a culture specimen of the site and drainage and notify the HCP at once.
- If a catheter-related infection is suspected, blood cultures are drawn. A chest x-ray is taken to detect changes in pulmonary status.

Transitioning to Oral Nutrition

- Encourage oral nourishment and keep a careful record of intake. A general rule is that 60% of caloric needs should be met orally or through EN before discontinuing PN.
- Begin with clear liquids and advance as tolerated to a soft diet.

Assessing Effectiveness

- Monitor initial vital signs q4–8hr.
- Weigh patient daily as a measure of the patient's hydration status.
- Maintain accurate intake and output record.
- Determine the cause of any weight changes (e.g., fluid gained from edema, actual increase or decrease in tissue weight).
- Assess blood levels of glucose, electrolytes, and urea nitrogen.
- CBC and hepatic enzyme studies are obtained a minimum of 3 times per week until stable and then weekly as the patient's condition warrants.

hospitalized for fluid and electrolyte problems; dysrhythmias; and nutrition, endocrine, and metabolic problems. Menstrual problems may occur in women of childbearing age. Many of the nutrition problems associated with these disorders require you to implement a nutrition plan of care.

The 3 most common types of eating disorders are anorexia nervosa, bulimia nervosa, and binge-eating disorder. *Binge-eating disorder* is less severe than bulimia nervosa and anorexia nervosa. Those with binge-eating disorder do not have a distorted body image. They are often overweight or obese. Risk factors for eating disorders involve a range of biologic, psychologic, and sociocultural issues. Some persons report a history of anxiety, perfectionism, and social problems, such as bullying or a limited social network.[17]

Eating disorders also occur in some who are health conscious. For example, men with *bigorexia* or muscle dysmorphia (an extreme concern with becoming more muscular) may use steroids or other drugs to increase muscle mass. They may also use supplements and protein shakes to increase their body weight and mass.

The *female athlete triad* is a syndrome in which eating disorders, amenorrhea, and osteoporosis are present. The triad occurs in females taking part in sports that emphasize leanness and low body weight.

TABLE 44.16 Complications of PN

Catheter-Related Problems
- Air embolus
- Catheter-related sepsis
- Dislodgment
- Hemorrhage
- Occlusion
- Phlebitis
- Pneumothorax, hemothorax, and hydrothorax
- Thrombosis of vein

Metabolic Problems
- Altered renal function
- Essential fatty acid deficiency
- Hyperglycemia, hypoglycemia
- Hyperlipidemia
- Liver dysfunction
- Refeeding syndrome

Education and emotional support for the patient and family are vital. Support groups, such as the National Association of Anorexia Nervosa and Associated Disorders (ANAD) (www.anad.org), are helpful to those affected by these disorders.

ANOREXIA NERVOSA

Anorexia nervosa (AN) is characterized by restricting energy intake, difficulty maintaining an appropriate weight, an intense fear of gaining weight or being fat, and distorted body image.[18] AN most often occurs between the ages of 13 and 19. Up to 90% are female. Those with AN generally restrict the number of calories and the types of food they eat. Some exercise compulsively, purge via vomiting and laxatives, and/or binge eat. There may be an unwillingness to maintain a healthy weight, refusal to eat, continuous dieting, detailed food rituals, and avoiding social situations. They often go to great lengths to conceal their eating habits.

Common assessment findings include signs of malnutrition, significant weight loss or low BMI (under 17), hypothermia, and muscle weakness (Fig. 44.9). Diagnostic studies often show osteopenia or osteoporosis, iron-deficiency anemia, a high blood urea nitrogen level from marked intravascular volume depletion, and abnormal renal function. A lack of potassium intake and urinary potassium loss leads to decreased potassium. Manifestations of decreased potassium include muscle weakness, dysrhythmias, and renal failure. Leukopenia; hypoglycemia; and decreased sodium, magnesium, and phosphorus may be present.

Many patients with AN are anxious about treatment due to their fear of gaining weight. Therefore, building rapport with the patient is essential.[18] Treatment involves a combination of nutrition support and psychiatric care. Nutrition care focuses on reaching and maintaining a healthy weight and having normal eating patterns. A specialist closely supervises nutrition repletion to ensure consistent and ongoing weight gains. The patient may be hospitalized if there are complications

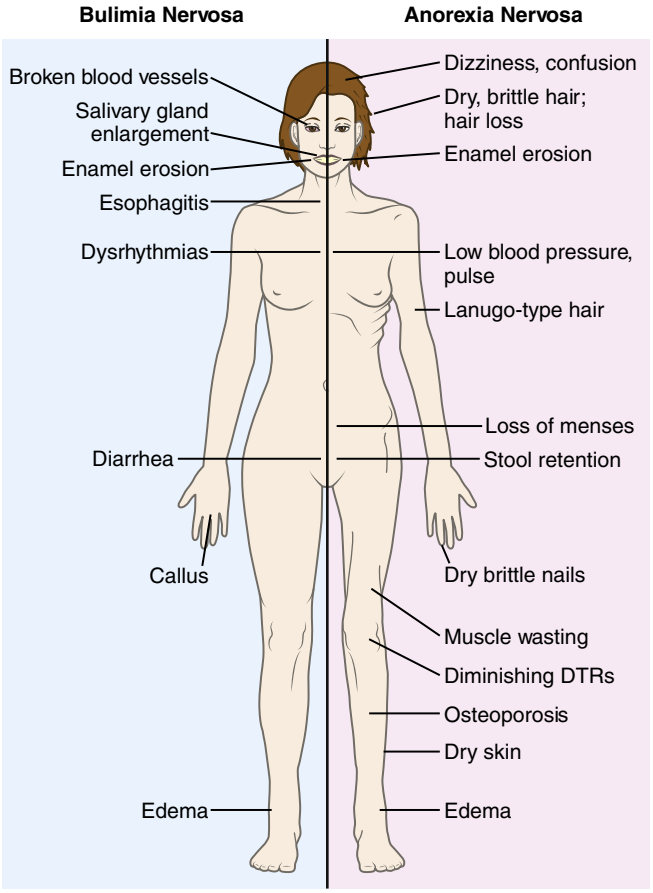

Fig. 44.9 Manifestations of anorexia nervosa and bulimia nervosa. (Modified from Mahan LK, Raymond JL: *Krause's food & the nutrition care process,* ed 14, St Louis, 2016, Saunders.)

that cannot be managed in an outpatient therapy program. Refeeding syndrome is a rare but serious complication of refeeding programs. The patient may need EN or PN. Family-based therapy is recommended in addition to behavior- and emotion-focused therapy.

BULIMIA NERVOSA

Bulimia nervosa (BN) is characterized by recurrent episodes of binge eating. To prevent weight gain, the person then engages in inappropriate compensatory behaviors (vomiting, laxative or diuretic misuse, overexercise). Like those with AN, the person with BN is concerned with body image. They may have normal weight for height, or their weight may fluctuate with bingeing and purging. There may have signs of frequent vomiting, such as macerated knuckles, swollen salivary glands, broken blood vessels in the eyes, and dental problems (Fig. 44.9). Abnormal laboratory values, including hypokalemia, metabolic alkalosis, and increased serum amylase, may occur from frequent vomiting.

Over time, problems associated with BN become increasingly hard to deal with effectively. A treatment combination of psychologic counseling (cognitive behavioral and family therapy) and nutrition counseling is essential. Fluoxetine (Prozac) is the only FDA-approved antidepressant for treating BN.

Case Study

Undernutrition

(© iStockphoto/Thinkstock.)

Patient Profile

M.S. is a 70-year-old woman who was recently admitted with malnutrition.

Subjective Data

- Reports 30-lb weight loss in past 2 months
- Recently had a thrombotic stroke with hemiparesis and dysphagia
- Has a history of rheumatoid arthritis
- Has had nothing by mouth for the past 24 hr and just started EN via PEG tube
- Lives with her daughter, who is at her bedside

Objective Data

Physical Assessment

- Has left-sided weakness
- BP is 150/90 mm Hg
- 5 ft, 4 in tall, weight 100 lb
- PEG tube recently placed

Laboratory Results

- Serum albumin 2.9 g/dL
- Prealbumin 11.0 mg/dL
- C-reactive protein 0.9 mg/L

Discussion Questions

1. ***Recognize***: What are M.S.'s risk factors for malnutrition?
2. ***Recognize:*** Calculate and interpret her BMI.
3. ***Analyze***: Which complications of EN is M.S. at risk for?
4. ***Plan:*** What should we include in a nutrition program for M.S.?
5. ***Prioritize:*** What is the nursing care priority for M.S.?
6. ***Prioritize:*** Based on the assessment data presented, what are the priority clinical problems?
7. ***Act:*** Which interventions can you delegate to assistive personnel (AP)?
8. ***Act:*** To ensure M.S.'s safety, what nursing interventions are needed considering M.S.'s recent weight loss?
9. ***Evaluate:*** What assessment data would you need to collect to decide if care was effective?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The percentage of daily calories for a healthy person consists of
   - **a.** 50% carbohydrates, 25% protein, 25% fat, and <10% of fat from saturated fatty acids.
   - **b.** 65% carbohydrates, 25% protein, 25% fat, and >10% of fat from saturated fatty acids.
   - **c.** 50% carbohydrates, 40% protein, 10% fat, and <10% of fat from saturated fatty acids.
   - **d.** 40% carbohydrates, 30% protein, 30% fat, and >10% of fat from saturated fatty acids.
2. Place in order the substrates the body uses for energy during starvation, beginning with 1 for the first component and ending with 4 for the last component.
   - **a.** Skeletal protein
   - **b.** Glycogen
   - **c.** Visceral protein
   - **d.** Fat stores
3. A complete nutrition assessment including anthropometric measurements is *most* important for the patient who
   - **a.** has a BMI of 25.5 kg/m^2.
   - **b.** reports episodes of nightly nocturia.
   - **c.** reports a 5-year history of chronic constipation.
   - **d.** reports unintentional weight loss of 10 lb in 2 months.
4. Which method is *best* to use when confirming initial placement of a blindly inserted small-bore NG feeding tube?
   - **a.** X-ray
   - **b.** Air insertion
   - **c.** Observing patient for coughing
   - **d.** pH measurement of gastric aspirate
5. A patient is receiving peripheral parenteral nutrition. The solution is completed before the new solution arrives on the unit. The nurse gives
   - **a.** 20% intralipids.
   - **b.** 5% dextrose solution.
   - **c.** 0.45% normal saline solution.
   - **d.** 5% lactated Ringer's solution.
6. A patient with anorexia nervosa shows signs of malnutrition. During initial refeeding, the nurse carefully assesses the patient for *(select all that apply)*
   - **a.** hypokalemia.
   - **b.** hypoglycemia.
   - **c.** hypercalcemia.
   - **d.** hypomagnesemia.
   - **e.** hypophosphatemia.

1. a; 2. b, a, d, c; 3. d; 4. a; 5. b; 6. a, d, e.

CONCEPTUAL FOCUS

Functional Ability
Health Promotion
Nutrition
Self-Management

LEARNING OUTCOMES

1. Discuss the epidemiology and etiology of obesity.
2. Explain the health risks associated with obesity.
3. Use classification systems to determine body size.
4. Discuss comprehensive therapy for the patient with obesity.
5. Distinguish among the bariatric surgical procedures used to treat obesity.
6. Describe the nursing and interprofessional management related to surgical therapies for obesity.
7. Describe the etiology, clinical manifestations, and nursing and interprofessional management of metabolic syndrome.

KEY TERMS

bariatric surgery
body mass index (BMI)
extreme obesity
lipectomy
metabolic syndrome
obese
obesity
overweight
waist-to-hip ratio (WHR)

OBESITY

Obesity is an excessively high amount of body fat or adipose tissue. Obesity is a global problem because it is a major risk factor for leading causes of death, including type 2 diabetes, heart disease, and certain cancers. Those who are overweight often have other problems, such as problems with mobility and sleeping, that affect health.

The consequences of obesity extend beyond the physical changes. Social stigma can take an emotional toll on a person's psychologic well-being. Many struggle with altered body image, depression, and low self-esteem and withdraw from social interaction. Attitudes about obesity can create biases and discrimination against people who are obese. Obesity should be viewed and treated as a chronic disease, just like other chronic diseases, such as diabetes and hypertension.

Epidemiology of Obesity

Obesity is a major public health issue in the United States (Fig. 45.1). Currently, about 43% of adults in the United States are obese. Significant geographic, racial and ethnic, and income disparities exist. Obesity rates are highest in the South and Midwest (Fig. 45.2), among Blacks and Hispanics (Fig. 45.3, Box 45.1), and among lower-income, less-educated Americans.[1]

Obesity in adulthood is often a problem that begins in childhood or adolescence. More than 1 in 10 children becomes obese as early as age 2 to 5.[1] Reversing the childhood obesity crisis is a key part of addressing the obesity epidemic.

Etiology and Pathophysiology

Obesity is a complex, multifactorial disease. It is the result of an energy imbalance where one takes in more calories than one needs for the body's physical and metabolic functions. This results in an abnormal increase and accumulation of fat cells. Many factors, including genetic and environmental influences, can contribute to obesity. Personal decisions about food choices, portion sizes, and exercise also are factors.

In obesity, there is an increase in the number of adipocytes, or fat cells, and an increase in their size *(hypertrophy).* Adipocyte *hypertrophy* is a process by which fat cells can increase their volume several thousand times to accommodate large increases in lipid storage. When storage of existing fat cells is exceeded, preadipocytes are triggered to become adipocytes. This process

occurs mainly in the visceral (intraabdominal) and subcutaneous tissues. The greatest increase in the number of fat cells occurs from infancy through adolescence.

Most obese persons have *primary obesity,* which is excess calorie intake over energy expenditure for the body's metabolic demands. Others have *secondary obesity*, in which a medical problem caused the weight gain. These problems include some congenital conditions, endocrine disorders, central nervous system (CNS) lesions and disorders, or drugs (e.g., corticosteroids, antipsychotics).

Fig. 45.1 The obesity epidemic has taken its toll on both adults and children in the United States. (© iStock.com/IPGGutenbergUKLtd.)

Genetic Link

We have linked over 400 genes to obesity. Having one or more of these genes means the person is more predisposed to obesity than people without these genes, but it does not mean that they will become obese. Genes contribute to obesity in many ways. They affect appetite, satiety (the sense of fullness), food cravings, body-fat distribution, and how we store calories. Having a family history of obesity increases a person's chance of developing obesity.[2]

Several rare forms of obesity result from mutations in a single gene. Obesity is also part of several genetic syndromes caused by mutation or chromosomal abnormalities, such as Prader–Willi syndrome.[2] The best link is with a gene known as *FTO* (fat mass and obesity-associated gene). People with a certain allele of the *FTO* gene appear to have an increased appetite and reduced satiety, with a higher calorie intake.

Physiologic Regulatory Mechanisms in Obesity

Knowing how appetite is triggered and energy is spent is important for understanding obesity and specific targets for drug therapy. The hypothalamus, gut, and adipose tissue synthesize hormones and peptides that stimulate or inhibit appetite (Fig. 45.4). The hypothalamus is a major site for regulating appetite. Neuropeptide Y, made in the hypothalamus, is a powerful appetite stimulant. When it is imbalanced, it leads to overeating and obesity. Hormones and peptides made in the gut and adipocyte cells affect the hypothalamus and have a critical role in appetite and energy balance

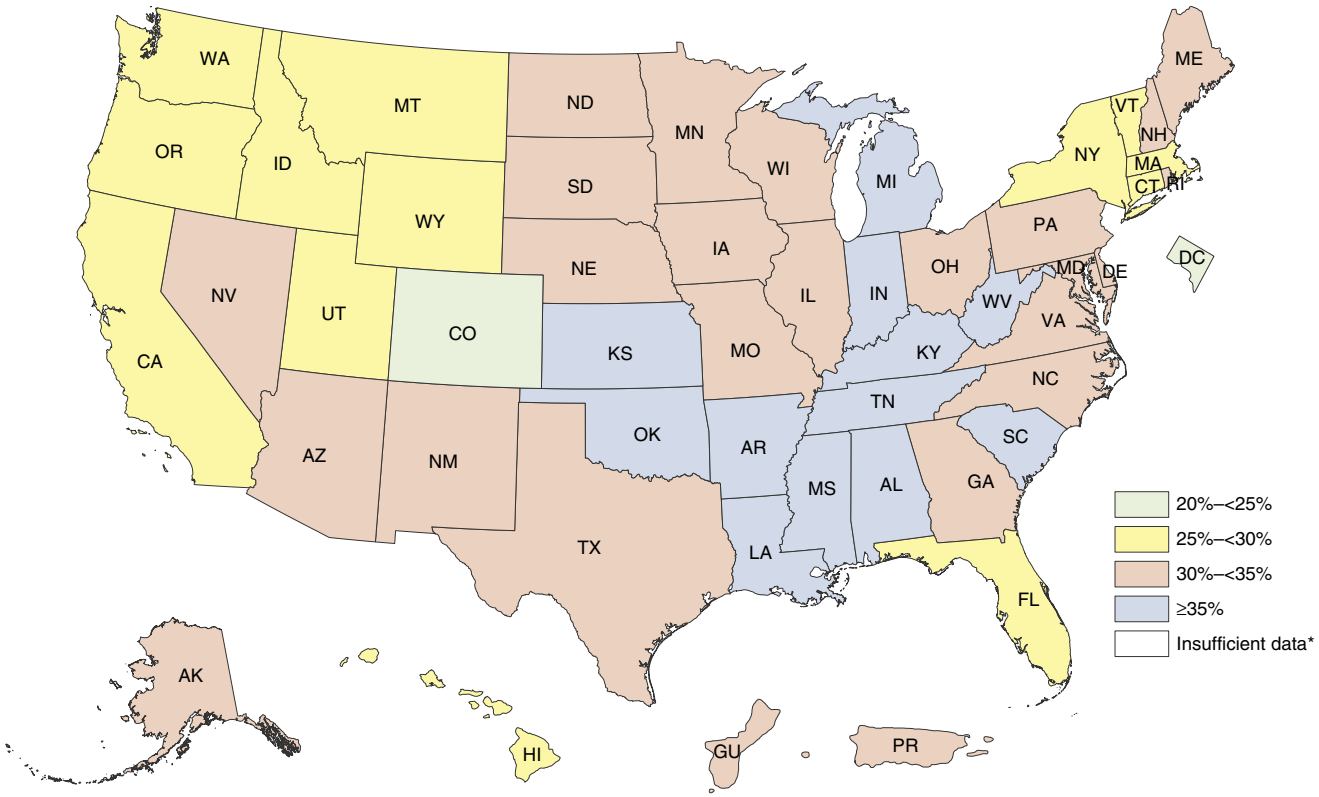

Fig. 45.2 Prevalence of obesity among US adults by state and territory. (Source: Behavioral Risk Factor Surveillance System. Retrieved from https://www.cdc.gov/obesity/data/prevalence-maps.html.)

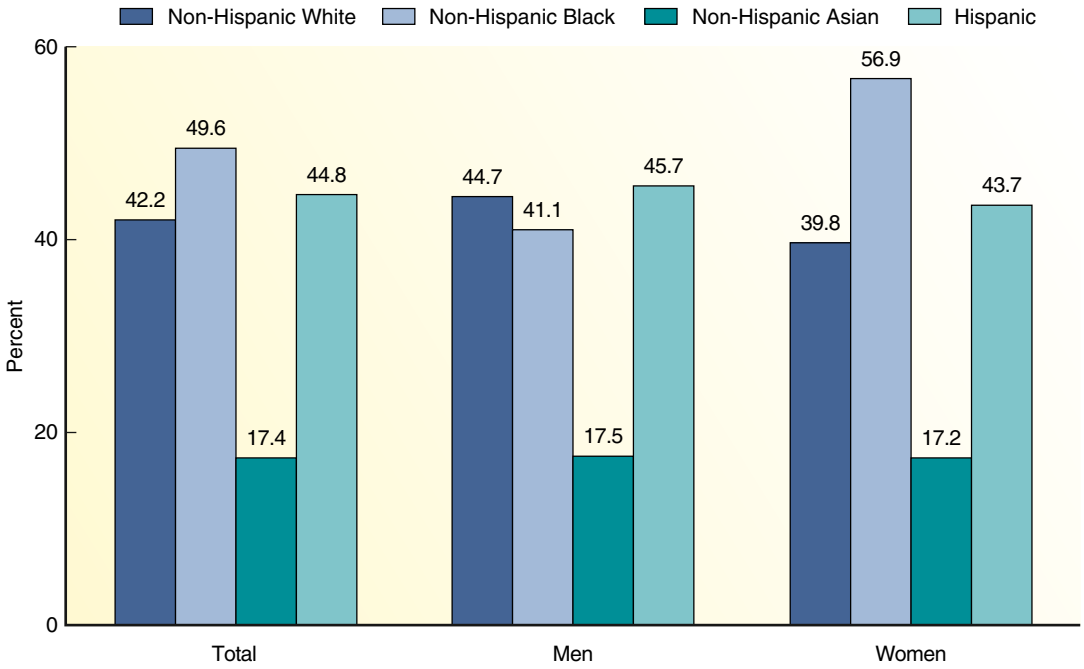

Fig. 45.3 Obesity affects some groups disproportionately. Among US adults, Black and Hispanic populations have the highest rates of obesity. (Source: Centers for Disease Control and Prevention: Prevalence of obesity and severe obesity among adults: US, 2017–2018. Retrieved from https://www.cdc.gov/nchs/products/databriefs/db360.htm.)

BOX 45.1 PROMOTING HEALTH EQUITY

Obesity

- Hispanics (44.8%) and Blacks (49.6%) have the highest rates of obesity.
- Among women, Blacks (56.9%) have the highest prevalence of being obese.
- Among men, Hispanics (45.7%) have the highest prevalence of being obese.
- Asian Americans have the lowest prevalence of being obese.

(Table 45.1). When overeating develops at an early age and continues into adulthood, it alters one's ability to sense fullness *(satiety)*.

Leptin is made in the adipocyte. It acts in the hypothalamus to suppress appetite and increase fat metabolism. A genetic deficiency of leptin causes extreme obesity. However, most obese persons have high leptin levels, suggesting they are leptin resistant.[3] This may be due to a failure to make enough leptin receptors or producing faulty receptors.

Ghrelin, a gut hormone, regulates appetite by inhibiting leptin. It acts in the hypothalamus and the brain's pleasure centers to stimulate hunger. In a non-obese person, ghrelin levels are higher when a person is hungry and decrease after eating. Gastric bypass patients do not have the premeal increase in ghrelin.[2] The low ghrelin levels help suppress appetite and contribute to the surgery's effectiveness.

Adipocytes make substances we call adipokines. Adipokines play roles in glucose and lipid metabolism, insulin sensitivity, energy homeostasis, inflammation, immunity, and vascular function. Excess visceral fat is associated with adipokine dysfunction, which leads to insulin resistance, dyslipidemia, and high blood pressure.[4] This causes people with abdominal (android) obesity more complications of obesity.

Environmental Factors

Environmental factors play a key role in obesity. In today's culture, people have greater access to high-calorie, energy-dense food and highly sweetened drinks. Eating outside of the home lends to obesity because one eats higher calorie foods with large portion sizes. Portion size has increased dramatically (Fig. 45.5). Lack of physical exercise is another factor that contributes to weight gain and obesity. We expend less energy in our everyday lives due to economic growth, technology use, and social changes. Increased time spent gaming, surfing the Internet, and watching TV contribute to the increase in sedentary habits.

Socioeconomic status is a known risk factor for obesity in several ways.[5] There may be a lack of access to affordable and nutritious food at full-service grocers and farmer's markets. People with low incomes stretch their limited food dollars by buying less expensive foods that often have poor nutritional quality with greater caloric content. Low-income neighborhoods often lack locations for healthy exercise, such as parks, playgrounds, walking trails, and swimming pools.

Psychosocial Factors

People use food for many reasons besides nutrition. Associations with food begin in childhood, such as the use of food for comfort or rewards. The social component of eating begins early in life when food is associated with pleasure and fun at such events as birthday parties and holidays. Stress, sadness, anxiety, and other emotions can lead people to eat too much. Eating

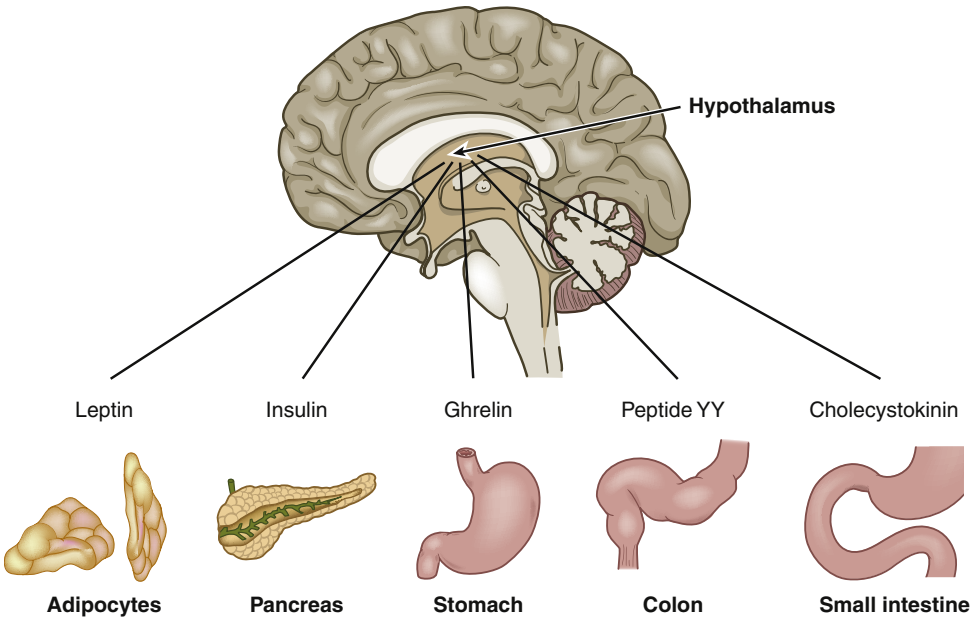

Fig. 45.4 Common hormones and peptides that interact with the hypothalamus to control and influence eating patterns, metabolic activities, and digestion. Obesity disrupts this balance (Table 45.3).

while watching television, working, studying, or browsing the Internet can lead to consuming unnecessary calories and an increase in weight.

HEALTH RISKS ASSOCIATED WITH OBESITY

Many problems occur at a higher rate in people who are obese than in people of normal weight (Fig. 45.6). Mortality rates rise as obesity increases, especially when obesity is primarily visceral fat.[4] In addition to health problems, many persons have a reduced quality of life (Box 45.2). Fortunately, most of these conditions can improve if a person loses weight.

Cardiovascular Problems

Obesity is a significant risk factor for cardiovascular disease (CVD) and stroke in both men and women. Android obesity is the best predictor of these risks. It is linked with increased low-density lipoproteins (LDLs), high triglycerides, and decreased high-density lipoproteins (HDLs).[6] Hypertension can occur because of increased circulating blood volume, abnormal vasoconstriction, increased inflammation (damaging blood vessels), and increased risk for sleep apnea (raises BP). Excess body fat can lead to chronic inflammation throughout the body, especially in blood vessels, thus increasing the risk for heart disease.

Diabetes

Obesity is the greatest risk factor for developing type 2 diabetes. Hyperinsulinemia and insulin resistance, common features of type 2 diabetes, are found in obesity.

Excess weight decreases the effectiveness of insulin. When insulin does not work effectively, too much glucose stays in the bloodstream. The body then makes more insulin to compensate. Pancreatic beta cells (cells that make insulin) may get overworked and become worn out. Over time, the pancreas is no longer able to keep glucose in the normal range.

Obesity complicates the management of type 2 diabetes by increasing insulin resistance and glucose intolerance. Adiponectin, an adipokine that increases insulin sensitivity, is decreased in those who are obese. These factors make drug treatment for diabetes less effective.

Gastrointestinal and Liver Problems

Gastroesophageal reflux disease (GERD) and gallstones are more prevalent. Gallstones occur due to the supersaturation of the bile with cholesterol. Nonalcoholic steatohepatitis (NASH) is a condition in which lipids are deposited in the liver, resulting in a fatty liver. NASH may increase hepatic glucose production. NASH can eventually progress to cirrhosis and can be fatal. Weight loss can improve NASH.

Respiratory and Sleep Problems

The increased fat mass from obesity may lead to sleep apnea and obesity hypoventilation syndrome. Sleep apnea results from increased fat around the neck, leading to snoring and hypoventilation while sleeping. The increased distribution of fat around the diaphragm causes reduced chest wall compliance, increased work of breathing, and decreased total lung capacity. Weight loss can improve lung function.

Poor sleep and sleep deprivation may increase appetite. Sleep deprivation can occur with obesity. Building up a sleep debt over a matter of days can impair metabolism and disrupt hormone levels. Leptin levels fall in people who are sleep deprived, thus increasing appetite.

Musculoskeletal Problems

Obesity is associated with an increased incidence of osteoarthritis because of the stress put on weight-bearing joints, especially

TABLE 45.1 Hormones and Peptides in Obesity

Where Produced	Normal Function	Alteration in Obesity
Anorexins (Suppress Appetite)		
Cholecystokinin		
Small intestine	Inhibits gastric emptying Sends satiety signals to hypothalamus	Unknown
Glucagon-Like Peptide-1 (GLP-1)		
Small intestine	Stimulates insulin secretion from pancreas Increases satiety (mediated by GLP-1 receptors in brain)	Unknown
Insulin		
Pancreas	Decreases appetite	Increased insulin secretion, which stimulates ↑ liver synthesis of triglycerides and ↓ HDL production
Leptin		
Adipocytes	Suppresses appetite and hunger Regulates eating behavior	Obesity is associated with high levels Leptin resistance develops so people who are obese may lose the effect of appetite suppression
Peptide YY		
Colon	Inhibits appetite by slowing GI motility and gastric emptying	Circulating levels are decreased. ↓ Release after eating
Orexins (Stimulate Appetite)		
Ghrelin		
Stomach (primarily)	Stimulates appetite ↑ After food deprivation ↓ In response to food in the stomach	Normal postprandial decline does not occur, which can lead to increased appetite and overeating
Neuropeptide Y		
Hypothalamus	Stimulates appetite	Imbalance causes increased appetite

the knees and hips. Increased body fat also triggers inflammatory mediators and contributes to cartilage deterioration. Hyperuricemia and gout often occur in people who are obese and in those who have metabolic syndrome (discussed later in this chapter).

Cancer

Obesity is one of the most important preventable causes of cancer. The cancers most strongly linked to excess body fat are breast, colorectal, endometrial, esophagus, gallbladder, kidney, liver, ovarian, stomach, and thyroid cancer.[7]

The links between obesity and cancer are complex. Several hormones and factors often present in obese states increase the risk for cancer. Adipokines from fat cells may stimulate cell and blood vessel growth. For example, leptin, which is increased in people who are obese, promotes cell proliferation. Fat tissue plays a role in changing androgens into estrogens. The resulting increased estrogen levels, especially after menopause, may lead to breast and endometrial cancer. Esophageal cancer may be related to acid reflux caused by abdominal obesity. Insulin, a powerful cellular growth factor, is increased in obesity and linked to colorectal cancer.

Metabolic Syndrome

Metabolic syndrome is a growing obesity-related health concern. It is discussed later in this chapter.

Psychosocial Problems

The consequences of obesity extend beyond the physical changes. Those who are obese often experience stigma, and in some cases discrimination, in 3 important areas of living: employment, education, and health care. The social stigma associated with obesity has an emotional toll on a person's psychologic well-being. Many obese persons have low self-esteem, are lonely, and have major depression.[8]

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: OBESITY

◆ Assessment

The first step in the treatment of obesity is to determine whether any physical conditions are present that may be causing or contributing to obesity. This requires a thorough history and physical assessment (Table 45.2). Before you begin, examine your own personal beliefs and any potential biases related to obesity. If you associate obesity with a lack of willpower and overindulgence, you may convey your attitude to patients. They may experience shame in a setting that claims to be a caring one.

When assessing a person who is overweight or obese, be sensitive and nonjudgmental in asking specific and leading questions about weight, diet, and exercise (Table 45.3). In doing so, you can often obtain information that the patient may have withheld out of embarrassment or shyness. Patients need to understand the reason for questions asked about weight or diet habits. You must be ready to respond to their concerns.

CHECK YOUR PRACTICE

You are working in the hypertension clinic, and the provider has asked you to do an assessment on a 54-year-old man for referral to a weight loss program. He is 5 ft, 9 in and weighs 242 lb. His BP has been hard to control with drugs and diet. While you are trying to do an assessment, he interrupts you and asks you if he can leave. He angrily tells you, "I am not going to give up my favorite foods, quit drinking, or exercise. Do you understand that?"

- How would you respond?

Assess a patient's willingness to change and potential for change. If people are not ready for change, offer them the

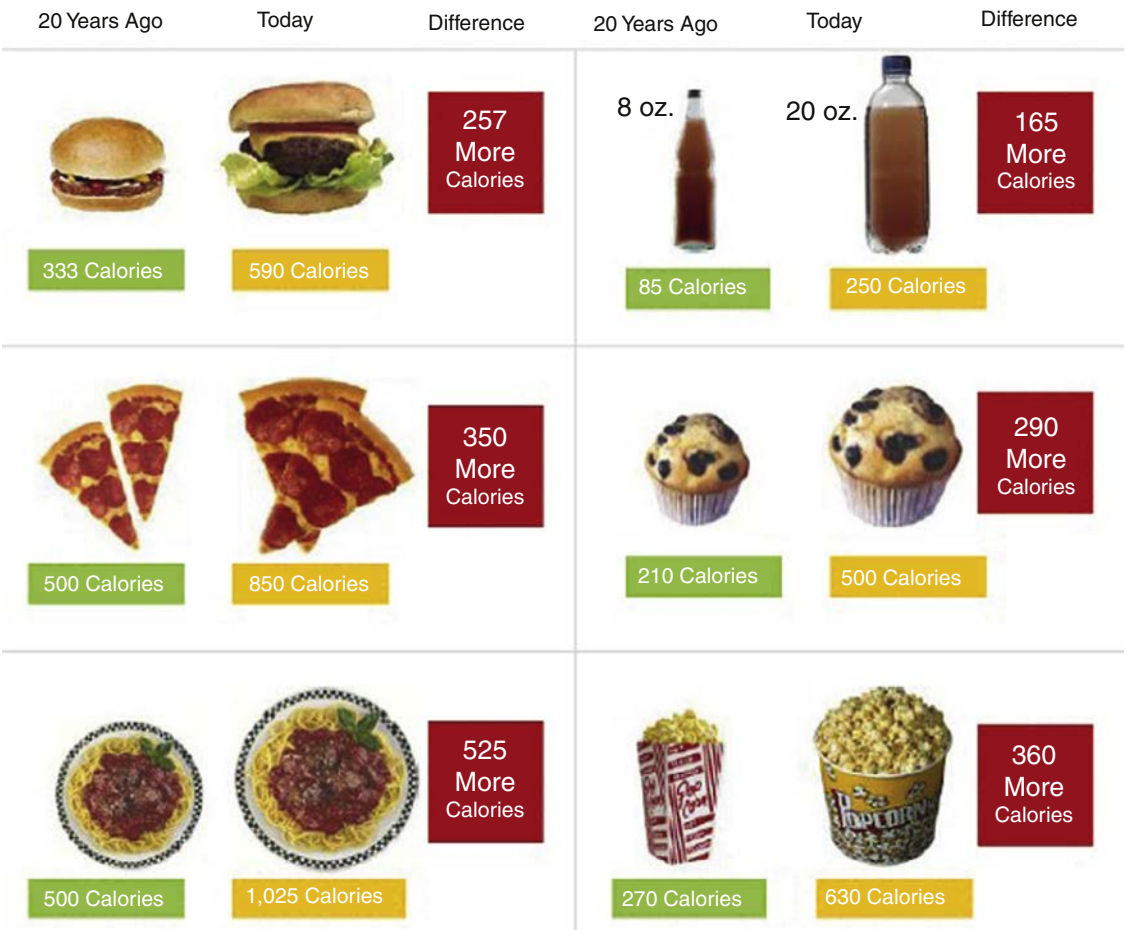

Fig. 45.5 Changes in portion size over the years. (Adapted from https://www.nhlbi.nih.gov/health/educational/wecan/portion/documents/PD1.pdf.)

opportunity to return for further discussion when they are ready to discuss their weight again and make lifestyle changes.

When obtaining the history, explore genetic and endocrine factors, such as hypothyroidism, hypothalamic tumors, Cushing syndrome, hypogonadism in men, and polycystic ovary syndrome in women. Laboratory tests of liver function and thyroid function, a fasting glucose level, and a lipid panel (triglyceride level, LDL and HDL cholesterol levels) aid in evaluating the cause and effects of obesity. Assess for any comorbid diseases related to obesity, such as hypertension, sleep apnea, and diabetes. These problems will require special treatment.

Assess each body system with particular attention to any areas in which the patient has expressed a problem or concern. Measurements may include height (without shoes), weight (obtain in a private location and in a gown, if possible), waist circumference, and BMI. Have the right equipment to take these measurements. Provide special chairs, examination tables, and scales that can accommodate an obese person.

Classifications of Body Weight and Obesity

An important part of the assessment is to determine and classify a patient's body weight. Common assessment methods include BMI, waist circumference, waist-to-hip ratio (WHR), and body shape. The most widely used and endorsed measures are BMI and waist circumference. These measures are cost-effective, reliable, and easily used in all practice settings.

Body Mass Index

The most common way we classify weight is the **body mass index (BMI).** We calculate BMI by dividing a person's weight (in kilograms) by the square of the height in meters (Fig. 45.7). Table 45.4 shows the classification of overweight and obesity by BMI. Persons with a BMI less than 18.5 kg/m^2 are considered underweight. A BMI between 18.5 and 24.9 kg/m^2 reflects a normal body weight. A BMI of 25 to 29.9 kg/m^2 is classified as being **overweight.** Those with a BMI of 30 kg/m^2 or above are considered **obese**. The term **extreme obesity** *(morbid* or *severe obesity)* is used for those with a BMI greater than 40 kg/m^2.

There are some limitations to using BMI. You need to consider BMI in relation to the patient's age, gender, and body build. For example, an athlete may have a high BMI, but because of a high muscle mass, the BMI is not an accurate assessment. In contrast, in those who have lost body mass (e.g., older adults), the BMI would underestimate the degree of obesity. For this reason, we combine other measures with the BMI for an accurate evaluation of a person's weight.

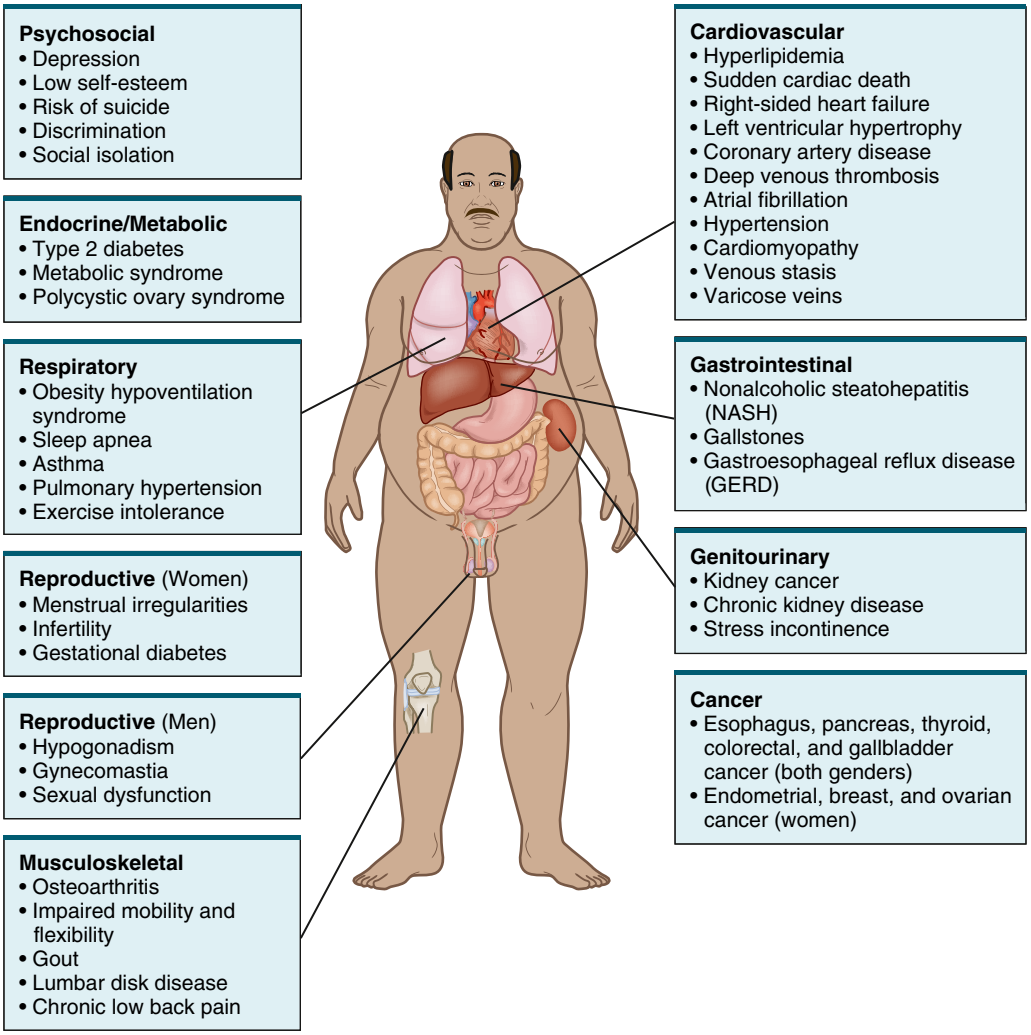

Fig. 45.6 Health risks associated with obesity.

BOX 45.2 PROMOTING POPULATION HEALTH

Health Impact of Maintaining a Healthy Weight

- Lowers the risk for hypertension and high cholesterol
- Increases chance for longevity and better quality of life
- Reduces the risk for developing type 2 diabetes
- Reduces the risk for heart disease, stroke, and gallbladder disease
- Reduces the risk for breathing problems, including sleep apnea and asthma
- Decreases the risk for developing osteoarthritis, low back pain, and some types of cancers

Waist Circumference

Waist circumference is another way to assess and classify a person's weight. It is measured just above the iliac crest after the patient has exhaled. Health risks increase if the waist circumference is greater than 40 inches in men and greater than 35 inches in women.[9] People who have visceral fat with android obesity have an increased risk for CVD and metabolic syndrome.

Waist-to-Hip Ratio

The **waist-to-hip ratio (WHR)** is another way to assess obesity. Calculate the WHR by dividing the waist measurement by the hip measurement. In women, the ratio should be 0.8 or less, and in men, it should be 1.0 or less. This means that in women the waist should be narrower than the hips, and in men, the waist should be narrower or the same as the hips. A higher WHR indicates abdominal obesity, which puts a person at a greater risk for health complications.

Body Shape

Body shape is another way we can identify those who are at a higher risk for health problems (Table 45.5). People with fat mainly in the abdominal area and an *apple-shaped body* have *android obesity.* Those with fat distribution in the upper legs with a *pear-shaped body* have *gynoid obesity.* Genetics plays an important role in determining a person's body shape and weight.

Clinical Problems

Clinical problems for the patient with obesity may include:

- Bodyweight problem
- Altered blood glucose level

TABLE 45.2 NURSING ASSESSMENT

Patient With Obesity

Subjective Data

Important Health Information

Health history: Obesity onset; diseases related to metabolism and obesity, including hypertension, CVD, stroke, cancer, chronic joint pain, respiratory problems, diabetes, cholelithiasis, metabolic syndrome

Medications: Endocrine preparations, diet pills, herbal products

Surgery or other treatments: Prior weight-loss procedures (bariatric surgery)

Functional Health Patterns

Health perception–health management: Family history of obesity; perception of problem; methods of weight loss tried

Nutritional-metabolic: Table 45.3

Elimination: Constipation

Activity-exercise: Typical exercise; drowsiness, somnolence; dyspnea on exertion, orthopnea, paroxysmal nocturnal dyspnea

Sleep-rest: Sleep apnea, CPAP use

Cognitive-perceptual: Feelings of rejection, depression, isolation, guilt, or shame; meaning or value of food; adherence to prescribed reducing diets, degree of long-term commitment to a weight loss program

Role-relationship: Change in financial status or family relationships; personal, social, and financial resources to support a reducing diet; food environment, including who prepares food

Sexuality-reproductive: Menstrual irregularity, heavy menstrual flow in women, birth control practices, infertility; effect of obesity on sexual activity and attractiveness to significant other

Objective Data

General

Body mass index ≥30 kg/m^2; waist circumference: woman >35 in (89 cm), man >40 in (102 cm)

Respiratory

Increased work of breathing; wheezing; rapid, shallow breathing

Cardiovascular

Hypertension, tachycardia, dysrhythmias

Musculoskeletal

Decreased joint mobility and flexibility; knee, hip, and low back pain

Reproductive

Gynecomastia and hypogonadism in men

Possible Diagnostic Findings

Increased serum glucose, cholesterol, triglycerides; chest x-ray showing enlarged heart; ECG showing dysrhythmia; abnormal liver function tests

TABLE 45.3 Nutrition Assessment

Patient With Obesity

When assessing the patient with obesity and before selecting a weight loss strategy, ask the following questions:

- What is your history with weight gain and weight loss?
- Are other family members overweight?
- How has your body weight affected your health?
- What do you think contributes to your weight?
- What does food mean to you? How do you use food, such as stress relief, provide comfort, boredom?
- Describe your normal diet. What types of foods do you usually eat? What types of beverages and how much are you drinking?
- Describe your motivation for losing weight.
- What have you already tried to lose weight? Was it successful? If not, why not?
- Would you like to manage your weight differently? If so, how?
- What sort of barriers do you think impede your weight loss efforts?
- Are there any major stresses that will make it hard to focus on weight control?
- How much time can you devote to exercise on a daily or weekly basis?
- Describe the support you have from family and/or friends for losing weight.

- Musculoskeletal problem
- Risk for disease
- Negative self-image

◆ Planning

The overall goals are that the patient with obesity will (1) modify eating patterns, (2) take part in regular exercise, (3) achieve and maintain weight loss to a specified level, and (4) minimize or prevent health problems related to obesity.

◆ Implementation

Obesity is one of the most challenging health problems. Despite knowing the benefits of weight loss, most people find the process tough. Successful weight management will be a hard, lifelong commitment. Obesity treatment begins with patients understanding their weight history and deciding on a plan that is best for them. It is rare to find an obese person who has not tried to lose weight. Some people have met with limited and temporary success, and others have met only with failure.

Achieving an "ideal" BMI is not necessary and may not be a realistic goal. Modest weight loss of even 5% of starting weight can have health benefits.[10] Greater weight losses produce greater benefits. In general, the average weight loss program (except for bariatric surgery) results in a 10% loss of body weight. This average should not be considered a failure since it is associated with significant health benefits.

Effective treatment requires continuous attention and reinforcement from the health care team. Barriers to counseling patients about obesity include (1) time constraints, (2) not wanting to cause the patient embarrassment, and (3) lack of reimbursement for weight management services. Other barriers are bias from low patient adherence to treatment plans and patients having a "quick fix" mentality. This can make team members feel that treating obesity is not worth the long-term effort needed.[11]

Together with other members of the health care team, you have a key role in planning for and managing the care of a patient with obesity. You can help patients by building their motivation and being a source of information. Using motivational interviewing (see Chapter 4) helps patients understand why they want to lose weight and helps them gain confidence in their ability to do so. Focusing on the reasons for wanting to lose weight may help patients develop strategies for a weight loss program. While teaching patients, stress healthy eating habits and adequate exercise as lifestyle patterns to develop and maintain (Box 45.3).

A weekly check of body weight is a good method of monitoring progress. Daily weighing is not recommended because of fluctuations that result from retained water (including urine) and feces. Teach the patient to record the weight at the same time of the day, wearing the same type of clothing.

TABLE 45.4 Diagnostic Criteria

Classification of Overweight and Obesity

	BMI (kg/m²)	Obesity Class	DISEASE RISK RELATIVE TO NORMAL WEIGHT AND WAIST CIRCUMFERENCE	
			Men ≤40 in (102 cm) Women ≤35 in (89 cm)	Men >40 in (102 cm) Women >35 in (89 cm)
Underweight	<18.5	—	—	—
Normal	18.5–24.9	—	—	—
Overweight	25.0–29.9	—	Increased	High
Obesity	30.0–34.9	Class I	High	Very high
	35.0–39.9	Class II	Very high	Very high
Extreme obesity	≥40.0	Class III	Extremely high	Extremely high

$$\text{BMI (kg/m}^2) = \frac{\text{Weight (pounds)} \times 703}{\text{Height (inches)}^2}$$

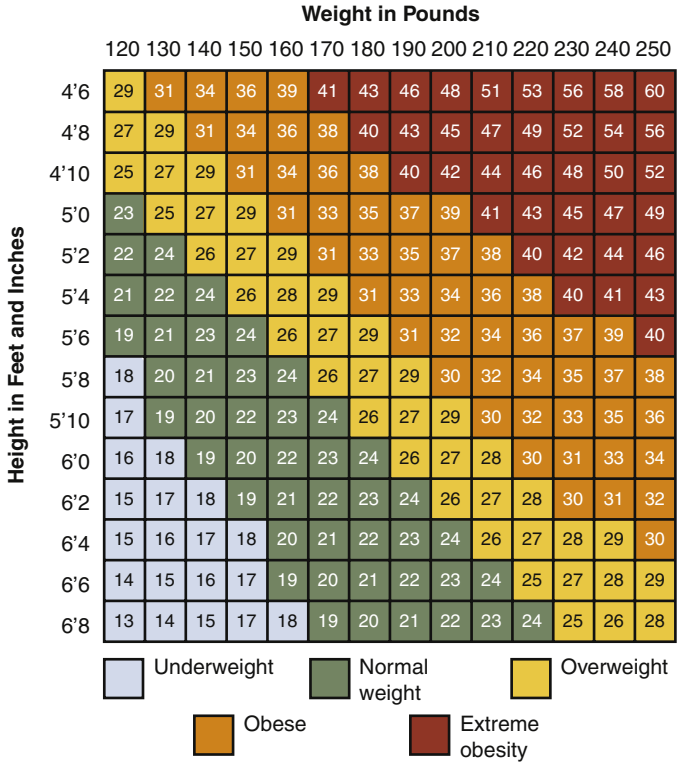

Fig. 45.7 Body mass index *(BMI)* chart. Healthy weight: BMI 18 to 24.9 kg/m²; overweight: BMI 25 to 29.9 kg/m²; obesity: BMI 30 kg/m². BMI = weight (kg)/height (m²).

TABLE 45.5 Relationship Between Body Shape and Health Risks

Body Shape	Characteristics	Health Risks
Android (apple) 	• Fat mainly in abdominal area • Fat also found over upper body (neck, arms, shoulders) • Greater risk for obesity-related complications	• Breast, endometrial cancer • Diabetes • ↓ HDL cholesterol • Heart disease • Hypertension • ↑ Triglycerides • Visceral fat more active, causing ↓ insulin sensitivity
Gynoid (pear)	• Fat mainly in the upper legs • Has a better prognosis but hard to treat	• Cellulite • Osteoporosis • Varicose veins • Subcutaneous fat traps and stores fat • Trapped fatty acids stored as triglycerides

BOX 45.3 PROMOTING POPULATION HEALTH

Maintaining a Healthy Weight

- Weigh yourself regularly.
- Eat 5 or more servings of fruits and vegetables daily.
- Choose whole-grain foods, such as brown rice and whole-wheat bread.
- Avoid highly processed foods made with refined white sugar, flour, and saturated fat.
- Avoid foods that are high in "energy density" or have a lot of calories in a small amount of food.
- Take part in exercise:
  - 150 min of moderate-intensity aerobic activity (i.e., brisk walking) every week
  - Muscle-strengthening activities on 2 or more days a week

A holistic approach to weight loss is most effective. This includes nutrition therapy, exercise, behavior therapy, and, for some, drugs or surgical intervention (Table 45.6). Combining more than one aspect supports more effective weight loss and weight control efforts. Any supervised plan of care must be directed at 2 different processes: (1) successful weight loss, which requires a short-term energy deficit, and (2) successful weight control, which requires long-term behavior changes.

Setting a realistic and healthy goal, such as losing 1 to 2 lb per week, should be mutually agreed on at the beginning of a weight loss program. Trying to lose too much too fast usually results in a sense of frustration and failure for the patient. You can help

patients understand that losing large amounts of weight in a short period causes skin and underlying tissue to lose elasticity and tone. Slower weight loss offers better cosmetic results.

Inevitably, the patient reaches plateau periods during which they lose no weight. These plateaus may last from several days to several weeks. Remind the patient that plateaus are normal occurrences during weight loss.

Encourage the patient to keep an electronic or paper journal. Have them record their daily food and drink consumption and exercise. They should note where they eat and with who. This can give insight into factors that influence eating habits that the patient can control or change. Reviewing the journal can help find relationships among food intake, exercise, and weight loss. Apps can give immediate access to nutrition information and track nutrient intake.

Nutrition Therapy

Restricting diet intake so that it is below energy requirements is a cornerstone for any weight loss or maintenance program. There is no best diet for weight loss. Any diet can work if it reduces caloric intake compared to expenditure and is one to which the patient will adhere.[12] The ability to adhere to a diet depends on food preferences, cultural traditions, food availability, and motivation.

It is best to recommend a diet in which calorie restriction includes a variety of healthy foods. Table 45.7 shows an example of a 1200-calorie diet. In general, the diet should emphasize fruits, vegetables, whole grains, and fat-free or low-fat dairy products. Lean meat, fish, poultry, beans, and eggs provide sufficient protein and the B-complex vitamins. The patient should limit the intake of saturated fats, cholesterol, salt, and added sugars. Encourage the appropriate fluid intake in the form of water. Have them limit or avoid alcoholic and sugary beverages. They increase caloric intake and are low in nutrition value.

Restrictive diets are hard to maintain on a long-term basis. The more restrictive the diet, the greater the demand for discipline in the face of an intense desire to eat foods not allowed on the diet. Patients will find it easier to fit a diet with a variety

TABLE 45.7 NUTRITION THERAPY

1200-Calorie–Restricted Weight-Loss Diet

General Principles

1. Eat regularly. Do not skip meals.
2. Measure foods to determine the correct portion size.
3. Avoid concentrated sweets, such as sugar, candy, honey, pies, cakes, cookies, and regular sodas.
4. Reduce fat intake by baking, broiling, or steaming foods.

Sample Meal Plan

Meal	Exchanges	Menu Plan
Breakfast	1 starch	½ cup cooked oatmeal
	1 fat	6 almonds, chopped
	1 fruit	¾ cup blueberries
	1 dairy	1 cup fat-free milk
	Beverage	Coffee
Lunch	2 starches	1 pita, 6 inches across
	2 meats	2 oz tuna fish in water
	1 fat	1 Tbsp reduced fat mayonnaise
	1 vegetable	1 cup raw carrots
	Beverage	Diet soda
Snack	1 fruit	1 small apple
Dinner	3 meats	3 oz grilled chicken
	2 starches	⅔ cup brown rice
	2 vegetables	1 cup sautéed spinach
	2 fats	2 tsp olive oil
	Free	1 cup tossed salad greens with 1 Tbsp fat-free dressing
	Beverage	Decaffeinated iced tea
Snack	1 milk	6 oz low-fat yogurt

of foods into their lifestyle and not become as bored with their food options. A list of healthy or low-calorie foods serves as a good reference and allows the patient to dine out on occasion.

There is no clear consensus on the number of meals a person on a diet should eat. Some advocate several small meals per day because the body's metabolic rate temporarily increases right after eating. However, patients eating several small meals a day might consume more calories unless they carefully adhere to portion sizes and total daily calorie allotment.

A very low-calorie diet plan that limits calories to a total of 800 or less per day may be prescribed if rapid weight loss is needed. These diets are not sustainable on a long-term basis. They should be provided only by trained HCPs in a medical setting. Persons on very low-calorie diets need frequent monitoring because the severe energy restriction places them at risk for multiple health complications.

Many people try to lose weight by following a fad diet. A *fad diet* promises fast weight loss with minimal effort and quick results. They are often promoted widely on social media and on television to gain publicity. Often, fad diets advocate eliminating one category of foods, such as carbohydrates. People who follow a fad diet may lose a large amount of weight in a short time, but it is not sustainable. Most regain the weight they lost, if not more. Therefore, discourage using a fad diet.

The degree of success of any diet depends in part on the amount of weight to lose. A moderately obese person will

obviously reach a weight goal more easily than a person with extreme obesity. Because men have a higher percentage of lean body mass, they are often able to lose weight more quickly than women. Women have a higher percent of body fat, which is metabolically less active than muscle tissue. Postmenopausal women are particularly prone to weight gain, especially increased abdominal fat.

When a person first starts a weight loss program, food portion sizes must be carefully determined to stay within diet guidelines. Food portions can be weighed using a scale. Everyday objects can be used as a visual cue to determine portion sizes. The size of a woman's fist or a baseball is equivalent to a serving of vegetables or fruit. The recommended portion size of meat is 3 oz. This is about the size of a person's palm or a deck of cards. A serving of cheese is about the size of a thumb or 6 dice. The standard size for chopped vegetables is ½ cup. A portion size quiz is available at www.nhlbi.nih.gov/health/educational/wecan/eat-right/portion-distortion.htm.

Exercise

Exercise plays a key role in losing and maintaining a healthy weight. Patients should aim for at least 150 minutes of moderate exercise or 75 minutes a week of vigorous exercise per week. That works out to 30 minutes of brisk walking or 15 minutes of running for 5 days a week. The type of exercise (high vs. low intensity) does not seem to affect overall weight loss. More intensive exercise may result in weight loss with a reduced time commitment, making it preferable to some people. 200 to 300 minutes per week of moderate exercise is recommended to maintain weight loss or prevent weight regain after weight loss.[11]

Explore ways to incorporate exercise in daily routines. It may be as simple as parking farther from entry doors or taking the stairs versus an elevator. Encourage the person to use a tracker to monitor progress towards their goals. Patients can swim and cycle, which both have long-term benefits. Joining a health club can help with getting exercise. Stress to patients that engaging in weekend exercise only or in spurts of strenuous exercise is not helpful and can be dangerous.

Behavior Therapy

The assumptions behind behavior therapy are (1) persons who are obese have maladaptive eating and exercise patterns, and (2) these habits can be modified with specific interventions. Behavior therapy provides the person with tools to help change eating and physical activity patterns. It should include counseling sessions with a trained interventionist. The interventionist and patient should mutually set specific, attainable goals that identify the behavior to be modified and how goals will be achieved. Persons who are in behavior therapy are more successful in maintaining weight loss over an extended time than those who do not take part in such training.[13]

Behavior techniques include (1) self-monitoring, (2) stimulus control, and (3) rewards. *Self-monitoring* involves keeping a record of food and calorie intake, physical activity, and body weight. Record-keeping helps the patient see behavior patterns and areas for change. Regular review of self-monitoring records helps us evaluate progress toward goals.

Stimulus control is aimed at eliminating cues that trigger eating. By looking at the cues and events before eating, the person can identify areas in which to make behavior changes to break the chain and prevent overeating. For example, if the patient overeats while watching television, limiting eating to a certain area (e.g., kitchen table) can be an effective way to weaken the link between eating and television watching. The more often the person does not eat in front of the television, the less likely television watching will trigger overeating.

Rewards may be incentives for weight loss. Short- and long-term goals are useful benchmarks for earning rewards. It is important that the reward for a specified weight loss not be related to food, such as dinner out or a favorite treat. Reward items do not need to cost money. For example, time for a hot bath or an hour of pleasure reading would be an enjoyable reward for many people. Changing existing behaviors is hard. Praise your patient's successes, even small ones, at every opportunity.

Support Groups

People who are on a weight management plan are often encouraged to join a group in which others are also trying to change their eating habits. Many self-help groups offer support, tips, and information on dieting. For example, Take Off Pounds Sensibly (TOPS) (www.tops.org) is the oldest organization of this type. Behavior therapy and nutrition education are key parts of the program. WW (www.weightwatchers.com) offers a food plan that is nutritionally balanced and practical to follow. Group leaders, all of whom have successfully lost weight, support members in following their weight loss plan and achieving their weight goals.

Jenny Craig (www.jennycraig.com) and Nutrisystem (www.nutrisystem.com) are other popular weight-loss group programs. They offer special prepackaged foods and supplements that a person buys as part of their weight loss plan. The person only consumes the program's foods and drinks until they lose an agreed-on amount of weight. The person is encouraged to buy the same type of foods for the maintenance phase of the program, lasting from 6 months to 1 year. Behavior modification training is part of these programs. People must learn how to adjust their diet once they are no longer using commercial products. This can be challenging for many, and they may regain the weight they lost. A downside is these centers are cost-prohibitive for those with limited financial resources.

In recent years, many employers have begun workplace weight loss programs. The reason for such programs is that better health repays the cost of the programs through improved work performance, decreased absenteeism, less hospitalization, and lower insurance costs. Both employees and employers report benefiting from such programs.

Drug Therapy

Drug therapy should be part of a holistic weight loss program that includes a reduced-calorie diet, exercise, and behavior therapy. Drug therapy is reserved for adults with a BMI of 30 kg/m^2 or greater (obese) or adults with a BMI of 27 kg/m^2 or greater (overweight) who have at least 1 weight-related condition, such as hypertension, type 2 diabetes, or dyslipidemia.[14] The FDA -approved drugs for weight loss are shown in Table 45.8.

TABLE 45.8 Drug Therapy

Obesity

Drug	Mechanism of Action	Nursing Considerations
bupropion/naltrexone (Contrave)	• *bupropion:* antidepressant • *naltrexone:* opioid antagonist	• Side effects: nausea, constipation, headache, dizziness, insomnia, dry mouth • Monitor for suicidal thoughts and behaviors and neuropsychiatric reactions • Can increase BP and heart rate. Should not be used in patients with uncontrolled hypertension • Can cause seizures. Must not be used in patients who have seizure disorder
liraglutide (Saxenda)	• Glucagon-like peptide 1 (GLP-1) agonist • Induces satiety	• Used to treat type 2 diabetes • Injected • Side effects: nausea, diarrhea, headache, fatigue, dizziness • Monitor for suicidal ideation, pancreatitis
orlistat (Xenical, Allī [low-dose form available over the counter])	• Inhibits gastrointestinal (GI) lipase • Blocks fat breakdown and absorption in intestine • Results in undigested fat excreted in feces	• Side effects: stool leakage, flatulence, diarrhea, abdominal bloating, especially if a high-fat diet is consumed • Liver injury, kidney stones may occur • May need daily multivitamin supplement • Taken with each main meal containing fat
phentermine/topiramate ER (Qsmyia)	• *phentermine*: Sympathomimetic • *topiramate:* Decreases appetite	• Side effects: dizziness, insomnia, dry mouth, headache, high blood pressure • Do not use in patients with glaucoma or hyperthyroidism • Must avoid pregnancy • Can increase heart rate. Should not be used in patients with uncontrolled hypertension or heart disease
Plenity	• Gel pieces increase the volume of stomach and small intestine contents • Induces satiety	• Side effects: abdominal pain, constipation • Taken twice a day orally, 20 min before lunch and dinner, with 16 oz of water • Should not be used in patients with GI disease
semaglutide (Wegovy)	• Mimics GLP-1 • Induces satiety	• Side effects: GI distress • Subcut injection once weekly • Can cause hypoglycemia in persons with type 2 diabetes

Your role related to drug therapy is to teach the patient about proper administration, side effects, and how the drugs fit into the overall weight loss plan. Drugs will not cure obesity. People must understand that without substantial changes in food intake and increased exercise, they will gain weight when they stop drug therapy. Careful evaluation for other medical conditions can help determine which drug, if any, is best for the patient.

Review with the patient their insurance coverage for weight loss treatments. Many insurance companies do not pay for weight-loss drugs. Tell the patient not to change drug dosages without consulting with the HCP. Finally, discourage patients from buying over-the-counter diet aids unless recommended by an HCP.

BARIATRIC SURGERY

Bariatric surgery involves surgery on the stomach and/or intestines to help a person with extreme obesity lose weight. Surgery is currently the only treatment that has a successful and lasting impact for sustained weight loss for those with extreme obesity.[15]

Criteria for bariatric surgery include having a BMI of 40 kg/m^2 or more or a BMI of 35 kg/m^2 or more with at least 1 weight-related comorbidity, such as type 2 diabetes, hypertension, sleep apnea, heart failure, or liver failure. Most people who have bariatric surgery successfully improve their overall quality of life. In addition to losing weight, outcomes include better glucose control with improvement or reversal of diabetes, normalization of BP, decreased total cholesterol and triglycerides, decreased GERD, and decreased sleep apnea.[16]

Insurance coverage for bariatric surgery varies. Those who cover surgery often require extensive documentation. This often includes taking part in a supervised weight loss program for at least 6 months and a psychologic evaluation.

Because of the risks and costs of surgery, surgical candidates are screened for psychologic, physical, and behavioral problems that are associated with poor surgical outcomes. These include mood disorders, binge eating disorders, and substance use that may interfere with a commitment to lifelong behavior changes. Other contraindications include illnesses that are known to reduce life expectancy and are not likely to improve with weight loss. These include advanced cancer; end-stage kidney, liver, heart, and lung disease; or inability to comply with medical care.

Bariatric surgeries fall into 1 of 3 broad categories: restrictive, malabsorptive, or a combination of malabsorptive and restrictive (Table 45.9 and Fig. 45.8). *Restrictive procedures* reduce the size of the stomach, so less food is eaten. In *malabsorptive procedures,* the small intestine is shortened or bypassed, so less food is absorbed. Most procedures are done laparoscopically. This results in fewer wound infections, shorter hospital stays, and a faster recovery period.

Restrictive Surgeries

Restrictive bariatric surgery reduces either the size of the stomach, which causes the patient to feel full more quickly, or the

TABLE 45.9 Surgical Therapy for Obesity

Description	Advantages	Disadvantages
Restrictive Surgery		
Adjustable Gastric Banding (AGB) (Lap-Band, Realize Band) (Fig. 45.8A)		
• Inflatable band encircles stomach • Creation of gastric pouch with about 30 mL (1 oz) capacity • Later stretches to 60–90 mL (2–3 oz) • Upper gastric pouch connected by very narrow channel to lower section of stomach	• Food digestion occurs normally • Band can be adjusted to ↑ or ↓ restriction • Can be reversed • No dumping syndrome • No malabsorption • Low complication rate	• Some nausea and vomiting initially (eating too much too quickly) • May have food intolerance, gastric dysmotility, regurgitation • Problems with adjusting device • Band may slip or erode into stomach wall • Gastric perforation or obstruction may occur, requiring surgery • Weight loss may be more limited than with other types of surgery
Sleeve Gastrectomy (Gastric Sleeve) (Fig. 45.8B)		
• About 75% of stomach removed • Creation of sleeve-shaped stomach with 60–150 mL (2–5 oz) capacity	• Preserves stomach function • Does not bypass intestines • Weight loss can occur rapidly	• Leakage related to stapling • Not reversible • Nutrition problems common
Gastric Plication		
• Adapted version of sleeve gastrectomy (gastric sleeve) • Sleeve created by suturing rather than removing stomach	• Minimal surgery compared to sleeve gastrectomy • Does not bypass intestines	• Requires hospital stay of 24–48 hr • Nausea common after procedure • Risks include stomach leakage from sutured areas, blockage of stomach from swelling or fold too tight
Intragastric Balloon		
• Involves placing a deflated balloon into stomach • Balloon then filled with saline and occupies space in stomach	• Most are placed endoscopically as an outpatient procedure	• Left in place up to 6 months • Once device is in stomach, nausea, vomiting, abdominal pain, indigestion, gastric ulcers can occur
Malabsorptive Surgery		
Biliopancreatic Diversion (BPD) With or Without Duodenal Switch (Fig. 45.8C)		
• 70% of the stomach removed horizontally • Anastomosis between stomach and intestine • Decreases the amount of small intestine available for nutrient absorption • Duodenal switch cuts the stomach vertically and is shaped like a tube	• Able to eat larger meals than with gastric bypass or banding procedures • Less food intolerance • Rapid weight loss • Greater long-term weight loss	• Abdominal bloating, foul-smelling gas (steatorrhea) common • Often have 3 or 4 loose bowel movements a day • Nutrition problems include malabsorption of fat-soluble vitamins, iron deficiency anemia, protein-calorie malnutrition • Dumping syndrome common • Most complicated of weight loss surgeries
Combination of Restrictive and Malabsorptive Surgery		
Roux-en-Y Gastric Bypass (RYGB) (Fig. 45.8D)		
• Surgery on stomach to create a pouch (restrictive) • Small gastric pouch connected to jejunum • Remaining stomach and first segment of small intestine are bypassed (malabsorptive)	• Better weight loss results than with restrictive procedures • Lower incidence of malnutrition and diarrhea • Rapid improvement of weight-related co-morbidities • Good long-term results	• Leak at site of anastomosis can occur • Nutrition problems include anemia (iron deficiency, cobalamin deficiency, folic acid deficiency); calcium deficiency • Dumping syndrome common • Not reversible
Other		
Gastric Pacemaker (Gastric Electrical Stimulation Device) (Fig. 45.9)		
• Device implanted into abdomen • Works like a pacemaker to deliver electrical impulses to vagus nerve, which tells brain when stomach is full	• Least invasive of weight loss surgeries • Procedure done on outpatient basis	• Must charge device 1–2 times/week • If battery completely drained, device must be reprogrammed • Side effects include nausea, vomiting, heartburn, belching, swallowing problems

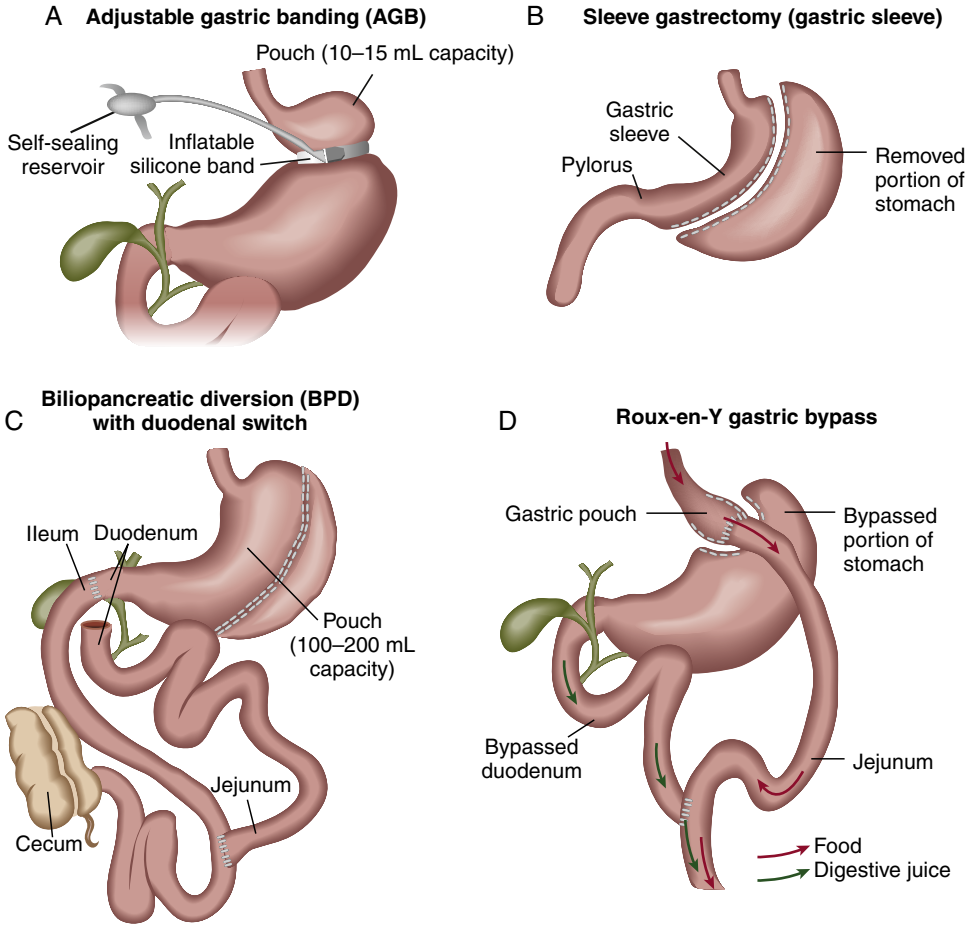

Fig. 45.8 Bariatric surgical procedures. (A) Adjustable gastric banding (AGB) uses a band to create a gastric pouch. (B) Sleeve gastrectomy involves creating a sleeve-shaped stomach by removing about 75% of the stomach. (C) Biliopancreatic diversion *(BPD)* with duodenal switch procedure creates an anastomosis between the stomach and intestine. (D) Roux-en-Y gastric bypass procedure involves constructing a gastric pouch whose outlet is a Y-shaped limb of small intestine.

amount allowed to enter the stomach. Digestion is not altered, so the risk for anemia or cobalamin deficiency is low. The most common restrictive surgeries include adjustable gastric banding and sleeve gastrectomy.

Adjustable Gastric Banding

Adjustable gastric banding (AGB) involves limiting the stomach size with an inflatable band placed around the fundus of the stomach (Fig. 45.8A). The band is connected to a subcutaneous port that can be inflated or deflated (by fluid injection in the HCP's office) to meet the patient's needs. The band divides the stomach into 2 unequal parts. The upper part acts as the new stomach. Because it holds much less, the patient feels full more quickly. The band also causes a delay in stomach emptying, providing patients with further satiety.

AGB can be either modified or reversed at a later date if needed. AGB is the preferred option for patients who are surgical risks because it is done laparoscopically. Risks include the band slipping and some food intolerance. Because it is restrictive only, patients must follow a strict diet to lose, and not regain, the weight.

Sleeve Gastrectomy (Gastric Sleeve)

In the sleeve gastrectomy (gastric sleeve), about 75% of the stomach is removed, leaving a sleeve-shaped stomach (Fig. 45.8B). While the stomach is drastically reduced in size, its function is preserved. Removing most of the stomach eliminates hormones made in the stomach that stimulate hunger, such as ghrelin.

An *endoscopic sleeve gastroplasty* is a minimally invasive procedure that requires no resection or bypass of the GI tract. The HCP places sutures endoscopically in the stomach, making it smaller and changing its shape.

Gastric Plication

Gastric plication is similar to a gastric sleeve in that it reduces the size of the stomach. It is done by folding the stomach wall inward and then placing sutures to secure the folded stomach wall. An advantage is reversibility since there is no gastric resection.

Intragastric Balloons

Intragastric balloon systems use an inflated balloon to occupy space in the stomach. The balloon does not change the stomach's

anatomy. It is meant to help patients feel more full and reduce the amount of food they can eat.

Balloons are less invasive than having gastric bypass surgery. Several different balloons are available. They differ in volume, means of insertion and removal, duration used, and adjustability. Fluid-filled balloons are placed endoscopically with the patient under mild sedation. Once in place, the balloon is filled with saline so that it expands. They can be filled with different amounts of saline (from 400 to 700 mL).

With air balloons, the patient swallows the balloon in a capsule that is attached to a thin catheter. The balloon is inflated with nitrogen gas through the catheter. After inflation, the catheter is detached and removed, leaving the balloon in the stomach. When it is time to remove either type of balloon, it is first deflated and then removed under endoscopy.

Balloons should not be used in patients who have had GI surgery or have inflammatory bowel disease, large hiatal hernia, delayed gastric emptying, or active *Helicobacter pylori* infection. Patients may have vomiting, nausea, abdominal pain, and indigestion. Other risks are gastric ulcers and changes in balloon size.

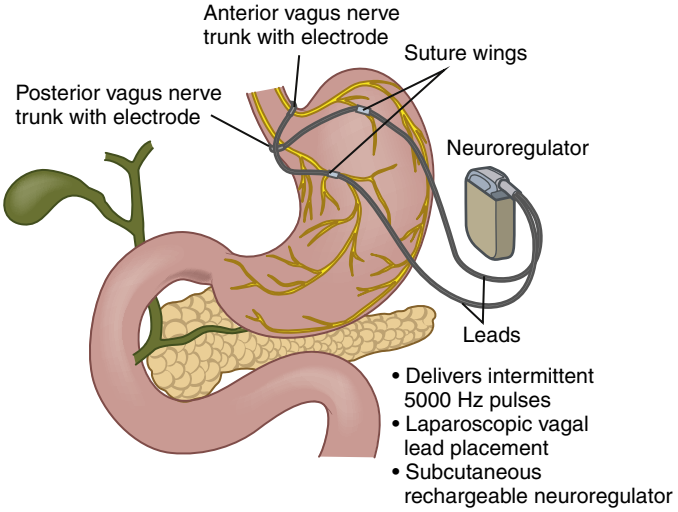

Fig. 45.9 Gastric pacemaker system. An electrical stimulator is surgically implanted into the abdomen. It sends intermittent electrical pulses to the vagus nerve, which is involved in regulating stomach emptying and signaling to the brain that the stomach feels empty or full.

Combination of Restrictive and Malabsorptive Surgery

Roux-en-Y Gastric Bypass

The Roux-en-Y gastric bypass (RYGB) procedure is a combination of restrictive and malabsorptive surgery. The RYGB involves creating a small gastric pouch and attaching it directly to the small intestine using a Y-shaped limb of the small bowel (Fig. 45.8D). After the procedure, food bypasses 90% of the stomach, the duodenum, and a small segment of the jejunum.

Many complications can occur, including GI tract leaks, gastric remnant distention, ulcers, gallstones, and hernias. Because sections of the small intestine are bypassed, poor iron absorption can cause iron deficiency anemia. Patients need to take a multivitamin with iron and calcium supplements. Chronic anemia caused by cobalamin deficiency may occur. This problem can usually be managed with parenteral or intranasal cobalamin.

Another complication is *dumping syndrome,* in which gastric contents empty too rapidly into the small intestine, overwhelming its ability to digest nutrients. Symptoms can include vomiting, nausea, weakness, sweating, faintness, and, on occasion, diarrhea. Patients are discouraged from eating sugary foods after surgery to avoid dumping syndrome.

Other Bariatric Procedures

A gastric pacemaker, or gastric electrical stimulation, controls nerve impulses from the brain to the stomach. It is an implantable pacemaker-like device surgically placed under the skin in the abdomen with lead wires around the vagus nerve just above the stomach (Fig. 45.9). The device sends signals to block vagus nerve impulses, resulting in decreased hunger and increased satiety. External controllers allow the patient to charge the device and HCPs to adjust the device's settings.

Aspiration therapy involves removing a portion of gastric contents 20 to 30 minutes after each meal through a modified percutaneous endoscopic gastrostomy tube. It requires significant patient engagement because the patient is responsible for taking the time to manually perform the procedure.

NURSING MANAGEMENT: PERIOPERATIVE CARE OF THE PATIENT WITH OBESITY

This section discusses general nursing considerations for the care of a patient with obesity who is having surgery. Special nursing considerations are described for the patient who is having bariatric surgery (Table 45.10). See Chapters 18 through 20 for more on the care of the surgical patient.

Preoperative Care

Special considerations are needed for the patient with obesity, especially extreme obesity, who is having surgery. Before surgery, interview the patient to obtain past and current health information and any assistive devices currently in use (e.g., continuous positive airway pressure [CPAP] for sleep apnea). Focus on identifying comorbidities that increase the risk for complications in the perioperative period. You may need to coordinate care with the patient's specialists.

Have a plan in place before the patients arrive so that they receive optimal care and do not feel embarrassed. You must have available appropriately sized hospital gowns, beds, and commodes that accommodate an increased body size and necessary patient transfer equipment. Use a larger BP cuff size to avoid measurement errors. Ensure that the cuff is available and placed in the patient's room.

Consider how the patient will be weighed and transported throughout the hospital. A wheelchair with removable arms that is large enough to safely accommodate the patient and pass easily through doorways should be available.

TABLE 45.10 NURSING MANAGEMENT

Care of the Patient Undergoing Bariatric Surgery

Preoperative

- Assess for use of assistive devices. Note any physical limitations or mobility issues.
- Perform baseline assessment, including vital signs, pulse oximetry, height, weight, BMI, skin condition, nutrition status, and heart, lung, and bowel sounds.
- Assess baseline laboratory values and diagnostic test results (e.g., pulmonary function tests).
- Teach patient and caregiver about the procedure and postoperative care. Review coughing and deep breathing techniques, incentive spirometer use, and methods of turning and positioning to prevent pulmonary complications.
- Explain the need for frequent assessment and interventions to prevent VTE.
- Have available proper-sized hospital gowns, beds, BP cuffs, and transfer equipment.

Immediate Postoperative

- Perform assessment and compare to baseline: vital signs, pulse oximetry, and heart and lung sounds.
- Assess abdominal wound for the amount and type of drainage, condition of the incision, and signs of infection.
- Observe for anastomosis leak (tachycardia, fever, tachypnea, chest and abdominal pain).
- Help patient turn, cough and deep breath, and use incentive spirometer at least every 2 hr.
- Protect the incision against any straining that accompanies turning and coughing.
- Give pain medications as needed.
- Position the patient upright at a minimum of a 45-degree angle.
- Maintain IV and/or oral fluid intake and monitor urine output.
- Institute measures to prevent VTE.
- Nutrition
  - Start with room temperature water and low-sugar clear liquids.
  - Teach the patient to avoid drinking with a straw.
  - Begin with 15 mL every 10–15 min, gradually increase to 90 mL every 30 min.
  - Move to a low-fat, full-liquid diet after 48 hr if tolerating clear liquids.
  - Observe for dehydration (thirst, decreased urine output, headache, dizziness).

You may need to use different assessment techniques to assess heart, lung, and bowel sounds. For example, because of the large chest wall, breath and heart sounds are often distant. You can use an electronic stethoscope to amplify lung, heart, and bowel sounds. Excess adipose tissue may make obtaining venous access difficult. A longer IV catheter is helpful (longer than 1 in) to go through the overlying tissue to the vein. It is important that the cannula is far enough into the vein, so it does not dislodge or infiltrate.

Teach the patient coughing and deep breathing techniques and methods of turning and positioning to prevent pulmonary complications after surgery. If possible, show how to use a spirometer before surgery. Spirometer use helps prevent and treat postoperative lung congestion. Practicing these strategies beforehand can help the patient perform them correctly after surgery. If the patient uses CPAP at home for sleep apnea, arrange for CPAP use while the patient is hospitalized.

Special Considerations for Bariatric Surgery

Ensure that the patient scheduled for bariatric surgery understands the surgical procedure. Your teaching depends on the type of procedure and surgical approach (Table 45.9). Stress that we will frequently assess vital signs and general assessment to monitor for complications. Tell the patient that we will help them with ambulation soon after surgery. They will be encouraged to cough and deep breathe to prevent pulmonary complications.

Postoperative Care

The initial postoperative care focuses on careful assessment and immediate intervention for cardiopulmonary complications. The transfer from surgery may require many staff members. During the transfer, keep the patient's airway stabilized.

The body stores anesthetics in adipose tissue. This places the patient with excess adipose tissue at risk for resedation. As adipose cells release anesthetics back into the bloodstream, the patient may become sedated after surgery. If this happens, be prepared to perform a head-tilt or jaw-thrust maneuver. Keep the patient's oral and nasal airways open.

Obesity can cause a patient's breathing to become shallow and rapid. The extra adipose tissue in the chest and abdomen compresses the diaphragm, thoracic, and abdominal structures. This compression restricts the chest's ability to expand, preventing the lungs from working as efficiently as they would otherwise. The patient retains more CO_2 with less O_2 delivered to the lungs. This results in hypoxemia. Keep the head of the bed elevated to reduce abdominal pressure and increase lung expansion.[17] Administer O_2 therapy as needed.

Implement venous thromboembolism (VTE) precautions. Diligence in turning and ambulation postoperatively will help prevent complications. The patient will typically begin walking the evening after surgery and then at least 3 or 4 times each day. Help the patient as needed. The patient may be reluctant to move or may not have the stamina to walk even a short distance. Have proper help and equipment when moving the patient.

Wound infection, dehiscence, and delayed healing are potential problems. Assess the patient's skin often. Keep skin folds clean and dry to prevent dermatitis and bacterial or fungal infections. Implement measures to reduce the risk of pressure injury.

Special Considerations for Bariatric Surgery

Patients have significant abdominal pain after bariatric surgery (Table 45.10). Give pain medications as needed. Be aware that pain could be from an anastomosis leak rather than typical surgical pain. Abdominal wounds require frequent observation for the amount and type of drainage, condition of the incision, and signs of infection. Monitor vital signs to help identify problems, such as infection or anastomosis leak.

The patient usually starts a low-sugar, clear-liquid diet within 24 hours after surgery. Begin with 15-mL increments every 10 to 15 minutes. If the patient does not have any nausea or other problems, gradually increase intake to a goal of 90 mL every 30 minutes. Teach the patient to avoid gulping fluids or drinking with a straw to reduce the incidence of air swallowing. Avoid

drinks with caffeine. The patient who tolerates clear liquids is advanced to a low-calorie, full-liquid diet.

Ambulatory and Home Care

The patient who is having bariatric surgery has not been successful in the past in following or maintaining a prescribed diet. Now the patient must reduce oral intake because of the anatomic changes from their surgery. The patient must clearly understand their diet. A dietitian is usually part of the bariatric team and helps the patient with the transition to the new diet.

Patients usually are discharged on a full liquid diet. Within 10 to 14 days after surgery, depending on tolerance, the patient may begin a pureed or soft foods diet with vitamin supplementation.[18] Most patients transition to the usual diet 4 to 6 weeks after surgery.

The usual diet is high in protein with some carbohydrates and fiber. It should consist of 6 small feedings daily. Many need a protein supplement once or twice a day for the first few months after surgery to meet their protein needs. Patients should not consume fluids with meals. Fluids and foods high in carbohydrates tend to promote diarrhea and dumping syndrome. Calorie-dense foods should be avoided to permit more nutritious food to be consumed. Teach the patient to eat slowly and stop eating when feeling full. The person cannot overeat or binge eat without consequences, such as vomiting and abdominal pain.

Stress the importance of long-term follow-up care, in part because of potential complications. Teach patients to inform the HCP of any changes in their physical or emotional condition. Nutrition deficiencies are expected after malabsorptive bariatric surgery, including anemia, vitamin deficiencies, and diarrhea. Patients should take multivitamins with folate, calcium, vitamin D, iron, and vitamin B_{12} for life.[18] Peptic ulcer formation, dumping syndrome, and small bowel obstruction may be seen late in the recovery and rehabilitation stage.

Several potential psychologic problems may arise after surgery. Assess social functioning, self-esteem, sexual life, and activities of daily living in follow-up care. Some patients feel guilty that they had to achieve weight loss by having surgery rather than the "willpower" of reduced diet intake and exercise. Be ready to provide support and assist the patient in moving away from such negative feelings.

By 6 to 8 months after surgery, most patients have lost considerable weight and are able to see how much their appearance has changed. Help the patient adjust to a new body image. Massive weight loss may leave the patient with large quantities of flabby skin that can result in problems related to altered body image (Fig. 45.10). Discuss this possible outcome with the patient before surgery and again during the rehabilitation phase. Cosmetic surgery may help with this situation. Do not hesitate to encourage counseling for unresolved psychologic issues.

Often one result of bariatric surgery is the return of fertility in women. Women must carefully consider the risk for pregnancy after bariatric surgery. Pregnancy complications can result from anemia and nutrition deficiencies. Depending on the type of surgery, intestinal obstructions and hernias may occur with pregnancy. In general, encourage women to postpone pregnancy for 12 to 18 months after bariatric surgery.

Fig. 45.10 (A) Preoperative view of a 37-year-old woman with massive weight loss who had gastric bypass surgery. (B) View 2½ years after abdominoplasty. She had breast surgery, thigh lift, back lift with excision of excess skin of the lower back and upper buttocks, and upper arm surgery. (From Shermak MA: Contouring the epigastrium, *Aesthet Surg J.* 25:506, 2005.)

CHECK YOUR PRACTICE

You are working in the bariatric surgery outpatient clinic. When you walk into the clinic room where a 36-year-old woman is waiting for her follow-up visit, you find her distraught and crying. You ask her what is wrong. She responds, "I am a total failure. I have been fat all my life, and I had to have this horrible surgery to help me. Why couldn't I do it on my own?"

- How can you handle this situation?

Evaluation

The expected outcomes are that the patient with obesity will:

- Achieve and maintain optimal weight
- Have improvement in obesity-related comorbidities
- Integrate healthy practices into daily routines
- Be free from adverse side effects of surgery
- Have an improved self-image

Gerontologic Considerations: Obesity in Older Adults

The prevalence of obesity is increasing in older people. The number of obese older persons has markedly risen because of increases in both the total number of older persons and the percent of the older adults who are obese. Obesity is more common in older women than in older men. A decrease in energy expenditure is an important contributor to a gradual increase in body fat with age.

Obesity in older adults can worsen age-related declines in physical function and lead to frailty and disability. Obesity is associated with decreased survival. Those who are obese live 6 to 7 years less than people of normal weight.

Obesity worsens many changes associated with aging. Excess body weight places more demands on arthritic joints. The mechanical strain on weight-bearing joints can lead to

premature immobility. Excess intraabdominal weight can cause problems with urinary incontinence. Excess weight may contribute to hypoventilation and sleep apnea.

Obesity affects the quality of life for older adults. Weight loss can improve physical functioning and obesity-related health complications. The same therapeutic approaches for obesity discussed earlier also apply to older adults.

COSMETIC SURGERY

Lipectomy

A **lipectomy** (adipectomy) is the surgical removal of excess skin and adipose tissue. It is often done on the abdomen of people who are obese or have lost a lot of weight to remove flabby folds of tissue (Fig. 45.10). Other areas such as the waist, hips, back, buttocks, breasts, and arms may also be targeted. Body image and self-esteem usually improve after surgery. A lipectomy is not without complications. Monitor afterward for the effects of anesthesia and the potential for poor wound healing and infection. Stress to the patient that tissue removal does not prevent obesity from recurring, especially if eating habits stay the same.

Liposuction

Another cosmetic surgical procedure is liposuction, a suction-assisted lipectomy. This surgery helps improve facial appearance or body contours. A good candidate is a person who has excess fat under the chin, along the jawline, in the nasolabial folds, over the abdomen, or around the waist and upper thighs. A long, hollow, stainless steel cannula is inserted through a small incision over the fatty tissue to be suctioned. This procedure is not usually recommended for an older person because the skin is less elastic and will not accommodate the new underlying shape.

METABOLIC SYNDROME

Metabolic syndrome is a group of metabolic risk factors that increase a person's chance of developing CVD, stroke, and diabetes. Just over 1 in 3 adults have metabolic syndrome. The prevalence is 50% for those 60 years of age and older. We are seeing the number of persons aged 20 to 39 years with metabolic syndrome steadily increasing.[19] Metabolic syndrome is diagnosed if a person has 3 or more of the conditions listed in Table 45.11. These include obesity, hypertension, abnormal lipid levels, and high glucose.

Etiology and Pathophysiology

The main underlying risk factor for metabolic syndrome is insulin resistance related to excess visceral fat (Fig. 45.11). Insulin resistance is the decreased ability of the body's cells to respond to the action of insulin. The pancreas compensates by secreting more insulin, resulting in hyperinsulinemia.

Other characteristics include hypertension, increased risk for clotting, and abnormal cholesterol levels. The net effect of these states is an increased prevalence of coronary artery disease.

Clinical Manifestations

The signs of metabolic syndrome are impaired fasting glucose, hypertension, abnormal cholesterol levels, and obesity. Medical problems develop over time if the condition is not addressed.

TABLE 45.11 Diagnostic Criteria

Metabolic Syndrome

Any 3 of the 5 measures are needed to diagnose metabolic syndrome:

Measure	Criteria
Waist circumference	≥40 in (102 cm) in men ≥35 in (89 cm) in women
Triglycerides	>150 mg/dL (1.7 mmol/L) *OR* Drug treatment for high triglycerides
HDL cholesterol	<40 mg/dL (0.9 mmol/L) in men <50 mg/dL (1.1 mmol/L) in women *OR* Drug treatment for high cholesterol
BP	≥130 mm Hg systolic BP *OR* ≥85 mm Hg diastolic BP *OR* Drug treatment for hypertension
Fasting glucose	≥100 mg/dL *OR* Drug treatment for elevated glucose

Pathophysiology map

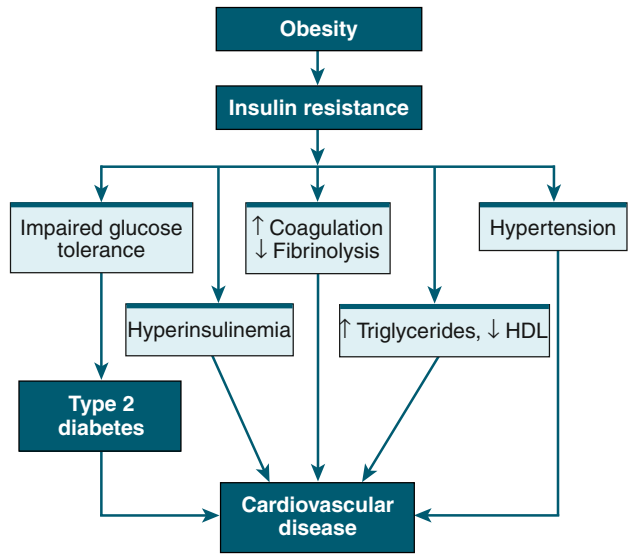

Fig. 45.11 Relationship among insulin resistance, obesity, diabetes, and CVD.

Patients are at a higher risk for heart disease, stroke, diabetes, renal disease, and polycystic ovary syndrome. Patients who have metabolic syndrome and smoke are at an even higher risk.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: METABOLIC SYNDROME

There is no specific management of metabolic syndrome. The adoption of a healthy lifestyle is the cornerstone of treatment. Other interventions focus on weight loss and controlling risk factors for CVD and type 2 diabetes. The person needs to

maintain a healthy weight, increase exercise, and follow healthy diet habits.

You can help patients by giving information on healthy diets, exercise, and smoking cessation. The diet, which should be low in saturated fats, should promote weight loss. Weight loss and maintaining a lower weight are a priority in those with abdominal obesity and metabolic syndrome.

Because sedentary lifestyles contribute to metabolic syndrome, increasing regular exercise will lower a patient's risk factors. In addition to helping with weight loss, regular exercise decreases triglyceride levels and increases HDL cholesterol levels in those with metabolic syndrome.

There are no specific medications for metabolic syndrome. Patients may receive drugs to lower cholesterol and BP as needed. Metformin (Glucophage) can lower glucose levels and enhance the cells' sensitivity to insulin. Patients with obesity may be candidates for bariatric surgery.

Case Study

Obesity

(© Thinkstock.)

Patient Profile

S.R. is a 48-year-old woman who comes to the clinic reporting hip pain.

Subjective Data

- States that it is "getting hard to get around"
- Reports gradual weight gain of 40 lb over past 20 years
- Lives in a rural community with no sidewalks
- Spends her free time watching television
- Reports a history of type 2 diabetes, shortness of breath, hypertension, osteoarthritis
- Had knee replacement surgery at age 46 for osteoarthritis
- Tried orlistat (Xenical) but hated the side effects

Objective Data

Physical Assessment

- 5 ft, 6 in tall; weighs 230 lb; BMI 37 kg/m^2, waist circumference of 40 in
- Has obese, nontender, soft, round abdomen
- BP 160/100 mm Hg
- Moderate pain with range of motion of both hips

Laboratory Results

- Fasting glucose 250 mg/dL (13.9 mmol/L)
- Total cholesterol 205 mg/dL (5.3 mmol/L)
- Triglyceride 298 mg/dL (3.36 mmol/L)
- HDL cholesterol 31 mg/dL (0.8 mmol/L)
- LDL cholesterol 114 mg/dL

Interprofessional Care

- Referral to a community weight loss program
- Consultation with bariatric surgeon
- Diagnosed with bilateral osteoarthritis of the hips

Discussion Questions

1. ***Recognize:*** What risk factors may have led to S.R.'s obesity?
2. ***Analyze:*** Based on the assessment, what complications of obesity does S.R. have? Why did she develop them?
3. ***Analyze:*** Describe the significance of her laboratory results.
4. ***Plan:*** Is S.R. a candidate for bariatric surgery? Why or why not?
5. ***Plan:*** How could a comprehensive community weight loss program be beneficial to S.R.?
6. ***Prioritize:*** What are her priority clinical problems?
7. ***Act:*** What teaching would you provide as part of an effective weight loss program?
8. ***Evaluate:*** What parameters do you need to continue to monitor?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which statement *best* describes the cause of obesity?
- **a.** Obesity primarily results from a genetic predisposition.
- **b.** Psychosocial factors can override the effects of genetics in causing obesity.
- **c.** Genetic factors are more important than environmental factors in causing obesity.
- **d.** Obesity is the result of complex interactions between genetic and environmental factors.

2. Health risks associated with obesity include *(select all that apply)*
- **a.** colorectal cancer.
- **b.** rheumatoid arthritis.
- **c.** polycystic ovary syndrome.
- **d.** nonalcoholic steatohepatitis.
- **e.** systemic lupus erythematosus.

3. The obesity classification that is *most* often associated with cardiovascular health problems is
- **a.** primary obesity.
- **b.** secondary obesity.
- **c.** gynoid fat distribution.
- **d.** android fat distribution.

4. The *best* nutrition therapy plan for a person who is obese
- **a.** is high in animal protein.
- **b.** is fat-free and low in carbohydrates.
- **c.** restricts intake to under 800 calories per day.
- **d.** lowers calories with foods from all the basic groups.

5. This bariatric surgical procedure involves creating a gastric pouch that is reversible, and no malabsorption occurs. Which procedure is this?
- **a.** Vertical gastric banding
- **b.** Biliopancreatic diversion
- **c.** Roux-en-Y gastric bypass
- **d.** adjustable gastric banding

6. A patient with extreme obesity has undergone Roux-en-Y gastric bypass surgery. In planning postoperative care, the nurse expects that the patient
   a. may have severe diarrhea early in the postoperative period.
   b. will not be allowed to ambulate for 1 to 2 days postoperatively.
   c. will have small amounts of oral liquids within the first 24 hours.
   d. will require nasogastric suction until the drainage is pale yellow.
7. Which criteria must be met for a diagnosis of metabolic syndrome? *(select all that apply)*
   a. Hypertension
   b. High triglycerides
   c. Elevated plasma glucose
   d. Increased waist circumference
   e. Decreased low-density lipoproteins

1. d; 2. a, c, d; 3. d; 4. d; 5. d; 6. c; 7. a, b, c, d.

LEARNING OUTCOMES

1. Describe the etiology, complications, and interprofessional and nursing management of nausea and vomiting.
2. Discuss the etiology, clinical manifestations, and interprofessional and nursing management of common oral inflammations and infections.
3. Describe the etiology, clinical manifestations, complications, and interprofessional and nursing management of oral cancer.
4. Explain the types, pathophysiology, clinical manifestations, complications, and interprofessional and nursing management of gastroesophageal reflux disease and hiatal hernia.
5. Relate the pathophysiology, clinical manifestations, complications, and interprofessional management of esophageal cancer, diverticula, achalasia, and esophageal strictures.
6. Compare acute and chronic gastritis, including the etiology, pathophysiology, and interprofessional and nursing management.
7. Distinguish gastric and duodenal ulcers, including the etiology, pathophysiology, clinical manifestations, complications, and interprofessional and nursing management.
8. Outline the clinical manifestations and interprofessional and nursing management of stomach cancer.
9. Explain the common etiologies, clinical manifestations, and interprofessional and nursing management of upper gastrointestinal bleeding.
10. Identify common types of foodborne illnesses and nursing responsibilities related to food poisoning.

KEY TERMS

achalasia
Barrett esophagus
dysphagia
esophageal cancer
esophagitis
gastritis
gastroesophageal reflux disease (GERD)
hiatal hernia
nausea
peptic ulcer disease (PUD)
stomach (gastric) cancer
stress-related mucosal disease (SRMD)
vomiting

This chapter reviews several upper gastrointestinal (GI) problems and the care of the patient undergoing upper GI surgery. These include nausea and vomiting, oral and gastric cancers, gastroesophageal reflux, ulcerative disease, inflammatory and infectious bowel disorders, GI bleeding, and structural problems. Conceptually, patients with impaired GI function may have malnutrition from decreased intake. Many are at risk for altered fluid, electrolyte, and acid-base balance. Problems with eating, drinking, or talking may cause pain and impair the ability to communicate. Pain can disrupt sleep and cause fatigue. Problems swallowing increase the risk for aspiration.

NAUSEA AND VOMITING

Nausea and vomiting are the most common manifestations of GI disease. Although nausea and vomiting can occur

independently, they are closely related and usually treated as one problem. **Nausea** is a feeling of discomfort in the epigastrium with a conscious desire to vomit. **Vomiting** is the forceful ejection of partially digested food and secretions *(emesis)* from the upper GI tract.

Etiology and Pathophysiology

Nausea and vomiting occur in a wide variety of GI problems and in many conditions unrelated to GI disease. These include pregnancy, infection, central nervous system (CNS) problems (e.g., meningitis, tumor), and cardiovascular disease (CVD) (e.g., myocardial infarction, heart failure). They can occur with psychologic states (e.g., stress, fear) or when the GI tract becomes overly irritated, excited, or distended. Patients may have nausea and vomiting after surgery with general anesthesia or as a drug side effect (e.g., chemotherapy, opioids). Women are more likely to have nausea and vomiting associated with anesthesia and motion sickness.[1]

A vomiting center in the medulla coordinates the multiple components involved in vomiting. This center receives input from various stimuli. Neural impulses reach the vomiting center via afferent pathways through branches of the autonomic nervous system. Receptors for these afferent fibers are found in the GI tract, kidneys, heart, and uterus. When stimulated, these receptors relay information to the vomiting center, which then initiates the vomiting reflex (Fig. 46.1).

Vomiting is a complex act. It requires the coordinated activity of several structures: closure of the glottis, deep inspiration with contraction of the diaphragm in the inspiratory position, closure of the pylorus, relaxation of the stomach and lower esophageal sphincter (LES), and contraction of the abdominal muscles with increasing intraabdominal pressure. These simultaneous activities force the stomach contents up through the esophagus, into the pharynx, and out the mouth.

The chemoreceptor trigger zone (CTZ), found in the brainstem, responds to chemical stimuli from drugs, toxins, and labyrinthine stimulation (e.g., motion sickness). Once stimulated, the CTZ transmits impulses directly to the vomiting center. This activates the autonomic nervous system, resulting in both parasympathetic and sympathetic stimulation. Sympathetic activation causes tachycardia, tachypnea, and diaphoresis. Parasympathetic stimulation causes relaxation of the LES, an increase in gastric motility, and increased saliva.

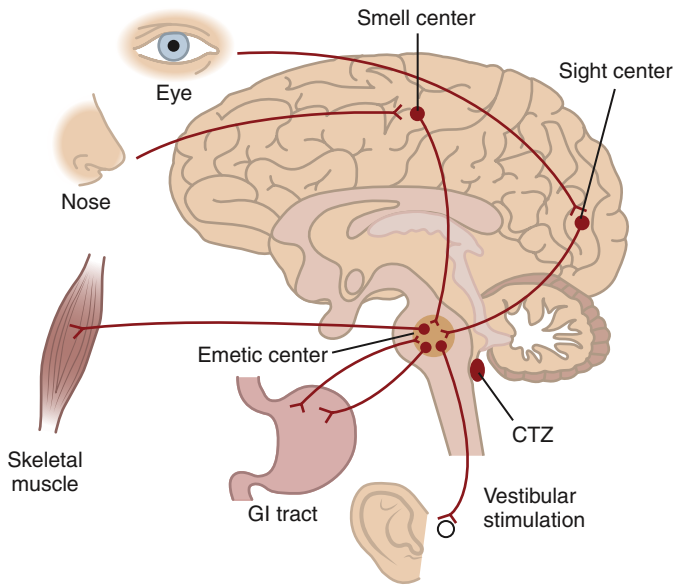

Fig. 46.1 Stimuli involved in the act of vomiting. *CTZ,* Chemoreceptor trigger zone.

Clinical Manifestations

Nausea is subjective. *Anorexia* (lack of appetite) usually accompanies nausea. When nausea and vomiting occur over a long period, dehydration can develop rapidly. Water and essential electrolytes (e.g., potassium, sodium, chloride) are lost. As vomiting persists, the patient may have severe electrolyte imbalances, fluid volume loss, and, eventually, circulatory failure.

Metabolic alkalosis can result from loss of gastric hydrochloric (HCl) acid. Metabolic acidosis can occur with vomiting of small intestine contents. However, metabolic acidosis is less common than metabolic alkalosis. Weight loss resulting from fluid loss can occur in a short time with severe vomiting.

Interprofessional Care

In managing nausea and vomiting, the goals of care are to determine and treat the underlying cause, recognize and correct any complications, and provide symptomatic relief.

Drug Therapy

The use of drugs to treat nausea and vomiting depends on the cause (Table 46.1). Many antiemetic drugs act in the CNS via the CTZ to block the neurochemicals that trigger nausea and vomiting. When the cause has not been determined, use drugs with caution. Using antiemetics before knowing the cause can mask the underlying problem and delay diagnosis and treatment.

DRUG ALERT

Promethazine

- Avoid parenteral routes because of the risk for severe tissue injury.
- Use oral or rectal formulations.

5-HT_3 (Serotonin) receptor antagonists are effective in reducing chemotherapy-induced vomiting (CINV), postoperative nausea and vomiting (PONV), and nausea and vomiting related to migraine headache and anxiety. Dexamethasone is given with other antiemetics to manage acute and delayed CINV.[2] Neurokinin-1 receptor antagonists (NK_1RAs) (e.g., aprepitant [Emend], rolapitant [Varubi]) can treat CINV and PONV.

DRUG ALERT

Metoclopramide (Reglan)

- Chronic use or high doses carry the risk for tardive dyskinesia.
- Tardive dyskinesia is a neurologic condition characterized by involuntary and repetitive movements of the body (e.g., extremity movements, lip smacking).
- It may persist after stopping the drug.

TABLE 46.1 Drug Therapy

Nausea and Vomiting

Drug	Mechanism of Action	Side Effects
Anticholinergics		
scopolamine transdermal	Block cholinergic pathways to vomiting center	Dry mouth, somnolence
Antihistamines		
dimenhydrinate (Dramamine) diphenhydramine hydroxyzine meclizine (Antivert)	Block histamine receptors that trigger nausea and vomiting	Dry mouth, hypotension, sedation, rashes, constipation
Cannabinoids		
dronabinol (Marinol) nabilone (Cesamet)	Inhibit vomiting control mechanism in the medulla oblongata	Dry mouth, amnesia, ataxia, confusion, coordination problems, dizziness, somnolence
Corticosteroids		
dexamethasone	Not well understood how it prevents nausea and vomiting	Hyperglycemia, insomnia, euphoria
Dopamine D2/D3 Receptor Antagonist		
amisulpride (Barhemsys)	Block dopaminergic receptors in the CTZ	Chills, hypokalemia, hypotension, abdominal distention
5-HT_3 (Serotonin) Antagonists		
granisetron ondansetron (Zofran) palonosetron (Aloxi)	Block action of serotonin	Constipation, diarrhea, headache, fatigue, malaise, ↑ liver function tests
Phenothiazines		
chlorpromazine prochlorperazine promethazine	Act in the CNS level of the CTZ. Block dopamine receptors that trigger nausea and vomiting	Dry mouth, hypotension, sedation, rashes, constipation
Prokinetic		
metoclopramide (Reglan)	Inhibit action of dopamine. ↑ Gastric motility and emptying	CNS side effects ranging from anxiety to hallucinations, extrapyramidal side effects, including tremor and dyskinesias
Substance P/Neurokinin-1 Receptor Antagonists		
aprepitant (Emend) netupitant and palonosetron (Akynzeo) rolapitant (Varubi)	Block interaction of substance P at NK-1 receptor	Headache, hiccups, fatigue, constipation, diarrhea, anorexia

An oral cannabinoid (e.g., dronabinol) may be part of the plan to manage CINV. Because of the potential for abuse and sedation, this is an option only when other therapies are not effective.

❖ NURSING MANAGEMENT: NAUSEA AND VOMITING

◆ Assessment

Each patient with prolonged or persistent nausea or vomiting needs a thorough assessment. You need to be able to identify the patient who is at high risk. Assess the patient for precipitating factors and describe the contents of the emesis. Table 46.2 presents subjective and objective data to obtain from a patient with nausea and vomiting.

When food is the precipitating cause of nausea and vomiting, help the patient identify the specific food. Determine when it was eaten, prior history with the food, and whether anyone else who ate the food is sick. Emesis containing partially digested food several hours after a meal indicates gastric outlet obstruction or delayed gastric emptying. The presence of fecal odor and bile after prolonged vomiting suggests intestinal obstruction below the level of the pylorus. Bile in the emesis suggests obstruction below the ampulla of Vater.

The color of the emesis helps determine the presence and source of any bleeding. Bright red blood occurs with active bleeding. This could be due to a *Mallory-Weiss tear* (disruption of the mucosal lining near the esophagogastric junction), esophageal varices, gastric or duodenal ulcer, or cancer. Vomitus with a "coffee-grounds" appearance is related to gastric bleeding. The blood changes to dark brown because of its interaction with HCl acid.

Discern among vomiting, regurgitation, and projectile vomiting. *Regurgitation* is an effortless process in which partially digested food slowly comes up from the stomach. Retching or vomiting rarely occurs before it. *Projectile vomiting* is a forceful expulsion of stomach contents without nausea. It often occurs with brain and spinal cord tumors.

TABLE 46.2 NURSING ASSESSMENT

Nausea and Vomiting

Subjective Data

Important Health Information

Health history: GI problems, chronic indigestion, food allergies, pregnancy, infection, CNS problems, recent travel, eating disorders, metabolic problems, cancer, CVD, renal disease

Medications: Antiemetics, digitalis, opioids, ferrous sulfate, aspirin, aminophylline, alcohol, antibiotics, chemotherapy. General anesthesia

Surgery or other treatments: Recent surgery

Functional Health Patterns

Nutritional-metabolic: Amount, frequency, character, and color of vomitus. Dry heaves. Anorexia, weight loss

Activity-exercise: Weakness, fatigue

Cognitive-perceptual: Abdominal tenderness or pain

Coping–stress tolerance: Stress, fear

Objective Data

General

Lethargy, sunken eyeballs

GI

Amount, frequency, character (e.g., projectile), content (undigested food, blood, bile, feces), and color of vomitus (red, coffee-grounds, green-yellow)

Skin

Pallor, dry mucous membranes, poor skin turgor

Urinary

Decreased output, concentrated urine

Possible Diagnostic Findings

Altered serum electrolytes (especially hypokalemia), metabolic alkalosis, abnormal upper GI findings on endoscopy or abdominal x-rays

The timing of nausea and vomiting can help determine its cause. Early morning vomiting is common in pregnancy. Emotional stressors may elicit vomiting during or right after eating. Those with *cyclic vomiting syndrome* have recurring episodes of nausea, vomiting, and fatigue that last from a few hours up to 10 days.

Clinical Problems

Clinical problems for the patient with nausea and vomiting may include:

- Fluid imbalance
- Electrolyte imbalance
- Nutritionally compromised
- Impaired GI function

More information on clinical problems and interventions are in eNursing Care Plan 41.1 (available on the website for this chapter).

Planning

The overall goals are that the patient with nausea and vomiting will (1) have minimal or no nausea and vomiting, (2) have normal electrolyte levels and hydration status, and (3) return to their normal fluid and nutrient intake.

Implementation

Acute Care

Most people with nausea and vomiting are at home. When symptoms persist, the patient may need hospitalized to diagnose the underlying problem. Until we confirm a diagnosis, the patient is NPO and given IV fluids. The patient with persistent vomiting, a possible bowel obstruction, or paralytic ileus may need a nasogastric (NG) tube connected to suction to decompress the stomach. Secure the NG tube to prevent its movement in the nose and back of the throat. This can stimulate nausea and vomiting.

With prolonged vomiting, there is a chance of dehydration and acid-base and electrolyte imbalances. Record intake and output. Monitor vital signs and assess for signs of dehydration. Maintain a quiet, odor-free environment. Provide oral care. Observe for changes in mentation. Pulmonary aspiration is a concern when vomiting occurs in older or unconscious patients or in those with an impaired gag reflex. To prevent aspiration, put the patient who cannot manage self-care in a semi-Fowler's or side-lying position.

Nutrition Therapy

The patient with severe vomiting needs IV fluid therapy with electrolyte and glucose replacement until able to tolerate oral intake. Start oral nutrition beginning with clear liquids once symptoms have subsided. A patient may be reluctant to resume intake because of fear of symptoms recurring. Water is the initial fluid of choice for oral rehydration. Have the patient sip small amounts of room temperature fluids (5 to 15 mL) every 15 to 20 minutes. Other options include carbonated beverages with the carbonation removed at room temperature and warm tea. Very hot or cold liquids are often hard to tolerate. Broth and sports drinks (e.g., Gatorade) are high in sodium, so give them with caution. Dry toast, crackers, and plain gelatin may be helpful.

As the patient's condition improves, provide a diet high in carbohydrates and low in fat. Bland foods, such as a baked potato, rice, cooked chicken, and cereal, are ideal. Many patients do not tolerate coffee, spicy foods, highly acidic foods, and those with strong odors. Tell the patient to eat food slowly and in small amounts to prevent stomach distension. Liquids taken between meals rather than with meals reduce distention. Consult a dietitian about nutritious foods that the patient can tolerate.

CHECK YOUR PRACTICE

You are caring for a newly admitted 76-year-old man who reports vomiting for the past 3 days. He says, "I cannot keep anything down, not even water."

- What assessment do you need to perform?
- What findings would show he is dehydrated?
- What are your priority nursing interventions?

Ambulatory Care

Teach the patient and caregiver (1) how to manage nausea, (2) ways to prevent nausea and vomiting, and (3) how to maintain fluid and nutrition intake. Tell them to keep the immediate environment quiet, free of noxious odors, and well ventilated. Avoiding sudden changes of position and unnecessary activity are helpful. Encourage the use of relaxation techniques, frequent rest periods, and diversion. Provide effective pain management. Cleansing the

TABLE 46.3 Oral Infections and Inflammation

Infection or Inflammation	Cause	Manifestations	Treatment
Aphthous stomatitis (canker sore)	• Recurrent and chronic form of infection • Related to systemic disease, trauma, stress, or unknown causes	• Painful ulcers of mouth and lips • White or gray shallow ulcer surrounded by redness	• Corticosteroids (topical or systemic) • Tetracycline oral suspension
Gingivitis	• Neglected oral hygiene, malocclusion, missing or irregular teeth, faulty dentistry • Eating soft rather than fibrous foods	• Inflamed gingivae and interdental papillae • Bleeding during tooth brushing • Development of pus, abscess formation with loosening of teeth (periodontitis)	• Prevention through health teaching, dental care, gingival massage, professional cleaning of teeth • Eat fibrous foods • Conscientious brushing habits with flossing
Herpes simplex (cold sore, fever blister) (see Table 25.6)	• Herpes simplex virus (type 1 or 2) • Risk factors of upper respiratory tract infections, excessive exposure to sunlight, food allergies, emotional tension, onset of menstruation	• Lip lesions, mouth lesions, vesicle formation (single or clustered) • Shallow, painful ulcers	• Spirits of camphor, corticosteroid cream, mild antiseptic mouthwash, viscous lidocaine • Remove or control risk factors • Antiviral agents (e.g., acyclovir, valacyclovir)
Oral candidiasis (moniliasis or thrush)	• *Candida albicans* (yeastlike fungus) • Debilitation • Prolonged high-dose antibiotic or corticosteroid therapy	• Pearly, bluish white "milk-curd" membranous lesions on mucosa of mouth and larynx • Sore mouth, yeasty halitosis	• Miconazole buccal tablets (Oravig) • Nystatin or amphotericin B as oral suspension or buccal tablets • Good oral hygiene
Parotitis (inflammation of parotid gland, surgical mumps)	• *Staphylococcus* species usually • *Streptococcus* species occasionally • Debilitation and dehydration with poor oral hygiene • Extended NPO status	• Pain in area of gland and ear • Absence of salivation • Purulent exudate from gland, redness, ulcers	• Antibiotics, mouthwashes, warm compresses • Preventive measures, such as chewing gum, sucking on hard candy • Adequate fluid intake
Stomatitis (inflammation of mouth)	• Trauma, pathogens, irritants (tobacco, alcohol) • Renal, liver, hematologic diseases • Side effect of chemotherapy and radiation	• ↑ Saliva • Halitosis • Sore mouth	• Remove or treat cause • Oral hygiene with soothing solutions, topical medications • Soft, bland diet
Vincent's infection (acute necrotizing ulcerative gingivitis, trench mouth)	• Fusiform bacteria, Vincent spirochetes • Risk factors of stress, excessive fatigue, poor oral hygiene • Nutrition deficiencies (B and C vitamins)	• Painful, bleeding gingivae • Eroding necrotic lesions of interdental papillae • Ulcers that bleed • ↑ Saliva with metallic taste, fetid mouth odor • Anorexia, fever, malaise	• Physical and mental rest • Avoid smoking and alcohol • Soft, nutritious diet • Correct oral hygiene habits • Topical applications of antibiotics • Mouth irrigations with chlorhexidine and saline solutions

face and hands with a cool washcloth and providing mouth care between episodes increase the person's comfort level. When symptoms occur, stop all foods and drugs until the acute phase is over.

If you suspect a medication is the cause, notify the HCP at once. The HCP may change the dose or prescribe a new drug. Tell the patient that stopping the drug without consulting the HCP may have adverse effects on their health. The patient should take an antiemetic drug only if prescribed by the HCP. Taking over-the-counter (OTC) drugs to relieve symptoms may make the problem worse.

Some patients find that acupressure or acupuncture at specific points reduces PONV.[3] Others use herbs, such as ginger and peppermint oil. Changes in body position or exercise may help some patients.

Evaluation

Expected outcomes for the patient with nausea and vomiting include:

- Be comfortable, with minimal or no nausea and vomiting
- Have normal electrolyte levels
- Able to maintain adequate intake of fluids and nutrients

Gerontologic Considerations: Nausea and Vomiting

The older adult with nausea and vomiting needs careful assessment and monitoring, especially during periods of fluid loss and rehydration therapy. They are more likely to have heart or renal problems that place them at greater risk for life-threatening fluid and electrolyte imbalances. Excess fluid and electrolyte replacement may have adverse consequences for a person with heart failure or renal disease. The older adult with a decreased level of consciousness has a high risk for aspirating.

Older adults are especially susceptible to the CNS side effects of antiemetic drugs. These drugs may cause confusion and increase fall risk. Doses should be reduced, and efficacy closely evaluated. Use safety precautions.

ORAL INFLAMMATION AND INFECTIONS

Oral inflammations and infections are shown in Table 46.3. They may be due to specific mouth diseases or related to systemic problems, such as leukemia or vitamin deficiency. The patient who is immunosuppressed (e.g., receiving chemotherapy) or using corticosteroid inhalant treatment for asthma is at

risk for oral infections (e.g., candidiasis). Oral infections may predispose the patient to infections in other body organs. For example, the oral cavity is a potential reservoir for respiratory pathogens. Oral pathogens are associated with diabetes and heart disease.[4]

Managing oral problems focuses on identifying the cause, eliminating infection, providing comfort measures, and maintaining intake. They can severely impair oral intake. Regular and good oral and dental hygiene reduces oral infections and inflammation.

ORAL CANCER

There are 2 types of oral cancer: *oral cavity cancer,* which starts in the mouth, and *oropharyngeal cancer*. It develops in the part of the throat just behind the mouth (the oropharynx). *Head and neck squamous cell carcinoma* (HNSCC) is a broad term used for cancers of the oral cavity, pharynx, and larynx. Most oral cancer lesions occur on the lower lip. Other common sites are the lateral border and undersurface of the tongue, labial commissure, and buccal mucosa. Each year 51,540 Americans are diagnosed with oral cancer. An estimated 10,030 people die.[5]

Oral cancer is more common after age 35. The average age at diagnosis is 65 years. It is 2 times more common in men than in women (Box 46.1). The 5-year survival rate is 84% for localized cancer and 65% for all stages of oral cavity and pharynx cancer combined.[5] Lip cancer has the most favorable prognosis. The visibility of lip lesions usually leads to an earlier diagnosis.

BOX 46.1 PROMOTING HEALTH EQUITY

Oral, Pharyngeal, and Esophageal Problems

Oral Cancer
- Incidence and mortality rates are highest in Black men
- Death rates are decreasing in whites and increasing in nonwhites

Esophageal Cancer
- Highest incidence is in non-Hispanic white men
- Lowest incidence occurs in Asian Americans, Pacific Islanders, and Hispanics

Stomach Cancer
- Asian Americans and Pacific Islanders, Blacks, and Hispanics have the highest rates
- Asian Americans have the highest survival rates

Etiology and Pathophysiology

We do not know the exact cause of oral cancer. There are several risk factors (Table 46.4). About 75% to 90% report a history of either tobacco or frequent alcohol use. More than 30% of patients with lip cancer have outdoor occupations, showing that prolonged exposure to sunlight is a risk factor. Irritation from the pipe stem resting on the lip is a factor in pipe smokers. Human papillomavirus (HPV) contributes to 25% of oral cancer cases. HPV-associated oropharyngeal cancer is associated with multiple sexual partners, especially multiple oral sex partners.[6]

Clinical Manifestations

Common manifestations are shown in Table 46.4. Patients may report nonspecific symptoms such as chronic sore throat, sore mouth, and voice changes. *Leukoplakia,* called "smoker's patch," is a white patch on the mouth mucosa or tongue. It is a precancerous lesion, with 15% transforming into cancer. The patch becomes *keratinized* (hard and leathery), which is called hyperkeratosis. Leukoplakia results from chronic irritation, especially from smoking. *Erythroplasia* (erythroplakia), a red velvety patch on the mouth or tongue, is another precancerous lesion. More than 50% of cases of erythroplasia progress to squamous cell cancer. About 30% of patients with oral cancer have an asymptomatic neck mass.

Lip cancer usually appears as an indurated, painless ulcer on the lip. The first sign of tongue cancer is an ulcer or area of thickening. The tongue may be sore or painful, especially when eating hot or highly seasoned foods. Lesions are most likely to develop in the proximal half of the tongue. Some patients have limited tongue movement. Later symptoms include increased saliva, slurred speech, **dysphagia** (difficulty swallowing), toothache, and earache.

Diagnostic Studies

Diagnostic tests can identify oral dysplasia, which is a precursor to oral cancer (Table 46.5). Oral exfoliative cytologic study involves scraping the suspicious lesion and spreading the scraping on a slide for microscopic examination. The toluidine blue test is a screening test for oral cancer. When toluidine blue is

TABLE 46.4 Types and Characteristics of Oral Cancer

Location	Risk Factors	Manifestations	Treatment
Lip	Constant overexposure to sun, ruddy and fair complexion, recurrent herpetic lesions, pipe stem irritation, syphilis, immunosuppression	Indurated, painless ulcer	Surgery, radiation
Oral cavity	Poor oral hygiene, tobacco usage (pipe and cigar smoking, snuff, chewing tobacco), chronic alcohol use, chronic irritation (jagged tooth, ill-fitting prosthesis, chemical or mechanical irritants), HPV	Leukoplakia, erythroplakia, ulcers, sore spot, rough area, pain, dysphagia, a lump or thickening in the cheek A sore throat or a feeling that something is stuck Difficulty chewing and speaking (later signs)	Surgery (mandibulectomy, radical neck dissection, resection of buccal mucosa), internal and external radiation
Tongue	Tobacco and alcohol use, chronic irritation, syphilis	Ulcer or area of thickening, soreness, or pain Limited tongue movement ↑ Saliva, slurred speech, dysphagia, toothache, earache (later signs)	Surgery (hemiglossectomy or glossectomy), radiation

applied topically to stain an area, cancer cells take up the dye. A negative cytologic smear or negative toluidine blue test does not necessarily rule out cancer. Once cancer is diagnosed, CT scan, MRI, and positron emission tomography (PET) are used for staging cancer.

Interprofessional Management: Oral Cancer

Management usually consists of surgery, radiation, chemotherapy, or a combination of these. The curative treatments are usually surgery and radiation.

Surgical Therapy

Surgery is the most effective treatment, especially for early-stage disease.[7] The procedure done depends on the location and extent of the tumor. Some patients with small tumors in the mouth and throat are candidates for minimally invasive robotic-assisted surgery. However, many surgeries are radical procedures involving extensive resections. Some examples are partial *mandibulectomy* (removal of the mandible), *hemiglossectomy* (removal of half of the tongue), *glossectomy* (removal of the tongue), resections of the buccal mucosa and floor of the mouth, and radical neck dissection.

Radical neck dissection includes wide excision of the primary lesion with removal of the regional lymph nodes, the deep cervical lymph nodes, and their lymphatic channels. The structures that are removed or transected depend on the extent of the primary lesion. They include the sternocleidomastoid muscle and other closely associated muscles, internal jugular vein, mandible, submaxillary gland, part of the thyroid and parathyroid glands, and spinal accessory nerve. The patient usually has a tracheostomy. Drainage tubes inserted into the surgical area are connected to suction to remove fluid and blood. Head and neck surgery is described in more detail in Chapter 29.

Nonsurgical Therapy

Radiation therapy may be used alone to treat small cancers or when lesions cannot be removed. Patients usually do not have radiation before surgery because it is hard to remove radiated tissue. The tissue becomes fibrotic and heals slower. Most patients begin radiation about 6 weeks after surgery.

TABLE 46.5 Interprofessional Care

Oral Cancer

Diagnostic Assessment
- History and physical assessment
- Biopsy
- Oral exfoliative cytology
- Toluidine blue test
- CT, MRI, PET scans

Management
- Surgical excision
- Radiation therapy
- Chemotherapy
- Nutrition therapy

Chemotherapy can shrink lesions before surgery, decrease metastasis, sensitize cancer cells to radiation, or treat distant metastases. Common chemotherapy drugs include fluorouracil, cisplatin, carboplatin, paclitaxel, docetaxel, and hydroxyurea. A common combination is cisplatin and fluorouracil.[8] This combination is more effective than either drug alone. Chemotherapy is discussed in Chapter 16.

Palliative treatment is the best management when the prognosis is poor, the cancer is inoperable, or the patient decides against surgery. Palliation aims to treat the symptoms and make the patient more comfortable. If it becomes hard for the patient to swallow, placing a gastrostomy tube will allow for adequate nutrition intake. Give analgesic drugs freely. Frequent suctioning of the oral cavity is needed when swallowing becomes difficult. Other palliative and end-of-life nursing measures are discussed in Chapter 10.

Nutrition Therapy

Many patients are malnourished before surgery. They may need placement of a percutaneous endoscopic gastrostomy (PEG) and enteral nutrition (EN) before radiation treatment or surgery. After radical neck surgery, the patient may be unable to ingest nutrients orally because of mucositis, swelling, location of sutures, or problems swallowing. Parenteral nutrition (PN) is given for the first 24 to 48 hours. After that time, EN is given via NG, gastrostomy, or jejunostomy tube. See Chapter 44 for information on EN. Cervical esophagostomy and pharyngostomy are options for some patients.

Assess for feeding tolerance. Adjust the amount, time, and formula if nausea, vomiting, diarrhea, or distention occurs. Give small amounts of water when the patient can swallow. Observe for choking. Suction as needed to prevent aspiration.

❖ NURSING MANAGEMENT: ORAL CANCER

◆ Assessment

Subjective and objective data to obtain from a patient with oral cancer are outlined in Table 46.6.

◆ Clinical Problems

Clinical problems for the patient with oral cancer may include:
- Nutritionally compromised
- Pain
- Difficulty coping

◆ Planning

The overall goals are that the patient with cancer of the oral cavity will (1) have a patent airway, (2) be able to communicate, (3) have adequate intake to maintain nutrition, and (4) have relief of pain and discomfort.

◆ Implementation

You play a key role in the early detection and treatment of oral cancer. Identify patients at risk (Table 46.4) and provide information about risk factors (Box 46.2). Review information about smoking cessation with the patient who smokes or uses snuff or chewing tobacco.

TABLE 46.6 NURSING ASSESSMENT

Oral Cancer

Subjective Data

Important Health Information

Health history: Recurrent oral herpetic lesions, HPV infection or vaccination, syphilis, exposure to sunlight

Medications: Immunosuppressants

Surgery or other treatments: Removal of prior tumors or lesions

Functional Health Patterns

Health perception–health management: Alcohol and tobacco use, pipe smoking. Poor oral hygiene

Nutritional-metabolic: Reduced oral intake, weight loss, difficulty chewing food, increased saliva, intolerance to some foods or temperatures of food

Cognitive-perceptual: Mouth or tongue soreness or pain, toothache, earache, neck stiffness, dysphagia, difficulty speaking

Objective Data

GI

Areas of thickening or roughness, ulcers, leukoplakia, or erythroplakia on the tongue or oral mucosa. Limited tongue movement. Increased saliva, drooling. Slurred speech. Foul breath odor

Skin

Indurated, painless ulcer on lip. Painless neck mass

Possible Diagnostic Findings

Positive exfoliative smear cytology (microscopic examination of cells removed by scraping), positive biopsy

BOX 46.2 PROMOTING POPULATION HEALTH

Health Impact of Good Oral Hygiene

- Improves quality of life
- Lowers risk for teeth loss
- Reduces pain and disability
- Aids in early detection of oral and craniofacial cancers
- Decreases cost of care needed from dental professionals
- Decreases risk for periodontal disease, gingivitis, and dental caries

Early detection of oral cancer is important. Teach the patient to report unexplained pain or soreness of the mouth, unusual bleeding, dysphagia, sore throat, voice changes, or swelling or lump in the neck. Refer any person with an ulcerative lesion that does not heal within 2 to 3 weeks to the HCP.

Preoperative care for the patient who will have a radical neck dissection must consider the patient's physical and psychosocial needs. Physical preparation is the same as that for any major surgery, with special emphasis on oral hygiene. Include information on postoperative communication and feeding. See Chapter 29 for more information about the nursing management of a patient undergoing a radical neck dissection.

Evaluation

Expected outcomes for the patient with oral cancer include:

- Have no respiratory complications
- Be able to communicate

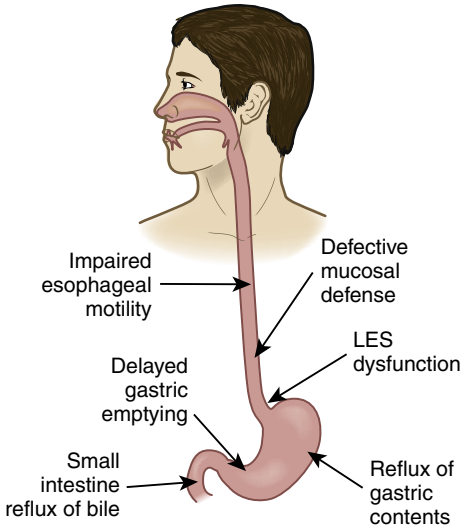

Fig. 46.2 Factors involved in the pathogenesis of GERD.

- Maintain an adequate intake to maintain nutrition
- Have minimal pain and discomfort with eating, drinking, and talking

ESOPHAGEAL PROBLEMS

GASTROESOPHAGEAL REFLUX DISEASE

Gastroesophageal reflux disease (GERD) is a symptom of mucosal damage caused by reflux of stomach acid into the lower esophagus. GERD is not a disease but a syndrome. It is the most common upper GI problem. About 15 million Americans have GERD symptoms each day.[9]

Etiology and Pathophysiology

GERD has no one single cause (Fig. 46.2). GERD results when the reflux of acidic gastric contents into the esophagus overwhelms the esophageal defenses. Gastric HCl acid and pepsin secretions in refluxate cause esophageal irritation and inflammation *(esophagitis)*. If it contains intestinal proteolytic enzymes (e.g., trypsin) and bile, this further irritates the esophageal mucosa. The degree of inflammation depends on the amount and composition of the gastric reflux and on the esophagus's mucosal defense mechanisms.

One of the primary factors causing GERD is an incompetent LES. Normally, the LES acts as an antireflux barrier. An incompetent LES lets gastric contents move from the stomach to the esophagus when the patient is supine or has an increase in intraabdominal pressure.

Decreased LES pressure can be due to certain foods and drugs (Table 46.7). Obesity is a risk factor. In an obese person the intraabdominal pressure increases, which can worsen GERD. Cigarette and cigar smoking can contribute to GERD. Hiatal hernia, discussed in the next section, often causes GERD. Some drugs, such as nonsteroidal antiinflammatory drugs (NSAIDs) and potassium, can irritate the esophageal mucosa, causing *medication-induced esophagitis.*

TABLE 46.7 Factors Affecting Lower Esophageal Sphincter Pressure

Decrease Pressure

- Alcohol
- Chocolate (theobromine)
- Drugs
  - Anticholinergics
  - β-Adrenergic blockers
  - Calcium channel blockers
  - Diazepam (Valium)
  - Morphine sulfate
  - Nitrates
  - Progesterone
  - Theophylline
- Fatty foods
- Nicotine
- Peppermint, spearmint
- Tea, coffee (caffeine)

Increase Pressure

- Bethanechol (Urecholine)
- Metoclopramide (Reglan)

Clinical Manifestations

The symptoms of GERD vary from person to person. We consider persistent mild symptoms (more than twice a week) or moderate to severe symptoms once a week as GERD.

Heartburn *(pyrosis)* is the most common symptom. Heartburn is a burning, tight sensation felt intermittently beneath the lower sternum and spreading upward to the throat or jaw. It may occur after ingesting food or drugs that decrease the LES pressure or directly irritate the esophageal mucosa. An HCP should evaluate heartburn that occurs more than twice a week, is severe, is associated with dysphagia, or occurs at night and wakes a person from sleep. Older adults who report the recent onset of heartburn should receive medical evaluation.

GERD-related chest pain can mimic angina. It is described as burning, squeezing, or radiating to the back, neck, jaw, or arms. Chest pain is more common in older adults with GERD. Unlike angina, antacids relieve GERD-related chest pain.

Patients may have dyspepsia or regurgitation. *Dyspepsia* is pain or discomfort centered in the upper abdomen (mainly in or around the midline). Regurgitation is described as hot, bitter, or sour liquid coming into the throat or mouth.

A person with GERD may report respiratory symptoms, including wheezing, coughing, and dyspnea. Nighttime discomfort and coughing can awaken the person, resulting in disturbed sleep. Otolaryngologic symptoms include hoarseness, sore throat, a *globus sensation* (sense of a lump in the throat), hypersalivation, and choking.

Complications

Complications are due to the direct local effects of gastric acid on the esophageal mucosa. **Esophagitis** (inflammation of the esophagus) is a common complication of GERD. Ulcers with esophagitis may be present (Fig. 46.3). Repeated esophagitis may lead to scar tissue formation, stricture, and dysphagia.

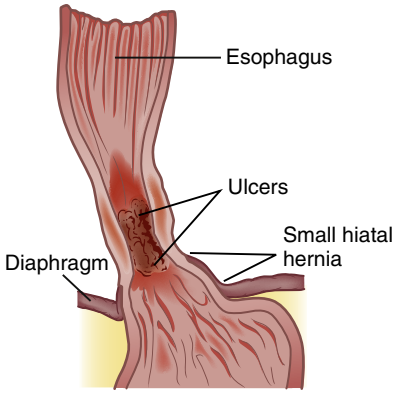

Fig. 46.3 Esophagitis with esophageal ulcers.

A complication of chronic GERD is **Barrett esophagus (BE)** (esophageal metaplasia). *Metaplasia* is the reversible change from one type of cell to another type because of an abnormal stimulus. In BE, the flat epithelial cells in the distal esophagus change into columnar epithelial cells. These cell changes are primarily due to GERD. However, some people with no history of GERD develop BE.

About 5% to 30% of people with chronic GERD have BE.[10] Other risk factors include being over age 60, being male, being white, and having central obesity. BE is a precancerous lesion that increases the patient's risk for esophageal cancer. Because of this risk, those with BE undergo surveillance endoscopy or radiofrequency ablation as needed.

Respiratory complications include cough, bronchospasm, laryngospasm, and cricopharyngeal spasm. These are due to gastric secretions irritating the upper airway. Asthma, chronic bronchitis, and pneumonia may develop from aspiration. Dental erosion, especially in the posterior teeth, may result from acid reflux into the mouth.

Diagnostic Studies

GERD is often diagnosed based on symptoms and the patient's response to behavioral and drug therapies. Diagnostic tests are done when usual therapy is ineffective or when we suspect complications (Table 46.8).

Endoscopy is useful in assessing LES competence and the degree of any inflammation, scarring, and strictures. Biopsy and cytologic specimens can distinguish stomach or esophageal cancer from BE. In addition, the degree of dysplasia (low grade versus high grade) is determined. Manometric studies measure pressure in the esophagus and LES and esophageal motility function. Ambulatory esophageal pH monitoring is an option for those with refractory symptoms and no evidence of mucosal inflammation. Radionuclide tests can detect reflux of gastric contents and the rate of esophageal clearance.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: GERD

Most patients with GERD can successfully manage the condition through lifestyle modifications, drug therapy, and nutrition therapy. These approaches require patient teaching and

TABLE 46.8 Interprofessional Care

GERD and Hiatal Hernia

Diagnostic Assessment

- History and physical assessment
- Upper GI endoscopy with biopsy and cytologic analysis
- Esophagram (barium swallow)
- Motility (manometry) studies
- pH monitoring (laboratory or 24 hr ambulatory)
- Radionuclide studies

Management

Conservative

- Elevate head of bed 30 degrees
- Avoid reflux-inducing foods (fatty foods, chocolate, peppermint)
- Avoid alcohol
- Reduce or avoid acidic pH beverages (colas, red wine, orange juice)

Drug Therapy (Table 46.10)

- PPIs
- H_2 receptor blockers
- Antacids
- Prokinetics

Surgical Therapy

- Nissen fundoplication
- Toupet fundoplication

Endoscopic Therapy

- Intraluminal valvuloplasty
- Radiofrequency ablation

TABLE 46.9 PATIENT & CAREGIVER TEACHING

GERD

Include the following instructions when teaching the patient and caregiver about managing GERD:

1. Follow a low-fat diet.
2. Eat small, frequent meals to prevent gastric distention.
3. Avoid alcohol and beverages that contain caffeine.
4. Stopping smoking causes an almost immediate, marked decrease in LES pressure.
5. Do not lie down for 2–3 hr after eating, wear tight clothing around the waist, or bend over, especially after eating.
6. Avoid eating within 3 hr of bedtime.
7. Sleep with head of bed elevated 30 degrees. Use on 4- to 6-in blocks or pillows.
8. Implement measures to reduce weight, if needed.
9. Share concerns about lifestyle changes and living with a chronic illness.

adherence to therapies. When these therapies are ineffective, surgery is an option (Table 46.8).

Lifestyle Modifications

Teach the patient with GERD to avoid factors that trigger symptoms. They should elevate the head of the bed 30 degrees. This can be done using pillows or with 4- to 6-in blocks under the bed. The patient should not be supine for 2 to 3 hours after a meal. A patient and caregiver teaching guide is shown in Table 46.9.

Encourage patients who smoke to stop. If needed, refer the patient to community resources for help in stopping smoking. If stress causes symptoms, teach ways to cope with stress (see Chapter 7). Discuss ways to maintain healthy weight, decrease alcohol use, and increase physical activity.

Drug Therapy

Drug therapy for GERD focuses on decreasing the volume and acidity of reflux, improving LES function, increasing esophageal clearance, and protecting the esophageal mucosa (Table 46.10). Proton pump inhibitors (PPIs) and histamine (H_2) receptor blockers are the most common and effective treatments for symptomatic GERD.[10] The goal of HCl acid suppression treatment is to reduce the acidity of the gastric refluxate. Patients with symptomatic GERD but not esophagitis *(nonerosive GERD)* achieve symptom relief with PPIs and H_2 receptor blockers.

Both PPIs and H_2 receptor blockers are available in prescription or OTC preparations. Teach the patient about side effects. Tell the patient to take medications as prescribed and not to stop without checking with the HCP. Have patients contact the HCP if symptoms persist.

PPIs are more effective in healing esophagitis than H_2 receptor blockers. Therapy should start with once-daily dosing, taken before the first meal of the day. PPIs decrease the incidence of esophageal strictures, a complication of chronic GERD. Long-term PPI use may decrease bone density, kidney disease, and vitamin B_{12} and magnesium deficiency.[11]

DRUG ALERT

PPIs

- Long-term use or high doses may increase the risk for hip, wrist, and spine fractures.
- Patients should take the lowest dose for the shortest duration needed to treat their condition.

H_2 receptor blockers reduce symptoms and promote esophageal healing in 50% of patients. The onset of action of H_2 receptor blockers is 1 hour. Depending on the specific drug, therapeutic effects last up to 12 hours. We can give famotidine and cimetidine orally or IV. Nizatidine is only available orally. Some preparations combine an H_2 receptor blocker with an antacid. For example, Pepcid Complete includes famotidine, calcium carbonate, and magnesium hydroxide.

Adjunctive treatments include antacids and prokinetic drugs. Antacids produce quick, short-lived relief of heartburn. Common antacids consist of magnesium hydroxide or aluminum hydroxide as single preparations or in various combinations (Table 46.10). The neutralizing effects of antacids taken on an empty stomach last only 20 to 30 minutes. They are most effective taken 1 to 3 hours after meals and at bedtime. When taken after meals, their effects may last 3 to 4 hours.

Antacids may be useful in patients with mild, intermittent heartburn. In patients with moderate to severe or frequent symptoms or patients with esophagitis, antacids are not effective in relieving symptoms or healing lesions. After an acute phase of

TABLE 46.10 Drug Therapy

GERD and Peptic Ulcer Disease

Drug	Mechanism of Action	Side Effects
Proton Pump Inhibitors (PPIs)		
dexlansoprazole (Dexilant) esomeprazole (Nexium) lansoprazole (Prevacid) omeprazole (Prilosec) omeprazole and sodium bicarbonate (Zegerid) pantoprazole (Protonix) rabeprazole (Aciphex)	↓ HCl acid secretion by inhibiting the proton pump (H^+-K^+-ATPase) responsible for the secretion of H^+ ↓ Irritation of the esophageal and gastric mucosa	Headache, abdominal pain, nausea, diarrhea, vomiting, flatulence
Histamine (H_2) Receptor Blockers		
cimetidine famotidine (Pepcid) nizatidine	Block the action of histamine on the H_2 receptors to ↓ HCl acid secretion ↓ Conversion of pepsinogen to pepsin ↓ Irritation of the esophageal and gastric mucosa	Headache, abdominal pain, constipation, diarrhea
Antacids, Acid Neutralizers		
Single Substance aluminum hydroxide (Amphojel) calcium carbonate (Tums) sodium bicarbonate (Alka-Seltzer) ***Aluminum and Magnesium*** Maalox, Mylanta aluminum/magnesium trisilicate (Gaviscon)	Neutralize HCl acid Taken 1–3 hr after meals and at bedtime	*Aluminum hydroxide:* Constipation, phosphorus depletion with chronic use *Calcium carbonate:* Constipation or diarrhea, hypercalcemia, milk-alkali syndrome, renal calculi *Magnesium preparations:* Diarrhea, hypermagnesemia. Use with caution in patients with renal problems *Sodium preparations:* Milk-alkali syndrome if used with large amounts of calcium. Use with caution in patients on sodium restrictions
Cholinergic		
bethanechol	↑ LES pressure, ↑ esophageal emptying, ↑ gastric emptying	Lightheadedness, syncope, flushing, diarrhea, stomach cramps, dizziness
Cytoprotective		
sucralfate (Carafate)	Act to form a protective layer and serve as a barrier against acid, bile salts, and enzymes in the stomach	Constipation
Prokinetic		
metoclopramide (Reglan)	Block effect of dopamine ↑ Gastric motility and emptying ↓ Reflux	CNS side effects ranging from anxiety to hallucinations Extrapyramidal side effects (tremor and dyskinesias similar to Parkinson disease)
Prostaglandin (Synthetic)		
misoprostol (Cytotec)	Protect lining of stomach *Cytoprotective:* Increase production of gastric mucus and mucosal secretion of bicarbonate *Antisecretory:* ↓ HCl acid secretion	Abdominal pain, diarrhea, GI bleeding, uterine rupture if pregnant

bleeding, antacids may be given hourly, either orally or through the NG tube. If an NG tube is in place, periodically aspirate the stomach contents and test the pH level. If pH is less than 5, intermittent suction may be used, or the frequency or dosage of the antacid or antisecretory agent increased.

The type and dosage of antacid given depend on side effects and potential drug interactions. Antacids high in sodium are used cautiously in older adults and patients with CVD, liver, and renal disease. Patients with renal failure should not take magnesium preparations because of the risk for magnesium toxicity. An antacid combination of aluminum and magnesium decreases the side effects of both.

Antacids can interact unfavorably with many drugs. They enhance the effects of some drugs, like benzodiazepines and pseudoephedrine. In many instances, antacids decrease the absorption rates of other drugs, such as thyroid hormones, phenytoin, and tetracycline. Adjust the timing of administering medications as needed.

Prokinetics increase LES pressure and improve gastric emptying, which may result in a small improvement in regurgitation and vomiting. Common agents include cisapride, metoclopramide (Reglan), bethanechol, and baclofen. Many have significant side effects, so their use is limited only to those with delayed gastric emptying.

Nutrition Therapy

No specific diet is used to treat GERD. Some patients may need to avoid foods that decrease LES pressure. These include chocolate, peppermint, fatty foods, coffee, and tea (Table 46.7), Some foods (e.g., tomato-based products, orange juice, cola, red wine) and soda may irritate the esophagus.

Tell the patient to avoid late evening meals, nighttime snacking, and milk, especially at bedtime, since these increase gastric acid secretion. Small, frequent meals and drinking fluids between meals help prevent stomach distention. Increased saliva production by chewing gum and oral lozenges may help with mild symptoms. Recommend weight reduction if the patient is overweight.

Surgical Therapy

Antireflux surgery is reserved for patients with complications, such as esophagitis, medication intolerance, stricture, BE, and persistent severe symptoms. The goal of surgery is to reduce reflux by enhancing LES integrity. Most procedures are done laparoscopically. The fundus of the stomach is wrapped around the lower part of the esophagus to reinforce and repair the defective barrier. Nissen and Toupet fundoplications are common laparoscopic antireflux surgeries.

Laparoscopic fundoplication is often an outpatient procedure. Patients at risk for complications, including those with prior upper abdominal surgeries or co-morbidities (e.g., cardiac disease, obesity), may be hospitalized afterwards. Complications include gastric or esophageal injury, splenic injury, pneumothorax, perforation, bleeding, infection, and pneumonia.

After surgery, reflux symptoms should decrease. However, recurrence is possible. In the first month after surgery, the patient may report mild dysphagia. This is caused by edema and should resolve. Teach the patient to report persistent symptoms, such as heartburn and regurgitation.

A LINX Reflux Management System is an option for patients who have symptoms despite maximum medical management. A LINX system is a ring of small, flexible magnets enclosed in titanium beads and connected by titanium wires. Once implanted laparoscopically into the LES, the ring strengthens the weak LES. Under resting (non-swallowing) conditions, the magnetic attraction between the beads helps keep a weak LES closed to prevent reflux. When the person swallows, the force of pressure from the movement of fluids or foods overwhelms the magnetic forces and the fluid or food passes to the stomach. Problems with the system include nausea, swallowing problems, and pain when swallowing food. Patients who have a LINX system cannot have an MRI as it could cause serious harm.

Endoscopic Therapy

Alternatives to surgery include endoscopic mucosal resection (EMR) and radiofrequency ablation. The heat energy delivered through radiofrequencies creates lesions that we think thicken the LES. For patients with high-grade dysplasia, EMR can be used as a diagnostic test to obtain biopsy samples. Biopsy results determine whether cancer is present.

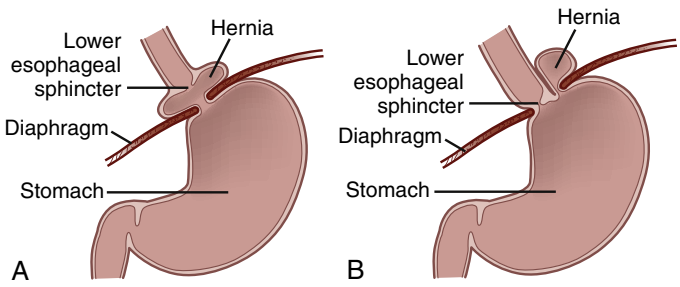

Fig. 46.4 (A) Sliding hiatal hernia. (B) Rolling or paraesophageal hernia.

HIATAL HERNIA

Hiatal hernia is herniation of part of the stomach into the esophagus through an opening, or hiatus, in the diaphragm. We also call it a *diaphragmatic hernia* or *esophageal hernia*. Hiatal hernias are the most common abnormality found on x-ray examination of the upper GI tract. They are common in older adults and occur more often in women.

There are 2 types of hiatal hernias (Fig. 46.4):

1. *Sliding:* The junction of the stomach and esophagus is above the diaphragm. A part of the stomach slides through the hiatal opening in the diaphragm. This occurs when the patient is supine. The hernia usually goes back into the abdominal cavity when the patient is standing upright. This is the most common type.
2. *Paraesophageal* or *rolling:* The fundus and greater curvature of the stomach roll up through the diaphragm, forming a pocket alongside the esophagus. The esophagogastric junction stays in the normal position. Acute paraesophageal hernia is a medical emergency.

Etiology and Pathophysiology

Many factors contribute to the development of a hiatal hernia. Structural changes (weakening of the muscles in the diaphragm around the esophagogastric opening) occur with aging. Factors that increase intraabdominal pressure may predispose patients to developing a hiatal hernia. These include obesity, pregnancy, ascites, tumors, intense physical exertion, and heavy lifting on a continual basis.

Clinical Manifestations and Complications

Some people with hiatal hernia are asymptomatic. When present, manifestations of hiatal hernia are similar to those of GERD.

Complications that may occur include GERD, esophagitis, bleeding from erosion, stenosis (narrowing of the esophagus), ulcerations of the herniated part of the stomach, strangulation of the hernia, and regurgitation with tracheal aspiration.

Diagnostic Studies

An esophagram (barium swallow) may show the protrusion of gastric mucosa through the esophageal hiatus. Endoscopic

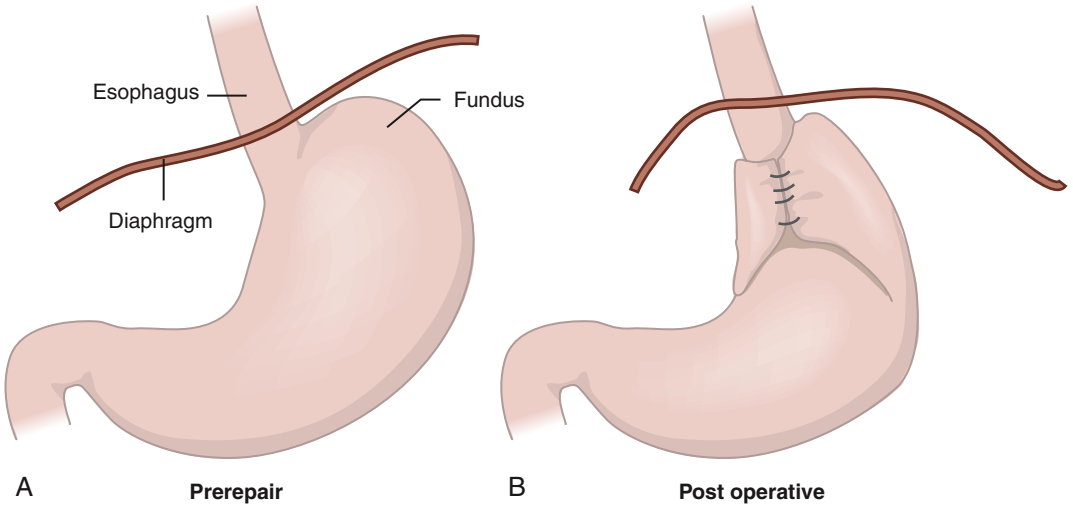

Fig. 46.5 Nissen fundoplication. (A) Fundus of stomach is wrapped around distal esophagus. (B) The fundus is then sutured to itself.

visualization of the lower esophagus gives information on the degree of mucosal inflammation or other abnormalities. Other tests done are the same as those for GERD (Table 46.8).

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: HIATAL HERNIA

Conservative therapy of hiatal hernia is similar to that described for GERD. Teach the patient to reduce intraabdominal pressure by eliminating constricting garments and avoiding lifting and straining.

Surgical treatment includes reducing the herniated stomach into the abdomen, *herniotomy* (excision of the hernia sac), *herniorrhaphy* (closure of the hiatal defect), fundoplication, and *gastropexy* (attachment of the stomach below the diaphragm to prevent re-herniation). The goals are to reduce the hernia, provide an acceptable LES pressure, and prevent movement of the gastroesophageal junction.

Surgery to repair hiatal hernia is often done laparoscopically by either Nissen or Toupet techniques (Fig. 46.5). The approach used (thoracic or abdominal) depends on the patient.

Gerontologic Considerations: GERD and Hiatal Hernia

The incidence of hiatal hernia and GERD increases with age. Hiatal hernia is associated with weakening of the diaphragm, obesity, kyphosis, or other factors that increase intraabdominal pressure. Older patients may take drugs known to decrease LES pressure (e.g., nitrates, calcium channel blockers, antidepressants). Some older adults are asymptomatic or have less severe symptoms. The first sign may be a serious problem, such as esophageal bleeding from esophagitis or respiratory complications (e.g., aspiration pneumonia) due to aspiration of gastric contents.

The clinical course and management of GERD and hiatal hernia in the older adult are similar to those for the younger adult. Changes in lifestyle, including smoking cessation and elevating the head of the bed on blocks, may be challenging for the older adult. Laparoscopic procedures reduce the risk associated with surgical repair. An older patient with heart and lung problems may not be a good candidate for surgical intervention.

ESOPHAGEAL CANCER

Esophageal cancer is not common. However, the rates are increasing. The United States had 18,400 new cases diagnosed and 16,170 deaths occur from esophageal cancer in 2020. The overall 5-year survival rate is 20%.[12]

Most esophageal cancers are adenocarcinomas. The others are squamous cell tumors. Adenocarcinomas arise from the glands lining the esophagus and resemble cancers of the stomach and small intestine. The incidence of esophageal cancer increases with age. Those between 65 and 75 are at greatest risk. The incidence is higher in men.

Etiology and Pathophysiology

The cause of esophageal cancer is unknown. Key risk factors include BE, smoking, excess alcohol use, and obesity. Current smoking or a history of smoking has a twice greater risk for esophageal cancer. Those with injury to the esophageal mucosa (e.g., from occupational exposure to asbestos and cement dust) are at greater risk. *Achalasia,* a condition marked by delayed emptying of the lower esophagus, is associated with squamous cell cancer.

Most esophageal tumors occur in the middle and lower portions of the esophagus. The tumor usually appears as an ulcerated lesion. It may penetrate the muscular layer and extend outside the wall of the esophagus. Many patients have advanced disease at the time of diagnosis. The cancer spreads via the lymph system. The liver and lung are common sites of metastasis.

Clinical Manifestations and Complications

By the time the patient has symptoms, the tumor is often advanced. Progressive dysphagia is the most common symptom. It may be described as a substernal feeling that food is not passing. At first the dysphagia occurs only with meat, then with soft foods, and eventually with liquids.

Pain develops late. It occurs in the substernal, epigastric, or back areas. Pain usually increases with swallowing. It may radiate to the neck, jaw, ears, and shoulders. If the tumor is in the upper third of the esophagus, symptoms, such as sore throat, choking, and hoarseness, may occur. Most patients lose weight. When esophageal stenosis (narrowing) is severe, regurgitation of blood-flecked esophageal contents is common.

Bleeding occurs if the cancer erodes through the esophagus and into the aorta. Esophageal perforation with fistula formation into the lung or trachea sometimes develops. The tumor may enlarge enough to cause esophageal obstruction, especially in the later stages.

Diagnostic Studies

Endoscopic biopsy is needed to diagnose esophageal cancer. Endoscopic ultrasonography (EUS) is important in staging esophageal cancer. Esophagram (barium swallow) may show narrowing of the esophagus at the tumor site (Table 46.11).

Interprofessional Management

Treatment depends on the tumor's location and whether invasion or metastasis is present. Esophageal cancer usually has a poor prognosis because it is often diagnosed at an advanced stage. The best results occur with a multimodal approach, including surgery, endoscopic ablation, chemotherapy, and radiation therapy. Depending on the location and cancer spread, only chemotherapy and radiation may be used. Palliative therapy consists of restoring swallowing function and maintaining nutrition and hydration.

Surgical Therapy

The types of surgical procedures done are (1) removal of part or all the esophagus *(esophagectomy)* with use of a Dacron graft to replace the resected part, (2) resection of a portion of the esophagus and anastomosis of the remaining portion to the stomach *(esophagogastrostomy),* and (3) resection of a portion of the esophagus and anastomosis of a segment of colon to the remaining portion *(esophagoenterostomy).* The surgical approaches may be open (thoracic, abdominal incision) or laparoscopic.

Minimally invasive esophagectomy (e.g., laparoscopic vagal nerve–sparing surgery) is being done more often. The smaller incisions result in decreased intensive care unit (ICU) and hospital stays with fewer pulmonary complications.

TABLE 46.11 Interprofessional Care

Esophageal Cancer

Diagnostic Assessment
- History and physical assessment
- Endoscopy of esophagus with biopsy
- Endoscopic ultrasonography
- Esophagram (barium swallow)
- Bronchoscopy
- CT, MRI, PET scans

Management
- Surgical therapy
  - Esophagectomy
  - Esophagoenterostomy
  - Esophagogastrostomy
- Endoscopic therapy
  - Dilation
  - Endoscopic mucosal resection
  - Laser therapy
  - Photodynamic therapy
  - Radiofrequency ablation
  - Stent or prosthesis placement
- Radiation therapy
- Chemotherapy

Endoscopic Therapy

Endoscopic therapy includes photodynamic therapy, EMR, and radiofrequency ablation. In photodynamic therapy, the patient receives an IV injection of porfimer sodium (Photofrin), a photosensitizer. Although most tissues absorb porfimer, cancer tissue absorbs it to a greater degree. The HCP directs light towards the cancerous area using a fiber passed through an endoscope. The light reacts with porfimer, starting a reaction that destroys the cancer cells. Patients must avoid direct sunlight for up to 6 weeks afterwards.

EMR is an option for some small, very early-stage cancers. It involves removing cancer tissue using an endoscope. Radiofrequency ablation uses electric currents to kill cancer cells by heating them.

Dilation, stent placement, or both can relieve obstruction. Dilation increases the lumen of the esophagus. It often relieves dysphagia and allows for better nutrition. There are various types of dilators. Placement of stents or expandable stents may help when dilation is no longer effective. Stents allow food and liquid to pass through the stenotic area of the esophagus. Self-expandable metal stents are available with features to prevent stent migration and tumor ingrowth. Stents placed before surgery may help improve the patient's nutrition status.

Endoscopic laser therapy may be used in combination with dilation. Laser therapy can be repeated if obstruction recurs as the tumor grows. Sometimes these procedures are combined with radiation therapy.

Radiation Therapy

Depending on the type and stage of esophageal cancer, the patient may receive chemotherapy with or without radiation therapy. Concurrent therapy is given for palliation of symptoms, especially dysphagia, and to increase survival. Some patients receive radiation therapy before surgery.

Chemotherapy

Many different chemotherapy drugs can be used to treat esophageal cancer. Regimens include carboplatin and paclitaxel, cisplatin and irinotecan, and oxaliplatin, paclitaxel, or cisplatin with either fluorouracil or capecitabine. DCF (docetaxel, cisplatin, fluorouracil) is an option for metastatic disease. New therapy focuses on combining chemotherapy with gene therapy. Chemotherapy is discussed in Chapter 16.

Targeted Therapy

Some esophageal cancers have too much HER-2 protein on their cell surfaces, which helps cancer cells to grow. Trastuzumab

(Herceptin) is a drug that targets the HER-2 protein and kills the cancer cells.

Ramucirumab (Cyramza), an angiogenesis inhibitor, binds to the receptor for *vascular endothelial growth factor* (VEGF). It prevents VEGF from binding to the receptor and signaling the body to make more blood vessels. This can help slow or stop the growth and spread of cancer. Ramucirumab treats advanced cancers that start at the gastroesophageal junction. Targeted therapies are discussed in Chapter 16.

Nutrition Therapy

After esophageal surgery, the patient receives IV fluids. A feeding tube may be placed depending on the type of surgery (e.g., esophagogastrectomy). The patient often has a swallowing study before starting oral fluids. When starting fluids, give water (30 to 60 mL) hourly and gradually progress to small, frequent, bland meals. Keep the patient in an upright position for 2 hours after to prevent regurgitation. With EN, observe the patient for signs of intolerance to the feeding or leakage of the feeding into the mediastinum. Symptoms of leakage include pain, fever, and dyspnea (see Chapter 44).

❖ NURSING MANAGEMENT: ESOPHAGEAL CANCER

◆ Assessment

Ask the patient about a history of GERD, hiatal hernia, achalasia, BE, and tobacco and alcohol use. Assess the patient for progressive dysphagia and *odynophagia* (burning, squeezing pain while swallowing). Are there foods or liquids that cause dysphagia? Assess for pain (substernal, epigastric, or back areas), choking, heartburn, hoarseness, cough, anorexia, weight loss, and regurgitation.

◆ Clinical Problems

Clinical problems for the patient with esophageal cancer include:

- Pain
- Nutritionally compromised
- Impaired GI function
- Difficulty coping

◆ Planning

The overall goals are that the patient with esophageal cancer will (1) have relief of symptoms, including pain and dysphagia, (2) achieve optimal nutrition intake, and (3) have a quality of life appropriate to stage of disease and prognosis.

◆ Implementation

◆ Health Promotion

Counsel the patient with GERD, BE, or hiatal hernia about the importance of regular follow-up evaluation. Health counseling should focus on smoking cessation and reducing risk factors for GERD (Table 46.7). Teach the patient to maintain good oral hygiene and diet habits (e.g., intake of fresh fruits and vegetables). Encourage patients to seek medical attention for any esophageal problems, especially dysphagia.

◆ Acute Care

Preoperative care. The patient and caregiver usually react with shock, disbelief, and depression when given the diagnosis of esophageal cancer. Provide emotional and physical support. Clarify test results and provide information. Maintain a positive attitude with respect to the patient's immediate recovery and long-term survival.

Pay attention to the patient's nutrition needs. Many are poorly nourished because of the inability to ingest adequate amounts of food and fluids. A high-calorie, high-protein diet is recommended. Some patients need a liquid form of this diet. Others may need IV fluid replacement or PN. Teach the patient and caregiver how to keep an intake and output record and assess for signs of fluid and electrolyte imbalance. Some treatment protocols include preoperative radiation and chemotherapy.

Meticulous oral care is essential. Cleanse the mouth thoroughly, including the tongue, gingivae, and teeth or dentures. It may be necessary to use swabs or a gauze pad and to scrub the mouth, including the tongue.

Teaching should include information about chest tubes (with a planned open thoracic approach), IV lines, NG tubes, pain management, EN, turning, coughing, and deep breathing. General preoperative care is discussed in Chapter 17.

Postoperative care. During the immediate postoperative period, the patient usually receives care in the ICU for 1 to 2 days. In addition to usual postoperative complications, dysrhythmias may result from the proximity of the pericardium to the surgical site. Other complications include anastomotic leaks, fistula formation, interstitial pulmonary edema, and acute respiratory distress related to the disruption of the mediastinal lymph nodes.

The patient usually has an NG tube in place for 5 to 7 days. The drainage may be bloody for 8 to 12 hours. The drainage gradually changes to greenish yellow. Key nursing actions include assessing the drainage, maintaining the tube, and providing oral and nasal care. Do not irrigate the NG tube, reposition it, or reinsert it without consulting the HCP.

If the chest cavity is entered, postoperative drainage is achieved with chest tube insertion. Assess the amount and type of drainage. Notify the HCP of excess drainage (e.g., over 400 to 600 mL in 8 hours). Chest surgery and drainage tubes are discussed in Chapter 28.

Implement measures to prevent respiratory complications. Have the patient turn, cough and deep breathe, and use an incentive spirometer every 2 hours. Follow VTE prophylaxis measures. Provide effective pain management. Place the patient in a semi-Fowler's or Fowler's position to prevent reflux and aspiration of gastric secretions. When the patient can drink or eat, maintain the upright position for at least 2 hours after eating to assist with gastric emptying.

◆ Ambulatory Care

Many patients need long-term follow-up care after surgery for esophageal cancer. The patient may need chemotherapy and radiation treatment after surgery. Encourage and assist the patient in maintaining adequate nutrition. A permanent feeding gastrostomy may be needed. The patient usually is afraid

and anxious about the cancer diagnosis. Know what the HCP has told the patient about the prognosis and provide appropriate counseling.

Referral to a palliative care or home health nurse may be needed. See Chapter 16 for the care of the cancer patient and Chapter 10 for a discussion of palliative and end-of-life care.

◆ Evaluation

Expected outcomes for the patient with esophageal cancer include:

- Maintain a patent airway
- Have relief of pain
- Be able to swallow comfortably and consume adequate intake
- Have a quality of life appropriate to stage of disease and prognosis

OTHER ESOPHAGEAL DISORDERS

Eosinophilic Esophagitis

Eosinophilic esophagitis (EoE) is characterized by swelling of the esophagus from an infiltration of *eosinophils.* People with EoE often have a personal or family history of other allergic diseases. The most common food triggers are milk, egg, wheat, rye, and beef. Environmental allergens, such as pollens, molds, cat, dog, and dust mite allergens, may be involved.

Patients may have severe heartburn, difficulty swallowing, food impaction in the esophagus, nausea, vomiting, and weight loss. The diagnosis is based on symptoms and biopsy findings of eosinophils infiltrating esophageal tissue obtained from endoscopy.

Allergy skin testing helps to determine the person's allergens. Avoiding the foods to which the person has positive allergy tests is the first treatment. Other common treatments include the use of PPIs (Table 46.10) and corticosteroids. Corticosteroids are used to treat EoE when avoiding allergic triggers does not relieve symptoms.

Corticosteroids may be used orally (prednisone) or as a topical therapy with inhaled corticosteroids (e.g., fluticasone). The patient takes a puff of fluticasone, and rather than inhaling it, swallows the medication. This directly delivers the drug to the esophagus. The most common side effect is a yeast infection of the throat (esophageal candidiasis).

Esophageal Diverticula

Esophageal diverticula are saclike outpouchings of 1 or more layers of the esophagus. They occur in 3 main areas: (1) above the upper esophageal sphincter *(Zenker diverticulum),* which is the most common location, (2) near the esophageal midpoint (traction diverticulum), and (3) above the LES (epiphrenic diverticulum) (Fig. 46.6). Zenker diverticula occur most often in people older than 60 years.

Typical symptoms include dysphagia, regurgitation, chronic cough, aspiration, and weight loss. Food becomes trapped in outpouches. This causes tasting sour food and smelling a foul odor. Complications include malnutrition, aspiration, and perforation. Endoscopy or barium studies can easily establish a diagnosis.

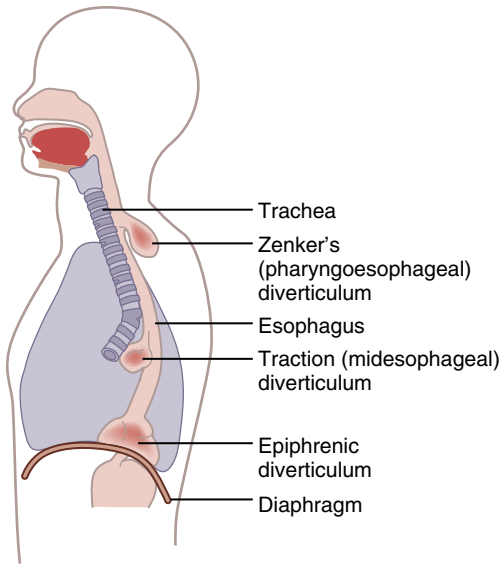

Fig. 46.6 Sites for esophageal diverticula. These hollow outpouchings may occur just above the upper esophageal sphincter (Zenker's), near the midpoint of the esophagus (traction), and just above the LES (epiphrenic).

There is no specific treatment. Some patients find that they can empty the pocket of food that collects by applying pressure at a certain point on the neck. The diet may have to be limited to foods that pass more readily, such as pureed foods. Surgery may be needed if nutrition is disrupted. Endoscopic stapling diverticulotomy or diverticulostomy is associated with decreased complications compared with the open approaches. The most serious surgical complication is esophageal perforation.

Esophageal Strictures

The most common cause of *esophageal strictures* (or narrowing) is chronic GERD. Ingesting strong acids or alkalis, external beam radiation, and surgical anastomosis can also cause strictures. Trauma, such as throat lacerations and gunshot wounds, can lead to strictures from scar formation. Strictures can cause dysphagia and regurgitation, leading to weight loss.

Strictures can be dilated using mechanical *bougies* (dilating instruments) or balloons. Dilation may be done with or without endoscopy, or with fluoroscopy. Surgical excision with anastomosis is sometimes needed. The patient may have a temporary or permanent gastrostomy.

Achalasia

In **achalasia**, peristalsis of the lower two thirds (smooth muscle) of the esophagus is absent. Achalasia is a rare, chronic disorder. The exact cause is unknown. With achalasia, the pressure in the LES increases along with incomplete relaxation. Esophageal obstruction at or near the diaphragm occurs. Food and fluid accumulate in the lower esophagus. The result is dilation of the esophagus above the tapered affected segment of the lower esophagus (Fig. 46.7). There is a selective loss of inhibitory neurons, resulting in unopposed contraction of the LES.

The onset of achalasia is usually slow. Dysphagia is the most common symptom. It occurs with both liquids and solids.

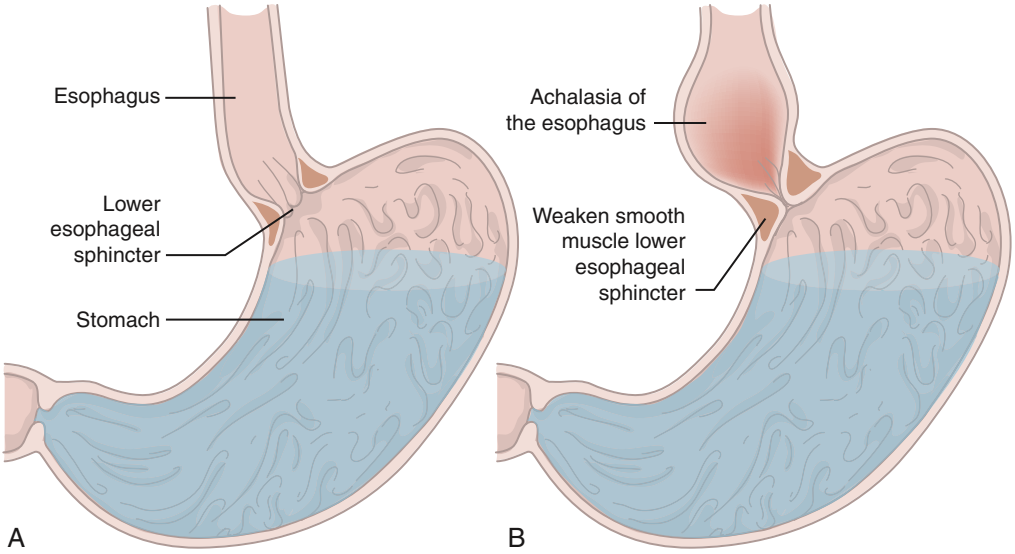

Fig. 46.7 Esophageal achalasia. (A) Healthy esophagus. (B) Achalasia.

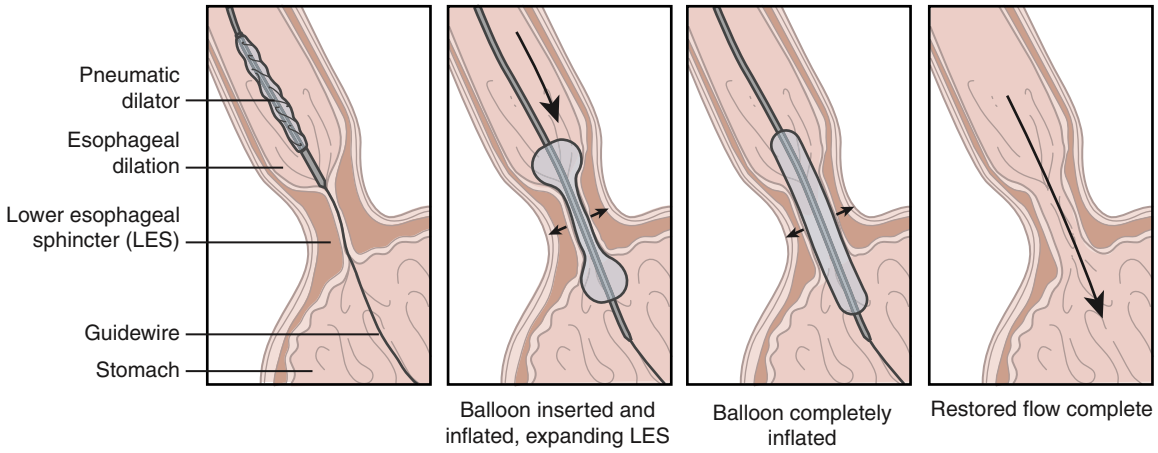

Fig. 46.8 Pneumatic dilation can treat achalasia by maintaining an adequate lumen.

Patients may report a globus sensation and/or substernal chest pain (similar to angina pain) during or right after a meal. About a third have nighttime regurgitation. *Halitosis* (foul-smelling breath) and the inability to eructate (belch) can occur. Patients may report symptoms of GERD and regurgitation of sour-tasting food and liquids, especially when they are lying down. Weight loss is common.

Diagnosis is made with esophagram (barium swallow), manometric evaluation (high-resolution manometry), and/or endoscopic evaluation. Treatment focuses on symptom management. The goals of treatment are to relieve dysphagia and regurgitation, improve esophageal emptying by disrupting the LES, and prevent the development of megaesophagus (enlargement of the lower esophagus).

Endoscopic pneumatic dilation involves dilating the LES muscle using balloons of progressively larger diameter (3.0, 3.5, and 4.0 cm) (Fig. 46.8). It is an outpatient procedure. If this is ineffective, the next option is a Heller myotomy, done laparoscopically. In this procedure, the HCP cuts through the muscles of the LES, allowing food to pass. Because GERD with esophagitis and stricture is a common complication, the patient often has anti-reflux surgery at the same time. The patient typically returns to usual activities 1 to 2 weeks afterward.

Medical therapy is less effective than invasive procedures. The injection of botulinum toxin endoscopically into the LES gives short-term relief of symptoms and improves esophageal emptying. It works by promoting relaxation of the smooth muscle. This treatment is used for older patients for whom surgery and pneumatic dilation may not be appropriate due to other chronic illnesses.

Nitrates (e.g., isosorbide dinitrate) and calcium channel blockers (e.g., nifedipine) relax the LES and may improve dysphagia. They are taken sublingually 10 to 30 minutes before meals. Side effects, drug tolerance, and short duration of action limit their use. Symptomatic treatment consists of eating a semi-soft diet, eating slowly, drinking fluid with meals, and sleeping with the head elevated.

Esophageal Varices

Esophageal varices are dilated, tortuous veins occurring in the lower part of the esophagus. They are due to portal hypertension. Esophageal varices are a common complication of liver

cirrhosis. They are discussed in Chapter 46. There is a high mortality with variceal bleeding.

STOMACH AND UPPER SMALL INTESTINE PROBLEMS

PEPTIC ULCER DISEASE

Peptic ulcer disease (PUD) is a condition characterized by erosion of the GI mucosa from the digestive action of HCl acid and pepsin. Any part of the GI tract that is in contact with gastric secretions is susceptible to ulcer development. This includes the lower esophagus, stomach, duodenum, and margin of a gastrojejunal anastomosis after surgical procedures. PUD affects about 4.6 million people in the United States each year.[13]

Types

We classify peptic ulcers as acute or chronic (depending on the degree and duration of mucosal involvement) and by location (gastric or duodenal). The *acute ulcer* (Fig. 46.9) causes superficial erosion and minimal inflammation. It is of short duration and resolves quickly when the cause is identified and removed. A chronic ulcer (Fig. 46.10) is of long duration, present continuously for many months or intermittently throughout the person's lifetime. It can erode through the muscular wall with the formation of fibrous tissue. Chronic ulcers are more common than acute ulcers.

Gastric and duodenal ulcers differ in their incidence and presentation (Table 46.12).

Etiology and Pathophysiology

Peptic ulcers develop only in an acid environment. However, an excess of HCl acid is not necessary for ulcer development. Pepsinogen, the precursor of pepsin, changes to pepsin in the presence of HCl acid and a pH of 2 to 3. When food or antacids neutralize the stomach acid level, or drugs block acid secretion, the pH increases to 3.5 or more. At a pH of 3.5 or more, pepsin has little or no proteolytic activity.

The pathophysiology of ulcer development is outlined in Fig. 46.11. The back diffusion of HCl acid into the gastric mucosa results in cellular destruction and inflammation. Histamine is released from the damaged mucosa. This results in vasodilation, increased capillary permeability, and further secretion of acid and pepsin. Fig. 46.12 shows the interrelationship between the mucosal blood flow and disruption of the gastric mucosal barrier. Several factors damage the mucosal barrier.

Helicobacter pylori

The major risk factor for PUD is infection with *Helicobacter pylori*. 80% of gastric and 90% of duodenal ulcers are related to *H. pylori*. In the United States, *H. pylori* affects 20% of persons younger than 30 years and 50% of those older than 60 years. Infection likely occurs during childhood with transmission from family members to the child, possibly through a fecal-oral or oral-oral route. The rate is highest in Hispanics and lowest in East Asians.[14] Most people with *H. pylori* do not develop ulcers. Those infected with *CagA*-positive strains are more likely to have PUD.

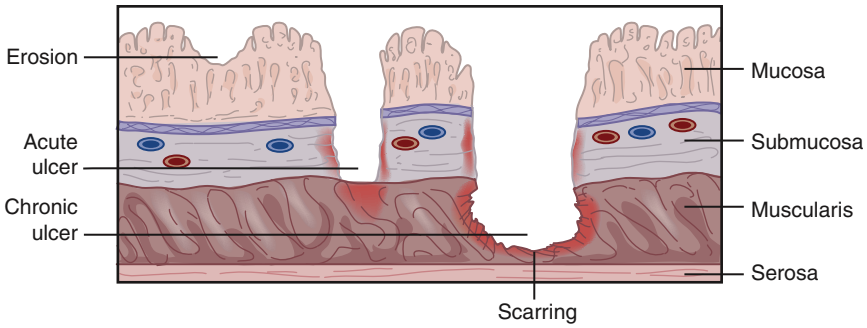

Fig. 46.9 Peptic ulcers, including an erosion, an acute ulcer, and a chronic ulcer. Both the acute ulcer and the chronic ulcer may penetrate the entire wall of the stomach.

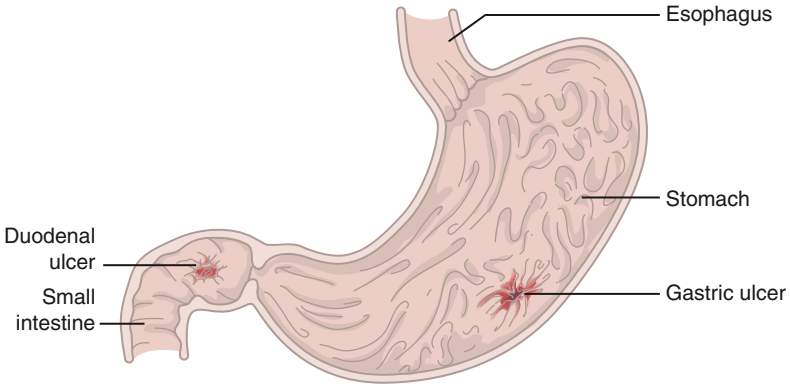

Fig. 46.10 Common sites for gastric and duodenal ulcers.

TABLE 46.12 Comparison of Gastric and Duodenal Ulcers

Gastric Ulcers	Duodenal Ulcers
Lesion	
Superficial, smooth margins. Round, oval, or cone shaped	Penetrating (deformity of duodenal bulb from healing of recurrent ulcers)
Location of Lesion	
Predominantly antrum, also in body and fundus of stomach	First 1–2 cm of duodenum
Gastric Secretion	
Normal to decreased	↑
Incidence	
↑ in women	↑ in men, but increasing in women (especially postmenopausal)
Peak age 50–60 years	Peak age 35–45 years
↑ Cancer risk	No ↑ in cancer risk
H. pylori infection in 80%	*H. pylori* infection in 90%
↑ With incompetent pyloric sphincter and bile reflux	Associated with other diseases (e.g., COPD, pancreatic disease, hyperparathyroidism, ZES, chronic renal failure)
Clinical Manifestations	
Burning or gaseous pressure in epigastrium	Burning, cramping, pressure-like pain across midepigastrium and upper abdomen. Back pain with posterior ulcers
Pain 1–2 hr after meals. If penetrating ulcer, aggravation of discomfort with food	Pain 2–5 hr after meals and midmorning, midafternoon, middle of night. Periodic and episodic. Pain relief with antacids and food
Recurrence Rate	
High	High

In the stomach, the bacteria can survive a long time by colonizing the gastric epithelial cells within the mucosal layer. The bacteria make urease, which metabolizes urea-producing ammonium chloride and other damaging chemicals. Urease activates the immune response with both antibody production and the release of inflammatory cytokines. This leads to increased gastric secretion and causes tissue damage, leading to PUD.

Medication-Induced Injury

NSAID use is responsible for most non–*H. pylori* peptic ulcers. NSAIDs inhibit prostaglandin synthesis, increase gastric acid secretion, and reduce the integrity of the mucosal barrier. NSAID use in the presence of *H. pylori* further increases the risk for PUD. Patients taking corticosteroids or anticoagulants with NSAIDs have a higher risk for PUD.[13] Corticosteroids affect mucosal cell renewal and decrease its protective effects.

Lifestyle Factors

High alcohol intake can cause acute mucosal lesions. Alcohol and smoking stimulate acid secretion. Coffee is a strong stimulant of gastric acid secretion. Smoking and psychologic distress, including stress and depression, can delay the healing of ulcers once they have developed.

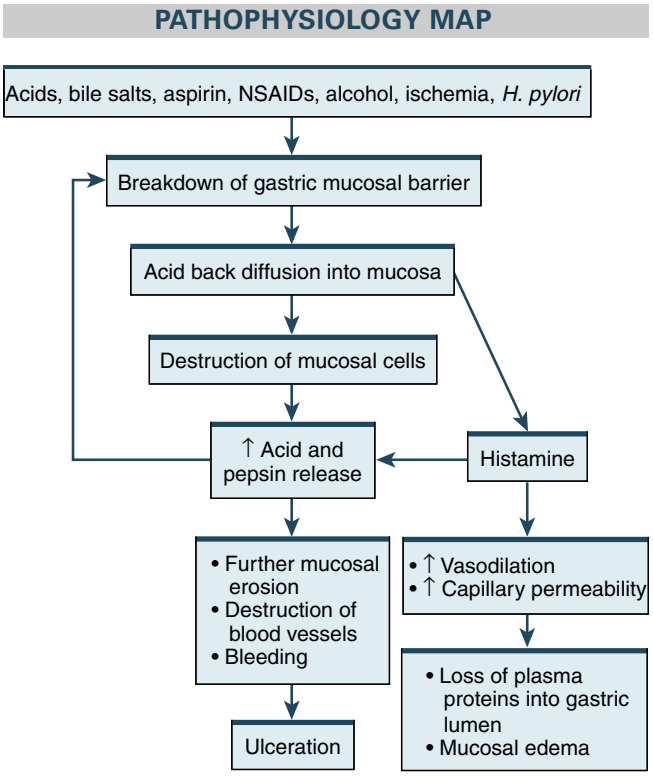

Fig. 46.11 Disruption of gastric mucosa and pathophysiologic consequences of back diffusion of acids.

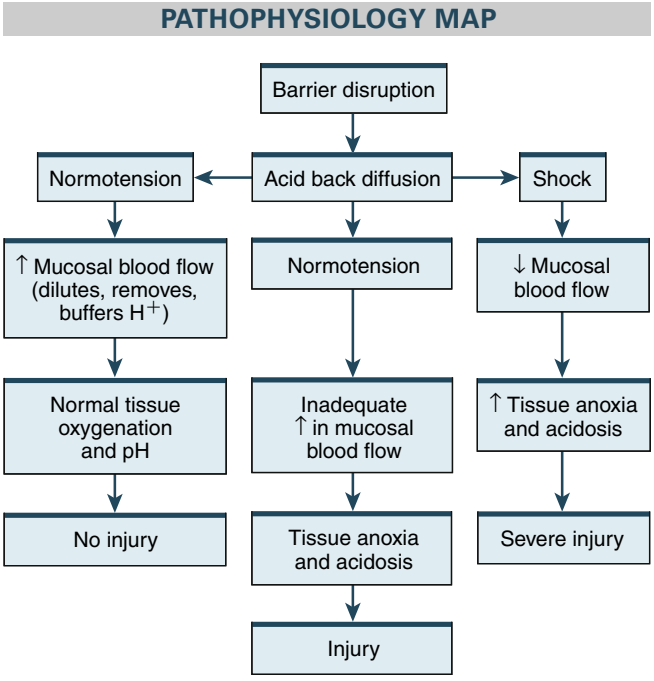

Fig. 46.12 Relationship between mucosal blood flow and disruption of the gastric mucosal barrier.

Gastric Ulcers

Gastric ulcers can occur in any part of the stomach. They most often occur in the antrum. Gastric ulcers are less common than duodenal ulcers. Gastric ulcers are more prevalent in women and those over 50 years of age. Because of the peak incidence

of gastric ulcers in older adults, the mortality rate from gastric ulcers is greater than that from duodenal ulcers. Gastric ulcers are more likely than duodenal ulcers to cause an obstruction. *H. pylori,* NSAIDs, and bile reflux are the main risk factors.

Duodenal Ulcers

Duodenal ulcers account for about 80% of all peptic ulcers. Duodenal ulcers occur at any age. The incidence is especially high between 35 and 45 years of age. While there are many factors for duodenal ulcers, *H. pylori* is the most common.

The development of duodenal ulcers is often related to high HCl acid secretion. Those at high risk include people with chronic obstructive pulmonary disease (COPD), cirrhosis, pancreatitis, hyperparathyroidism, chronic kidney disease, and *Zollinger-Ellison syndrome* (ZES). ZES is a rare condition characterized by severe peptic ulceration and HCl acid hypersecretion.

Duodenal ulcers tend to occur continuously for a few weeks or months and then disappear for a time, only to recur some months later.

Clinical Manifestations

In gastric ulcers, the discomfort is generally high in the epigastrium. It occurs about 1 to 2 hours after meals. The pain is described as "burning" or "gaseous." If the ulcer has eroded through the gastric mucosa, food tends to worsen the pain. For some patients, the earliest symptoms are due to a serious complication, such as perforation.

In duodenal ulcers, symptoms occur when gastric acid comes in contact with the ulcers. With meals, food is present to help buffer the acid. Symptoms occur generally 2 to 5 hours after a meal. The pain is described as "burning" or "cramplike." It is most often in the midepigastric region beneath the xiphoid process. Duodenal ulcers can also cause back pain.

Some patients have bloating, nausea, vomiting, and early feelings of fullness. Not all patients with ulcers will have pain or discomfort. *Silent* peptic ulcers are more likely to occur in older adults and those taking NSAIDs. The presence or absence of symptoms is not related to the size of the ulcer or the degree of healing.

Diagnostic Studies

Endoscopy is the most accurate procedure to determine the presence and location of an ulcer.[15] It allows for direct viewing of the gastric and duodenal mucosa (Fig. 46.13). During endoscopy, tissue specimens are taken to determine if *H. pylori* is present and rule out stomach cancer.

Several noninvasive and invasive tests are available to confirm *H. pylori* infection. The gold standard for diagnosing *H. pylori* infection is a biopsy of the antral mucosa with testing for urease (rapid urease testing). Urea is a byproduct of the metabolism of *H. pylori* bacteria. Noninvasive tests include serology, stool, and breath testing. The urea breath and stool antigen tests can identify active infection. Stool tests are not as accurate as the urea breath test. Antibody tests for *H. pylori* can remain positive for years. They are not good for evaluating treatment results.

A barium contrast study may be used to diagnose gastric outlet obstruction or for ulcer detection in those who cannot undergo endoscopy. High fasting serum gastrin levels may show the presence of a possible gastrinoma (ZES). A secretin stimulation test can discern a gastrinoma from other causes of hypergastrinemia.

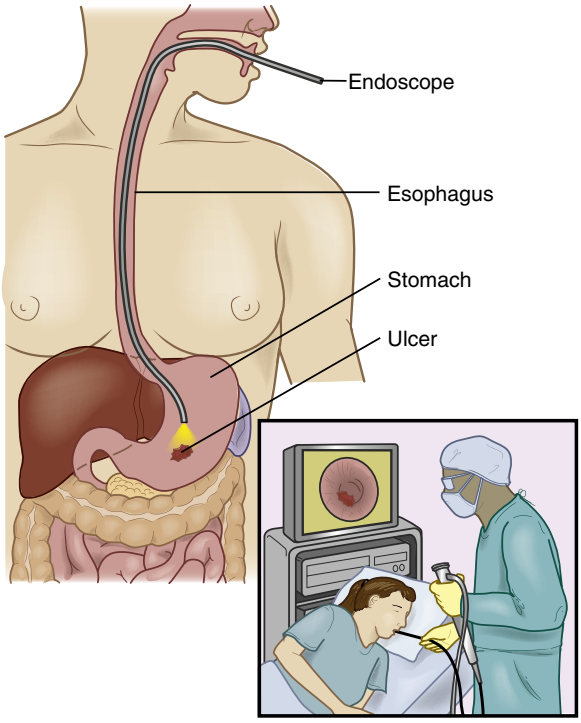

Fig. 46.13 Esophagogastroduodenoscopy (EGD) directly visualizes the mucosal lining of the stomach with a flexible endoscope. Ulcers or tumors can be directly seen, and biopsies obtained.

Laboratory tests, including a CBC, liver enzyme studies, serum amylase, and stool examination, may be done. A CBC may show anemia from ulcer bleeding. Liver enzyme studies help detect any liver problems (e.g., cirrhosis) that may complicate ulcer treatment. Stools are tested for blood. A serum amylase evaluates pancreatic function if we suspect posterior duodenal ulcer penetration of the pancreas.

Interprofessional Management

Conservative Care

Treatment consists of adequate rest, drug therapy, smoking cessation, diet modifications (if needed), and long-term follow-up care (Table 46.13). The aim of treatment is to decrease gastric acidity and enhance mucosal defense mechanisms.

Patients are generally treated in ambulatory care clinics. Pain disappears after 3 to 6 days. Ulcer healing is much slower. Complete healing may take 3 to 9 weeks, depending on ulcer size, treatment, and patient adherence. Endoscopic examination is the most accurate way to monitor ulcer healing. The usual follow-up endoscopic evaluation is done 3 to 6 months after diagnosis and treatment.

Aspirin and nonselective NSAIDs are stopped for 4 to 6 weeks. When aspirin must be continued, co-administration with a PPI, H_2 receptor blocker, or misoprostol may be prescribed. Patients receiving low-dose aspirin (LDA) for CVD and stroke risk who have a history of ulcer disease may need long-term

- Serum amylase
- Stool testing for blood

Management

Conservative Therapy
- Adequate rest
- Smoking and alcohol cessation
- Stress management (see Chapter 7)

Drug Therapy (Tables 46.10 and 46.14)
- Antibiotics for *H. pylori*
- PPIs
- Adjunctive therapy
  - H_2-receptor blockers
  - Cytoprotective drugs
  - Antacids

Acute Exacerbation Without Complications
- NPO
- NG suction
- Adequate rest
- IV fluid replacement

Drug Therapy (Tables 46.10 and 46.14)
- Antibiotics for *H. pylori*
- PPIs
- Adjunctive therapy
  - H_2 receptor blockers
  - Cytoprotective drugs
  - Antacids
  - Sedatives

Acute Exacerbation With Complications (Bleeding, Perforation, Obstruction)
- NPO
- NG suction
- IV PPI
- Bed rest
- IV fluid replacement
- Blood transfusions
- Stomach lavage (possible)

Surgical Therapy
- Gastric outlet obstruction: Pyloroplasty and vagotomy
- Perforation: Simple closure with omentum graft
- Ulcer removal or reduction
  - Billroth I and II
  - Vagotomy and pyloroplasty

treatment with a PPI. Enteric-coated aspirin decreases localized irritation but does not reduce the overall risk for GI bleeding.

Smoking has an irritating effect on the mucosa and delays mucosal healing. The patient should either stop or severely reduce smoking. Adequate rest, both physical and emotional, is important for ulcer healing and may require some changes in the patient's daily routine. Avoiding or restricting alcohol use will enhance healing.

Drug Therapy

Medications are a key part of therapy (Table 46.10). Drug therapy focuses on reducing gastric acid secretion and, if needed, eliminating *H. pylori* infection. Patients with *H. pylori* infection need treatment with antibiotics and a PPI. After the ulcer has healed, many patients can stop PPI therapy. Some may need to continue low-dose maintenance therapy.

Because ulcers often recur, interrupting or stopping therapy can have harmful results. Strict adherence to the prescribed drug regimen is important. Encourage the patient to adhere to therapy and continue with follow-up care as prescribed. Teach the patient and caregiver about each drug prescribed, why it is ordered, and the expected benefits. Review what to do if pain and discomfort recur or there is blood in vomitus or stools.

Antibiotic therapy. Eradicating *H. pylori* is the most important part of treating PUD in patients positive for *H. pylori.* Antibiotic therapy is prescribed concurrently with a PPI for 14 days (Table 46.14). If the patient has a penicillin allergy, metronidazole is used instead of amoxicillin in the triple-drug regimen. Bismuth can be given alone or as part of a combination capsule containing bismuth, tetracycline, and metronidazole.

Because of the existence of antibiotic-resistant organisms, a growing number of patients do not have *H. pylori* eradicated with a single round of therapy. Talicia is a rifabutin-based treatment for those with resistant H. pylori infection. Each capsule contains omeprazole, amoxicillin, and rifabutin.

Proton pump inhibitors. PPIs are more effective than H_2 receptor blockers in reducing gastric acid secretion and promoting ulcer healing. PPIs are used in combination with antibiotics to treat ulcers caused by *H. pylori*.

Cytoprotective drug therapy. Sucralfate is used for short-term ulcer treatment. It provides mucosal protection for the esophagus, stomach, and duodenum. Sucralfate does not have acid-neutralizing capabilities. Since it is most effective at a low pH, give it at least 60 minutes before or after an antacid. Adverse side effects are minimal. It binds with cimetidine, digoxin, warfarin, phenytoin, and tetracycline, reducing their bioavailability.

Adjunct drugs. H_2 receptor blockers and antacids may be used as adjunct therapy to promote ulcer healing. Antacids increase gastric pH by neutralizing HCl acid. As a result, they reduce the acid content of chyme reaching the duodenum. Some antacids (e.g., aluminum hydroxide) can bind to bile salts, thus decreasing the damaging effects of bile on the gastric mucosa.

Misoprostol is a synthetic prostaglandin analog prescribed to prevent gastric ulcers caused by NSAIDs and LDA. It has protective, and some antisecretory, effects on gastric mucosa. People who need chronic NSAID therapy, such as those with osteoarthritis, may benefit from its use. However, it can cause diarrhea and abdominal pain. It is teratogenic and must be used with caution in women of childbearing age.

Some patients may receive tricyclic antidepressants (e.g., imipramine, doxepin). They may contribute to overall pain

TABLE 46.14 Drug Therapy

H. pylori *Infection*

Drug Class	Drug	Triple Therapy	Bismuth Quadruple Therapy	Non-Bismuth Quadruple Therapy
Acid suppression	PPI	20–40 mg, 2 times daily	20–40 mg, 2 times daily	20–40 mg, 2 times daily
Standard antibiotics	Amoxicillin	1 g, 2 times daily		1 g, 2 times daily
	Bismuth compound		2 tablets, 2 times daily	
	Clarithromycin	500 mg, 2 times daily		500 mg, 2 times daily
	Metronidazole		500 mg, 4 times daily	500 mg, 3 times daily
	Tetracycline		500 mg, 4 times daily	

relief through their effects on afferent pain fiber transmission. Their anticholinergic properties result in reduced acid secretion. Anticholinergic drugs are sometimes used for PUD treatment.

Nutrition Therapy

There is no specific diet used to treat PUD. Patients should eat and drink foods and fluids that do not cause any distressing symptoms. Foods that may cause gastric irritation include pepper, carbonated beverages, broth (meat extract), and hot, spicy foods. Caffeine-containing beverages and foods can increase symptoms in some patients. Teach the patient to avoid alcohol use because it can delay healing.

Surgical Therapy

With the use of drug therapy and endoscopic therapy to treat PUD, surgery is less common. Surgery is an option for those with complications that are unresponsive to medical management or concerns about stomach cancer. Gastric surgeries are described later in this chapter.

Complications

The 3 major complications of chronic PUD are GI bleeding, perforation, and gastric outlet obstruction.[15] These complications are emergency situations. The patient may need surgical intervention.

GI Bleeding

GI bleeding is the most common complication of PUD. Duodenal ulcers cause more bleeding episodes than gastric ulcers.

Perforation

Perforation is the most lethal complication of PUD. Perforation risk is highest with large penetrating duodenal ulcers (Fig. 46.14). However, the mortality rate from a perforated gastric ulcer is higher. The patient with gastric ulcers is older and often has concurrent medical problems, which accounts for the higher mortality rate.

With perforation, the ulcer penetrates the serosal surface with spillage of either gastric or duodenal contents into the peritoneal cavity. The contents entering the peritoneal cavity may contain air, saliva, food particles, HCl acid, pepsin, bacteria, bile, and pancreatic fluid and enzymes.

The manifestations of perforation are sudden and dramatic in onset. During the initial phase (up to 2 hours after perforation), the patient has sudden, severe upper abdominal pain that quickly spreads throughout the abdomen. The pain radiates

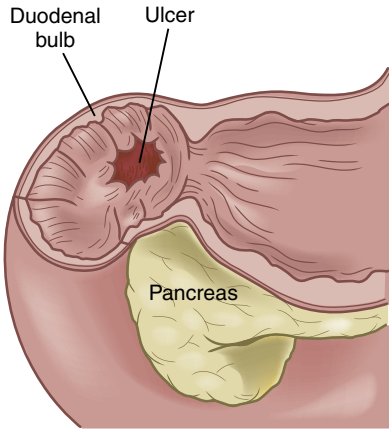

Fig. 46.14 Duodenal ulcer of the posterior wall penetrating the head of the pancreas, resulting in walled-off perforation.

to the back and shoulders. Food or antacids do not relieve the pain. The abdomen appears rigid and board-like. Bowel sounds are usually absent. Nausea and vomiting may occur. Pulse is increased and weak.

Without treatment, bacterial peritonitis may occur within 6 to 12 hours. The intensity of peritonitis is proportional to the amount and duration of the spillage through the perforation. It is hard to determine from symptoms alone whether a gastric or duodenal ulcer has perforated, because the manifestations of peritonitis are the same (see Chapter 47).

The immediate focus of managing a patient with a perforation is to stop the spillage of gastric or duodenal contents into the peritoneal cavity and restore blood volume. An NG tube can provide continuous aspiration and gastric decompression to stop spillage through the perforation. For duodenal aspiration, the tube is placed as near to the perforation site as possible to promote decompression.

Circulating blood volume is replaced with lactated Ringer's and albumin solutions. These solutions substitute for the fluids lost from the vascular and interstitial space as peritonitis develops. Packed RBCs may be needed. A central venous pressure line and an indwelling urinary catheter may be inserted and monitored hourly. The patient with a history of heart disease needs ECG monitoring or a pulmonary artery catheter for assessment of left ventricular function. Broad-spectrum antibiotic therapy is started immediately to treat bacterial peritonitis.

Small perforations may spontaneously seal themselves and symptoms cease. Spontaneous sealing occurs because of fibrin

production in response to the perforation. This can lead to fibrinous fusion of the duodenum or gastric curvature to adjacent tissue (mainly the liver) and strictures that can obstruct the flow of intestinal contents and the passage of stool.

Larger perforations need immediate surgical closure. Whether the patient has an open or laparoscopic repair depends on the ulcer's location and HCP preference. The procedure with the least risk to the patient is simple oversewing of the perforation and reinforcement of the area with a graft of omentum. Excess gastric contents are suctioned from the peritoneal cavity during the surgical procedure.

Gastric Outlet Obstruction

Both acute and chronic PUD can cause gastric outlet obstruction. Obstruction in the distal stomach and duodenum is the result of edema, inflammation, pylorospasm, or fibrous scar tissue formation. With obstruction the patient reports discomfort or pain that is worse toward the end of the day as the stomach fills and dilates. Belching or self-induced vomiting may provide some relief. Vomiting is common and often projectile. Vomitus may contain food particles that were ingested hours or days before. Constipation occurs from dehydration and decreased diet intake from anorexia. Over time, dilation of the stomach and visible swelling in the upper abdomen may occur.

The aim of therapy for obstruction is to decompress the stomach, correct any existing fluid and electrolyte imbalances, and improve the patient's general health. An NG tube can provide continuous decompression. This allows the ulcer to begin healing and the inflammation and edema to subside. Pain relief results from decompression.

IV fluids and electrolytes are replaced according to the degree of dehydration, vomiting, and electrolyte imbalance shown by laboratory studies. A PPI or H_2 receptor blocker is used if the obstruction is due to an active ulcer. Balloon dilation can open a pyloric obstruction. Surgery may be needed to remove scar tissue.

NURSING MANAGEMENT: PEPTIC ULCER DISEASE

Assessment

Subjective and objective data to obtain from a patient with PUD are outlined in Table 46.15.

Clinical Problems

Clinical problems for the patient with PUD may include:

- Pain
- Impaired GI function

Additional information on clinical problems and interventions for the patient with PUD are in eNursing Care Plan 46.2 available on the website for this chapter.

Planning

The overall goals are that the patient with PUD will (1) adhere to the therapeutic regimen, (2) achieve pain relief, (3) be free from complications, (4) have complete healing of the peptic ulcer, and (5) make appropriate lifestyle changes to prevent recurrence.

TABLE 46.15 NURSING ASSESSMENT

Peptic Ulcer Disease

Subjective Data

Important Health Information

Health history: Chronic kidney disease, pancreatic disease, COPD, serious illness or trauma, hyperparathyroidism, cirrhosis, ZES

Medications: Aspirin, corticosteroids, NSAIDs

Surgery or other treatments: Complicated or prolonged surgery

Functional Health Patterns

Health perception–health management: Chronic alcohol use, smoking, caffeine use. Family history of PUD

Nutritional-metabolic: Weight loss, anorexia, nausea and vomiting, hematemesis, dyspepsia, heartburn, belching

Elimination: Black, tarry stools

Cognitive-perceptual:

- *Duodenal ulcers:* Burning, midepigastric or back pain occurring 2–5 hr after meals and relieved by food; nighttime pain common
- *Gastric ulcers:* High epigastric pain occurring 1–2 hr after meals. Food may precipitate or worsen pain.

Coping–stress tolerance: Acute or chronic stress

Objective Data

General

Anxiety, irritability

Gastrointestinal

Epigastric tenderness

Possible Diagnostic Findings

Anemia. Guaiac-positive stools. Positive blood, urine, breath, or stool tests for *H. pylori*. Abnormal upper GI endoscopic and barium studies

Nursing Implementation

Health Promotion

You play a key role in identifying those at risk for PUD. Early detection and treatment of ulcers are important in reducing morbidity. Patients who are taking ulcerogenic drugs (e.g., NSAIDs, LDA) are at risk for PUD. Encourage patients to take these drugs with food. Teach patients to report symptoms related to gastric irritation, including epigastric pain, to their HCP.

Acute Care

During an acute exacerbation, the patient often reports increased pain, nausea, and vomiting. Some may have bleeding. Many patients try to cope with the symptoms at home before seeking medical care.

During the acute phase, the patient may be NPO for a few days, have an NG tube connected to intermittent suction, and receive IV fluid replacement. Explain to the patient and caregiver the reasons for these therapies so they understand that the advantages far outweigh any temporary discomfort. Regular mouth care relieves the dry mouth. Cleaning and lubricating the nares decrease soreness. Analysis of gastric contents may include pH testing and analysis for blood, bile, or other substances. When the stomach is empty of gastric secretions, pain decreases, and ulcer healing begins.

The volume of fluid lost, the patient's signs and symptoms, and laboratory test results (hemoglobin, hematocrit, electrolytes) determine the type and amount of IV fluids given. Take vital signs initially and then at least hourly to detect and treat shock. Give IV fluids as ordered. Record intake and output.

Physical and emotional rest is helpful to ulcer healing. The environment should be quiet and restful. Give pain medications as ordered. A mild sedative may help when the patient is anxious and apprehensive. Use good judgment before sedating a person who is becoming increasingly restless because the drug could mask the signs of shock from GI bleeding.

GI bleeding. Changes in vital signs and an increase in the amount and redness of aspirate often signal massive upper GI bleeding. With bleeding, the patient's pain often decreases because the blood helps neutralize the acidic gastric contents. Maintain the patency of the NG tube so that blood clots do not obstruct the tube. If the tube becomes blocked, the patient can develop abdominal distention. Use interventions similar to those described for upper GI bleeding.

Perforation. If the patient with an ulcer develops manifestations of a perforation, notify the HCP immediately. Take vital signs promptly and record them every 15 to 30 minutes. Temporarily stop all oral or NG drugs and feedings. If perforation exists, anything taken orally can add to the spillage into the peritoneal cavity and increase discomfort. Give IV fluid as ordered to replace the depleted plasma volume. Giving pain medications provides comfort.

Those with confirmed perforation will start on antibiotic therapy. If the perforation does not seal spontaneously, surgical closure is needed. Since surgery is done as soon as possible, there may not be time to prepare the patient and family.

Gastric outlet obstruction. Gastric outlet obstruction can happen at any time. It is most likely to occur in the patient whose ulcer is close to the pylorus. The onset of symptoms is usually gradual. Constant NG aspiration of stomach contents can help relieve symptoms. This allows edema and inflammation to subside and permits normal flow of gastric contents through the pylorus.

Regularly irrigate the NG tube with a normal saline solution per agency policy to assist proper functioning. It may be helpful to reposition the patient from side to side so that the tube tip is not constantly lying against the mucosal surface. Maintain accurate intake and output records, especially of the gastric aspirate.

To check for ongoing obstruction, clamp the NG tube intermittently and measure the gastric residual volume. The frequency and amount of time the tube is clamped are related to the amount of aspirate obtained and the patient's comfort level. A common method is to clamp the tube overnight (usually 8 to 12 hours) and measure the gastric residual volume in the morning. When the aspirate falls below 200 mL, it is within a normal range and the patient can begin oral intake of clear liquids. Oral fluids begin at 30 mL/hr and then gradually increase in amount. As the amount of gastric residual decreases, solid foods are added, and the tube removed.

If the patient has resumed oral feedings and you note symptoms of obstruction, promptly inform the HCP. Generally, all that is needed to treat the problem is to resume gastric aspiration until the edema and inflammation resulting from the acute episode resolve. IV fluids with electrolyte replacement keep the patient hydrated during this period. If conservative treatment is not successful, surgery is done after the acute phase has passed.

Ambulatory Care

Patients with PUD have specific needs to prevent recurrence and complications. Teaching should cover aspects of the disease process, drugs, lifestyle changes (alcohol use, smoking), and regular follow-up care. Table 46.16 provides a patient and caregiver teaching guide for PUD. Work with the dietitian to plan ways to incorporate diet modifications.

Teach the patient about prescribed drugs, including their actions, side effects, and dangers if omitted for any reason. Make sure the patient knows not to take OTC drugs (e.g., NSAIDs, LDA) unless approved by the HCP. Some H_2 receptor blockers and PPIs are available without a prescription. Tell the patient to check with the HCP before switching from a prescription to an OTC preparation to avoid side effects and incorrect dosing.

Obtain information about the patient's psychosocial status. The patient may be reluctant to talk about personal stress, their usual ways of coping, smoking habits, or the use of alcohol. Provide information about the negative effects of alcohol and cigarettes on PUD and ulcer healing. Changes such as smoking cessation and alcohol abstinence are hard for many people. The patient may do better in reducing, rather than eliminating, use of these substances. However, the goal is total cessation.

PUD is a chronic, recurring disorder. Teach patients with chronic PUD about potential complications and what to do until they see the HCP. Emphasize the need for long-term follow-up care. Encourage the patient to seek immediate intervention if symptoms return. Some patients have repeated exacerbations. Patients quickly

TABLE 46.16 PATIENT & CAREGIVER TEACHING

Peptic Ulcer Disease

Include the following instructions when teaching the patient and caregiver about management of PUD:

1. Avoid foods that cause epigastric distress, such as acidic foods.
2. Avoid cigarettes. Smoking promoting ulcer development and delays ulcer healing.
3. Reduce or stop alcohol use.
4. Avoid OTC drugs unless approved by the HCP. Many preparations contain ingredients, such as aspirin, which should not be taken unless approved by the HCP. Check with the HCP about the use of NSAIDs.
5. Do not interchange brands of PPIs, antacids, or H_2 receptor blockers that you can buy OTC without checking with the HCP. This can lead to harmful side effects.
6. Follow prescribed drug therapy to prevent a relapse. This includes both antisecretory and antibiotic drugs.
7. Report any of the following:
   - Increased nausea or vomiting
   - Increased epigastric pain
   - Bloody emesis or tarry stools
8. Stress can be related to PUD. Learn and use stress management strategies (see Chapter 7).
9. Share concerns about lifestyle changes and living with a chronic illness.

learn that they often have no discomfort when they omit prescribed drugs, smoke, or drink alcohol. Consequently, they make no or few changes in their lifestyle. After an acute exacerbation, the patient is likely to be more amenable to following the plan of care and open to suggestions for changes in lifestyle.

Evaluation

Expected outcomes for the patient with PUD include:

- Have pain controlled without the use of analgesics
- Commit to self-care and management of the disease
- Be free from complications

Gerontologic Considerations: Peptic Ulcer Disease

Morbidity and mortality rates in older adults with PUD are higher because of concurrent health problems and a decreased ability to withstand hypovolemia. Monitor older adults who use NSAIDs for PUD. In older patients, pain may not be the first symptom of an ulcer. For some patients the first sign is frank gastric bleeding or a decrease in hematocrit. The treatment and management of PUD in older adults are similar to those in younger adults. The emphasis is on preventing gastritis and PUD.

STOMACH CANCER

Stomach (gastric) cancer is an adenocarcinoma of the stomach wall (Fig. 46.15). It accounts for more than 27,600 new cancer cases and 11,010 deaths annually.[16] Asian Americans, Pacific Islanders, Blacks, and Hispanics have the highest rates of stomach cancer. In the United States, the incidence is higher in men by a 2:1 ratio. Stomach cancer mostly affects older people. The average age at the time of diagnosis is 68.[5]

At the time of diagnosis, only 10% to 20% of patients have disease confined to the stomach. The 5-year survival rate in this group is 71%. However, more than 50% have advanced metastatic disease. The overall 5-year survival rate of all people with stomach cancer is about 32%.[17]

Etiology and Pathophysiology

We do not know the exact cause of stomach cancer. It likely begins with a nonspecific mucosal injury because of infection *(H. pylori),* autoimmune-related inflammation, repeated exposure to irritants such as bile or NSAIDs, or tobacco use. It is possible that *H. pylori* and resulting cell changes can induce a sequence of transitions from dysplasia to cancer.

Fig. 46.15 Stomach cancer often begins in cells that line the stomach.

Lifestyle factors influence stomach cancer risk. Increased risk is related to smoking, obesity, and diets high in smoked foods, salted fish and meat, and pickled vegetables. Whole grains and fresh fruits and vegetables reduce stomach cancer risk.

Other risk factors include atrophic gastritis, pernicious anemia, adenomatous polyps, hyperplastic polyps, and *achlorhydria* (absent or low production of gastric HCl). People with lymphoma of the stomach (mucosa-associated lymphoid tissue [MALT]) have a higher risk. Although first-degree relatives of patients with stomach cancer are at increased risk, only about 10% of stomach cancers have an inherited component. 1% stomach cancers are hereditary diffuse gastric cancer (HDGC).[18]

Stomach cancer spreads by direct extension. It typically infiltrates rapidly to the surrounding tissue and liver. Seeding of tumor cells into the peritoneal cavity occurs late in the course of the disease.

Clinical Manifestations

Stomach cancers often spread to adjacent organs before any distressing symptoms occur. Manifestations include unexplained weight loss, indigestion, and abdominal discomfort or pain. Anemia is common. It is caused by chronic blood loss as the lesion erodes through the mucosa or from pernicious anemia (caused by loss of intrinsic factor). The person appears pale and weak. They may report fatigue, weakness, dizziness, and, in extreme cases, shortness of breath. The stool may be positive for occult blood. The patient may report *early satiety,* or a sense of being full sooner than usual. Hard and enlarged supraclavicular lymph nodes suggest metastasis via the thoracic duct. The presence of ascites is a poor prognostic sign.

Diagnostic Studies

The diagnostic studies for stomach cancer are outlined in Table 46.17. Upper GI endoscopy is the best diagnostic tool. The stomach can be distended with air during the procedure, stretching the mucosal folds. Tissue biopsy and histologic examination are important in diagnosing stomach cancer.

Endoscopic ultrasound, CT, MRI, and PET scanning can be used to stage the disease. Laparoscopy is done to determine peritoneal spread.

Blood studies detect anemia and determine its severity. Increased liver enzymes and serum amylase levels may mean liver and pancreas involvement. Stool examination provides evidence of occult or gross bleeding. The presence of tumor markers can help diagnose cancer.

Interprofessional Management

Surgical Therapy

The treatment of choice for stomach cancer is surgical removal of the tumor. The aim is to remove as much of the stomach as needed to remove the tumor and a margin of normal tissue. The location and extent of the lesion, the patient's physical

condition, and the HCP's preference determine the surgery done (e.g., open versus laparoscopic).

Patients with lesions in the antrum or pyloric region generally have either a Billroth I or II procedure (Fig. 46.16). When the lesion is in the fundus, a total gastrectomy with esophagojejunostomy is done (Fig. 46.17). When metastasis has occurred to adjacent organs, such as the spleen, ovaries, or bowel, the surgical procedure is extended as needed. If the tumor extends into the transverse colon, partial colon resection is done.

Preoperative management focuses on correcting nutrition deficits and treating anemia. Packed RBCs transfusions correct the anemia. If gastric outlet obstruction occurs, gastric decompression may be needed before surgery.

Chemotherapy and Radiation Therapy

Many chemotherapy drugs can be used to treat stomach cancer. These include fluorouracil, capecitabine, carboplatin, cisplatin, docetaxel, epirubicin, irinotecan, oxaliplatin, and paclitaxel. Combination therapies offer better outcomes. Examples include ECF (epirubicin, cisplatin, fluorouracil) and docetaxel, irinotecan, oxaliplatin, or cisplatin with fluorouracil or capecitabine.[19] Intraperitoneal chemotherapy may be used to treat metastatic disease. Chemotherapy is discussed in Chapter 16.

Combined radiation therapy and chemotherapy can reduce recurrence or be given as a palliative measure to decrease tumor mass and provide temporary relief of obstruction.

Targeted Therapy

Trastuzumab (Herceptin) and ramucirumab (Cyramza) are targeted therapies used to treat stomach cancer. About 20% of patients have too much HER-2 on the surface of the cancer cells. Trastuzumab targets the HER-2 protein and kills the cancer cells. Ramucirumab binds to the receptor for VEGF and prevents VEGF from binding to the receptor. This prevents the growth and spread of cancer.

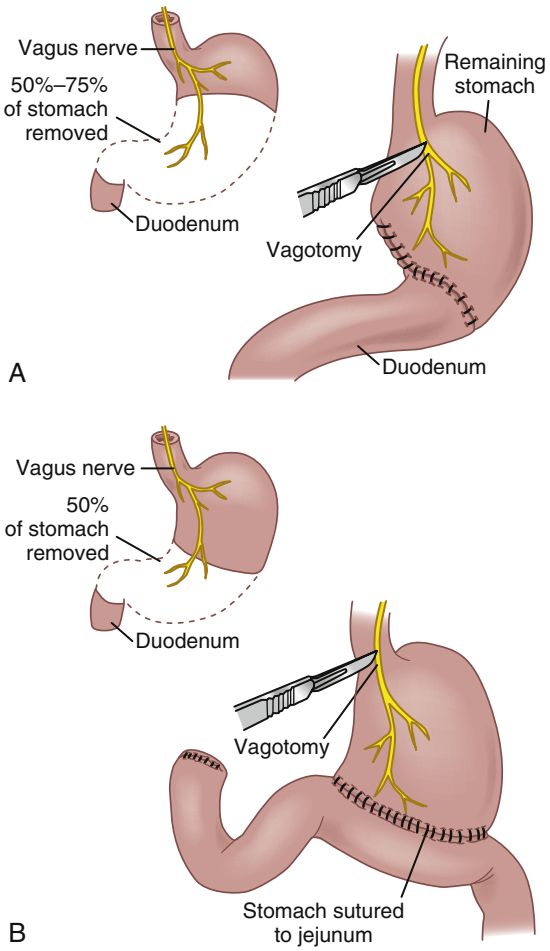

Fig. 46.16 (A) Billroth I procedure (subtotal gastric resection with gastroduodenostomy anastomosis). (B) Billroth II procedure (subtotal gastric resection with gastrojejunostomy anastomosis).

NURSING MANAGEMENT: STOMACH CANCER

Assessment

The assessment of a person with stomach cancer is similar to that for PUD (Table 46.15). Obtain a nutrition assessment, psychosocial history, and physical assessment. Assess how the patient and caregiver are coping with the cancer diagnosis.

The nutrition assessment includes information about appetite and changes in eating patterns over the previous 6 months. Determine the patient's normal weight and any recent weight changes. Unexplained weight loss and anorexia are common. Evaluate the patient's nutrition status. Cachexia may be present if oral intake has been reduced for an extended period. A malnourished patient does not respond well to chemotherapy or radiation therapy and is a poor surgical risk. The patient may have vague abdominal symptoms, including dyspepsia and intestinal gas discomfort or pain. If the patient reports pain, explore where and when it occurs and how it is relieved.

Determine the patient's usual method of coping. A cancer diagnosis and a treatment plan that may include surgery, chemotherapy, or radiation treatment is stressful. If surgery is

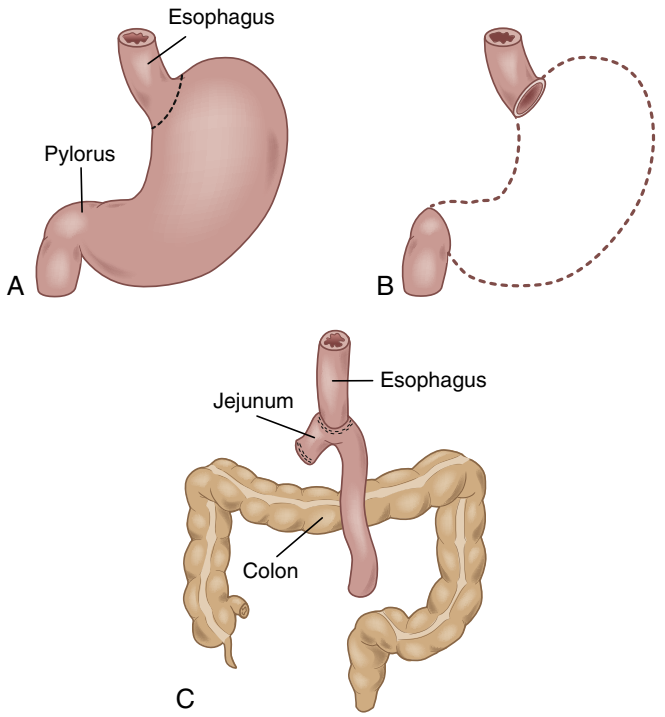

Fig. 46.17 Total gastrectomy for stomach cancer. (A) Normal anatomic structure of the stomach. (B) Removal of the stomach (total gastrectomy). (C) Anastomosis of the esophagus with the jejunum (esophagojejunostomy).

planned, assess the patient's expectations about surgery (cure or palliation) and how the patient has responded to previous surgical procedures.

Clinical Problems

Clinical problems for the patient with stomach cancer include:

- Nutritionally compromised
- Pain
- Impaired GI function
- Difficulty coping

Planning

The overall goals are that the patient with stomach cancer will (1) have minimal discomfort, (2) achieve optimal nutrition status, and (3) maintain a degree of spiritual and psychologic well-being appropriate to the disease stage.

Implementation

Health Promotion

Your role in the early detection of stomach cancer focuses on identifying patients at risk because of problems such as *H. pylori* infection, pernicious anemia, and achlorhydria. Be aware of symptoms of stomach cancer and pertinent findings on physical assessment. Symptoms often occur late and mimic other conditions, such as PUD. Encourage patients with a positive family history of stomach cancer to undergo diagnostic evaluation if anemia, PUD, or vague epigastric distress are present. Recognize the possibility of stomach cancer in a patient who was treated for PUD and did not achieve relief.

Acute Care

When diagnostic tests confirm cancer, the patient and family generally react with shock, disbelief, and depression. Provide emotional and physical support, provide information, and clarify test results. Maintain a positive attitude with respect to the patient's immediate recovery and long-term survival.

Because of changes in appetite and early satiety, the patient may be malnourished. Surgery may be delayed until the patient is more physically able to withstand it. A positive nutrition state enhances wound healing and the ability to deal with infection and other possible postoperative complications. The patient may better tolerate several small meals a day than 3 regular meals. It may be challenging to persuade the patient to eat when they have no appetite and are depressed. Getting the caregiver to help with meals and encourage intake may be helpful. Diet may be supplemented by commercial liquid supplements and vitamins. If the patient is unable to ingest oral feedings, the HCP may prescribe EN or PN (see Chapter 44).

If needed, packed RBCs and fluid volume restoration may be given during the preoperative period. Preoperative teaching and the postoperative care of the patient having stomach cancer surgery is described in the gastric surgery section.

Radiation therapy or chemotherapy is used as an adjuvant to surgery or for palliation. Your role is to provide detailed instructions, reassure the patient, and ensure completion of the designated number of treatments. Assess the patient's knowledge of these therapies. Teach the patient about skin care, need for nutrition and fluid intake, and the use of antiemetic drugs. Specific care of the patient receiving chemotherapy and radiation therapy is discussed in Chapter 16.

Ambulatory Care

When chemotherapy or radiation treatment is continuing after discharge, a referral to home health care may be helpful. The home health nurse can help with recovery and provide support to the patient and caregiver. Provide the patient with a list of available community agencies (e.g., American Cancer Society). Encourage the patient to adhere to the prescribed therapies, keep appointments for chemotherapy or radiation treatments, and keep the HCP informed of changes in physical condition. Recurrence of cancer is common. Patients need regular follow-up examinations and imaging assessments. Long-term management of the cancer patient is discussed in Chapter 16.

Evaluation

Expected outcomes for the patient with stomach cancer include:

- Have minimal discomfort, pain, or nausea
- Achieve optimal nutrition status
- Maintain a degree of psychologic well-being appropriate to the disease stage

GASTROINTESTINAL STROMAL TUMORS

Gastrointestinal stromal tumors (GISTs) are a rare cancer that originates in cells in the wall of the GI tract. These cells, known

as *interstitial cells of Cajal,* help control the movement of food and liquid through the stomach and intestines. About 60% of GISTs are in the stomach; 30% are in the small intestine. The rest are in the esophagus, colon, or peritoneum.[20] Most GISTs occur in people between the ages of 50 and 70. While the exact cause is unknown, genetic mutations likely play a role. A few GISTs occur in people with familial mutations in either KIT or platelet-derived growth factor receptor a (PDGFRa) or in those with neurofibromatosis type 1.

The manifestations depend on the part of the GI tract affected. Early manifestations are often subtle. They include early satiety, fatigue, bloating, nausea or vomiting, and a change in bowel habits. Because these are like those of many other GI problems, early detection is difficult. Later manifestations may include GI bleeding and obstruction caused by larger tumors.

GISTs are often found during imaging for other problems. Diagnosis is based on histologic examination of biopsied tissue. Endoscopic ultrasound, CT, or MRI are used to determine the extent of disease.

Surgery offers the only permanent cure. GISTs have usually metastasized by the time of diagnosis or often recur. They are unresponsive to conventional chemotherapy. The discovery of genetic mutations led to the development of tyrosine kinase inhibitor drugs (e.g., imatinib mesylate [Gleevec], sunitinib, regorafenib) that are effective against some GISTs.

GASTRIC SURGERY

Gastric surgeries are done to treat stomach cancer, as well as polyps, perforation, chronic gastritis, and PUD. Surgeries include partial gastrectomy, gastrectomy, vagotomy, and pyloroplasty. Partial gastrectomy with removal of the distal two thirds of the stomach and anastomosis of the gastric stump to the duodenum is a *gastroduodenostomy* or *Billroth I* operation (Fig. 46.16A). If the gastric stump is anastomosed to the jejunum, the surgery is a *gastrojejunostomy* or *Billroth II* operation (Fig. 46.16B). A total gastrectomy involves resecting the lower esophagus, removing the entire stomach, and anastomosis of the esophagus to the jejunum.

Vagotomy, the severing of the vagus nerve, decreases gastric acid secretion. It may be total *(truncal)* or selective *(highly selective vagotomy)*. *Pyloroplasty* is the surgical enlargement of the pyloric sphincter to promote the easy passage of contents from the stomach. It is often done after vagotomy or to enlarge an opening that is constricted from scar tissue.

Postoperative Complications

As with all surgeries, acute postoperative bleeding at the surgical site can occur. Monitoring is similar to that described later under acute upper GI bleeding. The most common long-term postoperative complications from gastric surgery are (1) dumping syndrome, (2) postprandial hypoglycemia, and (3) bile reflux gastritis.

Dumping Syndrome

Dumping syndrome is the direct result of surgical removal of a large part of the stomach and pyloric sphincter. Normally, gastric chyme enters the small intestine in small amounts. After surgery, the stomach no longer has control over the amount of gastric chyme entering the small intestine. A large bolus of hypertonic fluid enters the intestine, drawing fluid into the bowel lumen. This creates a decrease in plasma volume, distention of the bowel lumen, and rapid intestinal transit.

Symptoms begin within 15 to 30 minutes after eating. The patient usually reports generalized weakness, sweating, palpitations, and dizziness. Symptoms are due to the sudden decrease in plasma volume. The patient may have abdominal cramps, *borborygmi* (audible abdominal sounds made by hyperactive intestinal peristalsis), and the urge to defecate. These manifestations usually last less than 1 hour after eating. A short rest period after each meal reduces the chance of dumping syndrome.

Postprandial Hypoglycemia

Postprandial hypoglycemia is a variant of dumping syndrome. It is the result of uncontrolled gastric emptying of a bolus of fluid high in carbohydrate into the small intestine. This causes hyperglycemia and the release of excess amounts of insulin into the circulation. This results in reflex hypoglycemia. Symptoms are like those of any hypoglycemic reaction. They include sweating, weakness, mental confusion, palpitations, tachycardia, and anxiety. Symptoms generally occur 2 hours after eating.

Bile Reflux Gastritis

Gastric surgery that involves either reconstruction or removal of the pylorus can result in reflux of bile into the stomach. Prolonged contact with bile causes damage to the gastric mucosa, chronic gastritis, and PUD.

The main symptom is continuous epigastric distress that increases after meals. Vomiting relieves the distress, but only temporarily. Although only a small number of patients have bile reflux gastritis, caution the patient to notify the HCP of any continuous epigastric distress after meals. Cholestyramine before or with meals has been used to treat this problem. It binds with the bile salts that are the source of gastric irritation.

❖ NURSING MANAGEMENT: GASTRIC SURGERY

◆ Preoperative Care

Surgery can involve either laparoscopic or open surgical techniques. The HCP will provide the necessary information about the procedure and expected outcomes, so the patient can make an informed decision. Help by answering their questions. Teach them what to expect after surgery, including comfort measures, pain relief, coughing and breathing exercises, use of an NG tube, and IV fluid administration. See Chapter 18 for more on preoperative care.

◆ Postoperative Care

Postoperative care focuses on maintaining fluid and electrolyte balance, preventing respiratory complications, maintaining comfort, and preventing infection. Complications include

atelectasis, pneumonia, anastomotic leak, deep vein thrombosis, pulmonary embolus, and bleeding. Morbidly obese patients have a higher risk for complications.

After surgery, an NG tube is used for decompression. This decreases pressure on suture lines and allows edema and inflammation resulting from surgical trauma to resolve. Observe the gastric aspirate for color, amount, and odor. Expect small volumes of bloody drainage from the NG for the first 2 to 3 hours because bleeding at the anastomotic site is common. Report bright red bleeding that does not decrease after this period or bleeding that becomes excessive (more than 75 mL/hr) immediately to the HCP. The NG aspirate should gradually darken within the first 24 hours after surgery. Normally the color changes to yellow-green within 36 to 48 hours. After total gastrectomy, the NG tube does not drain a large quantity of secretions because removing the stomach has eliminated the reservoir capacity.

Observe the NG tube closely because blood easily clots and clogs the tube. Notify the HCP immediately if the tube stops draining or appears obstructed with blood. If the tube becomes clogged, the HCP may order periodic gentle irrigations with normal saline solution. It is essential that the NG suction is working and that the tube stays patent so that accumulated gastric secretions do not put a strain on the anastomosis. This can lead to distention of any remaining part of the stomach and result in (1) rupture of the sutures, (2) leakage of gastric contents into the peritoneal cavity, (3) bleeding, and (4) abscess formation. If the tube must be replaced or repositioned, call the HCP to perform this task because of the danger of perforating the gastric mucosa or disrupting the suture line.

While the NG tube is connected to suction, maintain IV therapy. Before the NG tube is removed, the patient begins clear liquids to determine the tolerance level. In a partial gastrectomy, the stomach may be aspirated within 1 or 2 hours to assess the amount remaining and its color and consistency. When the patient tolerates fluids, the NG tube is removed. Solids are added gradually with the goal of resuming a normal diet.

Closely observe the patient for an anastomotic leak and notify the HCP at once if you suspect one. A leak occurs when there is a breakdown of the suture line in an anastomosis that allows gastric or intestinal contents to enter the abdomen or mediastinum. It requires immediate treatment to prevent sepsis and death. Signs and symptoms include tachycardia, dyspnea, fever, abdominal pain, anxiety, and restlessness.

Since most procedures are done laparoscopically, there is less risk for respiratory complications. In an open surgical approach, the incision is in the epigastrium and respiratory complications may occur. Perform a respiratory assessment. Note signs of pneumothorax (e.g., dyspnea, chest pain, cyanosis). Have the patient cough, deep breathe, and use incentive spirometry to expand the lungs. Pain may interfere with deep breathing and coughing. Encourage the patient to splint the area with a pillow. Splinting also protects the abdominal suture line from rupturing during deep breathing and coughing. Encourage early ambulation and frequent position changes.

Give pain medications as needed. Be aware that pain could be from an anastomosis leak rather than typical surgical pain. Abdominal wounds need frequent observation. Note the amount and type of drainage, condition of the incision, and signs of infection. Monitor vital signs to help identify problems such as infection, bleeding, or anastomosis leak. Implement measures to control nausea and vomiting. Measure and record the intake and output. Obtain daily weights.

Nutrition Therapy

You need to understand the patient's surgery and their resulting anatomy. Long-term, many patients have malnutrition, metabolic bone disease, anemia, and weight loss. Nutrition interventions help minimize the occurrence of expected complications and maximize nutrient intake (Table 46.18). Start nutrition teaching as soon as the immediate postoperative period has passed. The dietitian usually provides diet instructions. You must reinforce them. Following diet measures will decrease symptoms and is essential to long-term adherence.

Postoperative wound healing may be impaired because of poor intake. Give potassium and vitamin supplements as ordered. For those who were malnourished preoperatively, a small bowel feeding tube may be placed during surgery. EN may be started on postoperative day 1 and adjusted depending on how oral intake is tolerated. Some may be discharged with nighttime tube feedings. PN is an option if the patient cannot tolerate EN or oral nutrition.

Pernicious anemia is a long-term complication of total gastrectomy and may occur after partial gastrectomy. It is

TABLE 46.18 NUTRITION THERAPY

Postgastrectomy Dumping Syndrome

The amount of time these restrictions should be followed varies. The HCP decides the amount of time to remain on this prescribed diet according to the patient's clinical condition and progress.

Purposes

- Slow the rapid passage of food into the intestine
- Control symptoms of dumping syndrome (dizziness, sense of fullness, diarrhea, tachycardia), which sometimes occurs after a partial or total gastrectomy

Diet Principles

- Divide meals into 6 small feedings to avoid overloading the stomach and intestine at mealtimes.
- Do not take fluids with meals but at least 30–45 min before or after meals. This helps prevent distention or a feeling of fullness.
- Avoid concentrated sweets (e.g., honey, sugar, jelly, jam, candies, pastries, sweetened fruit). They sometimes cause dizziness, diarrhea, and a sense of fullness.
- Protein consumption is unlimited to promote rebuilding of body tissues. Meat and eggs are specific foods to increase in the diet.
- Milk contains lactose, which may be hard to digest. Introduce milk and milk products slowly several weeks after surgery.
- Avoid carbonated beverages and foods that are gas forming to help prevent gastric distention.
- Low-roughage and raw foods are allowed as tolerated a few weeks after surgery.
- Increase complex carbohydrates (e.g., bread, vegetables, rice, potatoes) and fats to meet energy needs.

due to the loss of intrinsic factor, which is made by the parietal cells. *Intrinsic factor* is essential for the absorption of cobalamin in the terminal ileum. Cobalamin is essential for RBC growth and maturation. The patient will require cobalamin replacement therapy (see Chapter 34). Patients should take multivitamins with folate, calcium, vitamin D, and iron for life.

Because partial gastrectomy decreases the stomach's reservoir, patients must reduce their meal size accordingly. For the first few weeks after surgery, the patient should consume soft, bland foods with low fiber and high complex carbohydrates and protein content. Teach the patient to eat in small portions and not to drink fluids with meals. They should avoid simple sugars, lactose, and fried foods. Teach the patient to avoid extreme temperatures in food and to chew food thoroughly.

To avoid hypoglycemic episodes, teach the patient to limit the amount of sugar consumed with each meal and eat small, frequent meals with moderate amounts of protein and fat. The immediate intake of sugared fluids or candy relieves hypoglycemic symptoms.

Ambulatory Care

Patients who have had a total gastrectomy and are frail may need skilled care after discharge. For those going home, assist the patient and caregiver with symptom management. Make plans for pain relief, including comfort measures and the judicious use of analgesics. Teach wound care (if needed) to the primary caregiver. Dressings, special equipment, or special services may be needed. Collaborate with the dietitian to provide teaching about the diet that will optimize nutrition.

TABLE 46.19 Causes of Gastritis

Drugs
- Aspirin
- Bisphosphonates
- Corticosteroids
- Digitalis
- Iron supplements
- Nonsteroidal antiinflammatory drugs (NSAIDs)

Diet
- Alcohol
- Large amounts of spicy, irritating foods

Microorganisms
- *H. pylori*
- Cytomegalovirus
- *Mycobacterium* species
- *Salmonella* organisms
- *Staphylococcus* organisms
- *Treponema pallidum* (syphilis)

Environmental Factors
- Radiation
- Smoking

Diseases/Disorders
- Burns
- Crohn disease
- Large hiatal hernia
- Physiologic stress
- Reflux of bile and pancreatic secretions
- Renal failure
- Sepsis
- Shock

Other Factors
- Endoscopy procedures
- Nasogastric tube
- Stress

GASTRITIS

Gastritis is an inflammation of the gastric mucosa. It is a common problem affecting the stomach. Gastritis may be acute or chronic and diffuse or localized.

Etiology and Pathophysiology

Gastritis occurs as the result of a breakdown in the normal gastric mucosal barrier. This mucosal barrier normally protects the stomach tissue from the corrosive action of HCl acid and pepsin. When the barrier is broken, HCl acid and pepsin can diffuse back into the mucosa. This back diffusion results in tissue edema, disruption of capillary walls with loss of plasma into the gastric lumen, and possible bleeding.

Risk Factors

Table 46.19 lists risk factors and causes of gastritis. Some risk factors are discussed here.

Drug-related gastritis. Drugs contribute to the development of acute and chronic gastritis. NSAIDs and corticosteroids inhibit the synthesis of prostaglandins that protect the gastric mucosa. This makes the mucosa more susceptible to injury. Factors that increase the risk for NSAID-induced gastritis include being female; being over age 60; having a history of ulcer disease; taking anticoagulants, LDA, or corticosteroids; and having a chronic disorder, such as CVD. Some drugs such as digoxin and alendronate have direct irritating effects on the gastric mucosa.

Diet. Diet indiscretions can cause acute gastritis. After binge drinking alcohol, acute damage to the gastric mucosa can range from local injury of superficial epithelial cells to destruction of the mucosa with mucosal congestion, edema, and bleeding. Prolonged damage from repeated alcohol use results in chronic gastritis. Eating large quantities of spicy, irritating foods can cause acute gastritis.

Helicobacter pylori. *H. pylori* infection causes acute gastritis in most infected persons. Chronic gastritis may develop in some. Prolonged inflammation leads to functional changes in the stomach and may cause stomach cancer. *H. pylori* was discussed earlier in this chapter.

Other risk factors. Although not as common as *H. pylori*, other bacterial, viral, and fungal infections can cause chronic gastritis. Gastritis can occur from reflux of bile salts from the duodenum into the stomach because of anatomic changes after surgical procedures (e.g., gastroduodenostomy, gastrojejunostomy). Prolonged vomiting may cause reflux of bile salts. Intense emotional responses and CNS lesions may cause inflammation of the mucosal lining from hypersecretion of HCl acid.

Autoimmune Gastritis

Autoimmune metaplastic atrophic gastritis (also called *autoimmune atrophic gastritis*) is an inherited condition in which there is an immune response directed against parietal cells. It most often affects women of northern European descent. Patients often have other autoimmune disorders. The loss of parietal cells leads to low chloride levels, inadequate

production of intrinsic factor, cobalamin (vitamin B_{12}) malabsorption, and pernicious anemia. It increases the risk of stomach cancer.

Clinical Manifestations

The symptoms of *acute gastritis* include anorexia, nausea and vomiting, epigastric tenderness, and a feeling of fullness. GI bleeding is often associated with alcohol use and, at times, is the only symptom. Acute gastritis is self-limiting, lasting from a few hours to a few days. The mucosa should heal completely.

The manifestations of *chronic gastritis* are like those of acute gastritis. Some patients are asymptomatic. However, when parietal cells are lost because of atrophy, the source of intrinsic factor is also lost. *Intrinsic factor* is essential for cobalamin absorption. The lack of cobalamin results in pernicious anemia. Cobalamin deficiency anemia is discussed in Chapter 34.

Diagnostic Studies

Acute gastritis is usually diagnosed based on the patient's symptoms and the presence of risk factors. Occasionally, an endoscopic examination with biopsy is needed to make the diagnosis. Breath, urine, serum, stool, and gastric tissue biopsy tests are done to assess for *H. pylori* infection. A CBC may show anemia from blood loss or lack of intrinsic factor. Stools are tested for occult blood. Serum tests for intrinsic factor and antibodies to parietal cells may be done. A tissue biopsy can rule out gastric cancer.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: GASTRITIS

◆ Acute Gastritis

Eliminating the cause and preventing or avoiding it in the future are generally all that is needed to treat acute gastritis. The plan of care is supportive and similar to that described for nausea and vomiting. If vomiting is present, rest, NPO status, and IV fluids may be prescribed. Antiemetics are given (Table 46.1). Monitor for dehydration. It can occur rapidly in acute gastritis with vomiting.

In severe cases of acute gastritis, an NG tube may be used to (1) monitor for bleeding, (2) lavage the precipitating agent from the stomach, or (3) keep the stomach empty and free of noxious stimuli. Clear liquids are resumed when symptoms have subsided. Reintroduce solids gradually.

If the patient is at risk for GI bleeding, frequently check vital signs. Test the vomitus for blood. All the management strategies discussed in the section on upper GI bleeding apply to the patient with severe gastritis.

Drug therapy focuses on reducing irritation of the gastric mucosa and providing symptomatic relief. H_2 receptor blockers (e.g., cimetidine) or PPIs (e.g., omeprazole) reduce gastric HCl acid secretion (Table 46.10). Teach the patient about the therapeutic effects of PPIs and H_2 receptor blockers.

◆ Chronic Gastritis

The treatment of chronic gastritis focuses on evaluating and eliminating the specific cause. Examples include alcohol cessation or abstaining from drugs. Antibiotic combinations are used to treat *H. pylori* infection (Table 46.14). The patient with pernicious anemia needs lifelong cobalamin therapy (see Chapter 34).

The patient may have to adapt to lifestyle changes and strictly adhere to a drug regimen. Some patients find a nonirritating diet consisting of 6 small feedings a day helpful. Smoking is contraindicated in all forms of gastritis. A team approach in which the HCP, nurse, dietitian, and pharmacist provide consistent information and support will increase the patient's success in making these changes.

TABLE 46.20 Types of Upper GI Bleeding

Type	Manifestations
Obvious bleeding	
• Hematemesis	Bloody vomitus appearing as fresh, bright red blood or "coffee-grounds" appearance (dark, grainy digested blood).
• Melena	Black, tarry stools (often foul smelling) caused by digestion of blood in the GI tract. Black appearance is from the presence of iron.
Occult bleeding	Small amounts of blood in gastric secretions, vomitus, or stools not apparent by appearance. Detectable by guaiac test

UPPER GASTROINTESTINAL BLEEDING

In the United States, the incidence of acute upper GI (UGI) bleeding is 103 cases per 100,000 adults per year.[21] The mortality rate in hospital admitted patients is 14%, with 11% succumbing in the ED.[21] Mortality from an UGI bleed increases with age.

Etiology and Pathophysiology

Table 46.20 describes types of UGI bleeding. The most serious loss of blood from a UGI bleed has a sudden onset. Insidious occult bleeding can also be a major problem. The severity of bleeding depends on whether the origin is venous, capillary, or arterial. Bleeding from an arterial source is profuse. The blood is bright red because it has not been in contact with gastric HCl acid secretion. In contrast, coffee-grounds vomitus means that the blood has been in the stomach for some time. *Melena* (black, tarry stools) occurs with slow bleeding from an upper GI source. The longer the blood passes through the intestines, the darker the stool color because of the breakdown of hemoglobin and release of iron.

Discovering the cause of the bleeding is not always easy. A variety of areas in the GI tract may be involved. Table 46.21 lists common causes of UGI bleeding.

Stomach and Duodenal Origin

Peptic ulcers, due to *H. pylori* infection and NSAID use, are the most common causes of UGI bleeding. About 25% of people on chronic NSAIDs (e.g., ibuprofen) develop ulcer

TABLE 46.21 Causes of Upper GI Bleeding

Stomach and Duodenum
- Drug-induced
  - Corticosteroids
  - NSAIDs
  - Salicylates
- Erosive gastritis
- Polyps
- PUD
- Stress-related mucosal disease
- Stomach cancer

Esophagus
- Esophageal varices
- Esophagitis
- Mallory-Weiss tear

Systemic Diseases
- Blood dyscrasias (e.g., leukemia, aplastic anemia)
- Renal failure

disease. Of these, 2% to 4% will bleed. Even LDA increases risk for GI bleeding. Many OTC preparations contain aspirin. Obtain a careful medication history whenever we suspect UGI bleeding.

Stress-related mucosal disease (SRMD), or *physiologic stress ulcers,* describes mucosal damage in the GI tract associated with serious illness. Damage ranges from small single lesions to multiple gastric ulcers and major bleeding. SRMD most often occurs in critically ill patients who have had severe burns, trauma, or major surgery. Patients with coagulopathy, liver disease, or organ failure and those receiving renal replacement therapy are at highest risk for SRMD.[22]

Esophageal Origin

Bleeding from the esophagus is likely due to chronic esophagitis, Mallory-Weiss tear, or esophageal varices. Chronic esophagitis can be caused by GERD, smoking, alcohol use, and the use of drugs irritating to the mucosa. Esophageal varices most often occur from cirrhosis. Esophageal varices are discussed in Chapter 48.

Diagnostic Studies

Endoscopy is the primary tool for diagnosing the source (e.g., esophageal varices, PUD, gastritis) of UGI bleeding. Angiography is used when endoscopy cannot be done or when bleeding persists after endoscopic therapy. Angiography requires preparation and setup time and may not be appropriate for a high-risk, unstable patient. In this procedure, a catheter is inserted into the femoral artery and advanced to the left gastric or superior mesenteric artery until the site of bleeding is found.

Laboratory studies include CBC, blood urea nitrogen (BUN), serum electrolytes, prothrombin time, partial thromboplastin time, liver enzymes, arterial blood gases (ABGs), and a type and crossmatch for possible blood transfusions. All vomitus and stools are tested for gross and occult blood.

Monitor laboratory results to estimate the effectiveness of therapy. The hemoglobin and hematocrit values are not of immediate help in estimating the degree of blood loss, but they provide a baseline for guiding further treatment. The initial hematocrit may be normal. It may not reflect the loss until 4 to 6 hours after fluid replacement since initially the loss of plasma and RBCs is equal.

Assess the patient's BUN level. With significant bleeding, GI tract bacteria break down proteins, resulting in increased BUN levels. An increased BUN level may also show renal hypoperfusion or renal disease.

Interprofessional Management

A massive UGI hemorrhage is a loss of more than 1500 mL of blood or 25% of intravascular blood volume. Although 80% to 85% of patients with massive hemorrhage spontaneously stop bleeding, the cause must be identified, and treatment started at once.

Emergency Assessment and Management

A complete history of events leading to the bleeding episode is deferred until emergency care has been started. To facilitate early intervention, focus your assessment on identifying signs and symptoms of shock. These include tachycardia, weak pulse, hypotension, cool extremities, prolonged capillary refill, and apprehension. Shock is discussed in Chapter 42.

Urine output is one of the best measures of vital organ perfusion. An indwelling urinary catheter is inserted so that hourly output can be accurately assessed. Hemodynamic monitoring provides an accurate and quick assessment of blood flow and pressure in the cardiovascular system (see Chapter 35). A central venous pressure line may be used for fluid volume status assessment. If the patient has a history of valvular heart disease, coronary artery disease, or heart failure, a pulmonary artery catheter may be needed. Give supplemental O_2 to increase blood O_2 saturation.

The patient is at risk for perforation and peritonitis. Do a thorough abdominal assessment. Note the presence of a tense, rigid, board-like abdomen and the presence or absence of bowel sounds.

The type and amount of fluids infused are based on physical and laboratory findings. Generally, we start an isotonic crystalloid solution (e.g., lactated Ringer's solution). Whole blood, packed RBCs, and fresh frozen plasma may be used for volume replacement in massive hemorrhage. When UGI bleeding is less profuse, isotonic saline solution followed by packed RBCs restores the hematocrit more quickly and does not create complications related to fluid volume overload.

Endoscopic Therapy

The first-line management of UGI bleeding is endoscopy. Endoscopy within the first 24 hours of bleeding is important for diagnosis, determining the need for surgical intervention, and providing treatment.

The goal of endoscopic hemostasis is to coagulate or thrombose the bleeding vessel. Several techniques are used. These include (1) mechanical therapy with clips or bands, (2) thermal ablation, and (3) injection (e.g., epinephrine). Clips and bands directly compress the bleeding vessel. Thermal ablation cauterizes tissue through applying heat to the bleeding site. Common devices include neodymium: yttrium-aluminum-garnet (YAG) laser, monopolar or bipolar electrocoagulation, heater probes, and argon plasma coagulation (APC).[21]

For variceal bleeding, other strategies include variceal ligation, injection sclerotherapy, and balloon tamponade (see Chapter 48).

Surgical Therapy

Surgical intervention is needed when bleeding continues despite therapy and there is an identified site of bleeding. Surgery may be done if the patient continues to bleed after rapid transfusion of up to 2000 mL of whole blood or is still in shock after 24 hours. The site of the bleeding determines the choice of surgery. Mortality rates increase greatly in older patients.

Drug Therapy

During the acute phase of UGI bleeding, drugs are used to decrease bleeding, decrease HCl acid secretion, and neutralize HCl acid. Empiric PPI therapy with high-dose IV bolus and subsequent infusion to decrease acid secretion is often started before endoscopy (Table 46.10).[23] Efforts are made to reduce acid secretion because the acidic environment can alter platelet function and interfere with clot stabilization. This may decrease the amount of bleeding and need for endoscopic therapy.

After an acute phase of bleeding, antacids may be given hourly, either orally or through the NG tube. If an NG tube is in place, aspirate the stomach contents and test periodically for pH level. If pH is less than 5, intermittent suction may be used or the frequency or dosage of the antacid or antisecretory agent increased.

❖ NURSING MANAGEMENT: UPPER GASTROINTESTINAL BLEEDING

◆ Assessment

A thorough assessment is essential when you care for the patient with UGI bleeding. The patient may not be able to give specific information about the cause of the bleeding until immediate physical needs are met. Perform an immediate assessment while getting the patient ready for initial treatment. Assess level of consciousness, vital signs, skin color, and capillary refill. Check the abdomen for distention, guarding, and peristalsis. Vital signs indicate whether the patient is in shock from blood loss and provide a baseline BP and pulse for monitoring the patient's progress. Signs and symptoms of shock include low BP; rapid, weak pulse; increased thirst; cold, clammy skin; and restlessness. Monitor vital signs every 15 to 30 minutes. Inform the HCP of any significant changes.

Once the immediate interventions have begun, the patient or caregiver should answer the following questions: Is there a history of bleeding episodes? Has the patient received blood transfusions? Were there any transfusion reactions? Are there any other illnesses (e.g., liver problems) or medications that may contribute to bleeding or interfere with treatment? Does the patient have a religious preference that prohibits the use of blood or blood products?

Subjective and objective data to obtain from the patient or caregiver are outlined in Table 46.22.

TABLE 46.22 NURSING ASSESSMENT

Upper GI Bleeding

Subjective Data

Important Health Information

Health history: Precipitating events before bleeding episode, prior bleeding episodes and treatment, PUD, esophageal varices, esophagitis, acute and chronic gastritis, stress-related mucosal disease

Medications: Aspirin, NSAIDs, corticosteroids, anticoagulants

Functional Health Patterns

Health perception–health management: Family history of bleeding, smoking, alcohol use

Nutritional-metabolic: Nausea, vomiting, weight loss, thirst

Elimination: Diarrhea. Black, tarry stools. Decreased urine output. Sweating

Activity-exercise: Weakness, dizziness, fainting

Cognitive-perceptual: Epigastric pain, abdominal cramps

Coping–stress tolerance: Acute or chronic stress

Objective Data

General

Fever

Cardiovascular

Tachycardia, weak pulse, orthostatic hypotension, slow capillary refill

GI

Red or coffee-grounds vomitus. Tense, rigid abdomen, ascites. Hypoactive or hyperactive bowel sounds. Black, tarry stools

Neurologic

Agitation, restlessness. Decreasing level of consciousness

Respiratory

Rapid, shallow respirations

Skin

Clammy, cool, pale skin. Pale mucous membranes, nail beds, and conjunctivae. Spider angiomas, jaundice, peripheral edema

Urinary

Decreased urine output, concentrated urine

Possible Diagnostic Findings

↓ Hematocrit and hemoglobin, hematuria. Guaiac-positive stools, emesis, or gastric aspirate. ↓ Levels of clotting factors, ↑ liver enzymes, abnormal endoscopy results

◆ Clinical Problems

Clinical problems for the patient with UGI bleeding include:

- Fluid imbalance
- Inadequate tissue perfusion
- Impaired GI function

◆ Planning

The overall goals are that the patient with UGI bleeding will (1) have no further GI bleeding, (2) have the cause of the bleeding identified and treated, and (3) return to a normal hemodynamic state.

Implementation

Health Promotion

You play a key role in identifying patients at high risk for GI bleeding. Always consider the patient with a history of chronic gastritis, cirrhosis, or PUD at high risk. The patient who has had a UGI bleeding episode is more likely to have another bleed. Patients on LDA and anticoagulants are at risk for UGI bleeding, especially those over 60 years old with a history of PUD.

Teach the patient who takes regular doses of drugs that cause GI toxicity (peptic ulcer formation, bleeding), such as corticosteroids and NSAIDs, about the risk for GI bleeding. They may need to receive long-term treatment with a PPI, H_2 receptor blocker, or misoprostol. Taking these drugs with meals or snacks lessens irritation.

Teach the at-risk patient to avoid known gastric irritants, such as alcohol and smoking, and to take only prescribed medications. OTC drugs can be harmful because they may contain ingredients (e.g., aspirin) that increase the risk for bleeding. Review how to test vomitus or stools for occult blood. Teach them to report positive results promptly to the HCP. Stress the importance of treating an upper respiratory tract infection promptly. Severe coughing or sneezing can increase pressure on the already fragile varices and may result in massive hemorrhage (see Chapter 48).

Patients with blood dyscrasias (e.g., aplastic anemia) or liver problems or those who are taking chemotherapy drugs are at risk due to a decrease in clotting factors and platelets. Teach patients about their disease process, drugs, and increased risk for GI bleeding.

Acute Care

Emergency management of acute GI bleeding is outlined in Table 46.23. Place IV lines, preferably 2, with a 16- or 18-gauge needle for fluid and blood replacement. Give fluid or blood replacement as ordered. An accurate intake and output record is essential so you can assess the patient's hydration status. Measure urine output hourly. If a central venous pressure line or pulmonary artery catheter is in place, record these readings every 1 to 2 hours. Apply ECG monitoring. Monitor vital signs closely, especially in the patient with CVD, because dysrhythmias may occur.

CHECK YOUR PRACTICE

You are admitting a 71-year-old man to the unit from the ED. He has a diagnosis of UGI bleeding. He reports heartburn and pain (6 on a scale of 10) in the upper epigastric region. He just had a 250 mL coffee-grounds emesis.

- What assessment data do you need to obtain?
- What are the priority nursing interventions?

Observe the older adult or the patient with CVD closely for signs of fluid overload. However, volume overload and pulmonary edema are concerns in all patients who are receiving large amounts of IV fluids within a short time. Auscultate breath sounds. Closely observe the respiratory effort. Elevate the head of the bed to provide comfort and prevent aspiration.

When an NG tube is present, pay special attention to keeping it in proper position. Check the aspirate for blood. Although gastric lavage (room temperature, cool, iced) is used in some agencies, its effectiveness as a treatment for UGI bleeding is questionable. When lavage is used, around 50 to 100 mL of fluid is instilled at a time into the stomach. The lavage fluid may be aspirated from the stomach or drained by gravity. When aspirating, it is important to stop if you feel resistance. The tip of the NG tube may be up against the gastric mucosal lining. When resistance is a factor, use the gravity method.

Approach the patient in a calm manner to help decrease their anxiety level. Use caution when giving sedatives for restlessness. It is a warning sign of shock and may be masked by the drugs.

Assess the stools for blood (black-tarry, bright red). Black, tarry stools usually indicate prolonged bleeding. Determine if menses is a source of blood in the stool. When vomitus contains blood, but the stool contains no gross or occult blood, the hemorrhage is likely of short duration.

When beginning oral intake, observe the patient for symptoms of nausea and vomiting and a recurrence of bleeding. Start with feedings with clear fluids. Give them hourly until tolerance is determined. Gradually introduce foods if the patient has no signs of problems.

When bleeding is the result of chronic alcohol use, closely observe the patient for delirium tremens as alcohol withdrawal takes place. Symptoms indicating the onset of delirium tremens are agitation, uncontrolled shaking, sweating, and hallucinations. Alcohol withdrawal is discussed in Chapter 11.

TABLE 46.23 EMERGENCY MANAGEMENT

Acute GI Bleeding

Assessment Findings	Interventions
Abdominal and GI Findings • Abdominal pain • Abdominal rigidity • Hematemesis • Melena • Nausea **Hypovolemic Shock** • ↓ BP • Cool, clammy skin • ↑ HR • ↓ Level of consciousness • Slow capillary refill • ↓ Urine output (<0.5 mL/kg/hr)	**Initial** • If unresponsive, assess circulation, airway, and breathing. • If responsive, monitor airway, breathing, and circulation. • Establish IV access with large-bore catheter and start fluid replacement therapy. Insert a second large-bore catheter if shock present. • Give O_2 via nasal cannula or nonrebreather mask. • Initiate ECG monitoring. • Obtain blood for CBC, clotting studies, and type and crossmatch as needed. • Insert NG tube as needed. • Insert indwelling urinary catheter. • Give IV PPI therapy to decrease acid secretion. **Ongoing Monitoring** • Monitor vital signs, level of consciousness, O_2 saturation, ECG, bowel sounds, and intake/output. • Assess amount and character of emesis. • Keep patient NPO. • Provide reassurance and emotional support to patient and caregiver.

Ambulatory Care

Teach the patient and caregiver ways to avoid future bleeding episodes. Encourage the patient and caregiver to adhere to drug therapy. Emphasize not to take any drugs (especially aspirin,

TABLE 46.24 Bacterial Food Poisoning

Type and Cause	Sources	Manifestations	Treatment and Prevention
Botulism Toxin from *Clostridium botulinum;* ingested toxin absorbed from gut and blocks acetylcholine at neuromuscular junction	Improperly canned or preserved food, home-preserved vegetables (most common), preserved fruits and fish, canned commercial products	*Onset:* 12–36 hr *GI:* Nausea, vomiting, abdominal pain, constipation, distention *CNS:* Headache, dizziness, muscular incoordination, weakness, inability to talk or swallow, diplopia, breathing problems, paralysis, delirium, coma	*Treat:* Maintain ventilation, polyvalent antitoxin, guanidine hydrochloric acid (enhances acetylcholine release) *Prevent:* Correct processing of canned foods, boiling of suspected canned foods for 15 min before serving
Clostridial *Clostridium perfringens*	Meat or poultry dishes cooked at lower temperature (stew, pot pie), rewarmed meat dishes, gravies, improperly canned vegetables	*Onset:* 8–24 hr Diarrhea, nausea, abdominal cramps, vomiting (rare), midepigastric pain	*Treat:* Symptomatic, fluid replacement *Prevent:* Correct preparation of meat dishes. Serving food immediately after cooking or rapid cooling of food
Escherichia coli *E. coli* O157:H7	Contaminated beef, pork, milk, cheese, fish, cookie dough	*Onset:* 8 hr to 1 week (varies by strain) Bloody stools, hemolytic uremic syndrome, abdominal cramping, profuse diarrhea	*Treat:* Symptomatic, fluid and electrolyte replacement *Prevent:* Correct food preparation
Salmonella *Salmonella typhimurium* (grows in gut)	Improperly cooked poultry, pork, beef, lamb, and eggs	*Onset:* 8 hr to several days Nausea and vomiting, diarrhea, abdominal cramps, fever, and chills	*Treat:* Symptomatic, fluid and electrolyte replacement *Prevent:* Correct food preparation
Staphylococcal Toxin from *Staphylococcus aureus*	Meat, bakery products, cream fillings, salad dressings, milk Skin and respiratory tract of food handlers	*Onset:* 30 min to 7 hr Vomiting, nausea, abdominal cramping, diarrhea	*Treat:* Symptomatic, fluid and electrolyte replacement, antiemetics *Prevent:* Immediate food refrigeration, monitoring food handling

NSAIDs) other than those prescribed by the HCP. Support the patient in smoking and alcohol cessation. Long-term follow-up care may be needed because of possible recurrence. Teach the patient and caregiver what to do if acute bleeding occurs in the future.

◆ Evaluation

Expected outcomes for the patient with UGI bleeding include:

- Be free from UGI bleeding
- Maintain normal fluid volume
- Understand potential risk factors and make lifestyle modifications

FOODBORNE ILLNESS

Foodborne illness (food poisoning) is a nonspecific term that describes acute GI symptoms such as nausea, vomiting, diarrhea, and abdominal pain caused by the intake of contaminated food or liquids.[24] Each year 1 in 6 Americans, or 48 million people, gets a foodborne illness. Of these, 128,000 are hospitalized and around 3000 die.[24]

Bacteria account for most foodborne illnesses. The most common source is raw foods that become contaminated during growing, harvesting, processing, storing, shipping, or final preparation. Bacteria multiply quickly when the temperature of food is between 40°F and 140°F. So, bacteria can multiply if hot food is not kept hot enough or cold food is not cold enough. The most common bacterial food poisonings are described in Table 46.24.

Focus interventions on preventing infection. Teaching includes correct food preparation and cleanliness, adequate cooking, and refrigeration (Table 46.25). For the hospitalized patient, emphasize correcting fluid and electrolyte imbalances from diarrhea and vomiting. With botulism, additional assessment and care related to neurologic symptoms are needed (see Chapter 60).

TABLE 46.25 PATIENT & CAREGIVER TEACHING

Preventing Food Poisoning

Include these instructions when teaching the patient and caregiver how to prevent food poisoning:

1. Cook all ground beef and hamburger thoroughly.
   - Use a digital instant-read meat thermometer to ensure thorough cooking. Ground beef can turn brown before disease-causing bacteria are killed.
   - Cook ground beef until a thermometer inserted into several parts of the patty, including the thickest part, reads at least 160°F.
   - People who cook ground beef without using a thermometer can decrease their risk for illness by not eating ground beef patties that are still pink in the middle.
2. If you are served an undercooked hamburger or other ground beef product in a restaurant, send it back for further cooking. Ask for a new bun and a clean plate.
3. Avoid spreading harmful bacteria. Keep raw meat separate from ready-to-eat foods. Wash hands, counters, and utensils with hot soapy water after they touch raw meat. Never place cooked hamburgers or ground beef on the unwashed plate that held raw patties. Wash meat thermometers in between tests of patties that need more cooking.
4. Drink pasteurized milk, juice, or cider. Commercial juice with an extended shelf-life that is sold at room temperature (e.g., juice in cardboard boxes, vacuum-sealed juice in glass containers) is pasteurized. Juice concentrates are heated enough to kill pathogens.
5. Wash fruits and vegetables thoroughly, especially those you are not cooking.
6. Do not eat raw food products that are supposed to be cooked. Follow package directions for cooking at proper temperatures.
7. Avoid eating alfalfa sprouts if you are immunocompromised until you are sure of their safety.

Escherichia coli O157:H7 Poisoning

Most strains of *Escherichia coli* are harmless. They live in the intestines of healthy humans and animals. *E. coli* O157:H7 makes a powerful toxin that can cause severe illness with hemorrhagic colitis and kidney failure. In the very young and older adults, *E. coli* O157:H7 can be life threatening.

E. coli O157:H7 is found primarily in undercooked meats, especially poultry and hamburger. *E. coli* outbreaks have occurred with contaminated leafy vegetables, fruits, and nuts. Infection can occur after drinking raw milk, unpasteurized or contaminated fruit juices, and after swimming in or drinking sewage-contaminated water. Person-to-person contact in families, long-term care, and childcare centers is an important mode of transmission.

Illness starts 1 to 10 days after swallowing the organism and lasts 5 to 10 days. Manifestations include diarrhea (often bloody), vomiting, and abdominal cramping pain. The diarrhea is variable, ranging from mild to bloody. It may start out as watery but may progress to bloody. Systemic complications include hemolytic uremia and thrombocytopenic purpura. Death can occur.

Infection with *E. coli* O157:H7 is diagnosed by detecting the bacteria in the stool. All people who suddenly have diarrhea with blood should have a stool culture for *E. coli* O157:H7.

Treatment involves hydration to maintain blood volume. Patients should avoid antidiarrheal agents. They slow GI motility and can prolong infection. Other therapies may include dialysis and plasmapheresis. We seldom give antibiotics because they increase the risk of complications and do not appear to treat the infection.

A small number of patients, especially young children and older adults develop hemolytic uremic syndrome (HUS). The risk of HUS increases with antibiotic use. With HUS, the RBCs are destroyed, and the kidneys fail. It is a life-threatening condition usually treated in an ICU. Blood transfusions and kidney dialysis are often needed. The mortality rate is around 5%. About one-third of people have abnormal kidney function for years afterward. A few need long-term dialysis. Other long-term complications include hypertension, seizures, blindness, and paralysis.

Case Study

Peptic Ulcer Disease

(iStockphoto/Thinkstock.)

Patient Profile

F.H., a 40-year-old male immigrant from Vietnam, has a 1-year history of epigastric distress. Increasingly, it is not relieved by over-the-counter omeprazole. He is scheduled for an upper endoscopy this morning.

Subjective Data

- Reports increasing substernal pain, especially 2 to 3 hr after eating
- Currently avoids alcohol and is taking an over-the-counter PPI
- Smoking history of 1 pack of cigarettes per day for 20 years
- Has had increasing fatigue with exercise
- Reports occasional black bowel movement

Objective Data

Physical Assessment

- Height 5 ft, 5 in tall and weight 140 lb

Diagnostic Studies

- Endoscopy reveals a duodenal ulcer
- Hgb 10.2 g/dL; Hct 30%
- Histology of biopsied tissue reveals *H. pylori* infection

Interprofessional Care

- Omeprazole 20 mg twice daily × 10 days
- Clarithromycin 500 mg twice daily × 10 days
- Amoxicillin 1 gram twice daily × 10 days

Discussion Questions

1. ***Recognize***: What risk factors does F.H. have for PUD?
2. ***Analyze:*** What assessment findings are consistent with PUD?
3. ***Plan:*** How will you consider F.H.'s cultural preferences in planning care?
4. ***Prioritize:*** Based on the data provided, what are the priority clinical problems?
5. ***Prioritize:*** What are the priority nursing interventions for F.H.?
6. ***Act***: What lifestyle interventions would you recommend for F.H.?
7. ***Evaluation:*** F.H. asks you if the treatment will work and this will be the end of his problems. How will you respond?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. M.J. calls the clinic and tells the nurse that her 85-year-old mother has been nauseated all day and has vomited twice. Before the nurse hangs up and calls the HCP, she should tell M.J. to
   - **a.** administer antiemetic drugs and assess her mother's skin turgor.
   - **b.** give her mother sips of water and elevate the head of her bed to prevent aspiration.
   - **c.** offer her mother large quantities of Gatorade to decrease the risk for sodium depletion.
   - **d.** give her mother a high-protein liquid supplement to drink to maintain her nutrition needs.
2. The nurse explains to the patient with Vincent's infection that treatment will include
   - **a.** tetanus vaccinations.
   - **b.** viscous lidocaine rinses.
   - **c.** amphotericin B suspension.
   - **d.** topical application of antibiotics.
3. The nurse teaching young adults about behaviors that put them at risk for oral cancer includes
   - **a.** discouraging use of chewing gum.
   - **b.** avoiding use of perfumed lip gloss.
   - **c.** avoiding use of smokeless tobacco.
   - **d.** discouraging drinking of carbonated beverages.

4. Which instructions would the nurse include in a teaching plan for a patient with mild gastroesophageal reflux disease (GERD)?
   a. "The best time to take an as-needed antacid is 1 to 3 hours after meals."
   b. "A glass of warm milk at bedtime will decrease your discomfort at night."
   c. "Do not chew gum; the excess saliva will cause you to secrete more acid."
   d. "Limit your intake of foods high in protein because they take longer to digest."
5. A patient who had an esophagectomy for esophageal cancer develops increasing pain, fever, and dyspnea after starting a full-liquid diet. The nurse recognizes that these symptoms are *most* indicative of
   a. an intolerance to the feedings.
   b. extension of the tumor into the aorta.
   c. leakage of fluids into the mediastinum.
   d. esophageal perforation with fistula formation into the lung.
6. The nurse monitors a patient with gastritis for pernicious anemia due to
   a. chronic autoimmune destruction of cobalamin stores in the body.
   b. progressive gastric atrophy from chronic breakage in the mucosal barrier and blood loss.
   c. a lack of intrinsic factor normally produced by acid-secreting cells of the gastric mucosa.
   d. hyperchlorhydria from an increase in acid-secreting parietal cells and degradation of RBCs.
7. The nurse is teaching the patient and family that peptic ulcers are
   a. caused by a stressful lifestyle and other acid-producing factors, such as *H. pylori.*
   b. inherited within families and reinforced by bacterial spread of *Staphylococcus aureus* in childhood.
   c. promoted by factors that cause oversecretion of acid, such as excess diet fats, smoking, and alcohol use.
   d. promoted by a combination of factors that cause erosion of the gastric mucosa, including certain drugs and *H. pylori.*
8. An optimal teaching plan for an outpatient with stomach cancer receiving radiation therapy should include information about
   a. cancer support groups, alopecia, and stomatitis.
   b. nutrition supplements, ostomy care, and support groups.
   c. prosthetic devices, wound and skin care, and grief counseling.
   d. wound and skin care, nutrition, drugs, and community resources.
9. The discharge teaching plan for the patient after an acute episode of upper GI bleeding includes information about the importance of *(select all that apply)*
   a. limiting alcohol intake to 1 serving per day.
   b. only taking aspirin with milk or bread products.
   c. avoiding taking aspirin and drugs containing aspirin.
   d. only taking drugs prescribed by the health care provider.
   e. taking all drugs 1 hour before mealtime to prevent further bleeding.
10. Several patients come to the urgent care center with nausea, vomiting, and diarrhea that began 2 hours ago while attending a large family reunion potluck dinner. You ask the patients specifically about foods they ingested containing
    a. beef.
    b. meat and milk.
    c. poultry and eggs.
    d. home-preserved vegetables.

1. b; 2. d; 3. c; 4. a; 5. c; 6. c; 7. d; 8. d; 9. c; d; 10. b.

LEARNING OUTCOMES

1. Explain common causes and interprofessional and nursing management of diarrhea, fecal incontinence, and constipation.
2. Describe common causes of acute abdominal pain and nursing management of the patient after a laparotomy.
3. Describe the interprofessional and nursing management of acute appendicitis, peritonitis, and gastroenteritis.
4. Compare and contrast the inflammatory bowel diseases of ulcerative colitis and Crohn's disease, including pathophysiology, clinical manifestations, complications, and interprofessional and nursing management.
5. Distinguish among small and large bowel obstructions, including causes, clinical manifestations, and interprofessional and nursing management.
6. Describe the clinical manifestations and interprofessional and nursing management of colorectal cancer.
7. Select nursing interventions to manage the care of the patient after bowel resection and ostomy surgery.
8. Distinguish between diverticulosis and diverticulitis, including clinical manifestations and interprofessional and nursing management.
9. Compare and contrast the types of hernias, including etiology and surgical and nursing management.
10. Describe the types of malabsorption syndromes and interprofessional care of celiac disease, lactase deficiency, and short bowel syndrome.
11. Describe the types, clinical manifestations, and interprofessional and nursing management of anorectal conditions.

KEY TERMS

anal fistula
appendicitis
bowel obstruction
celiac disease
constipation
Crohn's disease
diarrhea
diverticulitis
fecal incontinence
fistula
gastroenteritis
hemorrhoids
hernia
inflammatory bowel disease (IBD)
irritable bowel syndrome (IBS)
lactase deficiency
ostomy
paralytic ileus
peritonitis
short bowel syndrome (SBS)
steatorrhea
ulcerative colitis (UC)

The wide variety of gastrointestinal (GI) problems discussed in this chapter include diarrhea, constipation, and fecal incontinence; inflammatory and infectious bowel problems; bowel trauma; bowel obstructions; colorectal cancer (CRC); abdominal and bowel surgery (including ostomy formation); and malabsorption problems. Conceptually, patients often have problems with impaired elimination and nutrition. Many have inflammation and pain and are at risk for altered fluid and electrolyte balance. Promoting optimal bowel habits and nutrition are common goals.

DIARRHEA

Diarrhea is the passage of at least 3 loose or liquid stools per day. It may be acute, lasting 14 days or less, or persistent, lasting longer than 14 days. Chronic diarrhea lasts 30 days or longer.

Health care–associated diarrhea is acute diarrhea in a hospitalized patient that was not present on admission and starts after 3 days of being hospitalized. It is fairly common, developing in up to one-third of patients.

Etiology and Pathophysiology

The primary cause of acute diarrhea is ingesting infectious organisms (Table 47.1). Viruses cause most cases of infectious diarrhea in the United States. While some viral infections can

TABLE 47.1 Causes and Manifestations of Acute Infectious Diarrhea

Type of Organism	Manifestations	Source of Infection/Susceptibility
Bacterial		
Campylobacter jejuni	• Diarrhea, abdominal cramps, fever. Sometimes nausea, vomiting • Lasts about 7 days	• Undercooked poultry and unpasteurized milk • Most frequent in summer months
Clostridioides difficile	• Watery diarrhea, fever, anorexia, nausea, abdominal pain	• Prolonged use of antibiotics followed by exposure to feces-contaminated surfaces • Spores on hands and environmental surfaces are extremely hard to kill
Clostridium perfringens	• Diarrhea, abdominal cramps, nausea, vomiting • Occurs 6–24 h after eating contaminated food and lasts about 24 h	• Associated with meats, gravies, stews, dried or precooked foods • Can cause serious illness in anyone, especially older adults
Enterohemorrhagic *Escherichia coli* (e.g., *E. coli* O157:H7)	• Severe abdominal cramping, bloody diarrhea, vomiting • Low-grade fever • Lasts 5–7 days	• Can cause serious illness, especially in older adults • May progress to life-threatening renal failure • Transmitted in water or food contaminated with infected feces
Enterotoxigenic *E. coli*	• Watery or bloody diarrhea, abdominal cramps • Nausea, vomiting, fever may be present • Lasts 3–4 days	• Most common cause of travelers' diarrhea • Transmitted in water or food contaminated with infected feces
Salmonella	• Diarrhea, fever, abdominal cramps • Lasts 4–7 days	• Reservoir is poultry, reptiles, and other animals (especially turtles, lizards, snakes, chicks, young birds) • Can be transmitted by handling animals • Found in undercooked poultry, meat, foods prepared with raw eggs
Shigella	• Diarrhea (sometimes bloody), fever, stomach cramps • Lasts 5–7 days • Postinfection arthritis may occur	• Transmitted via fecal-oral route or in food or water contaminated with infected feces • Can contaminate recreational water
Staphylococcus	• Nausea, vomiting, abdominal cramps, diarrhea • Usually mild • May cause illness in as little as 30 min • Lasts 1–3 days	• 25%–50% of people are carriers in mucous membranes, skin, or hair • Transmitted in food contaminated by food workers who are carriers or through contaminated milk and cheese
Parasitic		
Cryptosporidium	• Watery diarrhea • Lasts about 2 weeks • May have abdominal cramps, nausea, vomiting, fever, dehydration, weight loss • May be fatal in those who are immunocompromised (e.g., AIDS)	• Lives in human intestines • Transmitted in stool of infected human or animal • Outer shell allows it to live for long periods outside of body and makes it resistant to chlorine • Common cause of waterborne disease (swimming pools, lakes, drinking water, food contaminated with feces)
Entamoeba histolytica	• Diarrhea, abdominal cramping • Only 10%–20% are ill, and symptoms are usually mild • May last 2 weeks	• Fecally contaminated food, water, or hands • Most common in tropical areas • In the United States, high-risk groups include travelers, recent immigrants, and men who have sex with men
Giardia lamblia	• Abdominal cramps, nausea, diarrhea • May interfere with nutrient absorption	• Highly contagious • Transmitted via fecal-oral route • Found in fresh lakes and rivers. Can be transmitted in swimming pools, water parks, and hot tubs
Viral		
Norovirus (Norwalk-like virus)	• Nausea, vomiting, diarrhea, stomach cramping • Rapid onset • Lasts 1–2 days	• Very contagious • Virus is present in stool and emesis
Rotavirus	• Fever, vomiting, profuse watery diarrhea • Lasts 3–8 days	• Highly contagious • Transmitted mainly by fecal-oral route

be deadly, most are mild and last less than 24 hours. So, most patients rarely seek treatment.

Bacterial infection with *Escherichia coli* O157:H7, a type of enterohemorrhagic *E. coli,* is a common cause of bloody diarrhea in the United States. It is transmitted by undercooked beef or chicken contaminated with the bacteria or in fruits and vegetables exposed to contaminated manure. Other pathologic *E. coli* strains are endemic in developing countries and often cause travelers' diarrhea. *Giardia lamblia* is the most common GI parasite that causes diarrhea in the United States.[1]

Infectious organisms attack the intestines in different ways. Some organisms (e.g., Rotavirus A, Norovirus, *G. lamblia*) change the secretion and/or absorption of enterocytes in the small intestine. They do not cause inflammation. Other organisms (e.g., *Clostridioides difficile*) impair absorption by destroying cells, causing inflammation in the colon, and producing toxins that cause damage.

Secretory diarrhea is a common result of bacterial or viral infections. It occurs when ingested pathogens survive in the GI tract long enough to absorb into the enterocytes. The resulting chain reaction changes cell permeability and causes the oversecretion of water, sodium, and chloride into the bowel.

Organisms enter the body in contaminated food (e.g., *Salmonella* in undercooked eggs and chicken) or contaminated drinking water (e.g., *G. lamblia* in contaminated lakes or pools). Travelers often get diarrhea, especially if they travel to countries with poorer sanitation than their own. Infection can spread from person to person via the fecal-oral route. For example, adult day care workers can transmit infection from one resident to another if they do not wash their hands after changing soiled diapers or linens.

A person's age, gastric acidity, intestinal microflora, and immune status influence their susceptibility to pathogens. Older adults are most likely to have life-threatening diarrhea. Since stomach acid kills ingested pathogens, taking drugs to decrease stomach acid (proton pump inhibitors [PPIs]) increases the chance that pathogens will survive.

The healthy human colon normally contains a variety of bacteria, such as *E. coli*, viruses, and fungi we call the normal flora. The normal flora aid in fermentation and provide a microbial barrier against pathogens. Antibiotics kill the normal flora, making the person more susceptible to common viral, parasitic, and bacterial infections. For example, patients receiving broad-spectrum antibiotics (e.g., carbapenems, cephalosporins) are susceptible to pathogenic strains of *C. difficile. C. difficile* infection (CDI) causes the most serious hospital-associated diarrhea and is a common cause of hospital-acquired GI illness.

People who are immunocompromised because of disease (e.g., human immunodeficiency virus [HIV]) or immunosuppressive drugs are susceptible to GI tract infection. Immunocompromised patients receiving jejunal enteral nutrition (EN) are especially prone to CDI and other foodborne infections. Jejunostomy and nasointestinal feedings, which bypass the stomach's acid environment, do not contain the poorly digestible fiber that normal colonic bacteria need for survival.

Diarrhea is not always due to infection. Drugs and food intolerances can cause diarrhea. Large amounts of undigested carbohydrate in the bowel, lactose intolerance, and certain laxatives (e.g., lactulose, sodium phosphate, magnesium citrate) produce osmotic diarrhea. It results from rapid GI transit that prevents fluid and electrolyte absorption. Bile salts and undigested fats lead to excess fluid secretion into the GI tract. Diarrhea from celiac disease and short bowel syndrome (SBS) result from malabsorption in the small intestine.

Clinical Manifestations

Infections that attack the upper GI tract (e.g., Norovirus, *G. lamblia*) usually produce large-volume, watery stools, cramping, and periumbilical pain (Table 47.1). Patients have either a low-grade or no fever and often have nausea and vomiting before diarrhea begins. Infections of the colon and distal small bowel (e.g., *Shigella, Salmonella, C. difficile*) cause fever and frequent bloody diarrhea with a small volume.

Leukocytes, blood, and mucus may be present in the stool, depending on the causative agent. Severe diarrhea may cause life-threatening dehydration, electrolyte problems (e.g., hypokalemia), and acid-base imbalances (metabolic acidosis). CDI can progress to severe colitis and intestinal perforation.

Diagnostic Studies

Stool cultures are usually done only in patients who are very ill; have a fever, bloody diarrhea, or diarrhea lasting longer than 3 days; or were exposed during an outbreak. Those with travelers' diarrhea lasting longer than 14 days should be assessed for parasitic infections. Stools are examined for blood, mucus, white blood cells (WBCs), and parasites.[1] Stool cultures tests can detect common viral, parasitic, and bacterial pathogens from a single stool sample.

Blood cultures should be done in those with signs of sepsis or systemic infection (e.g., high fever) or who are immunocompromised. The WBC count may be high. People with long-standing diarrhea can develop anemia from iron and folate deficiencies. Increased hematocrit, blood urea nitrogen (BUN), and creatinine levels are signs of fluid deficit.

In patients with chronic diarrhea, measuring stool electrolytes, pH, and osmolality helps determine whether the diarrhea is from decreased fluid absorption or increased fluid secretion. Measuring stool fat and undigested muscle fibers may show fat and protein malabsorption conditions. Some patients with secretory diarrhea have high serum levels of GI hormones, such as vasoactive intestinal polypeptide and gastrin.

Interprofessional Care

Treatment of diarrhea depends on the cause. Acute infectious diarrhea is usually self-limiting. The major concerns are preventing transmission, replacing fluid and electrolytes, and protecting the skin. Most patients tolerate oral fluids. Solutions containing glucose and electrolytes may be enough to replace losses from mild diarrhea. If losses are severe, it will be necessary to give IV fluids, electrolytes, vitamins, and nutrition.

Antidiarrheal drugs have limited short-term use. They coat and protect mucous membranes, absorb irritating substances, inhibit intestinal transit, decrease intestinal secretions, or decrease central nervous system stimulation of the GI tract

TABLE 47.2 Drug Therapy

Antidiarrheal Drugs

Drug	Mechanism of Action	Nursing Considerations
bismuth subsalicylate (Pepto-Bismol)	Decreases secretions and has weak antibacterial activity. Used to prevent travelers' diarrhea	May cause tinnitus and confusion. Do not use with GI bleeding
difenoxin with atropine	Decreases peristalsis and intestinal motility	Caution patient to avoid alcohol. May cause drowsiness. Take as directed. Overdose may be life-threatening.
diphenoxylate with atropine (Lomotil)	Opioid and anticholinergic. Decreases peristalsis and intestinal motility	Blurred vision, dry mouth, drowsiness may occur. Take as directed. Overdose may be life-threatening.
loperamide (Imodium, Pepto Diarrhea Control)	Inhibits peristalsis, delays transit, increases absorption of fluid from stools	Caution patient to avoid alcohol. Do not use with GI bleeding. May cause drowsiness. Use caution with hazardous activities.
octreotide acetate (Sandostatin)	Suppresses serotonin secretion, stimulates fluid absorption from GI tract, decreases intestinal motility	Given subcut, IM, IV. May cause gall bladder or liver problems.
paregoric (camphorated tincture of opium)	Opioid. Decreases peristalsis and intestinal motility	Taken after each stool; up to 6 doses per day. May cause drowsiness. Use caution with hazardous activities.

(Table 47.2). Antidiarrheal drugs are not used in treating some infectious diarrheas because they potentially prolong exposure to the organism. They are used cautiously in inflammatory bowel disease (IBD) because of the danger of causing *toxic megacolon* (colon dilation greater than 5 cm).

Antibiotics rarely have a role in treating acute diarrhea. They are given only for certain infections or when the infected person is severely ill or immunosuppressed. The 2 antibiotics recommended for empiric therapy in adults are a fluoroquinolone, such as ciprofloxacin, and azithromycin.

Clostridioides difficile infection

CDI is a particularly hazardous health care–associated infection (HAI). The risk for contracting CDI is highest in patients receiving antimicrobial, chemotherapy, gastric acid–suppressing, or immunosuppressive drugs.[2] *C. difficile* spores can survive for up to 70 days on objects, including commodes, bedside tables, and floors. Health care workers who do not adhere to strict infection control precautions can transmit *C. difficile* from patient to patient. *Lactobacillus* probiotics may be used to prevent CDI or as an adjunct therapy to help prevent the risk for recurrent CDI.

CDI is treated with either oral vancomycin (125 mg 4 times a day) or fidaxomicin (200 mg twice daily) for 10 days.[3] All nonessential antibiotics, stool softeners, laxatives, and antidiarrheal drugs should be stopped. Metronidazole is an option when patients cannot be treated with vancomycin or fidaxomicin. Patients with severe, complicated CDI with shock, hypotension, ileus, or megacolon should receive vancomycin 500 mg 4 times daily orally with IV metronidazole.[2] Patients with an ileus can receive vancomycin via enema.

Recurrent CDI occurs in about 20% of patients. The risk increases with the use of additional antibiotics and CDI recurrences. *Fecal microbiota transplantation* (FMT) is emerging as an effective treatment for recurrent CDI.[2] FMT reestablishes healthy intestinal flora by infusing fecal bacteria obtained from healthy donor stool into the patient's colon. To perform an FMT, feces obtained from the donor is pureed into a liquid slurry consistency using saline, water, or pasteurized cow's milk. The donor stool is then placed in the GI tract via an enema, nasoenteral tube, or during colonoscopy. The major concern with FMT is the potential for transmitting infectious agents in the donor stool. Using feces from donors who have intimate physical contact with the recipient and careful screening minimize this risk. Most patients have diarrhea right after the procedure.

❖ NURSING MANAGEMENT: ACUTE INFECTIOUS DIARRHEA

◆ Assessment

Begin your assessment with a thorough history and physical assessment (Table 47.3). Ask the patient to describe their stool pattern and related symptoms (Fig. 47.1). Focus on the duration, frequency, character, and consistency of stool and the relationship to other symptoms, such as pain and vomiting. Ask about medical conditions that may cause diarrhea and whether the person is taking drugs, such as antibiotics and laxatives, which are known to cause diarrhea, decrease stomach acidity, or cause immunosuppression. Determine whether the patient has traveled to a foreign country or been at a daycare facility recently. Ask if other family members are ill. Assess food preparation practices, food intolerances (e.g., milk), and changes in diet and appetite.

Assess for fever and signs of dehydration (dry skin, low-grade fever, orthostatic changes in pulse and BP, decreased and concentrated urine). Assess the abdomen for distention, pain, and guarding. Inspect the perineal skin for signs of redness and breakdown from diarrhea.

◆ Clinical Problems

Clinical problems for the patient with acute infectious diarrhea include:

- Impaired bowel elimination
- Fluid imbalance
- Electrolyte imbalance

For more information on clinical problems and interventions for diarrhea, see eNursing Care Plan 47.1 on the website for this chapter.

TABLE 47.3 NURSING ASSESSMENT

Diarrhea

Subjective Data

Important Health Information

Health history: Recent travel, hospitalization, infections, stress. Diverticulitis or malabsorption, metabolic disorders, IBD, IBS

Medications: Laxatives or enemas, magnesium-containing antacids, sorbitol-containing suspensions or elixirs, antibiotics, methyldopa, digitalis, colchicine; OTC antidiarrheal drugs

Surgery or other treatments: Stomach or bowel surgery, radiation

Functional Health Patterns

Health perception–health management: Chronic laxative use, malaise

Nutritional-metabolic: Ingestion of fatty and spicy foods, food intolerances. Anorexia, nausea, vomiting, weight loss. Thirst

Elimination: Increased stool frequency, volume, and looseness. Change in color and character of stools. Steatorrhea, abdominal bloating. Decreased urine output

Cognitive-perceptual: Abdominal tenderness, abdominal pain, cramping, tenesmus

Objective Data

General

Lethargy, sunken eyeballs, fever, malnutrition

GI

Frequent soft to liquid stools that may alternate with constipation, altered stool color. Abdominal distention, hyperactive bowel sounds. Pus, blood, mucus, or fat in stools. Fecal impaction

Skin

Pallor, dry mucous membranes, poor skin turgor, perianal irritation

Urinary

Decreased output, concentrated urine

Possible Diagnostic Findings

Abnormal serum electrolyte levels. Anemia, ↑ WBC, eosinophilia, hypoalbuminemia. Positive stool cultures. Ova, parasites, leukocytes, blood, or fat in stool. Abnormal sigmoidoscopy or colonoscopy findings. Abnormal lower GI series

Type 1		Separate hard lumps, like nuts (hard to pass)
Type 2		Sausage-shaped but lumpy
Type 3		Like a sausage but with cracks on its surface
Type 4		Like a sausage or snake, smooth and soft
Type 5		Soft blobs with clear-cut edges (passed easily)
Type 6		Fluffy pieces with ragged edges, mushy
Type 7		Watery, no solid pieces, entirely liquid

Fig. 47.1 Bristol Stool Scale showing fecal consistency.

TABLE 47.4 NURSING MANAGEMENT

Diarrhea

- Ensure the patient maintains an adequate fluid intake:
  - Encourage oral fluids containing glucose and electrolytes.
  - Administer IV fluids and electrolytes as ordered.
- Administer antidiarrheal and antibiotic drugs as ordered.
- Implement proper isolation and infection control precautions.
- Maintain accurate intake and output records, recording weight daily.
- Assist the patient with keeping the perianal area clean.
- Apply a moisturizing skin barrier cream as needed.
- Have the patient use dibucaine, witch hazel, or sitz baths to reduce perianal irritation and pain.
- Implement measures to make toileting easier for patients, such as:
  - Call light in reach
  - Easy-to-manage clothing
  - Assistive devices available
- Provide privacy for toileting and use a deodorizer.
- Encourage the patient to increase high fiber foods, such as whole-grain breads and cereals, and fresh fruits and vegetables, unless contraindicated.
- Teach the patient to avoid foods and fluids known to worsen diarrhea.

◆ Planning

The overall goals are that the patient with diarrhea will have (1) resumption of normal bowel patterns; (2) normal fluid, electrolyte, and acid-base balance; (3) normal nutrition status; and (4) no perianal/perineal skin breakdown.

◆ Implementation

Nursing management of the patient with diarrhea is outlined in Table 47.4. Consider all cases of acute diarrhea as infectious until the cause is known. Strict infection control precautions are needed to prevent the illness from spreading to others. Wash your hands with soap and water before and after contact with each patient and when handling body fluids of any kind. Teach the patient principles of hygiene, infection control, and the potential dangers of an illness that is infectious to themselves and others. Discuss proper food handling, cooking, and storage with the patient and caregiver (see Tables 46.24 and 46.25).

Viruses and *C. difficile* spores are extremely hard to kill. Meticulous hand washing with soap and water is extremely important in limiting the spread of *C. difficile*. Alcohol-based hand cleaners and ammonia-based disinfectants are ineffective. Immediately put patients with CDI in isolation. Ensure that visitors and all providers wear gloves and gowns. Give infected patients their own disposable stethoscopes and thermometers. Consider all objects in the room contaminated. Ensure surfaces and equipment are disinfected with a 10% bleach solution or a disinfectant labeled as *C. difficile* sporicidal.

FECAL INCONTINENCE

Etiology and Pathophysiology

Fecal incontinence is the involuntary loss of stool. It occurs when the normal structures that maintain continence are damaged or disrupted. Defecation is a voluntary action when the neuromuscular system is intact (see Chapter 43). Problems

TABLE 47.5 Common Causes of Fecal Incontinence

Anal Sphincter Weakness
- Anorectal infection
- Injury
  - Anorectal surgery for hemorrhoids, fistula, fissures
  - Childbirth injury
  - Perineal trauma or pelvic fracture
- Internal sphincter thinning

Functional
- Physical or mobility problems affecting toileting ability (e.g., frail older person who cannot get to the bathroom in time)

Inflammation
- IBD
- Radiation

Neurologic Disease
- Brain tumor
- Congenital abnormalities (e.g., spina bifida, myelomeningocele)
- Dementia
- Diabetes
- Multiple sclerosis
- Neuropathy
- Spinal cord lesions
- Stroke

Pelvic Floor Dysfunction
- Fistula
- Rectal prolapse

Other
- Chronic constipation
- Denervation of pelvic muscles from chronic straining
- Diarrhea
- Fecal impaction

with motor function (contraction of sphincters and rectal floor muscles) and/or sensory function (ability to perceive the presence of stool or have the urge to defecate) can result in fecal incontinence. Contributing factors include altered bowel habits, weakness or disruption of the internal or external anal sphincter, damage to the pudendal nerve or other nerves that innervate the anorectum, and damage to the anal tissue (Table 47.5).

For women, obstetric trauma is the most common cause of sphincter injury.[4] Aging and menopause are contributing factors. Anorectal surgery can damage the sphincters and pudendal nerves. Radiation for prostate cancer decreases rectal compliance. Neurologic conditions, including stroke and multiple sclerosis, interfere with defecation.

People with normal functioning defecation can have incontinence if mobility problems prevent prompt access to a toilet or stool is accidentally discharged with diarrhea. Chronic constipation can lead to *fecal impaction,* a collection of hardened feces in the rectum or sigmoid colon that a person cannot expel. Incontinence occurs as liquid stool seeps around the hardened feces. Fecal impaction is a common problem in older adults with limited mobility. Straining with constipation contributes to incontinence because it weakens the pelvic floor muscles.

Diagnostic Studies

The diagnosis and effective management of fecal incontinence require a thorough health history and physical assessment. A rectal examination can reveal reduced anal canal muscle tone and contraction strength of the external sphincter and detect internal prolapse, rectocele, hemorrhoids, masses, and fecal impaction. Other tests, such as anorectal manometry, anorectal ultrasonography, and anal electromyography, are done when symptoms persist after treating underlying problems or if certain problems need further evaluation.

Interprofessional Care

Treatment of incontinence depends on the cause. Maintaining normal stool consistency and a bowel management program are important. This includes regular defecation, a high-fiber diet, and increased intake of caffeine-free fluids. Fiber supplements or bulk-forming laxatives, like psyllium (e.g., Metamucil), increase stool bulk, firm the consistency, and promote the sensation of rectal filling. Patients may need to reduce the intake of foods that cause diarrhea and rectal irritation. Common triggers include caffeine, products containing artificial sweeteners, dairy products, high gas-producing vegetables (e.g., broccoli, cabbage, cauliflower), and vegetables containing insoluble fiber (e.g., lettuce, tomatoes, corn).

Fecal incontinence from fecal impaction usually resolves after manual removal of the hard feces and cleansing enemas. Antidiarrheal drugs (e.g., loperamide) are useful in slowing GI transit.

Physical therapy and biofeedback training can improve awareness of rectal sensation, coordinate internal and external anal sphincters, and increase the strength of external sphincter contraction. Biofeedback training requires intact sensory and motor nerves and motivation to learn. It is a safe, painless, and effective treatment.

Mild electrical stimulation of the sacral nerves targets communication problems between the brain and nerves that control the pelvic floor muscles and sphincters. Electrical stimulation can improve quality of life. Some patients may achieve complete continence.

For patients who do not respond to conservative measures, treatment with dextranomer/hyaluronic acid gel (Solesta) may be used. In this treatment, the gel is injected into the deep submucosa of the patient's anal canal. It works by building up tissue in the anal area, narrowing the anal canal and allowing muscles to close better. No anesthesia is given. Postinjection pain and bleeding may occur.

Surgery, such as a sphincter repair procedure, is an option when other conservative treatments fail, the patient has a full-thickness prolapse, or the anal sphincter needs repair. A colostomy is sometimes needed.

❖ NURSING MANAGEMENT: FECAL INCONTINENCE

◆ Assessment

Fecal incontinence is embarrassing, uncomfortable, and irritating to the skin. Its unpredictable nature makes it hard to maintain school or work activities and hampers social and intimate contact. Be sensitive to the patient's feelings when discussing incontinence.

Ask about bowel patterns before the incontinence developed; current bowel habits; stool consistency, volume, and frequency; and symptoms, including pain during defecation and a

feeling of incomplete evacuation *(tenesmus)*. The Bristol Stool Scale is helpful to assess stool consistency (see Fig. 47.1). Assess whether the patient has a sensation of urgency to evacuate the bowel or sensation of passing flatus and leaking stool. Ask about daily activities (mealtimes and work), diet, family and social activities, and the degree to which incontinence interferes with these activities.

Check the perineal area for irritation or breakdown. Patients who have fecal incontinence are at risk for *incontinence-associated dermatitis* (IAD). IAD results from chemical irritants in the feces causing skin damage. Symptoms include redness, skin loss, and rash. The location of IAD is usually the perianal or perineal area, buttocks, or upper thighs. Fungal infection is common and seen as a dark red center surrounded by satellite lesions. Your assessment is important in distinguishing IAD from a pressure injury.

Implementation

Regardless of the cause, bowel training is effective for many patients. Knowing the patient's usual bowel pattern can help you plan a bowel program that will achieve optimal stool consistency and establish predictable bowel elimination patterns. For the hospitalized patient, placement on a bedpan, help to a bedside commode, or walks to the bathroom at a regular time daily help to establish regular defecation. The best time to schedule elimination is within 30 minutes after breakfast.

If these techniques are not effective in establishing bowel regularity, administer bisacodyl, a glycerin suppository, or a small phosphate enema 15 to 30 minutes before the usual evacuation time. These preparations stimulate the anorectal reflex. Since stimulation will not occur unless the suppository or enema touches the rectal wall, first check for stool in the rectum and digitally remove it before inserting the laxative. Once a regular pattern is established, stop these drugs. Digital stimulation is another method for stimulating the anorectal reflex. It is often included in bowel programs for people with neurogenic bowels (e.g., from spinal cord injury). Irrigating the rectum and colon (usually with tap water) at regular intervals is another way to achieve continence in patients with neurogenic bowel.

Maintaining perineal skin integrity is a priority, especially in immobile patients. Feces can contaminate wounds, damage skin, cause bladder infections, and spread infections such as *C. difficile*. Fecal containment is essential. One way to contain stool is a stool management system (e.g., Flexi-Seal, DigniCare, Actiflo). These systems funnel liquid stool from the rectum into a containment system. Common features include a retention cuff that sits above the anal sphincter and soft tubing that extends from this cuff to a secure hub that allows a person to change the containment canister when it is full. A system can remain in place for weeks. Their use may decrease the risk for CDI, skin damage from exposure to stool, IAD, and pressure injuries. Do not use a rectal tube or urinary catheter as a stool catheter. They can reduce the responsiveness of the rectal sphincter and ulcerate the rectal mucosa.

Perform frequent skin assessments when using absorbent products. Incontinence pads are an option when the patient is in bed. Briefs should be used only during ambulation or when sitting in a chair. Make sure they are changed promptly after each episode of incontinence.

Use absorbent products in combination with a skin care program. This includes prompt cleansing, moisturizing, and skin protection. Cleanse the skin gently, using a skin cleanser rather than soap and water. Options include a cotton cloth moistened with a hydrating skin cleansing foam, incontinence clean-up cloths, or baby wipes. Avoid products that contain alcohol. They can cause drying of the skin and discomfort if the skin is irritated. Pat the skin dry or use a blow dryer on a cool setting. Do not rub the skin dry. Apply a moisture barrier and, if needed, a skin barrier cream for more protection. For patients unable to care for themselves at home, teach caregivers how to maintain skin integrity.

Fecal incontinence is an overwhelming burden for most patients. Be sensitive to their fears. Teach them ways to reduce incontinence episodes and better cope with them when they do occur. Help patients identify food triggers that may worsen symptoms. Encourage them to avoid those foods and exercise after meals. Tell them to try to use bathrooms when they are available. Patients may be more confident when they use discreet, disposable briefs or pads. Have them wear dark-colored clothing that they can quickly remove for toileting. Ready access to a spare set of clothing and cleansing cloths is important.

CONSTIPATION

People with **constipation** have fewer than 3 stools per week, often accompanied by straining, a feeling of incomplete evacuation, a need for digital assistance to evacuate stool, bloating, and hard or lumpy stools.[5] Constipation is a symptom, not a disease. It can be acute, usually lasting less than 1 week, or chronic, lasting over 3 months.

Etiology and Pathophysiology

Risk factors for chronic constipation include a low-fiber diet, decreased physical activity, or ignoring the defecation urge. Ignoring the urge to defecate for a prolonged period can cause the muscles and mucosa of the rectum to become insensitive to the presence of feces. In addition, the prolonged retention of feces results in drying of stool due to water absorption. The harder and drier the feces, the harder it is to expel. Emotions, including anxiety, depression, and stress, affect the GI tract and can contribute to constipation.

Constipation occurs with diseases that slow GI transit and hamper neurologic function, such as diabetes, Parkinson disease, and multiple sclerosis (Table 47.6).[5] Many drugs, especially opioids, cause constipation (Table 47.7).

Some people think they are constipated if they do not have a daily bowel movement. This can result in chronic laxative use and *cathartic colon syndrome,* a condition in which the colon becomes dilated and atonic (lacking muscle tone). Ultimately, the person cannot defecate without a laxative.

TABLE 47.6 Diseases Associated With Constipation

Colonic Disorders
- Cancer
- Diverticular disease
- IBD
- Intestinal stenosis
- Intussusception
- Luminal or extraluminal obstructing lesions
- Prolapse
- Rectocele

Systemic Disorders

Collagen Vascular Disease
- Amyloidosis
- Systemic lupus erythematosus
- Systemic sclerosis (scleroderma)

Metabolic/Endocrine
- Chronic renal failure
- Diabetes
- Hypercalcemia/hyperparathyroidism
- Hypokalemia
- Hypothyroidism
- Pheochromocytoma
- Pregnancy

Neurologic Disorders
- Autonomic neuropathy (from diabetes)
- Hirschsprung megacolon
- Multiple sclerosis
- Neurofibromatosis
- Parkinson disease
- Spinal cord lesions or injury
- Stroke

TABLE 47.7 Drugs Associated With Constipation

Cardiovascular	• Antihypertensives (β-adrenergic blockers, calcium channel blockers) • Furosemide • Hypolipidemics (cholestyramine, colestipol, statins)
Central nervous system	• Antidepressants (tricyclics, selective serotonin reuptake inhibitors) • Antiepileptics (carbamazepine, phenytoin, clonazepam) • Antipsychotics (butyrophenones, phenothiazines, barbiturates) • Benzodiazepines
GI	• Antacids containing aluminum, calcium • Antidiarrheals • Proton-pump inhibitors • Supplements (bismuth, calcium, iron)
Other	• Analgesics (opiates and derivatives) • Antitussives (codeine, dextromethorphan)

Clinical Manifestations

The clinical presentation varies from mild discomfort to a more severe event mimicking an "acute abdomen." Stools are absent or hard, dry, and difficult to pass. Abdominal distention, bloating, increased flatus, and increased rectal pressure may be present.

Hemorrhoids are a common complication of chronic constipation. They result from venous engorgement caused by repeated *Valsalva maneuvers* (straining) and venous compression from hard, impacted stool. The Valsalva maneuver may have serious outcomes for patients with heart failure, cerebral edema, hypertension, and coronary artery disease. During straining, the patient inspires deeply and holds the breath while contracting abdominal muscles and bearing down. This increases both intraabdominal and intrathoracic pressures and reduces venous return to the heart. The heart rate temporarily decreases along with a decrease in cardiac output. This results in a transient drop in arterial pressure. When the patient relaxes, thoracic pressure falls, resulting in a sudden flow of blood into the heart, increased heart rate, and an immediate rise in arterial pressure. These changes may be fatal for the patient who cannot compensate for the sudden increased blood flow returning to the heart.

Rectal mucosal ulcers and fissures may occur from stool stasis or straining. Diverticulosis is another potential complication of chronic constipation. It is more common in older patients.

In the presence of *obstipation* (absolute constipation with no passage of gas or stool) or fecal impaction from constipation, colonic perforation may occur. Perforation, which is life threatening, causes abdominal pain, nausea, vomiting, fever, and a high WBC count.

Diagnostic Studies

In most patients, the diagnosis of constipation is based on findings from the history and physical assessment. The physical should include an abdominal assessment, inspection of the perianal and rectal region, and digital rectal examination (DRE). Concerning signs include a sudden, persistent change in bowel habits (>6 weeks) in those over 50 years, rectal bleeding or bloody stools, iron deficiency anemia, weight loss, significant abdominal pain, family or personal history of CRC, or IBD and a palpable mass. If any of these are present, tests are needed to rule out serious disease, such as CRC. These may include abdominal x-rays, barium enema, and colonoscopy or sigmoidoscopy. The patient with severe constipation may undergo anorectal manometry, GI tract transit studies, balloon expulsion test, or defecography.

Interprofessional Care

Increasing fiber intake, fluid intake, and exercise can prevent many cases of constipation. Laxatives (Table 47.8) and enemas are an option in treating constipation. All promote bowel movements, but each class works differently. Which one a patient receives depends on the severity and duration of constipation and the patient's health. Daily bulk-forming laxatives (psyllium) can prevent constipation because they work like diet fiber and do not cause dependence. In patients with chronic constipation who do not respond to diet and lifestyle modifications, osmotic laxatives are the next recommended treatment. Stimulant laxatives are given to patients who do not respond to osmotic laxatives. Enemas are fast-acting and offer immediate treatment of constipation but must be used cautiously. Those containing sodium phosphate and magnesium can cause electrolyte imbalances in older adults and patients with heart and kidney problems.

Other therapies target specific patient needs. Peripherally acting opioid receptor antagonists (methylnaltrexone, naldemedine, naloxegol) decrease constipation from opioid use. They do not block the analgesic effects of opioids. Biofeedback therapy

TABLE 47.8 Drug Therapy

Constipation

Mechanism of Action	Indications	Drugs	Nursing Considerations
Bulk Forming			
Absorbs water. Increases bulk, thereby stimulating peristalsis *Action:* Usually within 24 h	Acute and chronic constipation, IBS, diverticulosis	methylcellulose (Citrucel) psyllium (Metamucil, Konsyl, Hydrocil, Fiberall)	Do not use in patients with abdominal pain, nausea, vomiting, those suspected of having appendicitis, biliary tract obstruction, or acute hepatitis. Must be taken with fluids (≥8 oz). Best choice for initial treatment of constipation
Emollients			
Lubricate intestinal tract and soften feces, making hard stools easier to pass. Do not affect peristalsis *Action:* Softeners in 72 h, lubricants in 8 h	Acute and chronic constipation, fecal impaction, anorectal conditions	*Softeners:* docusate (Colace, Surfak) *Lubricants:* mineral oil (Fleet Mineral Oil Enema)	Can block absorption of fat-soluble vitamins, such as vitamin K, which may increase risk for bleeding in patients on anticoagulants
Prosecretory Drugs			
Increases intestinal fluid secretion through direct action on epithelial cells, speeding colonic transit *Action:* Usually within 24 h	Chronic idiopathic constipation, IBS-C (women only)	linaclotide (Linzess) lubiprostone (Amitiza) plecanatide (Trulance)	Do not use in patients with history of mechanical GI obstruction. Can cause nausea and watery diarrhea
Saline and Osmotic Solutions			
Cause retention of fluid in intestinal lumen, reducing stool consistency and increasing volume *Action:* Within 15 min to 3 hr	Chronic constipation, bowel preparation for diagnostic tests and surgery	lactulose magnesium salts (magnesium citrate, Milk of Magnesia) sodium phosphates (Fleet Enema) polyethylene glycol (MiraLAX, GoLYTELY)	May cause abdominal distention, diarrhea. Overuse of magnesium or sodium phosphates in older adults or those with renal failure can lead to fluid and electrolyte imbalances. Least effective agents in this class
Stimulants			
Increases peristalsis and speeds colonic transit by irritating colon wall and stimulating enteric nerves *Action:* Usually within 12 h	Acute constipation, bowel preparation for diagnostic tests and surgery	anthraquinones (cascara sagrada, senna) sennosides (Ex-Lax, Senokot) bisacodyl (Correctol, Dulcolax)	Cause melanosis coli (brown or black pigmentation of colon). Most widely abused laxatives. Should not be used in patients with impaction or obstipation

may help patients who have constipation because of *anismus* (uncoordinated contraction of the anal sphincter during straining).

A patient with severe constipation related to bowel motility or mechanical disorders may need more intense treatment. A patient with unrelenting constipation may need a colostomy, ileostomy, or continent fecal diversion. These procedures are discussed later in this chapter.

Nutrition Therapy

Diet is a key factor in preventing and treating constipation. Many patients have improved symptoms when they increase their fiber intake. Fiber is found in fruits, vegetables, and grains (Table 47.9). Wheat bran and prunes are especially effective for preventing and treating constipation. Whole wheat and bran are high in insoluble fiber.

Fiber adds to the stool bulk directly by attracting water. Adequate fluid intake (2 L/day) is essential. Large, bulky stools move through the colon much more quickly than small stools. However, the recommended fluid intake may be contraindicated in a patient with heart disease or renal failure. Tell the patient that increasing fiber intake may initially increase gas production because of fermentation in the colon, but this effect decreases over several days.

❖ NURSING MANAGEMENT: CONSTIPATION

◆ Assessment

Determine the patient's usual defecation patterns and habits. Ask the patient about the onset and duration of symptoms, the shape and consistency of the stool, and any difficulty with evacuation (see Fig. 47.1). Is the patient straining during defecation? Is there a feeling of incomplete evacuation or the need to use fingering to expel the feces? Ask about diet, exercise, laxative use, and history that could contribute to problems with defecation. Table 47.10 outlines the subjective and objective data to obtain from a patient with constipation.

◆ Implementation

Tailor the nursing management of constipation to your assessment of the patient's symptoms. Teach the patient about the role of diet, adequate fluid intake, and regular exercise in preventing and treating constipation (Table 47.11). Emphasize the importance of a high-fiber diet. Stress using laxatives and enemas as ordered.

TABLE 47.9 NUTRITION THERAPY

High-Fiber Foods

	Fiber/ Serving (g)	Serving Size	Calories/ Serving
Vegetables			
Asparagus	3.5	½ cup	18
Beans			
• Navy	8.4	½ cup	80
• Kidney	9.7	½ cup	94
• Lima	8.3	½ cup	63
• Pinto	8.9	½ cup	78
• String	2.1	½ cup	18
Broccoli	3.5	½ cup	18
Carrots, raw	1.8	½ cup	15
Corn	2.6	½ medium ear	72
Peas, canned	6.7	½ cup	63
Potatoes			
• Baked	1.9	½ medium	72
• Sweet	2.1	½ medium	79
Squash, acorn	7.0	1 cup	82

TABLE 47.10 NURSING ASSESSMENT

Constipation

Subjective Data

Important Health Information

Health history: Colorectal disease, neurologic problems, bowel obstruction, environmental changes, cancer, IBD, diabetes

Medications: Table 47.7

Functional Health Patterns

Health perception–health management: Chronic laxative, enema use. Rigid beliefs about bowel function. Malaise

Nutritional-metabolic: Changes in diet or mealtime. Fiber and fluid intake. Anorexia, nausea

Elimination: Change in usual bowel patterns. Hard, difficult-to-pass stool, decrease in stool frequency and amount. Flatus, abdominal distention. Straining, tenesmus, rectal pressure. Fecal incontinence (if impacted)

Activity-exercise: Daily activity routine. Immobility, sedentary lifestyle

Cognitive-perceptual: Dizziness, headache, anorectal pain. Abdominal pain on defecation

Coping–stress tolerance: Acute or chronic stress

Objective Data

General

Lethargy

Skin

Anorectal fissures, hemorrhoids, abscesses

GI

Abdominal distention. Hypoactive or absent bowel sounds. Palpable abdominal mass. Fecal impaction. Small, hard, dry stool. Stool with blood

Skin

Anorectal fissures, hemorrhoids, abscesses

Possible Diagnostic Findings

Guaiac-positive stools. Abdominal x-ray showing stool in lower colon

Teach the patient to establish a regular time to defecate and not to suppress the urge to defecate. Defecation is easiest when the person is sitting on a commode with the knees higher than the hips. The sitting position allows gravity to aid defecation, and flexing the hips straightens the angle between the anal canal and rectum so that stool flows out more easily. Place a footstool in front of the toilet to promote flexion of the hips. It is challenging to defecate while sitting on a bedpan. For a patient in bed, raise the head of the bed as high as the patient can tolerate.

The sights, odors, and sounds of defecation embarrass most people. Provide as much privacy as possible and use an odor eliminator. Encourage patients to maintain abdominal muscle tone. Prompt patients to contract abdominal muscles several times a day. Sit-ups and straight-leg raises can help improve abdominal muscle tone.

For the patient whose perceived constipation is related to rigid beliefs about bowel function, start a discussion about these concerns. Give appropriate information on normal bowel function and discuss the adverse consequences of overuse of laxatives and enemas.

ACUTE ABDOMINAL PAIN AND LAPAROTOMY

Etiology and Pathophysiology

Acute abdominal pain is pain of recent onset. It may signal a life-threatening problem, so it requires immediate attention. Causes include damage to organs in the abdomen and pelvis, which leads to inflammation, infection, obstruction, bleeding, and perforation (Fig. 47.2). Perforation of the GI tract results in irritation of the *peritoneum* (serous membrane lining the abdominal cavity) and peritonitis. Hypovolemic shock occurs from bleeding or obstruction and peritonitis, causing large amounts of fluid to move from the vascular space into the abdomen.

Clinical Manifestations

Pain is the most common symptom of an acute abdominal problem. The patient may have nausea, vomiting, diarrhea, constipation, flatulence, fatigue, fever, rebound tenderness, and bloating.

Diagnostic Studies

Diagnosis begins with a complete history and physical assessment. Description of the pain (frequency, timing, duration,

TABLE 47.11 PATIENT & CAREGIVER TEACHING

Constipation

Include the following instructions when teaching the patient and caregiver about managing constipation:

1. Eat Fiber

Eat 20 to 30 g of fiber per day. Gradually increase the amount of fiber eaten over 1 to 2 weeks. Fiber softens hard stool and adds bulk to stool, promoting evacuation. Eat prunes or drink prune juice daily. Prunes stimulate defecation.

- Foods high in fiber: raw vegetables and fruits, beans, breakfast cereals (All-Bran, oatmeal)
- Fiber supplements: Metamucil, Citrucel, FiberCon

2. Drink Fluids

Fluid softens hard stools. Drink 2 L/day. Drink water or fruit juices. Avoid caffeinated coffee, tea, and cola. Caffeine stimulates fluid loss through urination.

3. Exercise Regularly

Walk, swim, or bike at least 3 times per week. Contract and relax abdominal muscles when standing or by doing sit-ups to strengthen muscles and prevent straining. Exercise stimulates bowel motility and moves stool through the colon.

4. Establish a Regular Time to Defecate

First thing in the morning or after the first meal of the day is the best time because people often have the urge to defecate at this time.

5. Do Not Delay Defecation

Respond to the urge to have a bowel movement as soon as possible. Delaying defecation results in hard stools and a decreased "urge" to defecate. Water is absorbed from stool by the colon over time. The colon becomes less sensitive to the presence of stool in the rectum.

6. Record Your Bowel Elimination Pattern

Develop a habit of recording on your calendar when you have a bowel movement. Regular monitoring of bowel movement will help you identify a problem early.

7. Use Laxatives and Enemas as Ordered

Do not overuse laxatives and enemas because they cause dependence. People who overuse them become unable to have a bowel movement without them.

location), accompanying symptoms, and sequence of symptoms (e.g., pain before or after vomiting) provide vital clues about the origin of the problem. Note the patient's position. The fetal posture is common with peritoneal irritation (e.g., appendicitis). The patient may be supine with outstretched legs with visceral pain. Restlessness and inability to find a comfortable position occur with obstructions from kidney stones and gallstones.

Physical assessment includes assessment of the abdomen, rectum, and pelvis. A complete blood count (CBC), urinalysis, abdominal x-ray, and ECG are done, along with an ultrasound or CT scan. Women of childbearing age may need a pregnancy test to rule out an ectopic pregnancy.

Interprofessional Care

Emergency management of the patient with acute abdominal pain is shown in Table 47.12. The goal is to identify and treat the cause and monitor and treat complications, especially shock. Carefully use pain medications to provide pain relief without interfering with diagnostic accuracy when patients have nontraumatic acute abdominal pain.

An immediate surgical consult may be needed. The HCP may perform a diagnostic laparoscopy to inspect the surface of abdominal organs, obtain biopsy specimens, perform laparoscopic ultrasounds, and remove organs. A laparotomy is done when laparoscopic techniques are inadequate. If the cause of the acute abdomen can be surgically removed (e.g., inflamed appendix) or surgically repaired (e.g., ruptured abdominal aneurysm), surgery is considered definitive therapy.

❖ NURSING MANAGEMENT: ACUTE ABDOMINAL PAIN

◆ Assessment

For the patient with acute abdominal pain, take vital signs immediately and again at frequent intervals. Increased pulse and decreasing BP indicate impending shock. A fever suggests an inflammatory or infectious process. Intake and output give essential information about the adequacy of vascular volume. Altered mental status occurs with poor cerebral perfusion. Skin color, skin temperature, and peripheral pulse strength give information about perfusion.

Inspect the abdomen for distention, masses, abnormal pulsation, symmetry, hernias, rashes, scars, and pigmentation changes. Auscultate bowel sounds. Decreased or absent bowel sounds in a quadrant may occur with a bowel obstruction, peritonitis, or paralytic ileus. Perform gentle palpation to help determine the location and level of the patient's pain. Assess for involuntary guarding and rigidity, which occur with peritoneal irritation.

Ask the patient about the onset, location, intensity, duration, frequency, and character of pain. Note whether the pain has spread or moved to new sites (quadrants) and what makes the pain worse or better. Ask if the pain is related to other symptoms, such as nausea, vomiting, changes in bowel and bladder habits, or vaginal discharge in women. Assessment of vomiting includes the amount, color, consistency, and odor of the emesis. Ask about usual and changes in bowel patterns and habits.

◆ Clinical Problems

Clinical problems for the patient with acute abdominal pain include:

- Pain
- Fluid imbalance
- Risk for infection

◆ Planning

The overall goals are that the patient with acute abdominal pain will have (1) relief of abdominal pain, (2) resolution of inflammation, (3) freedom from complications (especially hypovolemic shock), and (4) normal nutrition status.

◆ Implementation

General care for patients with acute abdominal pain involves managing fluid and electrolyte imbalances, pain, and anxiety. Assess the quality and intensity of pain at regular intervals.

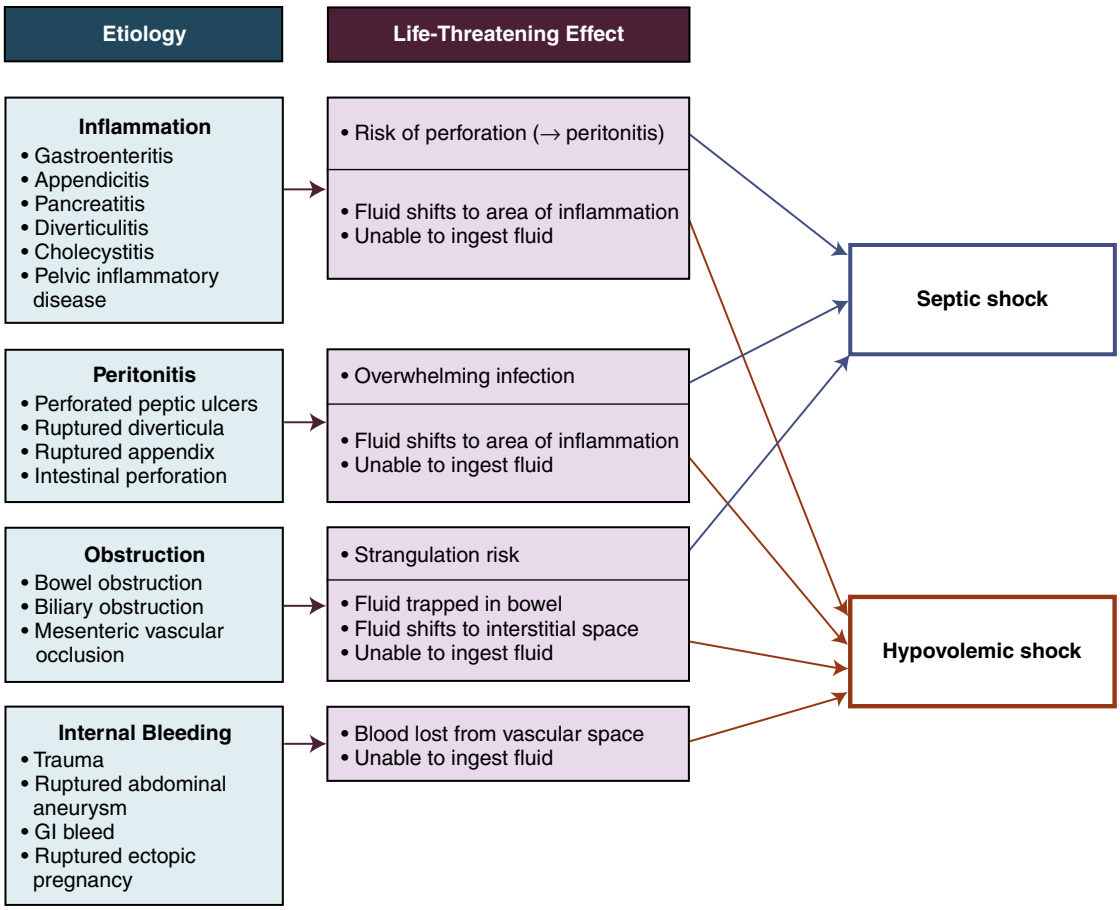

Fig. 47.2 Cause of acute abdominal pain and pathophysiologic sequelae.

TABLE 47.12 EMERGENCY MANAGEMENT

Acute Abdominal Pain

Etiology

Gynecologic Problems
- Pelvic inflammatory disease
- Ruptured ectopic pregnancy
- Ruptured ovarian cyst

Infectious Disease
- *Escherichia coli* O157:H7
- *Giardia*
- *Salmonella*

Inflammation
- Appendicitis
- Cholecystitis
- Diverticulitis
- Gastritis
- IBD
- Pancreatitis
- Pyelonephritis

Vascular Problems
- Mesenteric vascular occlusion
- Ruptured aortic aneurysm

Other
- Obstruction or perforation of abdominal organ
- GI bleeding or ischemia
- Myocardial infarction
- Trauma

Assessment Findings

Abdominal and GI Findings
- Diffuse, localized, dull, burning, or sharp abdominal pain or tenderness
- Abdominal distention
- Abdominal rigidity
- Diarrhea
- Hematemesis
- Melena
- Nausea and vomiting
- Rebound tenderness

Hypovolemic Shock
- ↓ BP
- Cool, clammy skin
- ↓ Level of consciousness
- ↑ HR
- ↓ Urine output (<0.5 mL/kg/h)

Interventions

Initial
- Ensure patent airway.
- Apply O_2 via nasal cannula or nonrebreather mask.
- Establish IV access with large-bore catheter and infuse warm normal saline or lactated Ringer's solution. Insert another large-bore catheter if shock present.
- Obtain blood for CBC and electrolyte levels.
- Obtain blood for amylase level, pregnancy tests, clotting studies, and type and crossmatch as appropriate.
- Insert indwelling urinary catheter.
- Obtain urinalysis.
- Insert NG tube as needed.

Ongoing Monitoring
- Monitor vital signs, level of consciousness, O_2 saturation, and intake/output.
- Obtain pain assessment.
- Assess amount and character of emesis.
- Anticipate surgical intervention.
- Keep patient NPO.

Provide medication and other comfort measures. Maintain a calm environment and give information to help decrease anxiety. A nasogastric (NG) tube with low suction may decrease vomiting and relieve discomfort from gastric distention. Conduct ongoing assessments of vital signs, intake and output, and level of consciousness, which are key indicators of hypovolemic shock.

Acute Care

Preoperative care. Preoperative care includes the emergency care of the patient described in Table 47.12 and general care of the preoperative patient (see Chapter 18).

Postoperative care. Postoperative care depends on the type of surgery. See eNursing Care Plan 20.1, a general plan for the postoperative patient, on the website for Chapter 20.

After surgery, some patients will have an NG tube with low suction to empty the stomach and prevent gastric dilation. If the upper GI tract was entered, drainage from the NG tube may be dark brown to dark red for the first 12 hours. Later it should be light yellowish-brown, or it may have a greenish tinge because of bile. If a dark red color continues or you see bright red blood, notify the HCP because of the risk for hemorrhage. "Coffee-grounds" granules in the drainage mean the blood has been changed by acidic gastric secretions.

Nausea and vomiting are common after a laparotomy and result from the surgery, decreased peristalsis, or pain medications. Antiemetics, such as ondansetron (Zofran), may be given. Monitor fluid and electrolyte status along with BP, heart rate, and respirations. See Chapter 46 for information about managing nausea and vomiting.

Swallowed air and reduced peristalsis from decreased mobility, manipulation of the abdominal organs during surgery, and anesthesia can result in abdominal distention and gas pains. Early ambulation helps restore peristalsis, expel flatus, and reduce gas pain. Gradually, as intestinal activity increases, distention and gas pain disappear.

Ambulatory Care

Preparation for discharge begins soon after surgery. Teach the patient and caregiver about any modifications in activity, care of the incision, diet, and drug therapy. Initially, the patient starts on clear liquids after surgery and then, if tolerated, progresses to a regular diet.

Early ambulation speeds recovery. Normal activities are resumed gradually with planned rest periods. Patients often have restrictions not to lift anything heavier than a few pounds. The patient and caregiver should be aware of possible complications. Teach them to notify the HCP at once if fever is greater than 101°F (38.6°C), vomiting, pain, weight loss, incisional drainage, or changes in bowel function occur.

Evaluation

The expected outcomes are that the patient with acute abdominal pain will:

- Have resolution of the cause of the acute abdominal pain
- Experience relief of abdominal pain and discomfort
- Be free from complications, especially hypovolemic shock and sepsis
- Have normal fluid, electrolyte, and nutrition status

ABDOMINAL TRAUMA

Etiology and Pathophysiology

Injuries to the abdominal area usually are a result of blunt trauma or penetrating injuries. Common injuries of the abdomen include lacerated liver, ruptured spleen, mesenteric artery tears, diaphragm rupture, urinary bladder rupture, great vessel tears, renal or pancreas injury, and stomach or intestine rupture.

Blunt trauma often occurs with motor vehicle accidents, direct blows, and falls. It may not be obvious because it does not leave an open wound. Both compression injuries (e.g., direct blow to the abdomen) and shearing injuries (e.g., rapid deceleration in a motor vehicle crash allowing some tissue to move forward while other tissues stay stationary) occur with blunt trauma. Penetrating injuries occur when a gunshot or stabbing produces an obvious, open wound into the abdomen.

When solid organs (liver, spleen) are injured, bleeding can be profuse, resulting in hypovolemic shock. When contents from hollow organs (e.g., bladder, stomach, intestines) spill into the peritoneal cavity, the patient is at risk for peritonitis. In addition, abdominal compartment syndrome can develop.

Abdominal compartment syndrome, or abdominal hypertension, is excessively high pressure in the abdomen. Anything that increases the volume in the abdominal cavity (e.g., edematous organs, bleeding) increases abdominal pressure. This high pressure restricts ventilation, potentially leading to respiratory failure. The high pressure decreases cardiac output, venous return, and arterial perfusion of organs. Decreased perfusion to the kidneys can lead to renal failure.

Clinical Manifestations

Careful assessment provides important clues to the type and severity of injury. Intraabdominal injuries are often associated with rib fractures, fractured pelvis, spinal injury, and thoracic injury. If the patient was in an automobile accident, a contusion or abrasion across the lower abdomen may indicate internal organ trauma from the seat belt. Seat belts can produce blunt trauma to abdominal organs by pressing the intestine and pancreas into the spinal column.

Classic manifestations of abdominal trauma are (1) guarding and splinting of the abdominal wall (indicating peritonitis); (2) a hard, distended abdomen (occurs with intraabdominal bleeding); (3) decreased or absent bowel sounds; (4) abrasions or bruising over the abdomen; (5) abdominal pain; (6) hematemesis or hematuria; and (7) signs of hypovolemic shock (Table 47.13). Bruising around the umbilicus *(Cullen sign)* or flanks *(Grey Turner sign)* may mean retroperitoneal hemorrhage. Loss of bowel sounds occurs with peritonitis. If the diaphragm ruptures, you may hear bowel sounds (if present) in the chest. Auscultation of bruits indicates arterial damage.

TABLE 47.13 EMERGENCY MANAGEMENT

Abdominal Trauma

Etiology	Assessment Findings	Interventions
Blunt • Assault with a blunt object • Crush injury • Explosions • Falls • Motor vehicle collisions • Pedestrian event **Penetrating** • Gunshot wounds • Impalement • Knife • Other missiles	**Abdominal and GI Findings** • Abdominal distention • Abdominal pain with palpation • Abdominal rigidity • Absent or ↓ bowel sounds • Hematemesis • Hematuria • Nausea and vomiting • Rebound tenderness **Hypovolemic Shock** • ↓ BP • ↑ HR • ↓ Level of consciousness • Tachypnea **Surface Findings** • Abrasions, bruising on abdominal wall, flank, or peritoneum • Impaled object • Open wounds: lacerations, eviscerations, puncture wounds, gunshot wounds	**Initial** • If unresponsive, assess circulation, airway, and breathing. • If responsive, monitor airway, breathing, and circulation. • Apply appropriate O_2 therapy. • Control external bleeding with direct pressure or sterile pressure dressing. • Establish IV access with 2 large-bore catheters and infuse normal saline or lactated Ringer's solution. • Obtain blood for type and crossmatch and CBC. • Remove clothing. • Stabilize impaled objects with bulky dressing—*do not remove.* • Cover protruding organs or tissue with sterile saline dressing. • Insert indwelling urinary catheter if there is no blood at the meatus, pelvic fracture, or boggy prostate. • Obtain urine for urinalysis. • Insert NG tube if no evidence of facial trauma. • Anticipate diagnostic peritoneal lavage. **Ongoing Monitoring** • Monitor vital signs, level of consciousness, O_2 saturation, and urine output. • Maintain patient warmth using blankets, warm IV fluids, or warm humidified O_2.

Diagnostic Studies

Laboratory tests include a baseline CBC and urinalysis. Even when bleeding, the patient will have normal hemoglobin and hematocrit because fluids are lost at the same rate as the red blood cells. Deficiencies are evident after fluid resuscitation begins. Blood in the urine may be a sign of kidney or bladder damage. Other laboratory work includes arterial blood gases, prothrombin time, electrolytes, BUN and creatinine, and type and crossmatch (in anticipation of possible blood transfusions). An abdominal CT scan and focused abdominal ultrasound are the most common diagnostic methods, but the patient must be stable before going for CT. Diagnostic peritoneal lavage can detect blood, bile, intestinal contents, and urine in the peritoneal cavity.

Interprofessional and Nursing Care

Emergency management of abdominal trauma is outlined in Table 47.13. Volume expanders or blood are given if the patient is hypotensive. An NG tube with low suction will decompress the stomach and prevent aspiration. Frequent, ongoing assessment is needed to monitor fluid status, detect deterioration in condition, and determine the need for surgery. The decision about whether to do surgery depends on clinical findings, diagnostic test results, and the patient's response to conservative management. Do not remove an impaled object until skilled care is available. Removal may cause further injury and bleeding.

CHRONIC ABDOMINAL PAIN

Chronic abdominal pain may originate from abdominal structures or be referred from a site with the same or a similar nerve supply. The pain is often described as dull, aching, or diffuse. Common causes include irritable bowel syndrome (IBS), peptic ulcer disease, chronic pancreatitis, hepatitis, pelvic inflammatory disease, adhesions, and vascular insufficiency.

Diagnosing the cause of chronic abdominal pain begins with a thorough history and description of specific pain characteristics, including severity, location, duration, and onset. Assess pain frequency and factors that increase or decrease the pain, such as eating, defecation, and activities. Endoscopy, CT scan, MRI, laparoscopy, and barium studies may be done. Treatment for chronic abdominal pain depends on the underlying cause.

IRRITABLE BOWEL SYNDROME

Irritable bowel syndrome (IBS) is a disorder characterized by chronic abdominal pain and altered bowel patterns. Patients may have diarrhea or constipation, or a mix of both. IBS affects women 2 to 2.5 times more often than men.

IBS has no known cause. Psychologic stressors (e.g., depression, anxiety, panic disorders, posttraumatic stress disorder) are associated with the development and exacerbation of IBS. Many people with IBS have a family member with the disorder. Patients may report a history of GI infections and adverse reactions to food. Diet intolerances that may contribute to symptoms include gluten and fermentable oligo-, di-, and monosaccharides and polyols (FODMAPs). Examples of oligosaccharides are wheat and rye products, some fruits and vegetables, onions, garlic, legumes, and nuts. The disaccharide lactose is found in milk and milk products. Fructose is a monosaccharide found in honey, apples, pears, and high-fructose corn syrup. Polyols are found in apples, pears, stone fruits, cauliflower, mushrooms, and artificial sweeteners, like sorbitol.

IBS is diagnosed solely on symptoms. The Rome IV criteria for diagnosing IBS require the presence of abdominal pain and/or discomfort at least 1 day per week for 3 months that is associated with 2 or more of the following: related to defecation, change in stool frequency, and change in the stool form.[6] Depending on the stool patterns, IBS is categorized as IBS with constipation (IBS-C), IBS with diarrhea (IBS-D), IBS mixed, and IBS unsubtyped. Other common symptoms include abdominal distention, nausea, flatulence, bloating, urgency, mucus in the stool, and sensation of incomplete evacuation. Non-GI symptoms may include fatigue, headache, and sleep problems.

The key to diagnosis is a thorough history and physical assessment. Ask patients to describe symptoms, health history (including psychosocial factors, such as stress and anxiety), family history, and drug and diet history. Determine if and how IBS symptoms interfere with school, work, and social activities. Diagnostic tests are used to rule out other disorders, such as CRC, IBD, endometriosis, and malabsorption disorders (lactose intolerance, celiac disease).

No single therapy is effective for all patients with IBS. Treatment includes psychologic support, diet and lifestyle changes, and drugs to regulate stool output and reduce discomfort. Patients may benefit from keeping a diary of symptoms, diet, and episodes of stress to help identify any factors that trigger the IBS symptoms. Cognitive behavior therapy and stress management techniques may help a patient cope. Participating in regular exercise reduces bloating, constipation, and stress-related symptoms.

Review with the patient foods that are high in FODMAPs. Teach them to follow a low-FODMAP diet.[7] If dairy products tend to cause symptoms, yogurt may be the best option because of the lactobacillus bacteria it contains. Probiotics can improve symptoms. Tell the patient with flatulence to avoid common gas-producing foods, such as broccoli and cabbage. For those with IBS-C, encourage a high-fiber diet to produce soft, painless bowel movements.

Drug therapy focuses on the dominant bowel symptom and pain. All patients with IBS may receive benefit from antidepressants and antispasmodic agents (hyoscyamine, dicyclomine). Antispasmodics decrease GI motility and smooth muscle spasms, reducing pain and diarrhea.

Treatment for IBS-D includes rifaximin, the opioid agonist eluxadoline (Viberzi), and the selective serotonin 5-HT_3 antagonist alosetron.[6] Eluxadoline decreases colonic contractions to reduce diarrhea and pain. Alosetron is only given to women with severe IBS-D that did not respond to other therapy. Because of serious side effects (severe constipation, ischemic colitis), it is available only in a restricted access program. Eluxadoline and alosetron are taken daily. Rifaximin is given as a 2-week course of treatment with repeated courses as needed. Loperamide may help some patients.

DRUG ALERT

Alosetron (Lotronex)

- Taking this drug can cause severe constipation and ischemic colitis (reduced blood flow to the intestines).
- Teach the patient to stop the drug and contact the HCP if constipation, rectal bleeding, bloody diarrhea, or abdominal pain occurs.

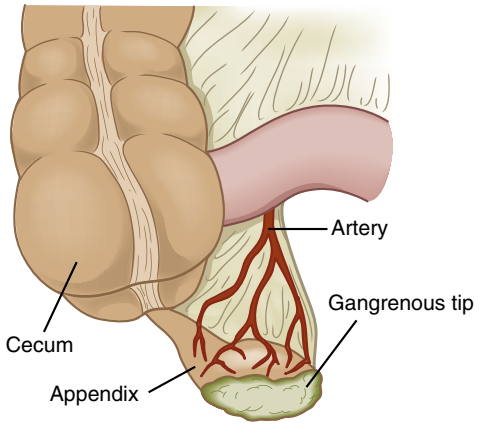

Fig. 47.3 In appendicitis, the blood supply of the appendix is impaired by inflammation and bacterial infection, which may result in gangrene.

Besides laxative therapy, those with IBS-C may take linaclotide (Linzess). It is contraindicated in patients with a history of mechanical obstruction or prior bowel surgery. Women with IBS-C may benefit from lubiprostone (Amitiza).

INFLAMMATORY DISORDERS

APPENDICITIS

Appendicitis is inflammation of the appendix, a narrow blind tube that extends from the inferior part of the cecum (Fig. 47.3). It is the most common reason for emergency abdominal surgery.

Etiology and Pathophysiology

About 7% of people will develop appendicitis sometime during their lifetime.[8] It is most common in those 10 to 30 years of age. Appendicitis is thought to be caused by luminal obstruction. Obstruction results in distention, venous engorgement, and the accumulation of mucus and bacteria. This can lead to gangrene, perforation, and peritonitis.

Clinical Manifestations

Diagnosis can be difficult because many patients do not have classic symptoms. Appendicitis typically begins with dull periumbilical pain, followed by anorexia, nausea, and vomiting. The pain is persistent and continuous, eventually shifting to the right lower quadrant and localizing at *McBurney point* (halfway between the umbilicus and right iliac crest). A low-grade fever may develop. Further assessment reveals rigidity, rebound tenderness, and muscle guarding. Positive psoas (pain with extension of right thigh), obturator (pain with passive internal rotation of the flexed thigh), and Rovsing signs (increased right lower quadrant pain occurring with left lower quadrant palpation) lend to the diagnosis.[8] Coughing or sneezing worsens pain. The patient usually prefers to lie still, often with the right leg flexed.

Diagnostic Studies and Interprofessional Care

The assessment includes a complete history, physical assessment, and a differential WBC count. Most patients have a

mildly to moderately high WBC count. A urinalysis is done to rule out genitourinary conditions that mimic appendicitis. CT scan is the preferred diagnostic procedure. However, ultrasound and MRI are options.

If there is a delay in diagnosis and treatment, the appendix can rupture, and the resulting peritonitis can be fatal. The standard treatment is an immediate *appendectomy* (surgical removal of appendix). If the inflammation is localized, surgery should be done as soon as the diagnosis is made. Antibiotics and fluid resuscitation are started before surgery.

If the appendix has ruptured and there is evidence of peritonitis or an abscess, giving IV fluids and antibiotic therapy for 6 to 8 hours before the appendectomy helps prevent dehydration and sepsis.

❖ NURSING MANAGEMENT: APPENDICITIS

Managing the patient who potentially has appendicitis focuses on preventing fluid volume deficit, relieving pain, and preventing complications. To ensure the stomach is empty in case surgery is needed, keep the patient NPO until the HCP evaluates the patient. Monitor vital signs and perform ongoing assessment to detect any deterioration in condition. Give IV fluids, analgesics, and antiemetics as ordered. Provide comfort measures.

Postoperative care for the patient who had an appendectomy is similar to the patient after a laparotomy. Patients are usually discharged within 24 hours after an uncomplicated laparoscopic appendectomy. Ambulation begins a few hours after surgery, and the diet is advanced as tolerated. Those who had a perforation usually have a longer length of stay and need IV antibiotic therapy. Most patients resume normal activities 2 to 3 weeks after surgery.

CHECK YOUR PRACTICE

A 28-year-old female patient comes to the emergency department with acute abdominal pain.

- What manifestations would make you suspect appendicitis is the cause of the abdominal pain?

PERITONITIS

Etiology and Pathophysiology

Peritonitis, inflammation of the peritoneum, may result from contamination of the peritoneal cavity with bacteria, irritating chemicals, or both. Common causes are listed in Table 47.14. Primary peritonitis occurs when blood-borne organisms enter the peritoneal cavity. It is not related to any other intraabdominal problem. For example, ascites from cirrhosis of the liver provides an excellent environment for bacteria to flourish.

Secondary peritonitis is much more common. It occurs when abdominal organs perforate or rupture and release their contents (bile, enzymes, bacteria) into the peritoneal cavity.

TABLE 47.14 Common Causes of Peritonitis

Primary

- Blood-borne organisms
- Cirrhosis with ascites

Secondary

- Appendicitis with rupture
- Blunt or penetrating trauma to abdominal organs
- Diverticulitis with rupture
- Intestinal cancer
- Ischemic bowel disorders
- Pancreatitis
- Perforated intestine, uterus, urinary bladder, stomach
- Perforated peptic ulcer
- Peritoneal dialysis
- Postoperative (breakage of anastomosis)

Common causes include a ruptured appendix, perforated ulcer, diverticulitis, and trauma from gunshot or knife wounds.

Intestinal contents and bacteria irritate the normally sterile peritoneum and produce an initial chemical peritonitis. Bacterial peritonitis develops a few hours later. The resulting inflammatory response leads to massive fluid shifts (peritoneal edema) and adhesions as the body tries to wall off the infection.

Clinical Manifestations

Severe, continuous abdominal pain is the most common symptom of peritonitis. A universal sign is tenderness over the involved area. Rebound tenderness, rigidity, and spasm are other signs of peritoneal irritation. Patients may lie still and take only shallow breaths because movement worsens the pain. Abdominal distention, fever, tachycardia, tachypnea, nausea, vomiting, and altered bowel habits may be present. These manifestations vary, depending on the severity and acuteness of the underlying condition. Complications include hypovolemic shock, sepsis, intraabdominal abscess formation, paralytic ileus, and acute respiratory distress syndrome. Peritonitis can be fatal if treatment is delayed.

Diagnostic Studies and Interprofessional Care

A CBC is done to determine elevations in WBC count and hemoconcentration from fluid shifts (Table 47.15). Peritoneal aspiration may be done with the fluid analyzed for blood, bile, pus, bacteria, fungus, and amylase content. An abdominal x-ray may show dilated loops of bowel consistent with paralytic ileus, free air if perforation has occurred, or air and fluid levels if an obstruction is present. Ultrasound and CT scans may be useful in identifying ascites and abscesses. Peritoneoscopy may be helpful in the patient without ascites. It allows for direct examination of the peritoneum and the ability to obtain biopsy specimens for diagnosis.

Patients with milder cases of peritonitis or those who are poor surgical risks receive conservative care. Treatment consists of antibiotics, NG suction, analgesics, and IV fluid administration. Surgery is indicated to locate the cause of the inflammation, drain purulent fluid, and repair any damage, such as to perforated organs.

TABLE 47.15 Interprofessional Care

Peritonitis

Diagnostic Assessment

- History and physical assessment
- CBC, including WBC differential
- Serum electrolytes
- Abdominal x-ray
- Abdominal paracentesis and culture of fluid
- CT scan or ultrasound
- Peritoneoscopy

Management

Preoperative or Nonoperative

- NPO status
- IV fluid replacement
- NG to low-intermittent suction
- O_2 PRN
- PN as needed

Drug Therapy

- Analgesics (e.g., morphine)
- Antibiotic therapy
- Antiemetics as needed

Postoperative

- NPO status
- NG to low-intermittent suction
- Semi-Fowler's position
- IV fluids with electrolyte replacement
- PN as needed
- Blood transfusions as needed

Drug Therapy

- Antibiotic therapy
- Sedatives and opioids
- Antiemetics as needed

❖ NURSING MANAGEMENT: PERITONITIS

◆ Assessment

Assessing the patient's pain, including the location, is important and may help to determine the cause of peritonitis. Assess for the presence and quality of bowel sounds, increasing abdominal distention, abdominal guarding, nausea, fever, and manifestations of hypovolemic shock.

◆ Clinical Problems

Clinical problems for the patient with peritonitis include:

- Pain
- Fluid imbalance
- Impaired GI function
- Risk for infection

◆ Planning

The overall goals are that the patient with peritonitis will have (1) resolution of inflammation, (2) relief of abdominal pain, (3) freedom from complications (especially sepsis, hypovolemic shock), and (4) normal nutrition status.

◆ Implementation

The patient with peritonitis is extremely ill and needs skilled supportive care. Establish IV access so that you can give replacement fluids lost to the peritoneal cavity and have access for antibiotic therapy. Monitor the patient for pain and response to analgesics. You may position the patient with knees flexed to increase comfort. Sedatives may relieve anxiety and promote rest.

Accurate monitoring of intake and output and electrolyte status is essential to determine replacement therapy. Frequently monitor vital signs. Give antiemetics to decrease nausea and vomiting and prevent further fluid and electrolyte losses. Place the patient on NPO status. The patient may need an NG tube to decrease gastric distention and further leakage of bowel contents into the peritoneum. Give oxygen therapy as needed.

If the patient had an open surgical procedure, drains are inserted to remove purulent drainage and excess fluid. Postoperative care is similar to that for the patient who had a laparotomy.

GASTROENTERITIS

Gastroenteritis is an inflammation of the mucosa of the stomach and small intestine. Features of *acute gastroenteritis* are sudden diarrhea accompanied by nausea, vomiting, fever, and abdominal cramping. Viruses are the most common cause of gastroenteritis (Table 47.1).

Norovirus is a leading cause of foodborne outbreaks of acute gastroenteritis. Laboratory testing to identify norovirus is useful when a number of people simultaneously have gastroenteritis and there is a clear avenue for virus transmission, such as a shared location or food.

Most cases of gastroenteritis are self-limiting. Encourage oral fluids containing glucose and electrolytes to prevent and treat dehydration. Older adults and chronically ill patients may be unable to consume enough fluids to make up for fluid loss. If dehydration occurs, IV fluid replacement may be needed. Nursing management of the patient with gastroenteritis is the same as for the patient with acute diarrhea.

INFLAMMATORY BOWEL DISEASE

Inflammatory bowel disease (IBD) is a chronic inflammation of the GI tract characterized by periods of remission interspersed with periods of exacerbation. We classify IBD as either Crohn's disease or ulcerative colitis (UC) based on clinical manifestations (Table 47.16). As the name suggests, **ulcerative colitis** is usually limited to the colon. **Crohn's disease** can involve any segment of the GI tract from the mouth to the anus. About 1.3 million Americans have IBD. It often begins during the teenage years and early adulthood. IBD has a second peak in the 6th decade.

Etiology and Pathophysiology

We do not know the exact cause of IBD. IBD is an autoimmune disease involving an immune reaction to a person's own intestinal tract. We think that it results from an overactive,

TABLE 47.16 Comparison of Ulcerative Colitis and Crohn's Disease

Characteristic	Ulcerative Colitis	Crohn's Disease
Clinical		
Usual age at onset	Teens to mid-30s; after 60	Teens to mid-30s; after 60
Abdominal pain	Common, severe constant	Common, cramping
Diarrhea	Common	Common
Fever (intermittent)	During acute attacks	Common
Malabsorption and nutrition deficiencies	Minimal incidence	Common
Rectal bleeding	Common	Sometimes
Tenesmus	Common	Rare
Weight loss	Rare	Common, may be severe
Pathologic		
Location	Usually starts in rectum and spreads in a continuous pattern up the colon	Occurs anywhere along GI tract. Most common site is distal ileum
Cobblestoning of mucosa	Rare	Common
Depth of involvement	Mucosa	Entire thickness of bowel wall (transmural)
Distribution	Continuous areas of inflammation	Healthy tissue interspersed with areas of inflammation (skip lesions)
Pseudopolyps	Common	Rare
Small bowel involvement	Minimal	Common
Complications		
Cancer	↑ Incidence of CRC after 10 years of disease	↑ Incidence of small intestinal cancer ↑ Incidence of CRC but less than with ulcerative colitis
C. difficile infection	↑ Incidence and severity	↑ Incidence and severity
Perforation	Common (because of toxic megacolon)	Common (because inflammation involves entire bowel wall)
Perianal abscess and fistulas	Rare	Common
Strictures	Occasional	Common
Toxic megacolon	More common	Rare

inappropriate, or sustained immune response to environmental and bacterial triggers in a genetically susceptible person. The resulting inflammation causes widespread tissue destruction.

The incidence and frequency of IBD varies depending on geographic location and racial or ethnic background. The highest rates are in the Northern Hemisphere and industrialized nations. The risk for having IBD is greater in urban compared with rural areas and those of White and Ashkenazic Jewish origin than in other racial and ethnic groups.[9] The strongest risk factor is family history. Many people with IBD have a family member with the disorder.

Lifestyle factors, such as diet, smoking, and stress, increase susceptibility by changing the environment of the GI microbial flora. We think that diet factors unique to industrialized countries contribute to the development of IBD. A high intake of refined sugar, total fats, polyunsaturated fatty acid (PUFA), and omega-6 fatty acids seems to increase the risk for IBD. Eating more raw fruits, vegetables, omega-3–rich foods, and fiber decreases risk.[9] Use of nonsteroidal antiinflammatory drugs (NSAIDs), antibiotics, and oral contraceptives also increase risk.[9]

Genetic Link

IBD occurs more often in family members of people with IBD, especially monozygotic twins. To date, we have found over 200 genes associated with IBD. Certain genetic mutations are associated with Crohn's disease, others with UC, and many with both.

The number of gene variations suggests that IBD is a group of diseases that produce similar types of mucosal destruction. The path from genetic mutation to abnormal immune responses varies depending on which gene or genes are affected. Several of the genes are involved in protective functions of the intestines. Others have a role in the immune system, especially in the maturation and function of T cells. Genetic variation may explain differences in patient responses to drug therapies for IBD.

Many of the major genes related to Crohn's disease, including *NOD2, ATG16L1, IL23R,* and *IRGM,* are involved in immune system function. The proteins made from these genes help the immune system sense and respond appropriately to bacteria in the lining of the GI tract. *NOD2* gene changes are associated with a form of Crohn's disease that affects the ileum in persons of northern European descent. Changes in the *NOD2* gene prevent normal immune responses, allowing bacteria to grow unchecked and invade intestinal cells. This causes chronic inflammation and digestive problems.[10]

IBD is more likely to occur in those with other genetic syndromes, including cystic fibrosis. An increased prevalence occurs in the presence of other inflammatory disorders with genetic susceptibility, such as psoriasis and multiple sclerosis.

Pattern of Inflammation in Ulcerative Colitis vs. Crohn's Disease

The pattern of inflammation differs between Crohn's disease and UC (Fig. 47.4). Crohn's disease can occur anywhere in the GI tract, from the mouth to the anus. It most often involves the distal ileum and proximal colon. Segments of normal bowel can occur between diseased portions, so-called "skip" lesions. The inflammation in Crohn's disease involves all layers of the bowel wall. Typically, ulcerations are deep, longitudinal, and penetrate between islands of inflamed edematous mucosa, causing the classic cobblestone appearance. Strictures at the areas of inflammation can cause bowel obstruction. Since the inflammation goes through the entire wall, microscopic leaks can allow bowel contents to enter the peritoneal cavity and cause abscesses or peritonitis. In active Crohn's disease, fistulas are common.

UC is a disease of the colon and rectum. It usually starts in the rectum and moves in a continual fashion toward the cecum. Mild inflammation may occur in the terminal ileum. The inflammation and ulcerations occur in the mucosal layer, the innermost layer of the bowel wall. Fistulas and abscesses are rare since inflammation does not extend through all bowel wall

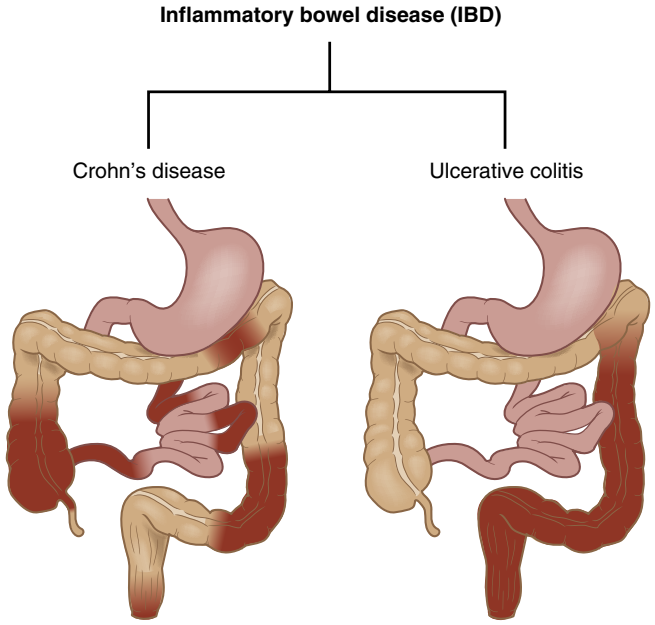

Fig. 47.4 Comparison of distribution patterns of UC and Crohn's disease.

layers. Because water and electrolytes are not absorbed through inflamed mucosa, diarrhea with large fluid and electrolyte losses is common. Breakdown of cells results in protein loss through the stool. Areas of inflamed mucosa form *pseudopolyps,* tongue-like projections into the bowel lumen.

Clinical Manifestations

Both forms of IBD are chronic disorders with mild to severe acute exacerbations that occur at unpredictable intervals. Although the manifestations of Crohn's disease and UC are similar (diarrhea, weight loss, abdominal pain, fever, fatigue), there are differences (Table 47.16).

In Crohn's disease, diarrhea and cramping abdominal pain are common symptoms. If the small intestine is involved, weight loss occurs from inflammation of the small intestine, causing malabsorption. Rectal bleeding sometimes occurs with Crohn's disease, although not as often as with UC.

In UC, the primary problems are bloody diarrhea and abdominal pain. Pain may vary from the mild lower abdominal cramping associated with diarrhea to severe, constant pain from acute perforations. With *mild disease,* diarrhea may consist of no more than 4 semiformed stools daily that contain small amounts of blood. The patient may have no other manifestations. In *moderate disease,* the patient has increased stool output (up to 10 stools/day), increased bleeding, and systemic symptoms (fever, malaise, mild anemia, anorexia). In *severe disease,* diarrhea is bloody, contains mucus, and occurs 10 to 20 times a day. In addition, fever, rapid weight loss (greater than 10% of total body weight), anemia, tachycardia, and dehydration are present.

Complications

Patients with IBD have both local (confined to the GI tract) and systemic (extraintestinal) complications (Fig. 47.5). GI tract complications include hemorrhage, strictures, perforation (with possible peritonitis), abscesses, fistulas, CDI, and toxic megacolon. Toxic megacolon is more common with UC. Patients with toxic megacolon are at risk for perforation and may need an emergency colectomy. Perineal abscesses and fistulas occur in up to a third of patients with Crohn's disease. CDI increases in frequency and severity in patients with IBD.

IBD is related to an increased risk for CRC. Those with Crohn's disease are at increased risk for small intestinal cancer. This makes regular cancer screening important in persons with IBD.[11]

People with IBD may have systemic complications, such as multiple sclerosis and ankylosing spondylitis. Some are related to the inflammatory activity in the bowel. They occur with active inflammation and improve when the IBD improves. Other complications include malabsorption, liver disease (primary sclerosing cholangitis), and osteoporosis. Routine liver function tests are important because primary sclerosing cholangitis can lead to liver failure. Both men and women with IBD are at risk for osteoporosis. They need a bone density scan at baseline and every 2 years.

Diagnostic Studies

The diagnosis of IBD includes ruling out diseases with similar symptoms and figuring out whether the patient has Crohn's disease or UC. The symptoms of early Crohn's disease are like those of IBS. Diagnostic studies provide information about disease severity and complications. A CBC typically shows iron deficiency anemia from blood loss. A high WBC count may be a sign of toxic megacolon or perforation. Decreased serum sodium, potassium, chloride, bicarbonate, and magnesium levels occur due to fluid and electrolyte losses from diarrhea and vomiting. Hypoalbuminemia is present with severe disease because of poor nutrition or protein loss. Increased erythrocyte sedimentation rate, C-reactive protein, and WBCs reflect inflammation. The stool is examined for blood, pus, and mucus. Stool cultures can determine if infection is present.

Imaging studies, such as double-contrast barium enema, small bowel series (small bowel follow-through), transabdominal ultrasound, CT, and MRI, are useful for diagnosing IBD. Colonoscopy allows for examination of the entire large intestine lumen and sometimes the distal ileum. The HCP can determine the extent of inflammation, ulcerations, pseudopolyps, and strictures and obtain biopsy specimens for a definitive diagnosis. Since a colonoscope can enter only as far as the distal ileum, capsule endoscopy (see Chapter 43) may be needed to diagnose Crohn's disease in the small intestine.

Interprofessional Care

The goals of treatment of IBD are to (1) rest the bowel, (2) control inflammation, (3) correct malnutrition, (4) provide symptomatic relief, and (5) improve quality of life. There is no cure for IBD. Treatment relies on drugs to treat the inflammation and maintain remission (Table 47.17). Several drugs are available to treat IBD. Since the recurrence rate is high after surgical treatment of Crohn's disease, drugs are the preferred treatment. Hospitalization is needed if the patient does not respond to drug therapy, the disease is severe, or complications are suspected.

Drug Therapy

The goal of drug treatment in IBD is to induce and maintain remission. Five major classes of drugs are used: aminosalicylates, antimicrobials, corticosteroids, immunomodulators, and biologic therapies (Table 47.18). Drug choice depends on the location and severity of inflammation. Initial treatment for UC includes a corticosteroid for symptom relief with an aminosalicylate or a biologic therapy, depending on the severity of the disease. The management of Crohn's disease also includes biologic therapy, along with a corticosteroid.[12] These therapies can be used alone or as combination therapy.[12]

Drugs containing 5-aminosalicylic acid (5-ASA) treat both UC and Crohn's disease. They are much more effective for UC.[13] Their exact mechanism of action is unclear. We think they suppress the production of proinflammatory cytokines and other inflammatory mediators in the intestine. People can take aminosalicylates orally or rectally. Oral forms are available with different coatings that affect where the medication is released in the GI tract. This allows for more effective treatment of specific symptoms. Rectal use offers the advantage of delivering the 5-ASA directly to the affected tissue. This is useful in treating inflammation in the rectum and/or large intestine. The combination of oral and rectal therapy is better than oral or rectal therapy alone.

Biologics reduce IBD-related inflammation by blocking specific proteins that play a role in inflammation. There are 4 main classes: anti-TNF agents, alpha 4-integrin inhibitors, interleukin (IL)-12/23 antagonists, and Janus kinase (JAK) inhibitors.[12]

The anti-TNF agent infliximab (Remicade) is given IV to induce and maintain remission in patients with UC and Crohn's disease and in patients with draining fistulas. The other anti-TNF agents are given subcutaneously.[13] They all have similar

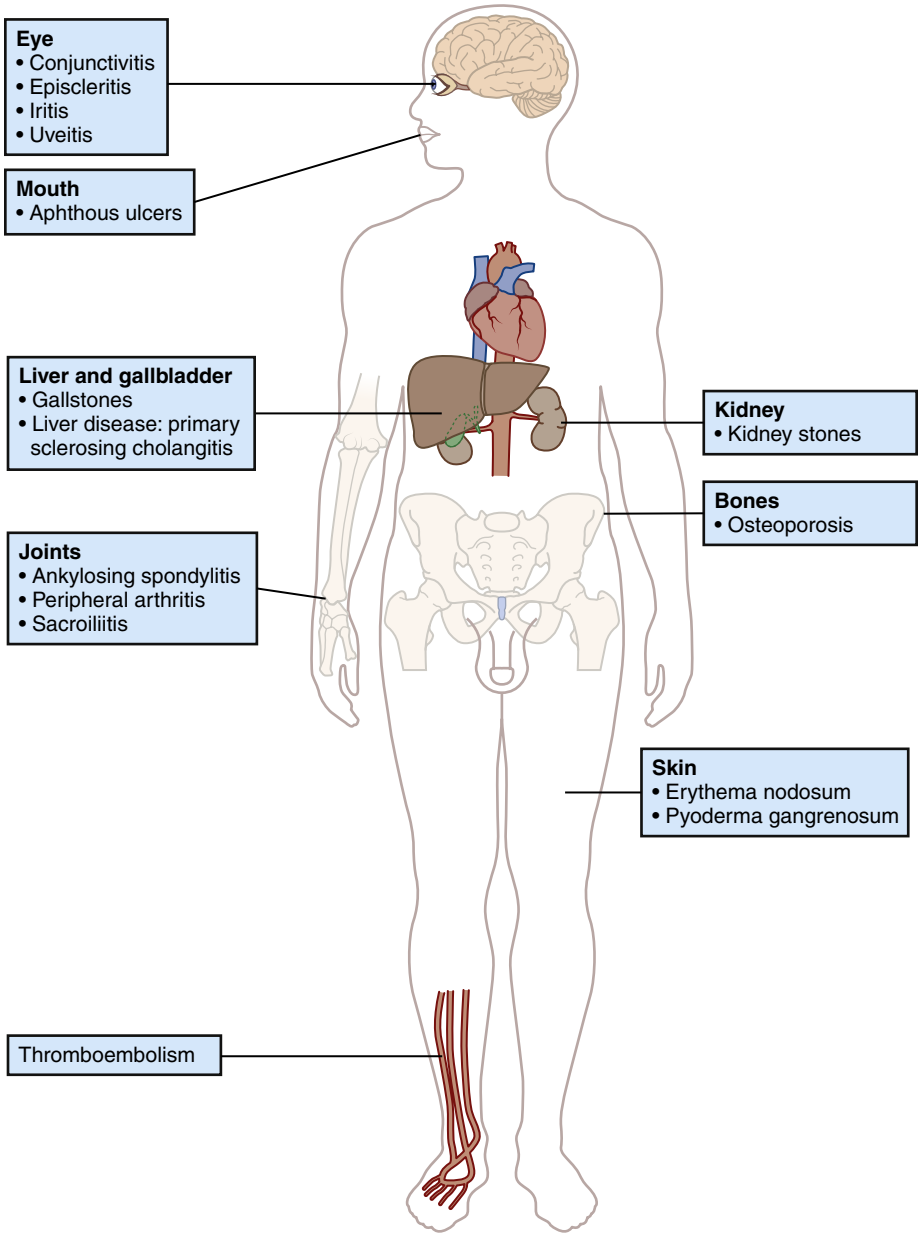

Fig. 47.5 Extraintestinal manifestations of IBD.

side effects. The most common ones are upper respiratory and urinary tract infections, headaches, nausea, joint pain, and abdominal pain. More serious effects include reactivation of hepatitis and tuberculosis (TB); opportunistic infections; and cancers, especially lymphoma. Patients are tested for TB and hepatitis before treatment begins. Therapy must be delayed if an active infection is present. They cannot receive live virus immunizations. Teaching includes how to prevent and recognize early signs and symptoms of infection, including fever, cough, malaise, and dyspnea.

TABLE 47.17 Interprofessional Care

Inflammatory Bowel Disease

Diagnostic Assessment

- History and physical assessment
- CBC, erythrocyte sedimentation rate
- Serum chemistries
- Testing of stool for occult blood and infection
- Capsule endoscopy
- Radiologic studies with barium contrast
- Sigmoidoscopy and/or colonoscopy with biopsy
- Ultrasound studies

Management

- High-calorie, high-vitamin, high-protein diet
- EN during exacerbations
- Drug therapy (Table 47.18)
  - Aminosalicylates
  - Antimicrobials
  - Biologic therapies
  - Corticosteroids
  - Immunomodulators
- Physical and emotional rest
- Referral for counseling or support group
- Surgical therapy (Table 47.19)

Alpha 4-integrin inhibitors include natalizumab (Tysabri) and vedolizumab (Entyvio). They inhibit leukocyte adhesion by blocking α_4-integrin, an adhesion molecule. Use is limited to those who have not had an adequate response with other therapies (corticosteroids, immunomodulators, anti-TNF agents). Both are given by IV infusion. Side effects include increased risk for infection, liver toxicity, and hypersensitivity reactions. Because of the risk for progressive multifocal leukoencephalopathy, natalizumab is available only through a restricted program.[13]

The IL-12/23 antagonists, ustekinumab and risankizumab, are given to patients with severe UC and Crohn's disease. They bind IL-12 and IL-23, preventing the activation of T-helper and natural killer cells.[14] Precautions and side effects are similar to the anti-TNF agents. The first dose of ustekinumab is given IV followed by injections every 8 weeks.

JAK inhibitors are the newest drugs used to treat UC. They suppress the immune system by blocking the JAK enzyme and preventing it from activating the specific immune system cells that cause inflammation.[12] Before starting tofacitinib, the patient must be tested for TB. It should not be given with other biologics or immunomodulators.

Patients need to know the risks before starting biologic therapy. The agents may cause allergic reactions. They are immunogenic, meaning that patients receiving them often make antibodies against them. Immunogenicity leads to acute infusion reactions and delayed hypersensitivity-type reactions. The drugs are most effective when given at regular intervals. Infusion reactions are more likely if a drug is stopped and then restarted.

Corticosteroids prevent or decrease inflammation of the intestinal mucosa. They are given for the shortest possible time because of the side effects related to long-term use. Patients with disease in the left colon, sigmoid, and rectum benefit from suppositories, enemas, and foams. They deliver the corticosteroid directly to the inflamed tissue with minimal systemic effects. Oral prednisone is given to patients with mild to moderate disease who did not respond to either 5-ASA or

TABLE 47.18 Drug Therapy

Inflammatory Bowel Disease

Class	Action	Examples
5-Aminosalicylates (5-ASA)	Decrease inflammation by suppressing proinflammatory cytokines and other inflammatory mediators	*Systemic:* balsalazide (Colazal), mesalamine (Asacol, Apriso, Delzicol, Lialda, Pentasa), olsalazine (Dipentum), sulfasalazine (Azulfidine) *Topical:* 5-ASA enema, foam, suppositories
Antimicrobials	Prevent or treat secondary infection	ciprofloxacin (Cipro), clarithromycin (Biaxin), metronidazole (Flagyl)
Biologic therapies	*Anti-TNF agents:* Inhibit the cytokine tumor necrosis factor (TNF)	adalimumab (Humira), certolizumab pegol (Cimzia), golimumab (Simponi), infliximab (Remicade)
	Integrin receptor antagonists: Prevent migration of leukocytes from bloodstream to inflamed tissue	natalizumab (Tysabri), vedolizumab (Entyvio)
	IL-12/23 antagonists: Bind IL-12 and IL-23, preventing the activation of T-helper and natural killer cells	Risankizumab (Skyrizi), ustekinumab (Stelara)
	JAK inhibitors: Block the JAK enzyme, preventing it from activating immune cells that cause inflammation	tofacitinib (Xeljanz)
Corticosteroids	Decrease inflammation	*Systemic:* corticosteroids (prednisone, budesonide); hydrocortisone, methylprednisolone (IV for severe IBD) *Topical:* hydrocortisone suppository, foam (Cortifoam), enema (Cortenema)
Immunomodulators	Suppress immune response	azathioprine, cyclosporine, methotrexate, 6-mercaptopurine

topical corticosteroids. Those with severe inflammation may need a short course of IV corticosteroids. Corticosteroids must be tapered to very low levels when surgery is planned to prevent postoperative complications (e.g., infection, delayed wound healing, fistula formation).

Immunomodulators are given for several reasons. They can maintain remission after corticosteroid therapy. Patients who do not respond to 5-ASA, corticosteroids, or antibiotics; have side effects from corticosteroids; or have fistulas may benefit. They have a delayed onset of action and are not useful for acute flare-ups.

These drugs require regular CBC monitoring because they can suppress the bone marrow and lead to infections and bleeding. Some develop liver and pancreas problems. Many patients have flu-like symptoms with use. Women of childbearing age must avoid pregnancy when taking methotrexate because use can cause birth defects and fetal death.

Surgical Therapy

Ulcerative colitis. Indications for surgery for UC are outlined in Table 47.19. Surgical procedures used include (1) proctocolectomy with ileal pouch/anal anastomosis (IPAA) and (2) proctocolectomy with permanent ileostomy. Since UC affects only the colon, a total proctocolectomy is curative. For more detail, see the section on bowel resection and ostomy surgery later in this chapter and Table 47.28.

Crohn's disease. Surgery for Crohn's disease is usually done for complications such as obstructions or those who do not respond to therapy (Table 47.19). Most patients with Crohn's disease eventually need surgery. The most common surgery involves resecting the diseased segments with reanastomosis of the remaining intestine. Unfortunately, the disease often recurs at the anastomosis site. Repeated removal of sections of the small intestine can lead to SBS. *Short bowel syndrome* occurs when either surgery or disease leaves too little small intestine surface area to maintain normal nutrition and hydration. Lifetime fluid boluses and parenteral nutrition (PN) may be needed. For more detail, see the section on short bowel syndrome.

The other common surgery for Crohn's disease is a stricturoplasty. This opens narrowed areas obstructing the bowel. Since the intestine stays intact, it reduces the risk of developing short-bowel syndrome and its associated complications. Recurrences at the site are uncommon.

TABLE 47.19 Indications for Surgery for IBD

- Bowel obstruction
- Drain abdominal abscess
- Fistulas
- Inability to decrease corticosteroids
- Lack of response to conservative therapy
- Massive hemorrhage
- Perforation, impending or actual
- Severe anorectal disease
- Strictures
- Suspicion of cancer

Nutrition Therapy

The goals of diet management are to (1) provide adequate nutrition without worsening symptoms, (2) correct and prevent malnutrition, (3) replace fluid and electrolyte losses, and (4) prevent weight loss. Many patients with IBD are malnourished.[15] This makes an individualized diet an important part of treating IBD. Patients need a balanced, healthy diet with enough calories, protein, and nutrients. Consult a dietitian about the ideal diet.

Nutrition problems are due to decreased oral intake, blood loss, and, depending on the location of the inflammation, impaired absorption. Patients may reduce food intake to reduce diarrhea. Inflammatory mediators reduce appetite. Blood loss and malabsorption lead to iron deficiency anemia (see Chapter 34). The patient may need oral iron supplements. IV iron is an option for those who cannot tolerate oral iron or if anemia is severe.[15] Zinc deficiency can result from ostomies or diarrhea. Zinc supplements may be needed.

Disease of the terminal ileum reduces absorption of cobalamin and bile acids. Reduced cobalamin contributes to anemia. Those who develop anemia should receive cobalamin injections. Bile salts are important for fat absorption and contribute to osmotic diarrhea. Cholestyramine, an ion-exchange resin that binds unabsorbed bile salts, helps control diarrhea.

Drug therapy can contribute to nutrition problems. Patients taking sulfasalazine or methotrexate should take folate (folic acid) daily to decrease the chance of folate deficiency.[15] Those receiving corticosteroids are prone to osteoporosis and need calcium supplements. Potassium supplements may be needed with corticosteroids.

During an acute exacerbation, patients with IBD may not be able to tolerate a regular diet. Liquid enteral feedings are preferred over PN because atrophy of the gut and bacterial overgrowth occur when the GI tract is not used. EN is high in calories and nutrients, lactose-free, and easily absorbed. They help achieve remission and improve nutrition status. EN is discussed in Chapter 44.

There are no universal food triggers for IBD, but some may find that certain foods cause diarrhea. A food diary helps to identify problem foods to avoid. Patients are typically taught to then avoid or limit foods that cause GI distress or worsen symptoms.

❖ NURSING MANAGEMENT: INFLAMMATORY BOWEL DISEASE

◆ Assessment

Table 47.20 outlines the subjective and objective data to obtain from a patient with IBD.

◆ Clinical Problems

Clinical problems for the patient with IBD include:

- Impaired bowel elimination
- Nutritionally compromised
- Difficulty coping
- Pain

For more information on clinical problems and interventions for IBD, see eNursing Care Plan 47.2 on the website for this chapter.

TABLE 47.20 NURSING ASSESSMENT

IBD

Subjective Data

Important Health Information

Health history: Infection, autoimmune disorders

Medications: Antidiarrheal drugs

Functional Health Patterns

Health perception–health management: Family history of ulcerative colitis, Crohn's disease. Fatigue, malaise

Nutritional-metabolic: Nausea, vomiting, anorexia. Weight loss

Elimination: Diarrhea. Blood, mucus, pus in stools

Cognitive-perceptual: Lower abdominal pain (worse before defecation), cramping, tenesmus

Objective Data

General

Intermittent fever, emaciated appearance, fatigue

Cardiovascular

↑ HR, ↓ BP

GI

Abdominal distention, hyperactive bowel sounds, abdominal cramps

Skin

Pale skin with poor turgor, dry mucous membranes. Skin lesions, anorectal irritation, skin tags, cutaneous fistulas

Possible Diagnostic Findings

Anemia, ↑ WBC. Electrolyte imbalance, hypoalbuminemia, vitamin, and trace metal deficiencies. Guaiac-positive stool. Abnormal sigmoidoscopy, colonoscopy, and/or barium enema findings

Planning

The overall goals are that the patient with IBD will (1) have fewer and less severe acute exacerbations, (2) maintain normal fluid and electrolyte balance, (3) be free from pain or discomfort, (4) adhere to medical regimens, (5) maintain nutrition balance, and (6) have an improved quality of life.

Implementation

Acute Care

During the acute phase, focus your attention on hemodynamic stability, pain control, fluid and electrolyte balance, and nutrition support. Maintain accurate intake and output records. Monitor the number and appearance of stools. Assess for the presence of blood in stools and emesis. Give IV fluids, electrolytes, analgesics, and antiinflammatory drugs as prescribed. Monitor serum electrolytes, CBC, and vital signs, being alert for changes related to diarrhea and dehydration. If the patient has orthostatic hypotension, teach the patient to change position slowly and use safety precautions.

Help the patient stay clean, dry, and free of odor until the diarrhea is under control. Place a deodorizer in the room. Meticulous perianal skincare using plain water (no harsh soap) with a moisturizing skin barrier cream prevents skin breakdown. Dibucaine, witch hazel, sitz baths, and other soothing compresses or ointments may reduce perianal irritation and pain.

Calculate the adequacy of the daily calorie intake. Obtain a daily weight. Assess the abdomen, including bowel sounds, as needed. Consult with a dietitian about diet modifications and the need for nutrition supplements.

Postoperative care after surgery for IBD is similar to that described in the bowel resection and ostomy surgery section and in the general nursing care of the postoperative patient (see Chapter 20).

Ambulatory Care

IBD is a chronic illness. Assist the patient in accepting the chronicity of IBD and learning ways to cope with its recurrent, unpredictable nature. Teaching includes (1) the importance of rest and diet management, (2) perianal care, (3) drug action and side effects, (4) symptoms of recurrence of disease, (5) when to seek medical care, and (6) ways to reduce stress. Excellent teaching resources, written in easily comprehensible language, are available from the Crohn's and Colitis Foundation of America (www.crohnscolitisfoundation.org).

It is important to establish rapport and encourage the patient to talk about self-care (Box 47.1). Ask patients what you can do to promote their self-care. An explanation of all procedures and treatments helps to build trust, decrease apprehension, and increase self-control. Once you have established a therapeutic relationship, talk with those who smoke who have Crohn's disease about quitting since it can cause more severe disease.

The patient and caregiver may need your help setting realistic short- and long-term goals. Patients may have severe fatigue, which limits their energy for physical activity. Rest is important. Patients may lose sleep because of frequent episodes of diarrhea and abdominal pain. Nutrition deficiencies and anemia worsen fatigue and leave the patient feeling weak. Teach them to schedule activities around rest periods.

Many patients have intermittent exacerbations and remissions of symptoms. Given the chronicity and uncertainty related to the frequency and severity of flares, many patients struggle with depression and anxiety. Behavioral therapy may help patients deal with their feelings about the disease and help to manage their symptoms. Because of the relationship between emotions and the GI tract, teach the patient ways to manage stress (see Chapter 7). Suggest the patient seek support through a local or online support group from the Crohn's and Colitis Foundation of America.

Evaluation

The expected outcomes are that the patient with IBD will:

- Have a decrease in the number of diarrhea stools
- Maintain body weight within a normal range
- Be free from pain and discomfort
- Use effective coping strategies

Gerontologic Considerations: Inflammatory Bowel Disease

A second peak in the occurrence of IBD is in the 6th decade. The cause, natural history, and clinical course of IBD are similar to those seen in younger patients. However, in older patients, proctitis and left-sided UC are more common. Diagnosis is

BOX 47.1 EVIDENCE-BASED PRACTICE

Self-Management Education for Ulcerative Colitis

You are caring for G.K., a 32-year-old patient with ulcerative colitis. G.K. tells you that dealing with disease symptoms has affected his ability to participate in favorite outdoor activities such as hiking, biking, and cross-country skiing. He describes unpredictable symptom fluctuations that have left him afraid to travel. He says the pain has led to frequent job absences. After previously prescribed medications were ineffective in symptom management, he confirms he recently began taking tofacitinib (Xeljanz).

Making Clinical Decisions

Synthesis of Best Available Evidence

Research suggests self-management education can help patients with IBD effectively address their symptoms, maintain independence, and improve function.

Clinician Expertise

The unit's EBP committee recently worked with the clinical nurse specialist (CNS) to develop a standardized education program for patients with IBD. The program includes several options based on patients' interest and willingness to participate. You know the program's goal is to help patients manage their symptoms so they can have improved quality of life through more comfortable participation in desired activities. You believe G.K. could benefit from the information. After watching a video presentation, G.K. has many questions, so you arrange a 1-on-1 session with the CNS to talk more about self-management strategies.

Patient Preferences and Values

"I'm open to anything that may help me," G. K. says. "I think these suggestions can be easily followed to help me management by colitis."

Implications for Nursing Practice

1. How would you informally assess G.K.'s understanding of disease self-management after his meeting with the CNS?
2. If G.K. adopted the self-management strategies identified in the education program, what would you expect about his future ability to take part in outdoor activities?

Reference for Evidence

Magharei M, Jaafari S, Mansouri P, et al.: Effects of self-management education on self-efficacy and quality of life in patients with ulcerative colitis: a randomized controlled clinical trial, *IJCBNM* 7:32, 2019.

sometimes difficult in older adults since IBD can be confused with CDI, diverticulitis, or colitis.

Though interprofessional care is similar, challenges exist. Drug therapy and surgery have an increased risk for adverse events, hospitalization, and mortality. Immunomodulator and biologic therapies have a higher risk for infection and cancer. Anemia and malnutrition are more common. They are more vulnerable to volume depletion from diarrhea. Those with physical limitations may have trouble managing fecal urgency and multiple trips to the bathroom without help.

BOWEL OBSTRUCTION

A **bowel obstruction**, or intestinal obstruction, occurs when intestinal contents cannot pass through the GI tract. The obstruction may occur in the small (SBO) or large (LBO) intestine. It can be partial or complete, simple or strangulated. Partial obstructions do not completely occlude the intestinal lumen, allowing for some fluid and gas to pass through. They usually resolve with conservative treatment. A complete obstruction totally occludes the lumen and usually requires surgery. A simple obstruction has an intact blood supply; a strangulated one does not.

Types of Bowel Obstruction

The causes of bowel obstructions are either mechanical or nonmechanical.

Mechanical

In *mechanical obstruction,* there is a physical obstruction of the intestinal lumen. Most obstructions occur in the small intestine. Surgical adhesions are the most common cause of SBO. They can occur within days of surgery or years later (Fig. 47.6). Other causes of SBO are hernia, cancer, strictures from Crohn's disease, and intussusception after bariatric surgery. The most common cause of LBO is CRC (malignant obstruction), followed by diverticular disease. Other causes include adhesions, ischemia, volvulus, and Crohn's disease.

Nonmechanical

A *nonmechanical obstruction* occurs with reduced or absent peristalsis due to altered neuromuscular transmission of the parasympathetic innervation to the bowel. It may result from a neuromuscular or vascular disorder. **Paralytic ileus** (lack of intestinal peristalsis and bowel sounds) is the most common form of nonmechanical obstruction. It occurs to some degree after any abdominal surgery. Other causes of paralytic ileus include peritonitis, inflammatory responses (e.g., acute pancreatitis, acute appendicitis), electrolyte imbalances (especially hypokalemia), and thoracic or lumbar spinal fractures.

Pseudo-obstruction is a GI motility disorder that mimics a mechanical obstruction. The patient has symptoms of obstruction but without any cause found with imaging. Several conditions are associated with pseudo-obstruction. These include neurologic conditions, drugs, endocrine and metabolic problems, lung disease, trauma, and burns.[16]

Vascular obstructions are rare. They result from an interference with the blood supply to a part of the intestines. The most common causes are emboli and atherosclerosis of the mesenteric arteries. Emboli may originate from thrombi in patients who have chronic atrial fibrillation, diseased heart valves, and prosthetic valves. Venous thrombosis may occur in conditions of low blood flow, such as heart failure and shock.

Etiology and Pathophysiology

About 6 to 8 L of fluid enter the small intestine daily. Most of the fluid is absorbed before it reaches the colon. Around 75% of intestinal gas is swallowed air. When an obstruction occurs, fluid, gas, and intestinal contents accumulate proximal to the obstruction. Distention reduces fluid absorption and initially stimulates intestinal secretions. Distal to the obstruction, the bowel empties and then collapses. As distention increases in the proximal bowel, intraluminal bowel

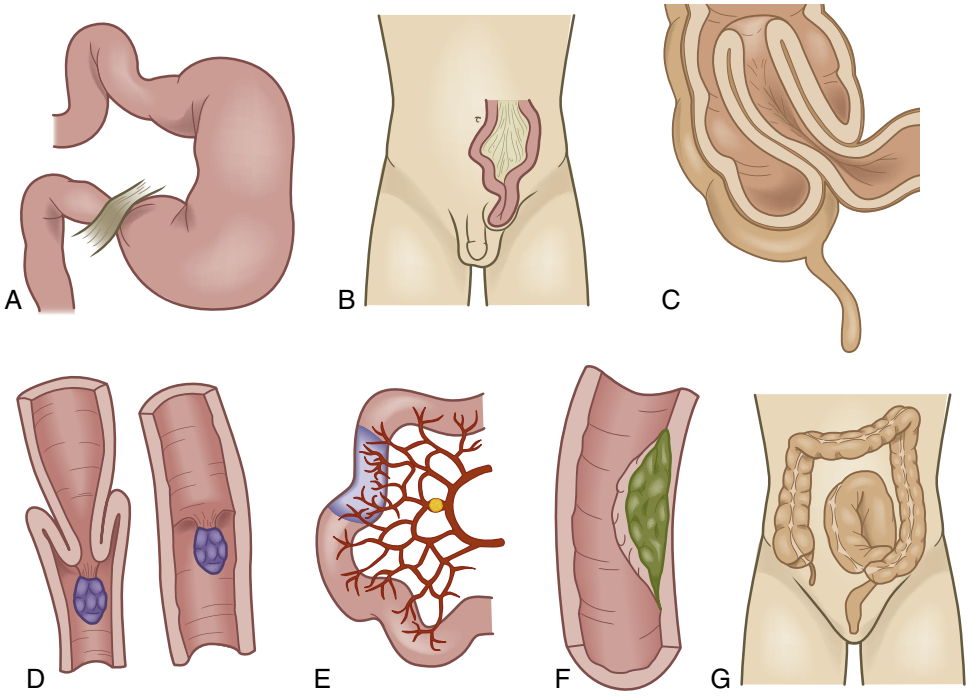

Fig. 47.6 Bowel obstructions. (A) Adhesions. (B) Strangulated inguinal hernia. (C) Ileocecal intussusception. (D) Intussusception from polyps. (E) Mesenteric occlusion. (F) Neoplasm. (G) Volvulus of the sigmoid colon.

pressure rises. The increased pressure leads to an increase in capillary permeability and extravasation of fluids and electrolytes into the peritoneal cavity. Eventually, the intestinal muscle becomes fatigued, and peristalsis stops. Retention of fluids in the intestine and peritoneal cavity leads to a severe decrease in circulating blood volume. This leads to hypotension and hypovolemic shock.

If blood flow is inadequate, bowel tissue becomes ischemic, then necrotic, and the bowel may perforate. In the most dangerous situation, the bowel becomes so distended that the blood flow stops, causing edema, cyanosis, and gangrene of a bowel segment. This is called *intestinal strangulation* or *intestinal infarction*. If not quickly corrected, the bowel will become necrotic and rupture, leading to infection, septic shock, and death.

Clinical Manifestations

The 4 hallmark manifestations of an obstruction are abdominal pain, nausea and vomiting, distention, and constipation. The order and degree these appear vary by the cause, location, and type of obstruction (Table 47.21). Colicky abdominal pain is usually the first symptom. In SBO, the pain is often of sudden onset. It occurs at 4- to 5-minute intervals for proximal obstructions and less often for distal obstructions. The nature of the vomiting gives a clue to the level of obstruction. In a proximal obstruction, patients rapidly develop nausea and vomiting. It may be projectile and contain bile. Vomiting usually gives temporary relief from abdominal pain in higher obstructions. Vomiting from a more distal small bowel obstruction is more gradual in onset and more fecal and foul smelling. Bowel sounds may be high-pitched above the area of obstruction. Bowel sounds are usually absent with paralytic ileus.

TABLE 47.21 Manifestations of Small and Large Bowel Obstructions

	SMALL INTESTINE		Large
Manifestation	**Proximal**	**Distal**	**Intestine**
Onset	Rapid	Rapid	Gradual
Vomiting	Frequent and copious	Less frequent	Late or absent
Pain	Colicky, cramping, occurs at frequent intervals	Colicky, occurs more intermittently	Persistent, cramping
Bowel movement	Feces for a short time	Gradual constipation	Obstipation
Abdominal distention	Minimal	↑	↑

Signs of LBO include abdominal distention, either obstipation or a marked change in bowel function, and lack of flatus. The patient has persistent, cramping abdominal pain. Bowel sounds are usually present and become progressively hypoactive. Vomiting is rare. Strangulation causes severe, constant pain that is rapid in onset.

With both types, abdominal tenderness and rigidity occur. The patient appears acutely ill, with signs of dehydration and sepsis. These include tachycardia, dry mucous membranes, and hypotension. The patient's temperature may rise above 100°F (37.8°C).

The location of the obstruction determines the extent of fluid, electrolyte, and acid-base imbalances. If the obstruction is high (e.g., upper duodenum), metabolic alkalosis may result from the loss of gastric hydrochloric (HCl) acid through vomiting or NG intubation and suction. When the obstruction is in the small intestine, dehydration occurs rapidly. Dehydration

and electrolyte imbalances do not occur early in large bowel obstruction.

Diagnostic Studies

Perform a thorough history and physical assessment. Imaging can identify an obstruction and guide decisions about surgery. Abdominal x-rays, CT scan, or contrast enema may be done. Sigmoidoscopy or colonoscopy provides direct visualization of an LBO.

Blood tests include a CBC and blood chemistries. A high WBC count may mean strangulation or perforation. Increased hematocrit values may reflect hemoconcentration. Decreased hemoglobin and hematocrit values may mean bleeding from cancer or strangulation with necrosis. Serum electrolytes, BUN, and creatinine are monitored to assess the degree of dehydration. Metabolic alkalosis can develop from vomiting.

Interprofessional Care

The treatment goal is to regain intestinal patency and resolve the obstruction. Treatment of a bowel obstruction depends on the cause. If a strangulated obstruction or perforation is present, the patient will need emergency surgery to relieve the obstruction and survive. In some, especially those due to surgical adhesions, an obstruction may resolve without surgery. If needed, the patient may have an NG tube for decompression. Some patients need PN to allow bowel rest and improve nutrition status before surgery.

Stents can be placed via endoscopic or fluoroscopic procedures. They are used for palliative purposes or as "a bridge to surgery," allowing a patient to avoid emergency surgery. This gives the health care team time to correct fluid volume and other problems, thus improving surgical outcomes. Corticosteroids with antiemetic properties that decrease edema and inflammation may be used with stent placement.

Surgery may involve simply resecting the obstructed segment of bowel and anastomosing the remaining healthy bowel back together. Partial or total colectomy, colostomy, or ileostomy may be done when extensive obstruction or necrosis is present. Sometimes, an obstruction can be removed nonsurgically. Colonoscopy offers a means to remove polyps, dilate strictures, and remove and destroy tumors with a laser.

❖ NURSING MANAGEMENT: BOWEL OBSTRUCTION

◆ Assessment

An obstruction is a potentially life-threatening condition. Major concerns are preventing fluid and electrolyte imbalances and early recognition of deterioration in the patient's condition (e.g., hypovolemic shock, sepsis, bowel strangulation). Your care begins with a detailed history and physical assessment. Determine the location, duration, intensity, and frequency of abdominal pain. The patient is often restless and constantly changes position to relieve the pain.

Record the onset, frequency, color, odor, and amount of vomitus. Assess bowel function, including the passage of flatus. Auscultate for bowel sounds and document their character and location. Inspect the abdomen for scars, visible masses, and distention. Assess whether abdominal tenderness or rigidity is present. Measure the abdominal girth. Check for signs of peritoneal irritation (e.g., muscle guarding, rebound pain). If the HCP decides to wait to see if the obstruction resolves on its own, assess the patient regularly. Notify the HCP of changes in vital signs, changes in bowel sounds, decreased urine output, increased abdominal distention, and pain.

Maintain a strict intake and output record, including emesis and tube drainage. A urinary catheter allows for hourly monitoring of urine output. Report if the urine output is less than 0.5 mL/kg of body weight per hour. This indicates inadequate vascular volume and the potential for acute kidney injury. Rising serum creatinine and BUN levels are other indicators of acute kidney injury.

Monitor laboratory and arterial blood gas values. A patient with a high obstruction is more likely to have metabolic alkalosis. A patient with a low obstruction is at greater risk for metabolic acidosis.

◆ Clinical Problems

Clinical problems for the patient with an obstruction include:

- Pain
- Impaired GI function
- Fluid imbalance

◆ Planning

The overall goals are that the patient with an obstruction will have (1) relief of the obstruction and return to normal bowel function, (2) minimal to no discomfort, and (3) normal fluid and electrolyte and acid-base status.

◆ Implementation

Care of the patient with an obstruction focuses on measures to promote comfort and fluid and electrolyte balance (Table 47.22). Nursing care of the patient after surgery for an obstruction is similar to care of the patient after a laparotomy.

POLYPS OF LARGE INTESTINE

Colonic polyps arise from the mucosal surface of the colon and project into the lumen. They may be *sessile* (flat, broad-based, and

TABLE 47.22 NURSING MANAGEMENT

Patient With a Bowel Obstruction

- Give IV fluids and electrolyte replacement as ordered
- Monitor for signs of dehydration and electrolyte imbalances
- Place the patient on NPO status
- Implement pain management measures and promote a restful environment
- Maintain a strict intake and output record
- Insert an indwelling urinary catheter, report if the urine output is less than 0.5 mL/kg/h
- Provide frequent oral care and water-soluble lubricant for the lips
- Implement measures to control nausea and vomiting (see Chapter 46)
- Check the NG tube every 4 hours for patency

attached directly to the intestinal wall) or *pedunculated* (attached to the bowel wall by a thin stalk). Polyps tend to be sessile when small and become pedunculated as they enlarge (Fig. 47.7). They may be found anywhere in the large intestine. As patients age, polyps are increasingly present in the proximal colon. Most patients with polyps are asymptomatic. Rectal bleeding and occult blood in the stool are the most common signs.

Types of Polyps

The most common types of polyps are hyperplastic and adenomatous. *Hyperplastic polyps* are noncancerous. They rarely grow larger than 5 mm and never cause clinical symptoms. Other benign polyps include inflammatory polyps, lipomas, and juvenile polyps.

Adenomatous polyps are neoplastic and closely linked to colorectal adenocarcinoma. There are 3 types: tubular, tubulovillous, and villous. Villous or large adenomatous polyps are more likely to have cancers develop in them. Removing adenomatous polyps decreases the occurrence of CRC.

Genetic Link

Familial adenomatous polyposis (FAP) is the most common polyposis syndrome (Box 47.2).[17] FAP is a genetic disorder characterized by hundreds or sometimes thousands of polyps in the colon that appear during adolescence and early adulthood. They eventually become cancerous, usually by age 40. Since CRC is inevitable, the colon and rectum are removed, usually by age 25, by proctocolectomy with an IPAA or an ileostomy. Patients with classic FAP are at risk for cancers of the thyroid, stomach, small intestine, liver, and brain, so lifetime cancer surveillance is essential.

Diagnostic Studies and Interprofessional Care

Colonoscopy, sigmoidoscopy, barium enema, and virtual colonoscopy (CT or MRI colonography) are used to discover polyps. Colonoscopy is preferred because it allows for evaluation of the total colon. All polyps are considered abnormal and should be removed *(polypectomy)*. Polyps can be removed during colonoscopy or sigmoidoscopy. They cannot be removed during barium enema and virtual colonoscopy. After polypectomy, watch the patient for rectal bleeding, fever, severe abdominal pain, and abdominal distention. These may indicate hemorrhage or perforation.

Fig. 47.7 Endoscopic image of pedunculated polyp in descending colon. (Courtesy David Bjorkman, MD, University of Utah School of Medicine, Department of Gastroenterology. In McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.)

COLORECTAL CANCER

CRC is the second leading cause of cancer-related deaths. Annually about 148,000 people in the United States are diagnosed with CRC, and 53,000 people die from CRC.[18]

The risk of CRC is higher in men. The risk for CRC increases with age. While about 85% of new CRC cases are detected in people older than 50, this rate has been slowly decreasing. The number of cases in people aged 20 to 49 years is rising and is expected to continue to do so.[19] This is thought to be related to diet, physical inactivity, and increasing rates of obesity (Box 47.3).

Etiology and Pathophysiology

Unlike some other cancers, no single risk factor accounts for most cases of CRC (Table 47.23). The risk is highest in those

BOX 47.2 GENETICS IN CLINICAL PRACTICE

Familial Adenomatous Polyposis (FAP)

Genetic Basis
- Autosomal dominant FAP
  - Classic form of disease
  - Mutations in adenomatous polyposis coli *(APC)* gene
  - Normally this is a tumor suppressor gene involved in DNA repair
  - Normally this gene makes a protein that keeps polyps from developing in the colon
  - 50% of the offspring of a parent with FAP carry the *FAP* gene
- Autosomal recessive FAP
  - Autosomal recessive disorder
  - Mutations in the *mutY* homolog *(MUTYH)* gene
  - Normally this gene is involved in DNA repair
  - Characterized by fewer polyps, typically <100

Incidence
- Affects 1 in 7000–22,000 people
- Causes 1% of all CRC

Genetic Testing
- DNA testing is available

Clinical Implications
- Anyone with a family history of FAP should undergo genetic testing during childhood
- If the FAP gene is present, colorectal screening begins at puberty, and annual colonoscopy begins at age 16
- Persons with a family history of FAP can benefit from genetic counseling

BOX 47.3 PROMOTING HEALTH EQUITY

Colorectal Cancer

- Blacks are most likely to develop and die from CRC.
- CRC may occur at an earlier age in Blacks and Hispanics.
- Hispanics and Asians are the least likely to undergo CRC screening.

TABLE 47.23 Risk Factors for Colorectal Cancer

- Alcohol (≥4 drinks/week)
- Cigarette smoking
- Family history of CRC in first-degree relative
- Family or personal history of familial adenomatous polyposis (FAP)
- Family or personal history of hereditary nonpolyposis colorectal cancer (HNPCC) syndrome
- Obesity (body mass index ≥30 kg/m^2)
- Personal history of CRC, IBD, or diabetes
- Red meat (≥7 servings/week)

BOX 47.4 GENETICS IN CLINICAL PRACTICE

Hereditary Nonpolyposis Colorectal Cancer (HNPCC) or Lynch Syndrome

Genetic Basis
- Autosomal dominant disorder
- Mutations in *MSH2, MLH1, MSH6,* or *PMS2* genes
- These genes are involved with the repair of mistakes in DNA replication

Incidence
- Affects 1 in 500–2000 people

Genetic Testing
- DNA testing is available

Clinical Implications
- Accounts for 3%–5% of all CRC
- Depending on the genetic mutation, the risk for developing CRC is from 50%–80%
- If colon polyps are present, they occur at an earlier age than do polyps in the general population and are more prone to become cancerous
- Have increased risk for stomach, brain, ovary, uterus, skin, urinary tract, small bowel, and bile ducts cancers
- Colonoscopy is recommended every 1–2 years
- Women with HNPCC should undergo ovarian and endometrial cancer screening

with first-degree relatives with CRC and people with IBD. About 20% of cases of CRC occur in patients with a family history of CRC. Hereditary forms of CRC, including FAP (see Box 47.2) and hereditary nonpolyposis colorectal cancer (HNPCC) syndrome (Box 47.4), account for another 5% of cases.[20]

About 30% to 50% of people with CRC have an abnormal *KRAS* gene. The *KRAS* gene, which is primarily involved in regulating cell division, belongs to a class of genes known as *oncogenes*. When mutated, oncogenes have the potential to cause normal cells to become cancerous.

Maintaining a healthy weight, being physically active, limiting alcohol use, not smoking, and eating a diet with large amounts of fruits, vegetables, and grains may decrease the risk for CRC.

CRC usually starts as a polyp on the inner lining of the colon or rectum that grows over a period of 10 to 20 years. Most polyps are adenomas, which arise from the cells that make mucus. As the tumor grows, the cancer invades and penetrates the wall of the colon or rectum (Fig. 47.8). Eventually, cancer cells gain

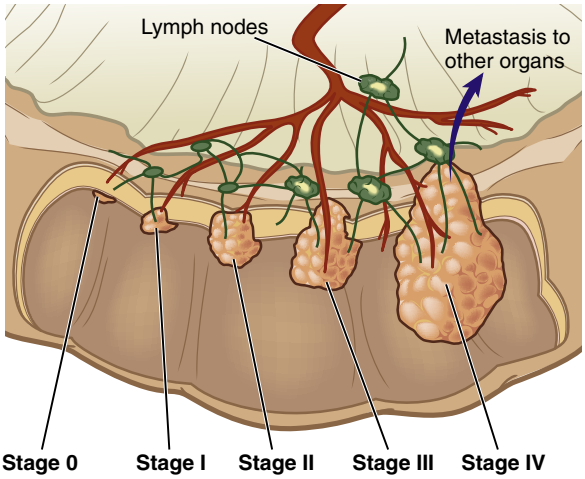

Fig. 47.8 The 5 stages of CRC. Stage 0 cancer has not grown beyond the mucosal layer. Stage I cancer has grown beyond the mucosa into the submucosa, but no lymph nodes are involved. Stage II cancer has grown beyond the submucosa into the muscle, but there is no lymph node involvement or metastasis. Stage III cancer is any tumor with lymph node involvement but no metastasis. Stage IV cancer is any tumor with lymph node involvement and metastasis.

access to the lymph nodes and vascular system and spread to distant sites. Since venous blood leaving the colon and rectum flows through the portal vein and the inferior rectal vein, the liver is a common site of metastasis. The cancer spreads from the liver to other sites, including the lungs, bones, and brain. CRC can also spread directly into adjacent structures.

Clinical Manifestations

CRC develops slowly. Symptoms often do not appear until the disease is advanced. Nonspecific findings in early disease include fatigue and weight loss. As the disease progresses, the patient may have abdominal pain and tenderness with a change in bowel habits. There may be a palpable abdominal mass, hepatomegaly, ascites

Bleeding can occur with both right- and left-sided CRC. Bleeding on the right side is more common than on the left side. It is often unrecognized, and an early manifestation is often anemia. Hematochezia (fresh blood in the stool) is more often caused by left-sided CRC than right-sided CRC.

Right-sided cancers are more likely to cause diarrhea. Left-sided cancers are usually detected later and could present with bowel obstruction (Fig. 47.9). Complications of CRC include obstruction, bleeding, perforation, peritonitis, and fistula formation.

Diagnostic Studies

Obtain a thorough history with close attention to family history (Table 47.24). Since symptoms of CRC often are not evident until the disease is advanced, there is an increased emphasis on screening. Beginning at age 45 and continuing until age 75, those at average risk for developing CRC should have screening tests to detect both polyps and cancer based on 1 of these testing schedules:

- Flexible sigmoidoscopy (every 5 years)
- Colonoscopy (every 10 years)

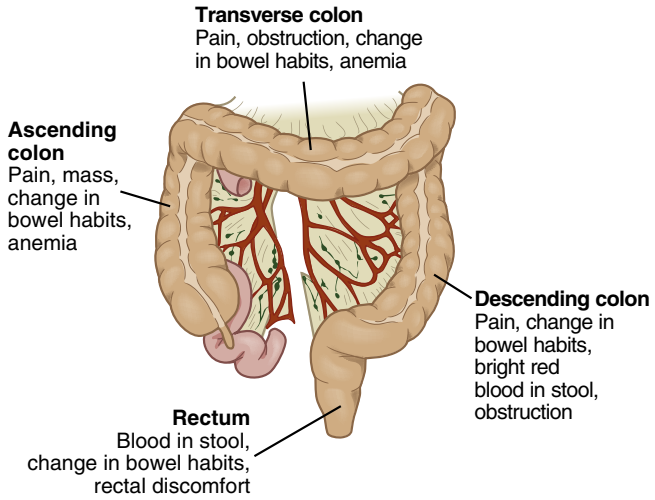

Fig. 47.9 Signs and symptoms of CRC by location of primary tumor. (Modified from McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children*, ed 6, St Louis, 2010, Mosby.)

TABLE 47.24 Interprofessional Care

Colorectal Cancer

Diagnostic Assessment

- History and physical assessment
- DRE
- Testing of stool for occult blood
- CBC
- Liver function tests
- Barium enema
- Sigmoidoscopy and/or colonoscopy with biopsy
- Abdominal CT scan, ultrasound, or MRI
- Carcinoembryonic antigen (CEA) test

Management

- Surgery
  - Right hemicolectomy
  - Left hemicolectomy
  - Abdominal-perineal resection
  - Laparoscopic colectomy
  - Low anterior resection
- Chemotherapy
- Targeted therapy
- Radiation therapy

- Double-contrast barium enema (every 5 years)
- CT colonography (virtual colonoscopy) (every 5 years)
- Tests that primarily find cancer include:
  - High-sensitivity fecal occult blood test (FOBT) (every year)
  - Fecal immunochemical test (FIT) (every year)
  - Stool DNA test (every 3 years)

Colonoscopy is the gold standard for CRC screening. It allows the entire colon to be examined, biopsies obtained, and polyps removed and sent to the laboratory for examination. People at average risk for CRC should undergo colonoscopy every 10 years beginning at age 45.

TABLE 47.25 Tumor, Node, Metastasis (TNM) Classification of Colorectal Cancer

T	Primary Tumor
T_x	Cannot assess primary tumor because of incomplete information.
T_{is}	Carcinoma in situ. Cancer is in earliest stage and has not grown beyond mucosa layer.
T_1	Tumor has grown beyond mucosa into the submucosa.
T_2	Tumor has grown through submucosa into muscularis propria.
T_3	Tumor has grown through the muscularis propria into the pericolorectal tissues.
T_4	Tumor invades the visceral peritoneum or invades or adheres to adjacent organ or structure.
N	Lymph Node Involvement
N_x	Cannot assess lymph nodes.
N_0	No regional lymph node involvement is found.
N_1	Cancer is found in 1–3 nearby lymph nodes.
N_2	Cancer is found in 4 or more nearby lymph nodes.
M	Metastasis
M_x	Cannot assess presence of metastasis.
M_0	No distant metastasis seen.
M_1	Distant metastasis is present.

Persons at risk (Table 47.23) should begin screening earlier and have screening done more often. Those who have a first-degree relative who developed CRC before age 60 or have 2 first-degree relatives with CRC should have a colonoscopy every 5 years beginning at age 40 or 10 years earlier than when the youngest relative developed cancer. Those who have 1 first-degree relative who had CRC after age 60 should have a colonoscopy every 10 years beginning at age 40.[20]

Less favorable, but acceptable, screening methods include stool testing for fecal blood. The FOBT and FIT look for blood in the stool. These tests must be done yearly since tumor bleeding occurs at intervals and may easily be missed if a single test is done. Stool DNA tests (PreGen-Plus, Cologuard) can detect cells with DNA mutations that may occur with CRC in the stool.

Once tissue biopsies confirm the diagnosis of CRC, the patient needs a CBC to check for anemia and liver function tests. A CT scan, PET scan, or MRI will be done to detect metastases and determine the depth of penetration of the tumor into the bowel wall.

Carcinoembryonic antigen (CEA) is a complex glycoprotein sometimes made by CRC cells. It may be used to detect CRC and monitor for recurrence after surgery or chemotherapy. It is not the best screening tool because of the large number of false-positive findings. CEA levels also may be increased in non-colon cancers (e.g., gastric, pancreatic, breast, thyroid cancers) as well as some noncancerous conditions, like IBD, pancreatitis, cirrhosis, and chronic obstructive pulmonary disease.

Interprofessional Care

The prognosis and treatment of CRC correlate with the pathologic staging of the disease. The most common staging system is the tumor, node, metastasis (TNM) staging (Table 47.25). As with other cancers, prognosis worsens with greater size and depth of tumor, lymph node involvement, and metastasis (Table 47.26).

TABLE 47.26 Classification System Used to Stage Colorectal Cancer

Stage[a]	TNM[b]	5-Year Survival Rate (%)
0	T_{is} N_0 M_0	>96
I	T_1 N_0 M_0	92
	T_2 N_0 M_0	87
II	T_3 N_0 M_0	70–80
III	Any T, $N_{1\text{-}2}$ M_0	53–84
IV	Any T, any N, M_1	12

[a]Staging system is shown in Fig. 47.8.
[b]See Table 47.25.

Surgical Therapy

Goals of surgical therapy include (1) complete resection of the tumor, (2) a thorough exploration of the abdomen to determine if the cancer has spread, (3) removing all lymph nodes that drain the area where the cancer is located, and (4) restoring bowel continuity to promote normal bowel function.

Some polyps can be removed during colonoscopy, while others require surgery. Polypectomy during colonoscopy can be used to resect CRC in situ. It is considered successful when the resected margin of the polyp is free of cancer, the cancer is well-differentiated, and there is no apparent lymphatic or blood vessel involvement.

The decision for surgical treatment depends on the staging and location of the cancer and the ability to restore normal bowel function and continence. Surgical therapy for stage I and stage II colon cancers include removing the tumor, surrounding tissues, and nearby lymph nodes. The remaining cancer-free ends are sewn back together (anastomosis) when possible. Laparoscopic surgery is sometimes used, especially for tumors in the left colon. Chemotherapy is used after surgery for high-risk stage II tumors. Stage III tumors are treated with surgery and chemotherapy. Radiation and chemotherapy may be done before surgery to reduce tumor size.

In rectal cancer, the location and size of the tumor determine the course of treatment. Local excision may be an option. If the tumor is in the distal rectum (1 to 2 cm from the anorectal junction) and the sphincters cannot be preserved, the patient will undergo an *abdominal-perineal resection (APR)*. An APR involves removing the entire rectum with the tumor, and the patient will have a permanent colostomy.

If the tumor is in the mid or proximal rectum, it may be possible to preserve the sphincters with a low anterior resection (LAR). A LAR involves removing the rectum and anastomosing the colon to the anal canal. A temporary ostomy may be done to divert stool and allow time for the anastomosis to heal. Another option if the anal sphincters remain is for the HCP to create an alternative reservoir with either a colonic J-pouch or coloplasty (Fig. 47.10). A LAR is increasingly common because of advancements in laparoscopy and stapling techniques.

When the tumor is not resectable or metastasis is present, palliative surgery can control hemorrhage or relieve a bowel obstruction. Chemotherapy and radiation can control the spread and provide pain relief. A few patients with limited lung or liver metastases can achieve a cure after primary and metastatic tumor resection and chemotherapy.

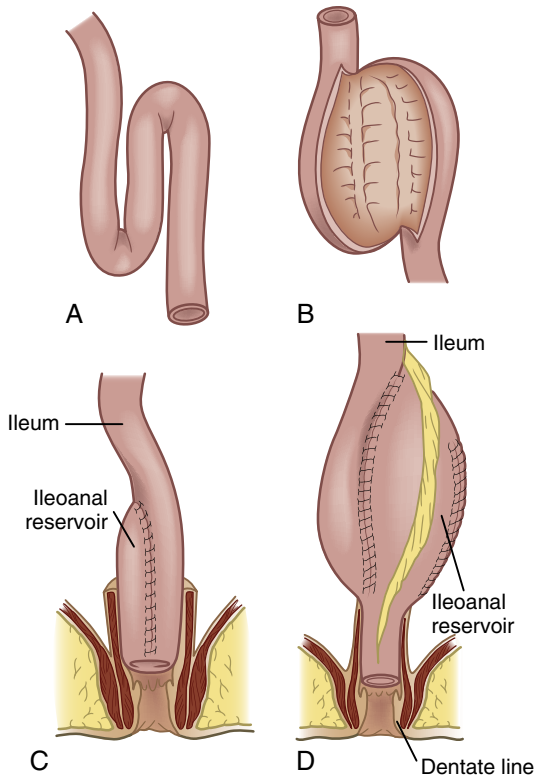

Fig. 47.10 Ileoanal pouch (reservoir). (A) Formation of a pouch. (B) Posterior suture lines completed. (C) J-shaped configuration for ileoanal pouch (J-pouch). (D) S-shaped configuration for ileoanal pouch (S-pouch).

Chemotherapy and Targeted Therapy

Chemotherapy can be used to shrink the tumor before surgery, as an adjuvant therapy after bowel resection, and as palliative treatment for nonresectable cancer. Adjuvant chemotherapy is recommended for patients with stage III tumors. Current protocols include varying doses of oxaliplatin (Eloxatin) with either fluorouracil (FU) and leucovorin (LV) or capecitabine (Xeloda). Irinotecan can be given with FU and LV alone or with oxaliplatin.[21] Capecitabine or FU can be used alone in patients for whom oxaliplatin therapy is not appropriate.

Several targeted therapies have a role in treating metastatic CRC. Angiogenesis inhibitors inhibit the blood supply to tumors. These include aflibercept (Zaltrap), bevacizumab (Avastin), and ramucirumab (Cyramza). Cetuximab (Erbitux) and panitumumab (Vectibix) block the epidermal growth factor receptor. These drugs are often given with a combination chemotherapy regimen.

Regorafenib (Stivarga) is a multikinase inhibitor that blocks several enzymes that promote cancer growth. It, or Lonsurf, a combination of trifluridine and tipiracil, are given to patients with metastatic CRC who are no longer responding to other therapies. Trifluridine impairs DNA function and angiogenesis. Tipiracil prevents the rapid metabolism of trifluridine, thus increasing its bioavailability.

Radiation Therapy

Some patients may receive radiation therapy as an adjuvant to surgery and chemotherapy or as a palliative measure for those

TABLE 47.27 NURSING ASSESSMENT

Colorectal Cancer

Subjective Data

Important Health Information

Health history: Previous breast or ovarian cancer, familial polyposis, villous adenoma, adenomatous polyps, IBD

Medications: Medications affecting bowel function (e.g., laxatives, antidiarrheal drugs)

Functional Health Patterns

Health perception–health management: Family history of colorectal, breast, or ovarian cancer; weakness, fatigue

Nutritional-metabolic: High-calorie, high-fat, low-fiber diet. Anorexia, nausea and vomiting, weight loss

Elimination: Change in bowel habits, alternating diarrhea and constipation, defecation urgency. Rectal bleeding, mucoid stools. Black, tarry stools. Flatus, decrease in stool caliber. Feelings of incomplete evacuation

Cognitive-perceptual: Abdominal and low back pain, tenesmus

Objective Data

General

Pallor, cachexia, lymphadenopathy (later signs)

GI

Palpable abdominal mass, distention, ascites, and hepatomegaly (liver metastasis)

Possible Diagnostic Findings

Anemia. Guaiac-positive stools, palpable mass on DRE. Positive sigmoidoscopy, colonoscopy, barium enema, or CT scan. Positive biopsy

with metastatic cancer. As a palliative measure, the primary goal is to reduce tumor size and provide symptomatic relief. Radiation therapy is described in Chapter 15.

NURSING MANAGEMENT: COLORECTAL CANCER

Assessment

Table 47.27 outlines the subjective and objective data to obtain from a patient with CRC.

Clinical Problems

Clinical problems for the patient with CRC include:

- Altered bowel elimination
- Anxiety
- Difficulty coping

Planning

The overall goals are that the patient with CRC will have (1) normal bowel elimination patterns, (2) quality of life appropriate to the disease progression, (3) relief of pain, and (4) feelings of comfort and well-being.

Implementation

Health Promotion

Encourage all persons over 45 to have regular CRC screening. Help identify those at high risk who need screening at an earlier age. Discuss with patients how taking part in cancer screening helps decrease mortality rates. Realize that barriers exist, including lack of accurate information and fear of diagnosis.

Endoscopic and radiographic procedures can only reveal polyps when the bowel has been properly prepared. Provide teaching about bowel cleansing for outpatient diagnostic procedures and give cleansing preparations to inpatients (see more on diagnostic procedures in Chapter 43).

Acute Care

Nursing care for the patient after a bowel resection is discussed in depth in the next section. If enough healthy bowel remained that the HCP could reconnect the bowel ends, normal bowel function is maintained. Routine postoperative care is appropriate. Patients with more extensive surgery, such as an APR, may have an open wound and drains (e.g., Jackson-Pratt, Hemovac) and a permanent ostomy. Postoperative care includes sterile dressing changes, care of drains, and patient and caregiver teaching about the ostomy.

Ambulatory Care

Psychologic support for the patient and caregiver dealing with the diagnosis of cancer is important. Discuss the patient's feelings about the prognosis and future screening. Patients need much emotional support. The special needs of the cancer patient are discussed in Chapter 16. You may need to address issues surrounding palliative care, end-of-life issues, and hospice (see Chapter 10).

Patients with CRC need to know how to manage changes that result from cancer and cancer treatment. Those who had sphincter-sparing surgery may have diarrhea and incontinence of feces and gas. They may need antidiarrheal drugs or bulking agents to control the diarrhea, but overuse can result in constipation. A consult with a dietitian or wound, ostomy, and continence nurse (WOCN) may help patients and caregivers understand how to manage food and fluid options. Ostomy rehabilitation, including teaching and ongoing support, should be available for all ostomy patients. Patients with skin changes from incontinence and/or radiation therapy will need help with managing these conditions.

Evaluation

The expected outcomes for the patient with CRC are that the patient will:

- Have minimal changes in bowel elimination patterns
- Achieve optimal nutrition intake
- Experience quality of life appropriate to disease progression
- Have feelings of comfort and well-being

BOWEL RESECTION AND OSTOMY SURGERY

Surgical resection of the bowel may be done to (1) remove cancer; (2) repair a perforation, fistula, or traumatic injury; (3) relieve an obstruction or stricture; and (4) treat an abscess, inflammatory disease, or hemorrhage (Table 47.28). For example, if a person has stage III CRC, the HCP will remove the diseased part of the colon along with a margin of healthy tissue. It may be a prophylactic procedure for those with complications

TABLE 47.28 Common Intestinal Surgical Procedures

Procedure	Description
Abdominal-perineal resection (APR)	Removal of the entire rectum with creation of a permanent colostomy
Anterior rectosigmoid resection	Removal of part of descending colon, the sigmoid colon, and upper rectum with the descending colon anastomosed to remaining rectum
Colectomy	Removal of the entire colon with the ileum anastomosed to the rectum
Left hemicolectomy	Removal of splenic flexure, descending colon, and sigmoid colon with the transverse colon anastomosed to rectum
Low anterior resection (LAR)	Removal of the rectum and with anastomosis of the colon to the anal canal. Temporary ileostomy or colostomy may be done to divert stool and allow time for the anastomosis to heal. After 8–12 weeks, the ostomy can be "taken down," and the ends of the colon surgically reconnected
Proctocolectomy with ileostomy	Removal of the colon, rectum, and anus with closure of the anal opening. End of the terminal ileum is brought out through the abdominal wall to form a permanent ileostomy
Proctocolectomy with ileal pouch/anal anastomosis (IPAA)	2 surgeries, 8–12 weeks apart. The first includes colectomy, rectal mucosectomy, ileal pouch (reservoir) construction, ileoanal anastomosis, and temporary ileostomy. Diverting ileostomy is done, and an ileal pouch is created and anastomosed directly to the anus (Fig. 47.10). Second surgery involves closure of the ileostomy to direct stool toward the new pouch
Right hemicolectomy	Removal of ascending colon and hepatic flexure with the ileum anastomosed to transverse colon

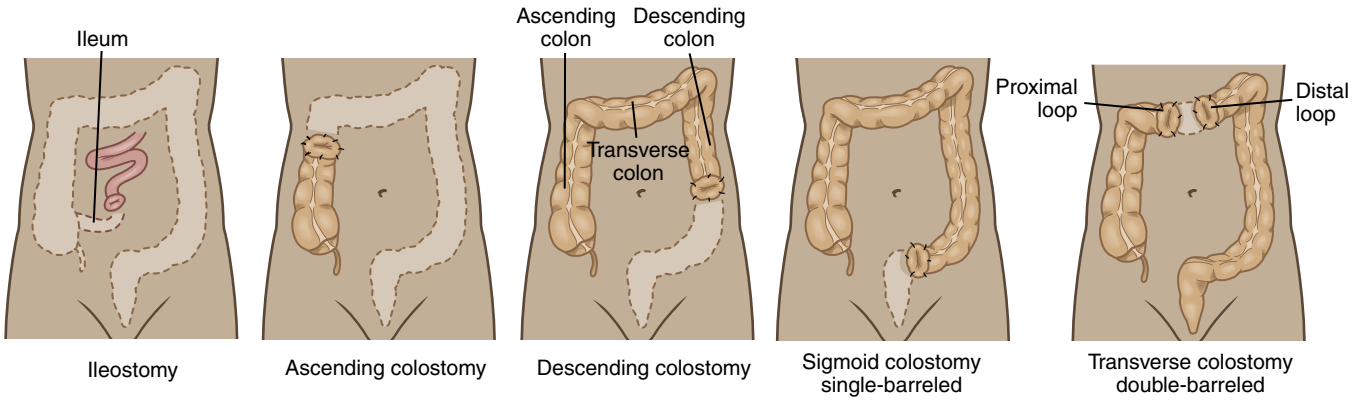

Fig. 47.11 Types of ostomies.

from IBD. Patients at high risk for CRC, such as those with FAP, and patients with UC may have a total colectomy and an ileostomy.

Ostomy

An **ostomy** is a surgically created opening on the abdomen that allows the discharge of body waste when the normal elimination route is no longer possible. The outermost part that is visible is a *stoma*. The stoma is the result of the large or small bowel being brought to the outside of the abdomen and sutured in place. When a stoma is created as a fecal diversion, feces will drain through the stoma instead of the anus.

Ostomies are named according to their location and type (Fig. 47.11). An ostomy in the ileum is an ileostomy. An ostomy in the colon is a colostomy. The ostomy is further characterized by its anatomic site (ascending, transverse, descending, sigmoid). The more distal the ostomy, the more functioning bowel remains, and the more likely that the intestinal contents will resemble the feces that would have been eliminated from an intact colon and rectum. Ileostomy output will be a liquid to thin paste since it did not enter the colon. Patients have no control over ileostomy drainage; it is involuntary. An ileostomy drains frequently, and the patient must wear an ostomy pouch to collect the drainage. In contrast, sigmoid colostomy output resembles normal formed stool. Some patients can regulate emptying time with colostomy irrigation and may not need to wear a pouch. See Table 47.29 for a comparison of colostomies and ileostomies.

Ostomies may be temporary or permanent. For example, the person with a draining fistula may need a temporary ostomy to prevent stool from reaching the diseased area. Cancer involving the rectum requires a permanent ostomy if all bowel distal to the ostomy is removed.

Permanent ostomies may be continent or traditional. *Continent ileostomies* (e.g., Koch pouch, Barnett Continent Ileal Reservoir) use 40 to 45 cm of the terminal ileum to fashion an internal pouch, nipple valve, and abdominal stoma. The pouch replaces the rectum as a reservoir for stool. It can hold around 500 mL of material. Continent ostomies are an option for patients who have had a prior APR with ileostomy for UC or FAP. Patients must be motivated and compliant. They must drain the pouch manually by inserting a catheter through the nipple valve. At first, this is done every 1 to 2 hours. As the pouch enlarges, the frequency decreases to 4 times daily and as needed. They must keep the stool consistency relatively fluid by following a low-residue diet.

The major types of traditional ostomies include end, double-barreled, and loop ostomy.

TABLE 47.29 Comparison of Ileostomy and Colostomy

		COLOSTOMY		
Characteristic	**Ileostomy**	**Ascending**	**Transverse**	**Sigmoid**
Stool consistency	Liquid to semiliquid	Semiliquid	Semiliquid to semiformed	Formed
Fluid requirement	↑	↑	Possibly ↑	No change
Bowel regulation	No	No	No	Yes, if there is a history of a regular bowel pattern
Pouch and skin barriers	Yes	Yes	Yes	Dependent on regulation
Indications for surgery	UC, Crohn's disease, diseased or injured colon, familial polyposis, trauma, cancer	Perforating diverticulum in lower colon, trauma, rectovaginal fistula, inoperable tumors of colon, rectum, or pelvis	Same as for ascending	Cancer of the rectum or rectosigmoid area, perforating diverticulum, trauma

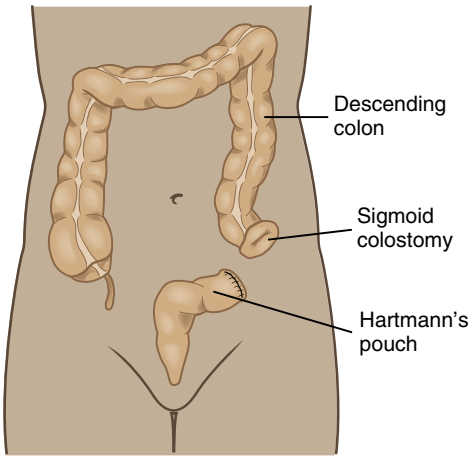

Fig. 47.12 Sigmoid colostomy. Distal bowel is oversewn and left in place to create Hartmann pouch.

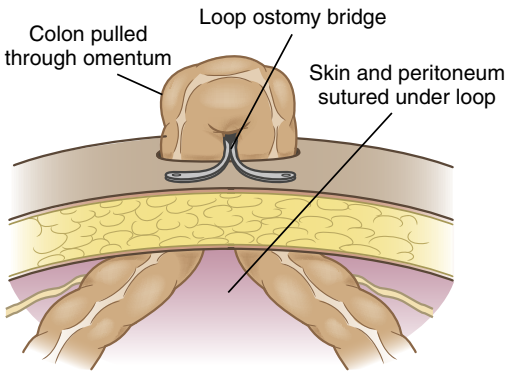

Fig. 47.13 Loop colostomy.

End stoma. An end stoma is made by dividing the bowel and bringing out the proximal end as a single stoma, making a colostomy or ileostomy. The distal part of the GI tract is surgically removed, or the distal segment is oversewn and left in the abdominal cavity with its mesentery intact. If the distal bowel is removed, the stoma is permanent. When the distal bowel is oversewn and not removed, the procedure is called a *Hartmann pouch* (Fig. 47.12). With a Hartmann pouch, the potential exists for the bowel to be reanastomosed and the stoma closed (referred to as a *takedown*).

Loop stoma. A loop stoma is made by bringing a loop of bowel to the abdominal surface and then opening the anterior wall of the bowel to provide fecal diversion. This results in 1 stoma with a proximal opening for feces and a distal opening for mucus drainage from the distal colon. An intact posterior wall separates the 2 openings. A plastic rod holds the loop of bowel in place for 7 to 10 days after surgery to prevent it from slipping back into the abdominal cavity (Fig. 47.13). A loop stoma is usually temporary.

Double-barreled stoma. To create a double-barreled stoma, the HCP divides the bowel, and both the proximal and distal ends are brought through the abdominal wall as 2 separate stomas (Fig. 47.11). The proximal stoma is the functioning stoma. The distal, nonfunctioning stoma is a *mucus fistula.* A double-barreled stoma is usually temporary.

❖ NURSING MANAGEMENT: BOWEL RESECTION AND OSTOMY SURGERY

◆ Preoperative Care

Care that is unique to ostomy surgery includes (1) psychologic preparation for the ostomy, (2) educational preparation, and (3) selecting the best site for the stoma. Ideally, the management of patients facing ostomy surgery begins preoperatively (Box 47.5). If available, a WOCN should visit with the patient and caregiver to determine the patient's ability to perform self-care, identify support systems, and determine any modifications that could promote learning during recovery.

Psychologic preparation and emotional support are particularly important as the person begins to cope with the changes in body image and elimination. The patient and caregiver should understand the extent of the surgery planned. It is normal for them to have questions about the procedures. Provide them with opportunities to share concerns and questions. This will enhance the patient's feelings of control and ability to cope.

A WOCN should choose the site where the ostomy will be and mark the abdomen before surgery. The site should be within the rectus muscle, on a flat surface, and in a place that the patient is able to see. A flat site makes it much easier to create a good seal and avoid bag leakage. Being able to see the stoma makes caring for it easier. Whenever possible, it should be discreetly hidden under clothing and appropriate for normal activities.

BOX 47.5 EVIDENCE-BASED PRACTICE

Preoperative Ostomy Education

F.S., a 68-year-old patient, and his wife meet you in the preoperative clinic. F.S. is scheduled for colostomy surgery for severe diverticular disease. As part of your interview, he tells you he has tried a high-fiber diet, fiber supplements, and probiotics to manage his condition. He was also prescribed oral antibiotics on many occasions. These treatments were not effective. The HCP recommended surgery after he developed rectal bleeding.

Making Clinical Decisions

Synthesis of Best Available Evidence

Research has reinforced the value of preoperative stoma site marking and early education. These measures are critical to achieving a better-situated stoma, with fewer complications related to appliance adherence and leakage. Preoperative education reduces the patient's anxiety. Decreased anxiety allows the patient to more easily learn the skills needed to care for a new ostomy. Routine preoperative education is a critical part of the Enhanced Recovery After Surgery (ERAS) initiative. This leads to shorter hospital stays through evidence-based changes in care delivery.

Clinician Expertise

As part of the preoperative education for F.S., you review what a stoma is and how it is created. Pictures of the sections of the bowel and types of stomas are highlighted in the patient information packet. You show F.S. and his wife several different pouching systems as options for postoperative use. F.S. performs a return demonstration of pouch emptying and changing. You discuss general ostomy care, as well as bathing, diet changes, and travel. The WOCN completes the stoma site marking. You review with F.S. the expectations for stool output the first 6 weeks after surgery.

Patient Preferences and Values

F.S. voices anxiety about the upcoming surgery and his ability to manage the colostomy. However, he and his wife are engaged in the educational session and ask many questions. They express hope that they will be able to travel to see their grandchildren again after he recovers from surgery.

Implications for Nursing Practice

- 1. How would you assess readiness to learn for F.S.?
- 2. How could you determine the anxiety level for F.S. before and after the session?
- 3. What teaching would need to be reinforced after surgery?

Reference for Evidence

Harris MS, Kelly K, Parise C: Does preoperative ostomy education decrease anxiety in the new ostomy patient? *J Wound Ostomy Continence* 47:137, 2020.

◆ Postoperative Care

If the patient's wound is closed or partially closed, assess the integrity of the incision. Monitor for complications, including delayed wound healing, hemorrhage, fistulas, and infections. Assess the wound regularly and record bleeding, excess drainage, and unusual odor. Monitor for edema, redness, and drainage, as well as fever and a high WBC count. Observe the skin and the area around any drains for signs of inflammation. Keep the area around any drains clean and dry.

A patient who has an open wound with packing needs meticulous care. Reinforce dressings and change them often during the first several hours postoperatively when drainage is likely to be profuse. Carefully assess all drainage for amount, color, and consistency. The drainage is usually serosanguineous.

TABLE 47.30 Characteristics of Stoma

Characteristic	Description or Cause
Color	
Rose to brick-red	Viable stoma mucosa
Pale	Anemia
Blanching, dark red to dusky blue or purple	Inadequate blood supply to the stoma or bowel
Brown-black	Necrosis
Edema	
Mild to moderate edema	Normal in initial postoperative period. Trauma to the stoma
Moderate to severe edema	Obstruction of the stoma, allergic reaction to food, gastroenteritis
Bleeding	
Small amount	Oozing from stoma mucosa when touched is normal because of its high vascularity
Moderate to large amount	Lower GI bleeding, coagulation factor deficiency, stomal varices from portal hypertension

If an ostomy is present, assess the stoma and place a clear pouching system. The stoma should be rosy pink to red and mildly swollen (Table 47.30). Assess and document stoma color every 4 hours and ensure that there is no excess bleeding. Report any sustained color changes or bleeding to the HCP. Edema will resolve over the first 6 weeks.

The colostomy starts functioning when peristalsis returns. Record the volume, color, and consistency of the drainage. When a colostomy is done on a colon that was not cleaned out before surgery, stool will drain when peristalsis returns. If the bowel was cleansed preoperatively, it will not begin producing stool until a few days after the patient is eating again. Excessive amounts of gas are common during the first 2 weeks. Because this can be distressing to patients, assure them this is temporary.

In the first 24 to 48 hours after surgery, the amount of drainage from an ileostomy may be negligible. When peristalsis returns, ileostomy output may be as high as 1500 to 1800 mL/24 hr. If the small bowel is shortened by surgery, drainage may be greater. This is because the patient has lost the absorptive functions provided by the colon and the delay provided by the ileocecal valve. Observe the patient for fluid deficits and electrolyte imbalances, particularly potassium and sodium. Over a period of days to weeks, the proximal small bowel adapts and increases fluid absorption. Then, feces will thicken to a paste-like consistency, and the volume will decrease to around 500 mL/day. Patients, especially those with Crohn's disease, are at risk for developing a bowel obstruction during the first 30 days after surgery.

After an IPAA, initially, patients may have 4 to 6 stools or more daily. Adaptation over the next 3 to 6 months will result in fewer bowel movements. The patient can control defecation at the anal sphincter.

After intraoperative manipulation of the anal canal, transient incontinence of mucus may occur. Have the patient start Kegel exercises about 4 weeks after surgery to strengthen the pelvic floor and sphincter muscles (see Table 50.18). Perianal skincare

is important to protect the epidermis from mucous drainage and maceration. Teach the patient to gently clean the skin with a mild cleanser, rinse well, and dry thoroughly. A moisture barrier ointment and a perineal pad may be used. Some patients have phantom rectal pain or still feel as if they need to have a bowel movement. This is normal and often subsides over time. Be astute in distinguishing phantom sensations from perineal abscess pain.

Sexual Function

Problems with sexual function depend on the surgery. Pelvic surgery can disrupt nerve and vascular supplies to the genitalia. Unfortunately, any pelvic surgery that removes the rectum has the potential of damaging the parasympathetic nerve plexus. The HCP should discuss the possibility with the patient.

For men, the main concern may be erection and ejaculation. Erection depends on intact parasympathetic and nonadrenergic noncholinergic nerves as well as an adequate blood supply. Sympathetic nerve damage in the presacral area can disrupt the ability to ejaculate. This can occur with the APR procedure. Sexual problems may be temporary and resolve in 3 to 12 months. Nerve-sparing surgical techniques are used when possible to preserve sexual function.

For women, nerve damage can result in vaginal dryness and decreased sensation in the vagina and clitoris, making arousal and achieving orgasm more challenging. Experimenting with positions and using lubrication may help.

Sexual function and sexuality concerns affect most patients with an ostomy. The patient may fear rejection by a partner or that others will not find them desirable. Discuss sexuality and sexual function. Help the patient realize that it takes time to adjust to the pouch and to body changes before feeling secure with sexual functioning.

Teach the patient to empty the pouch before sexual activities. Some may apply a smaller pouch or use a pouch cover during sexual activity. Women may consider wearing open panties, a short slip, or similar lingerie. Men may consider wearing a wrap or cummerbund around the midsection to secure the pouch.

Colostomy Care

Patients with new ostomies have complex needs and require frequent assessment, planning, intervention, and evaluation (Table 47.31). Two major aspects of nursing care are (1) patient and caregiver teaching about ostomy care and (2) emotional support as the patient copes with a change in body image. With shorter hospital stays, patient teaching should focus on the critical aspects that patients need to master. Teaching must include (1) basic skills about managing the ostomy (e.g., changing the pouch), (2) diet, and (3) how to get help for problems. Home care and outpatient follow-up may be helpful, especially if there is access to a WOCN. Patient and caregiver teaching is outlined in Table 47.32. Nursing care for the patient with an ostomy is discussed in eNursing Care Plan 47.3 on the website.

An appropriate pouching system is vital to protect the skin and provide dependable stool collection. Most pouching systems have an adhesive skin barrier and a pouch to collect the feces. If the abdominal stoma site has bends or creases, it is hard to get a good seal, and the skin barrier will pull away faster. Since the excess weight of collected stool pulls the wafer away from the skin, empty ostomy bags when one-third full.

TABLE 47.31 NURSING MANAGEMENT

Ostomy Care

- Assess and document stoma and peristomal skin appearance.
- For patient with a new ostomy, assess patient's preparation for ostomy care.
- Assist the patient with managing the psychologic impact of the stoma and its effect on body image and self-esteem.
- Choose appropriate ostomy pouching system for patient.
- Monitor the volume, color, and odor of the ostomy drainage.
- Develop plan of care for skincare around the ostomy.
- Teach ostomy self-care to patient and caregiver (Table 47.32).
- Irrigate new colostomy, if indicated.
- Teach patient and caregivers about appropriate diet choices (Table 47.33).
- Supervise AP:
  - Empty ostomy bag and measure liquid contents.
  - Place the ostomy pouching system for an established ostomy.
  - Assist stable patient with colostomy irrigation.

TABLE 47.32 PATIENT & CAREGIVER TEACHING

Ostomy Self-Care

Include the following points when teaching the patient and/or caregiver about self-care of an ostomy:

1. Explain what an ostomy is and how it functions.
2. Describe the underlying condition that resulted in the need for an ostomy.
3. Demonstrate and allow the patient and caregiver to practice the following:
   - Remove the old skin barrier, cleanse the skin, and correctly apply new skin barriers.
   - Apply, empty, clean, and remove the pouch.
   - Empty the pouch before it is one-third full to prevent leakage.
4. Irrigate the colostomy to regulate bowel elimination (optional).
5. Explain how to contact the WOCN.
6. Describe how to obtain ostomy supplies.
7. Explain diet and fluid management, including:
   - Well-balanced diet and supplements to prevent nutrition problems
   - Foods to avoid to reduce diarrhea or gas (see Table 47.33)
   - Fluid intake of least 3000 mL/day to prevent dehydration (unless contraindicated)
   - Increase fluid intake during hot weather, excess perspiration, and diarrhea to replace losses and prevent dehydration
   - Describe symptoms of fluid and electrolyte imbalance
   - How to contact the dietitian
   - Chew food very well to reduce the chance of blockage
   - Explain how to recognize problems (fever, diarrhea, skin irritation, stomal problems)
8. Describe community resources to assist with emotional and psychologic adjustment to the ostomy.
9. Explain the importance of follow-up care.
10. Describe the ostomy's potential effects on sexual activity, social life, work, and recreation and ways to manage these changes.

Use a transparent pouch in the initial postoperative period so that you can easily assess stoma viability and pouch application by the patient. Each time the pouch is changed, assess the skin for irritation. If the peristomal skin is irritated and raw, more products may have to be applied. Do not allow feces to remain on the skin, or irritation will quickly develop. Change a pouch that has failed at once.

A colostomy in the ascending and transverse colon has semiliquid stools. Have the patient use a drainable pouch. A drainable pouch may last up to 4 to 7 days. A colostomy in the sigmoid or descending colon has semiformed or formed stools. The patient can use a drainable pouch or a disposable, closed-end pouch changed every day. Charcoal filters can deodorize and automatically release flatus. They are available for both types of pouches.

An option when the stoma is in the distal colon is colostomy irrigation. It may be used to stimulate emptying of the colon. The patient may need to wear only a pad or small pouch over the stoma if spillage should occur between irrigations. Irrigation requires manual dexterity and adequate vision. People who irrigate should have ostomy bags in case they develop diarrhea.

Teach the patient about the importance of fluids and a healthy diet. The effect of food on stoma output is individual. Most patients with colostomies can eat anything they want. However, some choose to avoid certain foods because of possible increased gas, odor, or stoma output (Table 47.33).

The patient can resume activities of daily living within 6 to 8 weeks but should avoid heavy lifting. The patient's physical condition determines when they can resume sports. Swimming with an ostomy pouch intact is not a problem. The patient can bathe and shower with or without the pouching system in place because water does not harm the stoma.

Ileostomy Care

Nursing care for a patient with an ileostomy is similar to that for a patient with a colostomy. Because the stool from an ileostomy is caustic to the skin, a secure pouching system is important. The patient must always wear a pouch since regularity is not possible with an ileostomy. An open-ended, drainable pouch is best, so drainage can be easily emptied.

Patients need to increase fluid intake to at least 2 to 3 L/day or more when there are excess fluid losses from heat and sweating. They may need to ingest more sodium. Patients must learn signs and symptoms of fluid and electrolyte imbalance so that they can take appropriate action.

TABLE 47.33 NUTRITION THERAPY

Effects of Food on Stoma Output

Odor Producing	Gas Forming	Diarrhea Causing
Alcohol	Beans	Alcohol
Asparagus	Beer	Beer
Broccoli	Cabbage family	Cabbage family
Cabbage	Carbonated beverages	Coffee
Eggs	Cheeses (strong)	Fruits (raw)
Fish	Onions	Green beans
Garlic	Sprouts	Spicy foods
Onions		Spinach

An ileostomy is susceptible to obstruction because the lumen is less than 1 inch in diameter. It may narrow further at the point where the bowel passes through the fascia/muscle layer of the abdomen. Foods such as nuts, raisins, popcorn, coconut, mushrooms, olives, stringy vegetables, foods with skins, dried fruits, and meats with casings must be chewed very well before swallowing.

Psychologic Adaptation to an Ostomy

The patient's response to a new ostomy is highly individualized. Some have minimal difficulty and view their ostomy positively. It may be curative if their presenting condition was UC or a step toward remission if the diagnosis was CRC. Other patients may have a grief reaction from the change in body image. They may be angry, depressed, or fearful. Concerns about stool leaking, odor, sounds of flatus, pouch reliability, and changes in lifestyle are all common worries. Information, emotional support, and mastering basic skills will help patients learn to live a full life with an ostomy and accept the changes in body image.

Provide information in an easily understood manner and help patients develop confidence and competence in managing the stoma. The patient's emotional state may limit the ability to take part in teaching and ostomy care. Help the patient identify ways of coping. Support from the caregiver, family, and friends is vital. It reassures the patient of their value despite having the ostomy. Encourage patients to share their concerns and ask questions.

New ostomy patients will have questions on a variety of topics ranging from managing gas to intimacy to travel. Give the names and contact information for support groups. The Wound Ostomy Continence Nurses Society *(www.wocn.org)*, local support groups, and United Ostomy Associations of America *(www.ostomy.org)* provide practical information about living with an ostomy. Online support groups are also available. Some hospitals have a visitor's program. These programs give the patient and caregiver an opportunity to talk with a person who has adjusted well to an ostomy and had some of the same feelings and concerns they have.

DIVERTICULOSIS AND DIVERTICULITIS

Diverticula are saccular dilations or outpouchings of the mucosa that develop in the colon (Fig. 47.14). Diverticulosis is the

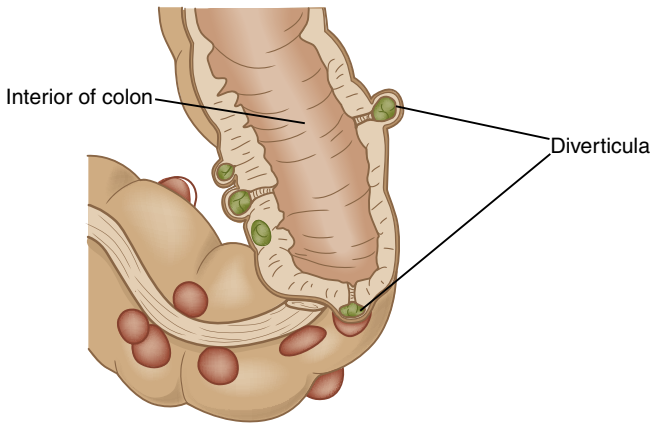

Fig. 47.14 Diverticula are outpouchings of the colon. When they become inflamed, the condition is diverticulitis. The inflammatory process can spread to the surrounding area in the intestine.

presence of multiple noninflamed diverticula. **Diverticulitis** is inflammation of 1 or more diverticula, resulting in perforation into the peritoneum. Clinically, diverticular disease covers a spectrum from asymptomatic, uncomplicated diverticulosis to diverticulitis with complications, such as perforation, abscess, fistula, and bleeding. Diverticula are common, especially in older adults, but most people never develop diverticulitis.

Etiology and Pathophysiology

Diverticula may occur anywhere in the GI tract but are most common in the left (descending, sigmoid) colon. They seem to occur at weak points in the intestinal wall, such as where the blood vessels pass through the muscle layer. The cause is thought to include both genetic and environmental factors. We think the main contributing factors are diet and lifestyle. The disease is more prevalent in Western, industrialized populations, where people tend to consume diets low in fiber and high in red meat and refined carbohydrates.[22] Diverticula are uncommon in vegetarians. Other risk factors are obesity, inactivity, smoking, excess alcohol use, and NSAID use.

Clinical Manifestations and Complications

Most patients with diverticulosis have no symptoms. Those with symptoms typically have abdominal pain, bloating, flatulence, and changes in bowel habits. In more serious situations, the diverticula bleed, or diverticulitis develops. The most common signs and symptoms of diverticulitis are acute pain in the left lower quadrant, distention, decreased or absent bowel sounds, nausea, vomiting, and systemic symptoms of infection. Older adults with diverticulitis may be afebrile, with a normal WBC count and little, if any, abdominal tenderness. Diverticulitis can cause erosion of the bowel wall and perforation into the peritoneum (Fig. 47.15). A localized abscess develops when the body walls off the perforated area. Peritonitis develops if it cannot be contained. Bleeding can be extensive but usually stops spontaneously.

PATHOPHYSIOLOGY MAP

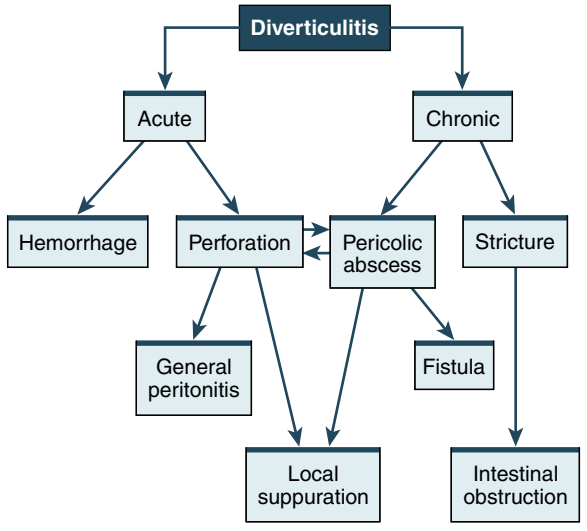

Fig. 47.15 Complications of diverticulitis.

Diagnostic Studies

Diverticular disease can be asymptomatic. It is typically found during routine sigmoidoscopy or colonoscopy. Diagnosis of diverticulitis is based on the physical assessment, CBC, and imaging (Table 47.34).[22] The preferred diagnostic test is a CT scan with oral contrast. Abdominal x-rays, ultrasound, and MRI are other options.

Interprofessional and Nursing Care

In acute diverticulitis, the goal of treatment is to let the colon rest and the inflammation subside (Table 47.35). Some patients can be managed at home with a clear liquid diet, bed rest, and analgesics. Hospitalization is needed if symptoms are severe, the

Management

Conservative Therapy

- High-fiber diet
- Fiber supplements
- Weight loss (if overweight)
- Smoking cessation

Acute Care: Diverticulitis

- Antibiotic therapy
- NPO status
- IV fluids
- Analgesics
- NG suction
- Surgery
  - Possible resection of involved colon
  - Possible temporary colostomy

TABLE 47.35 NURSING MANAGEMENT

Acute Diverticulitis

- Give IV fluids and electrolyte replacement as ordered.
- Place the patient on NPO status, moving to clear liquids with improvement.
- Administer IV fluids and antibiotics as ordered.
- Observe for signs of abscess, bleeding, and peritonitis.
- Monitor the WBC count.
- Implement pain management measures.
- Keep the patient on bedrest.
- Maintain a strict intake and output record.
- Provide frequent oral care and water-soluble lubricant for the lips.
- Institute NG suctioning and check every 4 hours for patency.

patient is unable to tolerate oral fluids, there are systemic manifestations of infection (fever, significant ↑ WBC), or the patient has co-morbid conditions (e.g., immunosuppression).

Patients with reoccurring diverticulitis or complications, such as an abscess or obstruction, may need surgery. The usual surgical procedure involves resection of the involved colon with a primary anastomosis.[22] If the HCP is not able to anastomose the colon, the patient will have a temporary diverting colostomy. After the colon heals, the temporary colostomy can be taken down and the ends of the colon reconnected.

Provide patients with diverticular disease with a full explanation of the condition. Patients who understand the disease process well and adhere to the prescribed regimen are less likely to have an exacerbation. Teach them the importance of following a high-fiber diet, mainly from fruits and vegetables with a decreased intake of fat and red meat (Table 47.9). Encourage a fluid intake of at least 2 L/day.

A patient with diverticular disease should avoid increased intraabdominal pressure because it may precipitate an attack. Factors that increase intraabdominal pressure are straining at stool, vomiting, bending, heavy lifting, and wearing tight, restrictive clothing. Weight loss (see Chapter 45) is important for the person with obesity. Encourage smoking cessation.

FISTULAS

A **fistula** is an abnormal tract between 2 hollow organs or a hollow organ and the skin. Fistulas are named by the track that they take from one body part to another. For example, an enterocutaneous fistula is an opening between the small intestine and skin. An enterovaginal fistula is between the small intestine and vagina, allowing stool and gas to drain through the vagina.

A GI fistula occurs between the lumen of the GI tract and another organ. GI fistulas are a serious complication associated with increased morbidity and mortality, extended hospital stays, and increased costs. Most fistulas occur after surgery or trauma. Other times fistulas can form with IBD, cancer, perforation, radiation, diverticulitis, or pancreatitis.[23] Fistulas are classified as simple or complex and by the amount of output. A simple fistula has only one short, direct tract. A complex fistula is associated with an abscess, involves multiple organs, and may open into the base of a wound. High-output fistulas drain more than 500 mL/day, moderate-output fistulas drain 200 to 500 mL/day, and low-output fistulas drain less than 200 mL/day.

Fever and abdominal pain are early signs of a fistula. Other manifestations depend on the type. With an enterocutaneous fistula, there may be pus or intestinal contents draining through the skin opening. Patients with a colocutaneous (colon to skin) fistula may have stool or pus draining through the opening. If a colovesical (colon to urinary tract) fistula is present, manifestations include fecaluria (passing stool with urination), recurrent urinary tract infections, dysuria, and hematuria.

Interprofessional and Nursing Care

Treatment of fistula requires (1) identifying the fistula tract, (2) maintaining fluid and electrolyte balance, (3) controlling infection, (4) protecting the surrounding skin, (5) managing output, and (6) providing nutrition support. Managing a fistula is often a difficult and complex process. It can be disheartening for the patient and caregiver. Surgery may be needed if there are complications.

Appropriate fluid and electrolyte replacement can be challenging, especially when the patient has a high-output fistula. Keep an accurate intake and output record. Monitor urine output and the volume of fistula output as these guide fluid replacement. Assess the character of the drainage, noting the color, consistency, and odor. Monitor laboratory values. Low serum levels of potassium, magnesium, and phosphorus from the loss of GI fluids are common. Give IV fluids and electrolyte replacement as ordered. Measure vital signs frequently and be alert for signs of dehydration.

Many patients are NPO as this reduces intestinal output. They may receive acid suppression with a proton-pump inhibitor or histamine H_2-receptor blocker. Antimotility drugs (e.g., loperamide) decrease intestinal fluid loss.[23]

Malnutrition is a significant problem, especially if the patient is NPO or has a small intestinal fistula. Consult a dietitian. High-calorie, high-protein PN or EN is needed to provide enough calories and protein to replace losses and support healing.[23] Many patients need trace elements (e.g., copper, zinc, magnesium) and vitamin supplements.

Maintaining skin integrity and optimizing healing are essential. Consult a WOCN if available. Low-output fistulas may be managed with a simple absorbent dressing. A high-output enterocutaneous fistula often needs advanced techniques, including specialty pouches; barrier creams, powders, and sealants to protect the skin; and negative pressure wound therapy.

CHECK YOUR PRACTICE

A 51-year-old woman is 4 days postop after a proctocolectomy for UC. You note 2.5 cm of redness in the center of her incision with heavy, foul-smelling tan drainage pooling on her skin. Suspecting she is developing an enterocutaneous fistula, you notify the HCP and WOCN.

- What will you do to protect her skin?

HERNIAS

A **hernia** is a protrusion of tissue, such as the intestines, through an abnormal opening or a weakened area in the wall of the cavity in which it is normally contained. A hernia may occur in any part of the body, but it usually occurs within the abdominal cavity. *Reducible* hernias easily return into the abdominal cavity. Reducing can be done manually or may occur spontaneously when the person lies supine. *Irreducible,* or *incarcerated,* hernias cannot be placed back into the abdominal cavity. They have abdominal contents trapped in the opening. Strangulation occurs if the blood supply to the contents trapped in an irreducible hernia becomes compromised. The result is an acute bowel obstruction. Gangrene and necrosis of the hernia contents are possible (Box 47.6).

Types

An *umbilical hernia* occurs when the rectus muscle is weak (as with obesity) or the umbilical opening does not close after birth

(Fig. 47.16A). A *femoral hernia* occurs when there is a protrusion through the femoral ring into the femoral canal. It appears as a bulge below the inguinal ligament. Femoral hernias easily strangulate (Fig. 47.16B).

The *inguinal hernia* is the most common type of hernia and occurs at the point of weakness in the abdominal wall where the spermatic cord (in men) or the round ligament (in women) emerges (Fig. 47.16C).

Ventral or *incisional hernias* are due to weakness of the abdominal wall at the site of a previous incision. They occur most often in those who are obese, have had multiple surgeries in the same area, or have had inadequate wound healing because of poor nutrition or infection. Peristomal hernias are ventral hernias.

Clinical Manifestations

Pain is the classic symptom of a hernia. It may worsen with activities that increase intraabdominal pressure, such as lifting, coughing, and straining. A hernia may be readily visible, especially when the person tenses the abdominal muscles. If the hernia becomes strangulated, the patient will have severe pain and symptoms of bowel obstruction, such as vomiting, cramping, abdominal pain, and distention.

Interprofessional and Nursing Care

Diagnosis of a hernia is usually based on history and physical assessment. Ultrasound, CT, and MRI can help identify a hernia and determine the contents. Laparoscopic surgery is the treatment of choice. The surgical repair of a hernia, known as a *herniorrhaphy,* is usually an outpatient procedure. Reinforcing the weakened area with wire, fascia, or mesh is known as a *hernioplasty.* Emergency surgery is needed for strangulated hernias or inflamed, irreducible hernias. Surgery for strangulated hernias involves resecting the involved area with possible placement of a temporary colostomy.

After a hernia repair, the patient may have problems voiding. Measure intake and output. Observe for a distended bladder. Scrotal edema is a painful complication after an inguinal hernia repair. A scrotal support with application of an ice bag and elevating the scrotum may help relieve pain and edema. Encourage deep breathing but not coughing. Teach patients to splint the incision and keep their mouths open when coughing or sneezing is unavoidable. The patient may be restricted from heavy lifting (>10 lb) for 6 to 8 weeks.

BOX 47.6 BIOLOGIC SEX CONSIDERATIONS

Hernia

Men
- More likely to have inguinal hernias
- Have a 25% lifetime risk for developing an inguinal hernia

Women
- More likely to have femoral hernias, especially older women
- Have less than a 5% lifetime risk for developing an inguinal hernia
- More likely to have umbilical hernias

MALABSORPTION SYNDROME

Malabsorption results from impaired absorption of fats, carbohydrates, proteins, minerals, and vitamins. The stomach, small intestine, liver, and pancreas regulate normal digestion and absorption. Digestive enzymes ordinarily break down nutrients so that absorption can take place. Malabsorption may occur if this process is interrupted at any point. Several problems can cause malabsorption (Table 47.36). Lactose intolerance is the most common malabsorption disorder, followed by IBD, celiac disease, tropical sprue, and cystic fibrosis.

The most common signs of malabsorption are weight loss and diarrhea. Other signs include fatigue, abdominal pain, and **steatorrhea** (bulky, foul-smelling, yellow-gray, greasy stools with putty-like consistency) (Table 47.37).

A complete history and physical along with testing are needed to make a diagnosis. Laboratory studies include a CBC, prothrombin time (to see if vitamin K absorption is adequate), liver function tests, and serum levels of vitamin A, carotene, electrolytes, iron, and calcium. Stool studies include assessing for fat (e.g., Sudan III stain), doing a microbiologic analysis, and assessing secretory function through elastase or chymotrypsin testing to assess pancreatic function.

Imaging studies include a CT scan and endoscopy. Barium studies can identify structural problems. Capsule endoscopy is

- Distal ileal resection, disease, or bypass
- SBS

useful in assessing the small intestine for changes in mucosal integrity and inflammation. Treatment depends on the cause.

CELIAC DISEASE

Celiac disease is an autoimmune disease that causes damage to the small intestinal mucosa. It is triggered by ingesting gluten, a protein in wheat, barley, and rye. It can occur at any age and has a wide variety of symptoms. *Celiac sprue* and *gluten-sensitive enteropathy* are other names for celiac disease.

Celiac disease is not the same disease as *tropical sprue,* a chronic disorder occurring primarily in tropical areas. Tropical sprue causes progressive disruption of jejunal and ileal tissue, resulting in nutrition problems. It is treated with folic acid and tetracycline.

Celiac disease affects about 1 in 100 people worldwide.[24] First-degree relatives of someone with celiac disease have a 10% chance of developing the disorder. It is associated with other autoimmune diseases, particularly rheumatoid arthritis and type 1 diabetes. It is slightly more common in women. Symptoms often begin in childhood.

Etiology and Pathophysiology

Three factors necessary for developing celiac disease are genetic predisposition, gluten ingestion, and an immune-mediated response. About 95% of people with celiac disease have human leukocyte antigen (HLA) allele HLA-DQ2. The other 5% have HLA-DQ8. However, not everyone with these genetic markers develops celiac disease. Some people with celiac disease do not have either of these HLA alleles.

TABLE 47.37 Manifestations of Malabsorption

Manifestations	Pathophysiology
Cardiovascular	
Hypotension	Dehydration
Peripheral edema	Protein malabsorption, protein loss in diarrhea
Tachycardia	Hypovolemia, anemia
GI	
Diarrhea	Impaired absorption of water, sodium, fatty acids, bile salts, carbohydrates
Flatulence	Bacterial fermentation of unabsorbed carbohydrates
Glossitis, cheilosis, stomatitis	Deficiency of iron, riboflavin, cobalamin, folic acid, other vitamins
Steatorrhea	Undigested and unabsorbed fat
Weight loss	Malabsorption of fat, carbohydrates, protein leading to loss of calories. Decrease in caloric intake or ↑ use of calories
Hematologic	
Anemia	Impaired absorption of iron, cobalamin, folic acid
Hemorrhagic tendency	Vitamin C deficiency. Vitamin K deficiency inhibiting production of clotting factors II, VII, IX, and X
Musculoskeletal	
Bone pain	Osteoporosis from impaired calcium absorption. Osteomalacia from hypocalcemia, hypophosphatemia, inadequate vitamin D
Muscle wasting	Protein malabsorption
Tetany	Hypocalcemia, hypomagnesemia
Weakness, muscle cramps	Anemia, electrolyte depletion (especially potassium)
Neurologic	
Altered mental status	Dehydration
Night blindness	Thiamine deficiency, vitamin A deficiency
Paresthesias	Cobalamin deficiency
Peripheral neuropathy	Cobalamin deficiency
Skin	
Brittle nails	Iron deficiency
Bruising	Vitamin K deficiency
Dermatitis	Fatty acid deficiency, zinc deficiency, niacin, other vitamin deficiencies
Hair thinning and loss	Protein deficiency

As with other autoimmune diseases, the tissue destruction that occurs with celiac disease is the result of chronic inflammation. Gluten contains specific peptides called *prolamins.* Partial digestion of gluten releases the prolamin peptides, which are absorbed into the intestinal submucosa. In genetically susceptible persons, the peptides bind to HLA-DQ2 and/or HLA-DQ8 and activate an inflammatory response. Inflammation damages the microvilli and brush border of the small intestine, decreasing the amount of surface area available for nutrient absorption. Damage is most severe in the duodenum, probably because it has more exposure to gluten. The inflammation lasts as long as gluten ingestion continues.

Clinical Manifestations

Classic manifestations of celiac disease include foul-smelling diarrhea, abdominal pain, flatulence, and abdominal distention. Some people have no obvious GI symptoms and may instead have atypical signs and symptoms. These include joint pain, liver problems, fatigue, peripheral neuropathy, and reproductive problems.[24] An intensely pruritic, vesicular skin lesion called *dermatitis herpetiformis*. It is sometimes present and occurs as a rash on the buttocks, scalp, face, elbows, and knees.

Protein, fat, and carbohydrate absorption is affected. Weight loss, muscle wasting, and other signs of malnutrition may be present. Abnormal serum folate, iron, and cobalamin levels can lead to anemia. Patients may have lactose intolerance and need to refrain from lactose-containing products until the disease is under control. Inadequate calcium intake and vitamin D absorption can lead to decreased bone density and osteoporosis.

Diagnostic Studies

Early diagnosis and treatment can prevent complications. Screening is recommended for close relatives of people known to have the disease, young patients with decreased bone density, those with anemia if other causes are ruled out, and certain autoimmune diseases.

Celiac disease is diagnosed by findings from the history and physical assessment and serology testing. Have the patient complete diagnostic testing before starting a gluten-free diet since the diet will change the results. The best serologic test is the tissue transglutaminase IgA antibody, plus an IgA antibody.[24] Though not done as often, histologic evidence is the gold standard for confirming the diagnosis. Biopsies show flattened mucosa and noticeable losses of villi. Genotyping involves testing for HLA-DQ2 and/or HLA-DQ8 antigens.

Interprofessional and Nursing Care

A strict gluten-free diet (Table 47.38) is the only effective treatment for celiac disease. Most patients need to stay on a gluten-free diet for the rest of their lives. Periodic nutrition evaluations and laboratory monitoring are done to monitor for anemia and malnutrition. They often require a daily vitamin and mineral supplement. The patient should undergo bone density screening every 2 to 3 years.

Refer all patients for a diet consultation. You can work with a dietitian to teach the patient how to eat a nutritionally adequate diet while considering food preferences, cultural traditions, and food availability. Teach the patient to read medication and food labels. Some medications and many food additives, preservatives, and stabilizers contain gluten. Although pure oats do not contain gluten, wheat, rye, and barley can contaminate oat products during the milling process. The patient needs to know where to buy gluten-free products. Good sources are health food stores, many grocery stores, and Internet sites.

Maintaining a gluten-free diet can be hard, especially when traveling or eating in restaurants. Many describe feeling embarrassed or like a burden when having to discuss gluten-free menu options with restaurant staff or when dining in others' homes. Mobile phone users will find apps listing gluten-free menu options at popular restaurants helpful. Many restaurants now indicate which food choices are gluten-free. The Celiac Disease Foundation (www.celiac.org) provides suggestions for maintaining a gluten-free diet and living with celiac disease.

TABLE 47.38 NUTRITION THERAPY

Celiac Disease

Foods that contain or often contain gluten:
- Baked goods, including muffins, cookies, cakes, pies, donuts, rolls
- Barley
- Bread, including wheat bread, white bread, and bagels
- Breakfast foods, such as pancakes, French toast
- Crackers
- Dressings, croutons
- Flour
- Flour tortillas
- Gluten stabilizers
- Granola
- Oats
- Pasta, noodles
- Pizza
- Rye
- Wheat

Foods that may contain gluten:
- Candy and candy bars
- Cream-based soups
- Energy bars
- French fries
- Potato chips, tortilla chips
- Processed lunch meat
- Salad dressings, marinades

LACTASE DEFICIENCY

Lactase deficiency is a condition in which the lactase enzyme is deficient or absent. Lactase is the enzyme that breaks down lactose into 2 simple sugars: glucose and galactose. Primary lactase insufficiency is often a result of genetic factors. Certain ethnic or racial groups, especially those with Asian or African ancestry, develop low lactase levels in childhood.[25] Less common causes include premature birth and congenital lactase deficiency, a rare genetic disorder. Lactose malabsorption can occur when conditions leading to bacterial overgrowth promote lactose fermentation in the small bowel or when intestinal mucosal damage interferes with absorption. The latter occurs with IBD and celiac disease.

Many do not have symptoms if they ingest lactose in small amounts.[25] When symptoms are present, they include bloating, flatulence, cramping abdominal pain, and diarrhea. Diarrhea results from the excess, undigested lactose in the small intestine attracting water molecules, which prevents them from being properly absorbed. Symptoms generally occur within 30 minutes to several hours after ingesting lactose. Lactose problems are often diagnosed with lactose tolerance tests, hydrogen breath tests, or genetic testing.[25]

Treatment aims to improve patient symptoms and prevent malnutrition. Limiting lactose in the diet by avoiding milk and milk products generally results in symptom improvement. Many lactose-free milk products are readily available. Lactase tablets

are available as an over-the-counter (OTC) product. They break down the lactose present in ingested milk. Some have improved symptoms by taking prebiotics or probiotics that produce lactase in the gut.

Teach the patient which foods to limit. Cheese has less lactose than milk and ice cream. Live culture yogurt has less lactose because the bacteria help digest the lactose. Teach the patient to read labels to detect any hidden sources of lactose. Some people tolerate lactose better if taken with meals. Since limiting milk and milk products can lead to calcium deficiency, supplements may be needed to prevent osteoporosis.

SHORT BOWEL SYNDROME

Short bowel syndrome (SBS) is a condition in which the small intestine does not have enough surface area to absorb enough nutrients. This leaves the person unable to meet energy, fluid, electrolyte, and nutrition needs to stay healthy on a normal diet. Causes of SBS include diseases that damage the intestinal mucosa, surgical removal of too much small intestine (e.g., with Crohn's disease, cancer), and congenital defects.

SBS is likely to develop in patients with a loss of 50% to 75% of the small intestine. The length and area of the small intestine present and the presence of the colon and ileocecal valve affect the patient's outcome. SBS is common in patients with a jejunoileal anastomosis. Parts of the jejunum and ileum are removed. The remaining parts are connected to the colon or an ostomy is formed. If the terminal ileum, ileocecal valve, and colon are intact, the patient will rarely have problems with SBS.

Clinical Manifestations

SBS results in reduced nutrient, fluid, and electrolyte absorption. This leads to dehydration, weight loss, diarrhea, malnutrition, vitamin deficiencies, and electrolyte imbalances. Other manifestations include abdominal pain, flatulence, and steatorrhea. The patient may develop lactase deficiency and bacterial overgrowth. Those who are malnourished may have manifestations from specific deficiencies. For example, patients may have peripheral neuropathy from vitamin B_{12}, vitamin E, copper, or thiamine deficiencies or fatigue due to anemia from decreased folate or iron.

Interprofessional Care

The treatment goals are that the patient will maintain normal nutrition, achieve a good quality of life, and be free from complications. The main treatment is nutrition support involving PN, EN, medications, and a tailored diet. In the immediate period after a major bowel resection, patients receive PN to replace fluid, electrolyte, and nutrient losses and rest the bowel. They may need PN indefinitely. EN and a normal diet are gradually resumed to stimulate the remaining intestine to function better. Some can eventually stop PN.

The patient requires a diet that maximizes nutrient and fluid absorption and decreases stool output. Refer the patient to a dietitian. The ideal diet is high in protein and complex carbohydrates and low in fat and simple sugars. Soluble fiber is encouraged if the colon is present. The patient should eat at least 6 small meals per day to increase the time of contact between food and the intestine. Oral vitamin and mineral supplements may be needed. Patients with severe malabsorption may need PN or EN at night (see Chapter 44).

Patients often take multiple medications. US Food and Drug Administration–approved drugs for the treatment of SBS include somatropin, glutamine, and teduglutide (Gattex). Somatropin enhances intestinal adaption and increases the flow of water, electrolytes, and nutrients into the bowel. Glutamine improves intestinal absorption. Teduglutide increases the surface area of the intestine and improves intestinal absorption of fluids and nutrients.

Antisecretory and antimotility drugs reduce fluid losses and GI motility. These include PPIs or H_2-blockers, α-adrenergic receptor agonists (e.g., clonidine), octreotide, and opioid antidiarrheal drugs (see Table 47.2). For patients who have limited ileal resections, cholestyramine reduces diarrhea resulting from unabsorbed bile acids by increasing their excretion in feces. Bile acids stimulate intestinal fluid secretion and reduce colonic fluid absorption. Antibiotic therapy is used to prevent bacterial overgrowth.

Intestinal transplantation is done at a few specialized transplant centers in the United States. It is considered the only long-term treatment option for patients with intestinal failure who have significant complications from PN or nutrition failure. The leading cause of intestinal failure is SBS. Transplantation may include the intestine alone, liver and intestine, or multivisceral combinations (stomach, duodenum, jejunum, ileum, colon, and/or pancreas).

ANORECTAL PROBLEMS

HEMORRHOIDS

Hemorrhoids are abnormally dilated hemorrhoidal veins. They may be internal (above the internal sphincter) or external (outside the external sphincter) (Figs. 47.17 and 47.18).

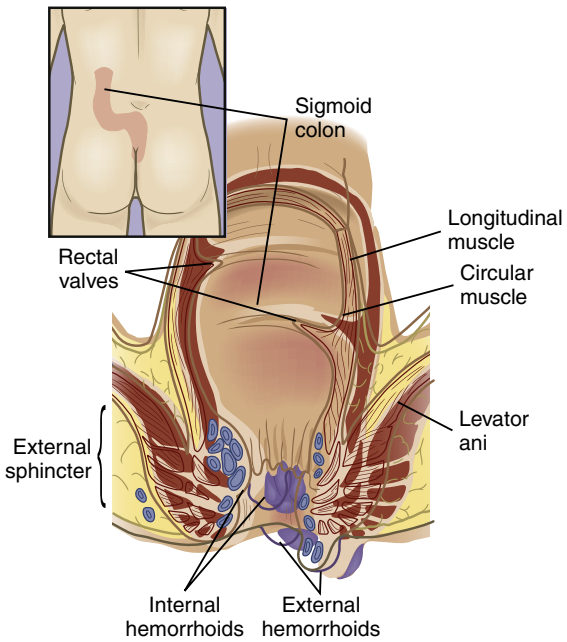

Fig. 47.17 Anatomic structures of the rectum and anus with external and internal hemorrhoids.

Hemorrhoids can appear periodically, depending on the amount of anorectal pressure.

Etiology and Pathophysiology

Hemorrhoids are thought to develop because of increased anal pressure and weakening of the connective tissue that supports the hemorrhoidal veins. Weakened supporting tissue allows for downward displacement of the hemorrhoidal veins, causing them to dilate. Blood flow through the veins of the hemorrhoidal plexus is impaired. An intravascular clot in the venule results in a thrombosed external hemorrhoid. Many factors increase the risk for hemorrhoids. These include pregnancy, constipation, straining to defecate, diarrhea, heavy lifting, prolonged standing and sitting, obesity, and ascites.[26]

Clinical Manifestations

Hemorrhoids are the most common reason for bleeding with defecation. Internal hemorrhoids most often cause painless, bright red bleeding with stools, on the toilet paper, or dripping into the toilet water. If internal hemorrhoids become constricted, the patient will report pain. Internal hemorrhoids can prolapse into the anal canal or externally. Symptoms of prolapse include pressure with defecation and a protruding mass.

External hemorrhoids are reddish-blue and seldom bleed. There may be itching, burning, and edema. They usually do not cause pain unless thrombosis (blood clots) is present. Thrombosed hemorrhoids are a bluish-purple tinge and palpable at the anal orifice. They usually cause pain and inflammation. The clot can erode through the overlying stretched skin, causing bleeding with defecation. Constipation or diarrhea can worsen these symptoms.

Fig. 47.18 Thrombosed external hemorrhoid. (From Hall J: Modern management of hemorrhoidal disease, *Gastroenterol Clin North Am* 42:759, 2013.)

It is easy to diagnose external hemorrhoids with visual inspection and DRE. DRE, anoscopy, and sigmoidoscopy are used to diagnose internal hemorrhoids.

Interprofessional and Nursing Care

First-line therapy typically involves normalizing stool consistency by treating constipation or diarrhea. Teach the patient measures to prevent constipation (see Table 47.11). A high-fiber diet and increased fluid intake prevent constipation and reduce straining. This allows engorgement of the veins to subside. The resulting stool bulk may decrease stool leakage and itching. Teach the patient to avoid straining and limiting time sitting on the toilet. Warm sitz baths (15 to 20 minutes, 2 or 3 times each day) may help to reduce discomfort and swelling. Teach the patient to seek medical care for severe symptoms of hemorrhoids (e.g., excessive pain or bleeding, prolapsed hemorrhoids).

OTC ointments, creams, and suppositories specifically made for hemorrhoid treatment can be used to shrink the mucous membranes and relieve pain. These drugs often contain anesthetics, corticosteroids, protectants, or antiseptics. Corticosteroid use should be limited to 1 week or less to prevent side effects, such as contact dermatitis and mucosal atrophy. Stool softeners can keep the stools soft. NSAIDs can be taken for pain.

Prolapsed or bleeding internal hemorrhoids or thrombosed external hemorrhoids may need medical treatment. Nonsurgical approaches (rubber band ligation, infrared coagulation, sclerotherapy, laser treatment) are options. Rubber band ligation is the most widely used technique. The HCP inserts an anoscope to identify the hemorrhoid and then ligates it with a rubber band. The rubber band around the hemorrhoid constricts circulation. The tissue becomes necrotic, separates, and sloughs off. There is some local discomfort with this procedure, but no anesthetic is needed.

A *hemorrhoidectomy* is the surgical excision of hemorrhoids. Surgery is needed when there is marked prolapse, excessive pain or bleeding, or large or multiple thrombosed hemorrhoids. After removing the hemorrhoids, the tissue is either sutured, and the wound heals by primary intention, or the area is left open, and healing takes place by secondary intention.

Nursing care after a hemorrhoidectomy focuses on pain control and promoting wound healing (Table 47.39). Be aware that

TABLE 47.39 NURSING MANAGEMENT

Care of the Patient After a Hemorrhoidectomy

- Administer analgesics as ordered, especially before bowel movements.
- Administer stool softeners and bulking agents as ordered.
- Administer warm sitz baths 15 to 20 min, 2 or 3 times each day.
- Encourage the patient to change positions frequently.
- Apply ice to the area several times a day for 10 min at a time.
- Teach the patient to use a pressure relief cushion, not a ring or "doughnut" when sitting.
- Have the patient use baby wipes or medicated pads instead of toilet paper.
- Assess for rectal bleeding, especially in those taking anticoagulants.
- Provide as much privacy as possible when providing wound care and performing assessments.
- Teach the patient care of the anal area, symptoms of complications (especially bleeding), and ways to avoid constipation and straining.

although the procedure is minor, the pain is severe and feared by many. There are several analgesic regimens using a combination of drugs. Most patients receive multimodal analgesia. This may involve an opioid and NSAID in conjunction with topical preparations that provide anesthesia or reduce internal sphincter spasms, such as topical lidocaine, 2% diltiazem, and glyceryl trinitrate.

The patient usually dreads the first bowel movement and often resists the urge to defecate. Give pain medication before the bowel movement to reduce discomfort. Stool softeners (e.g., docusate) and bulking agents are given to help form a soft, bulky stool that is easier to pass. If the patient does not have a bowel movement within 2 or 3 days, an oil-retention enema is given.

A warm sitz bath provides comfort and keeps the anal area clean. A sponge ring in the sitz bath helps relieve pressure on the area. Initially, do not leave the patient alone because of the possibility of weakness or fainting. The patient may have packing in the rectum to absorb drainage, with a T-binder to hold the dressing in place. Packing is usually removed on the first or second postoperative day.

ANAL FISSURE

An *anal fissure* is a linear skin tear in the anal mucosa. Many times, the inciting event is trauma from passing hard stools. Other fissures are related to trauma (anal intercourse, foreign body insertion, childbirth), local infection (syphilis, gonorrhea, *Chlamydia,* herpes simplex virus, HIV), or inflammation. An anal fissure is acute when it is of recent onset (less than 6 weeks) and chronic if it has been present for a longer period. Chronic fissures have a characteristic appearance that includes perianal skin tags and fibrotic edges.

Anal tissue ulcerates because of ischemia caused by a combination of high pressure in the internal anal sphincter and poor blood supply to the area. The ischemic tissue may ulcerate spontaneously or when traumatized by factors such as hard stools, which would not normally cause tissue breakdown. Ischemia must be corrected for a fissure to heal.

The hallmark of an anal fissure is severe anal pain. It is worse with defecation and with direct pressure on the site, such as from sitting. Acute fissures tend to bleed slightly. Patients may report red blood on the toilet paper. Constipation results because of fear of pain when having bowel movements.

Anal fissures are easy to diagnose with a physical assessment. Conservative care with fiber supplements, increased fluid intake, sitz baths, and topical analgesics is successful in most cases, especially if the fissure is acute. Pain is managed by softening stools with a bulk-producing agent (psyllium) or stool softener and warm sitz baths (15 to 20 minutes, 3 times per day). Topical calcium channel blockers decrease rectal pressure and allow the fissure to heal without sphincter damage. Local injections of botulinum toxin can decrease rectal pressure.

If conservative treatment fails, a lateral internal sphincterotomy is the recommended surgical procedure. It carries the risk of postoperative incontinence. Postoperative nursing care is the same as the care for the patient who had a hemorrhoidectomy.

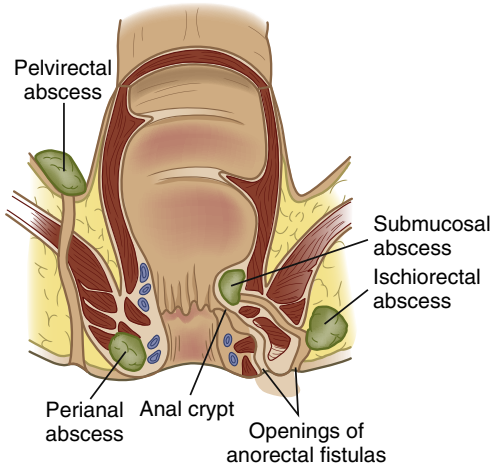

Fig. 47.19 Common sites of anorectal abscesses and fistula formation.

ANORECTAL ABSCESS

An *anorectal abscess* is a collection of perianal pus (Fig. 47.19). The abscess results from obstruction of the anal glands, leading to infection and abscess formation. Abscess formation occurs with anal fissures, trauma, or IBD. The most common causative organisms are *E. coli,* staphylococci, and streptococci. Manifestations include local severe pain and swelling, foul-smelling drainage, tenderness, and fever. Sepsis can occur as a complication. Anorectal abscesses are diagnosed by rectal examination.

Anorectal abscesses require surgical drainage. Larger abscesses need packing afterward with impregnated gauze or placement of drains (e.g., Penrose) to promote drainage. The area then heals by granulation. Patients who have diabetes, cellulitis, or are immunocompromised (e.g., chemotherapy) may need antibiotic therapy. Nursing care includes warm, moist heat applications and changing packing daily. The patient is usually more comfortable lying on the abdomen or side. A low-fiber diet is given. The patient may leave the hospital with the wound still open. Teach the patient about wound care and the importance of sitz baths, thorough cleaning after urinating or bowel movements, and follow-up visits with the HCP.

ANAL FISTULA

An **anal fistula** is an abnormal tunnel from the anus or rectum to the surface of the skin around the anus or the vagina. About 80% of anal fistulas are due to an anorectal abscess or infection. Other causes include Crohn's disease, cancer, chronic diarrhea, trauma, or radiation.[27]

Feces may enter the fistula and cause an infection. There may be persistent, bloody, or purulent discharge or stool leakage from the fistula. The patient may need to wear a pad to avoid staining clothes.

Surgical treatment of an anal fistula depends on the location and nature of the fistula. In a fistulotomy, the HCP opens the fistula, and healthy tissue is allowed to granulate in the wound. Care is the same as after a hemorrhoidectomy. Options for complex fistulas include ligation of the intersphincteric fistula tract

(LIFT) or the use of rectal flaps, setons, plugs, or fibrin glue injections to seal the fistula.

ANAL CANCER

Anal cancer is uncommon in the general population, but the incidence is increasing. In the United States, around 8700 people are diagnosed with anal cancer each year. It is more common in people over 50 years. Human papillomavirus (HPV) is associated with about 90% of the cases. Others at high risk include smokers, HIV-positive homosexual men, people who are immunocompromised (e.g., posttransplant immunosuppression), and women with cervical, vaginal, or vulvar cancer.

Rectal bleeding is the most common presenting sign. Other symptoms include rectal pain, itching, pressure, or a full feeling. Symptoms may be constant and worsen with sex or bowel movements. There may be a change in bowel frequency or size. The patient may report increased straining.[28]

It is especially important to screen high-risk persons using DRE and anal Pap tests. In an anal Pap test, the anal lining is swabbed, and the cells are examined to identify any cell changes (e.g., dysplasia, neoplasia). A high-resolution anoscopy allows the HCP to visualize the mucosa and obtain a biopsy. An endoanal *(endorectal) ultrasound* may be done.

Treatment of anal cancer depends on the size and depth of the lesions. It is primarily treated with a combination of low-dose radiation and chemotherapy. Chemotherapy regimens include combinations of mitomycin, cisplatin, and FU.[28] Options for precancerous lesions are surgical removal or treatment with topical imiquimod (Aldara) and FU. If the tumor involves the rectum and requires removal of the anal sphincters, the anus is sutured shut and a permanent ostomy created.

PILONIDAL SINUS

A *pilonidal sinus* is a small tract under the skin between the buttocks in the sacrococcygeal area. It is thought to be of congenital origin. It may have several openings and is lined with epithelium and hair, hence the name *pilonidal* ("a nest of hair"). The skin is moist, and movement of the buttocks causes the short, wiry hair to penetrate the skin. If the irritated skin becomes infected, it forms a pilonidal cyst or abscess. There are no symptoms with a pilonidal sinus unless there is an infection. Then the patient may have pain and swelling at the base of the spine.

An abscess requires incision and drainage. The wound may be closed or left open to heal by secondary intention. The wound is packed, and sitz baths are ordered. Nursing care includes warm, moist heat applications when an abscess is present. The patient is usually more comfortable lying on the abdomen or side. Teach the patient to avoid contaminating the dressing when urinating or defecating and to avoid straining whenever possible.

Case Study

Colorectal Cancer

(©iStockphoto/Thinkstock.)

Patient Profile

L.C., a 58-year-old Native American man, is from a Pueblo tribe in northern New Mexico. L.C.'s wife and family drove 50 miles to take him to the Indian Health Service hospital because of his deteriorating health (see the case study in Chapter 43).

Subjective Data

- See the case study in Chapter 43.
- Currently rates pain as a 7 on a scale of 0–10
- States he is not passing flatus

Objective Data

Physical Assessment

- 5 ft 9 in tall, weight 132 lb
- BP 140/72, Heart rate 90, RR 20, temperature 99.4°F (37.4°C), O_2 saturation 97% on room air
- Wound site and staples are intact, dry, without bleeding or signs of infection
- Abdomen slightly distended with hypoactive bowel sounds
- Lungs clear to auscultation, slightly diminished in posterior bases

Laboratory Tests

- CT scan and colonoscopy show 2 medium-sized tumors in the transverse colon
- Hgb of 8.8 g/dL, Hct of 24%.

Interprofessional Care

Surgical Procedure

- Had a transverse hemicolectomy with lymph node biopsies
- Pathology results: Adenocarcinoma, has invaded the muscle wall of colon, 2 of 5 lymph nodes are positive for cancer

Postoperative

- Feels like his life has ended and does not want to leave the hospital
- States that there is "no one" to take care of him at his home, and he is far away from the hospital

Follow-Up Treatment

Scheduled for outpatient chemotherapy

Discussion Questions

1. ***Recognize***: What signs and symptoms of CRC did L.C. have (see the case study in Chapter 43)?
2. ***Analyze***: What stage of CRC does L.C. likely have? What treatment is recommended for this stage of CRC?
3. ***Plan:*** What is a culturally sensitive way for you to support L.C. and his family in making decisions about his health care?
4. ***Plan:*** What referrals may be indicated at this time?
5. ***Prioritize:*** Based on the assessment data, what are the priority clinical problems?
6. ***Prioritize:*** What are the priority nursing interventions for L.C. at this stage of his illness?
7. ***Act:*** How could you provide emotional support to L.C. and his family?
8. ***Act:*** L.C. is worried that other members of his family may have colon cancer. What can you tell him about the recommendations for CRC screening?
9. ***Evaluate:*** What outcomes would indicate nursing interventions were successful?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The *most* appropriate therapy for a patient with acute diarrhea caused by a viral infection is to
   a. increase fluid intake.
   b. administer an antibiotic.
   c. administer an antimotility drug.
   d. quarantine the patient to prevent spread of the virus.
2. A 35-year-old female patient is admitted to the emergency department with acute abdominal pain. Which medical diagnoses should you consider as possible causes of her pain? *(select all that apply)*
   a. Gastroenteritis
   b. Ectopic pregnancy
   c. Gastrointestinal bleeding
   d. Irritable bowel syndrome
   e. Inflammatory bowel disease
3. Assessment findings suggestive of peritonitis include *(select all that apply)*
   a. abdominal pain.
   b. rebound tenderness.
   c. a soft, distended abdomen.
   d. shallow respirations with bradypnea.
   e. observing that the patient is lying still.
4. In planning care for the patient with Crohn's disease, the nurse recognizes that a major difference between ulcerative colitis and Crohn's disease is that Crohn's disease
   a. often results in toxic megacolon.
   b. causes fewer nutrition deficiencies than ulcerative colitis.
   c. often recurs after surgery, while ulcerative colitis is curable with a colectomy.
   d. is manifested by rectal bleeding and anemia more often than is ulcerative colitis.
5. The nurse performs an abdominal assessment of a patient with a possible bowel obstruction, knowing that manifestations of an obstruction in the large intestine are *(select all that apply)*
   a. persistent abdominal pain.
   b. marked abdominal distention.
   c. diarrhea that is loose or liquid.
   d. colicky, severe, intermittent pain.
   e. profuse vomiting that relieves abdominal pain.
6. A patient with stage I colorectal cancer is scheduled for surgery. Patient teaching for this patient would include an explanation that
   a. chemotherapy will begin after the patient recovers from the surgery.
   b. both chemotherapy and radiation can be used as palliative treatments.
   c. follow-up colonoscopies will be needed to ensure that the cancer does not recur.
   d. a wound, ostomy, and continence nurse will visit the patient to identify the site for the ostomy.
7. The nurse determines a patient undergoing ileostomy surgery understands the procedure when the patient states
   a. "I should only have to change the pouch every 4 to 7 days."
   b. "The drainage in the pouch will look like my normal stools."
   c. "I may not need to wear a drainage pouch if I irrigate it daily."
   d. "Limiting my fluid intake should decrease the amount of output."
8. In contrast to diverticulitis, the patient with diverticulosis
   a. has rectal bleeding.
   b. often has no symptoms.
   c. usually develops peritonitis.
   d. has localized cramping pain.
9. A nursing intervention that is *most* appropriate to decrease postoperative edema and pain after an inguinal herniorrhaphy is to
   a. maintain the patient on bedrest.
   b. allow the patient to stand to void.
   c. support the incision during coughing.
   d. apply a scrotal support with an ice bag.
10. The nurse determines that the goals of diet teaching have been met when the patient with celiac disease selects from the menu
    a. scrambled eggs and sausage.
    b. buckwheat pancakes with syrup.
    c. oatmeal, skim milk, and orange juice.
    d. yogurt, strawberries, and rye toast with butter.
11. What should a patient be taught after a hemorrhoidectomy?
    a. Take mineral oil before bedtime.
    b. Eat a low-fiber diet to rest the colon.
    c. Use a daily oil-retention enema to empty the colon.
    d. Take prescribed pain medications before a bowel movement.

1. a; 2. a, b, c, d, e; 3. a, b, e; 4. c; 5. a, b; 6. c; 7. a; 8. b; 9. d; 10. a; 11. d.

CONCEPTUAL FOCUS

Health Promotion
Infection
Inflammation
Nutrition
Pain

LEARNING OUTCOMES

1. Distinguish among the types of viral hepatitis.
2. Describe the interprofessional and nursing management of the patient with viral hepatitis.
3. Explain the pathophysiology, clinical manifestations, complications, and interprofessional and nursing management of the patient with cirrhosis.
4. Describe the clinical manifestations and management of liver cancer.
5. Distinguish between acute and chronic pancreatitis related to pathophysiology, clinical manifestations, complications, and interprofessional and nursing management.
6. Explain the clinical manifestations and interprofessional and nursing management of the patient with pancreatic cancer.
7. Describe the pathophysiology, clinical manifestations, and interprofessional care of gallbladder disorders.
8. Describe the nursing management of the patient undergoing surgical treatment of cholecystitis and cholelithiasis.

KEY TERMS

acute liver failure
acute pancreatitis
ascites
asterixis
cholecystitis
cholelithiasis
chronic pancreatitis
cirrhosis
esophageal varices
gastric varices
hepatic encephalopathy
hepatitis
hepatorenal syndrome
jaundice
nonalcoholic fatty liver disease (NAFLD)
nonalcoholic steatohepatitis (NASH)
portal hypertension

This chapter focuses on the management of patients with a wide range of liver, pancreatic, and gallbladder problems. These organs are closely positioned together anatomically and highly associated with their digestive functions. Liver and pancreas problems can lead to altered nutrient absorption and use, causing malnutrition and impaired elimination. Inflammation may be present, with the patient having pain, nausea, and vomiting. Nursing care focuses on helping the patient and caregiver manage symptoms and develop ways to cope with the diagnosis and, sometimes, prognosis. Health promotion focuses on reducing risk through immunizations and avoiding substance use.

LIVER PROBLEMS

HEPATITIS

Hepatitis is inflammation of the liver. The most common cause is viral. Other causes include substances (e.g., alcohol, medications, chemicals), autoimmune diseases, and metabolic problems.

TABLE 48.1 Characteristics of Hepatitis Viruses

Incubation Period and Mode of Transmission	Sources of Infection	Infectivity
Hepatitis A Virus (HAV)		
Incubation: 15–50 days (average 28) Fecal-oral (primarily fecal contamination and oral ingestion)	• Contaminated food, milk, water, shellfish • Crowded conditions (e.g., day care, nursing home) • Persons with subclinical infections, infected food handlers, sexual contact, IV drug users • Poor personal hygiene • Poor sanitation	• Most infectious during 2 weeks before onset of symptoms • Infectious until 1–2 weeks after the start of symptoms
Hepatitis B Virus (HBV)		
Incubation: 115–180 days (average 56–96) Percutaneous (parenteral) or mucosal exposure to blood or blood products Sexual contact Perinatal transmission	• Contaminated needles, syringes, and blood products • HBV-infected mother (perinatal transmission) • Sexual activity with infected partners. Asymptomatic carriers • Tattoos or body piercing with contaminated needles	• Before and after symptoms appear • Infectious for months • Carriers continue to be infectious for life
Hepatitis C Virus (HCV)		
Incubation: 14–180 days (average 56) Percutaneous (parenteral) or mucosal exposure to blood or blood products High-risk sexual contact Perinatal contact	• Blood and blood products • Needles and syringes • Sexual activity with infected partners, low risk	• 1–2 weeks before symptoms appear • Continues during clinical course • 75%–85% go on to develop chronic HCV and remain infectious
Hepatitis D Virus (HDV)		
Incubation: 2–26 weeks HBV must precede HDV Chronic carriers of HBV always at risk	• Same as HBV • Can cause infection only when HBV is present	• Blood infectious at all stages of HDV infection
Hepatitis E Virus (HEV)		
Incubation: 15–64 days (average 26–42 days) Fecal-oral route	• Contaminated water, poor sanitation • Found in Asia, Africa, and Mexico • Not common in United States but is increasing in some areas	• Not known • May be similar to HAV

Viral Hepatitis

There are several types of viral hepatitis. We designate each type by a letter (A, B, C, D, E). The different types have similar manifestations. Their modes of transmission and disease course vary (Table 48.1). Some can lead to chronic liver disease. Other less common viruses can also cause liver disease. These include cytomegalovirus (CMV), Epstein-Barr virus (EBV), herpesvirus, coxsackievirus, and rubella virus.

Hepatitis A Virus

Hepatitis A is a self-limiting infection. It can cause a mild flu-like illness and jaundice. In more severe cases, it can cause acute liver failure. Hepatitis A virus (HAV) is a ribonucleic acid (RNA) virus. It is transmitted primarily through the fecal-oral route. It often occurs in small outbreaks caused by fecal contamination of food or drinking water.

Poor hygiene, improper food handling, homelessness, crowded situations, and poor sanitary conditions are risk factors. Transmission occurs between family members, institutionalized persons, and children in daycare centers. Foodborne outbreaks are usually due to food contaminated by an infected food handler. People at increased risk for infection include drug users (both IV and non-injection drugs), men who have sex with men (MSM), and persons traveling to developing countries.[1]

Fig. 48.1 Jaundiced person. (© Jun/iStock.com.)

The greatest risk for transmission occurs before symptoms appear. The virus is in feces 1 to 2 weeks before the onset of symptoms and at least 1 week after the onset of illness (Fig. 48.1). This means it can be carried and transmitted by persons who have undetectable infection. It is present only briefly in blood, usually less than 3 weeks. Fecal excretion can occur in infants for months.

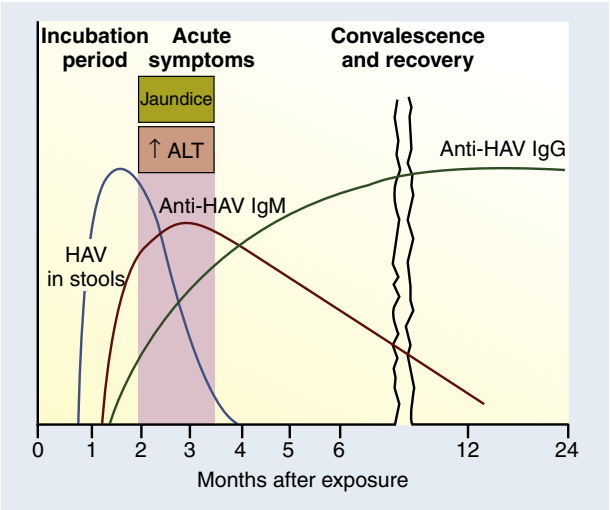

Fig. 48.2 Course of infection with hepatitis A virus *(HAV). ALT,* Alanine aminotransferase. (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.)

Antibody to HAV immunoglobulin M (IgM) (HAV IgM) appears during the acute phase. The presence of HAV IgM indicates acute hepatitis. Levels stay high for about 8 weeks. HAV IgG without HAV IgM indicates past infection. IgG antibody provides lifelong immunity (Fig. 48.2). HAV vaccination and thorough hand washing are the best ways to prevent outbreaks. In the United States, the incidence of HAV is low among children and adolescents due to vaccination and highest among adults due to low vaccination rates.[2]

Hepatitis B Virus

Hepatitis B virus (HBV) is a blood-borne pathogen that can cause either acute or chronic hepatitis. The global prevalence of HBV is 3.5% to 3.9%. The disease burden is largely in Sub-Saharan Africa, Western Pacific Regions, and Southeast Asia (Box 48.1). The United States has policies to prevent HBV transmission through immunizations of newborns, children, and high-risk populations.[3]

HBV is a deoxyribonucleic acid (DNA) virus. It can be transmitted in several ways: (1) perinatally from mothers infected with HBV to their infants; (2) percutaneously (e.g., IV drug use, accidental needle-stick punctures); or (3) via small cuts on mucosal surfaces and exposure to infectious blood, blood products, or other body fluids (e.g., semen, vaginal secretions, saliva).

Sexual transmission is a common mode of HBV transmission. MSM (especially those practicing unprotected anal intercourse) are at an increased risk for HBV infection. Most believe that casual encounters, like hugging, kissing, and sharing utensils do not transmit the disease.

Other at-risk persons include those who live with chronically HBV-infected persons, patients on hemodialysis, health care personnel, public safety workers, blood product recipients, prisoners, Veterans, and homelessness.

HBV has been detected in almost every body fluid. Infected semen, cervicovaginal secretions, and saliva contain much lower HBV concentrations than blood, but the virus can be transmitted via these secretions. If gastrointestinal (GI) bleeding occurs, virus in the blood can contaminate feces. There is no evidence of fecal-oral transmission. Organ and tissue transplantation is another potential source of infection. In some patients with acute HBV, there is no readily identifiable risk factor.

HBV is a complex structure with 3 distinct antigens: surface antigen (HBsAg), core antigen (HBcAg), and e antigen (HBeAg). Each antigen, along with its corresponding antibody, may appear or disappear in serum depending on the phase of infection and immune response.

In most people who acquire HBV infection as an adult, the infection completely resolves without any long-term complications. In those who develop chronic HBV infections, there is an association with liver cancer and severe liver inflammation and scarring (fibrosis). Those who become chronically infected have an increase in comorbidities. These include cardiovascular disease, hypertension, hyperlipidemia, renal disease, and osteoporosis.[3]

Screening for HBV includes identifying those at high risk for infection and testing the blood for the presence of hepatitis B surface antigen (HBsAg), hepatitis B antibody (anti-HBs), and hepatitis B core antibody (anti-HBc). The presence of anti-HBs in the blood indicates immunity from the HBV vaccine or from past HBV infection (Fig. 48.3). HBsAg in the serum for 6 months or longer after infection indicates chronic HBV infection.

Hepatitis C Virus

Hepatitis C virus (HCV) causes a type of hepatitis that can result in both acute illness and chronic infection. Acute HCV can be hard to detect unless a diagnosis is made with laboratory testing. The most common causes of acute HCV outbreaks are among IV drug users and MSM with HIV infection.

HCV is a blood-borne RNA virus that is primarily transmitted percutaneously. The most common mode of HCV transmission is the sharing of contaminated needles and equipment among IV drug users. High-risk sexual behavior especially among MSM is associated with increased risk.

BOX 48.1 PROMOTING HEALTH EQUITY

Liver, Pancreas, and Gallbladder Problems

Hepatitis
- Hepatitis B has a higher incidence among Asian Americans and Pacific Islanders
- Hepatitis C has a higher incidence among Blacks
- Deaths from hepatitis C are more common in Blacks

Liver and Pancreatic Cancer
- Primary liver cancer has the highest incidence in Hispanics
- Pancreatic cancer occurs more often among Blacks

Gallbladder Disease
- Whites and Native Americans have the highest incidence of gallbladder disease

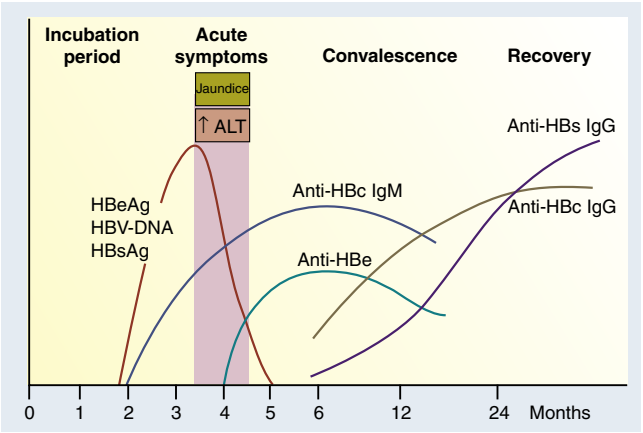

Fig. 48.3 Course of infection with hepatitis B virus *(HBV). ALT,* Alanine aminotransferase; *anti-HBc,* antibody to hepatitis B core antigen; *anti-HBe,* antibody to HBeAg; *anti-HBs,* antibody to HBsAg; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen. (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.)

Many people infected with HCV develop chronic infection. However, because signs and symptoms of HCV infection are generally mild, most people are unaware of their infection. We think that greater than 50% of people in the United States infected with HCV are undiagnosed. About 20% develop cirrhosis and eventually liver failure and/or liver cancer if left untreated. HCV hepatitis is a common reason for liver transplantation in the United States.[4]

Persons at risk for HCV infection are also at risk for HBV and HIV infections. About 30% to 40% of HIV-infected patients also have HCV. This high rate of co-infection is primarily related to IV drug use. Co-infection with HIV and HCV places the patient at greater risk for progression to cirrhosis if HCV is untreated. A positive antibody test for HCV (anti-HCV) is followed by a positive viral load test to confirm active infection because an anti-HCV can also indicate a past infection.

With the use of direct-acting antiviral (DAA) medications, it is possible to cure HCV in almost all cases. There is no vaccine for HCV. However, with DAA regimens and the ability to cure HCV, the focus in chronic HCV is now on efforts to prevent transmission, screening, and provide needed health care.[5]

Hepatitis D Virus

Hepatitis D virus (HDV), also called *delta virus,* is uncommon in the United States. HDV is a defective single-stranded RNA virus that cannot survive on its own. It requires HBV surface Ag to serve as its outer shell and to infect the hepatocyte. So, only those who with HBV infection can be infected with HDV. It can be acquired at the same time as HBV or a person with HBV can be infected with HDV later. HDV is transmitted like HBV. It causes more rapid progression of liver disease and mortality than HBV infection alone. There is no vaccine for HDV. However, HBV vaccination reduces the risk for HDV co-infection.[6]

Hepatitis E Virus

Like HAV, the hepatitis E virus (HEV) is an RNA virus transmitted by the fecal-oral route. The usual mode of transmission is through contaminated water. HEV infection epidemics occur in the tropics, but it is widely circulating in the west. It is generally acute and self-resolving. Chronicity in immunosuppressed persons, such as liver transplant recipients and HIV positive persons, can occur. Pregnant women may be affected severely. An IgM antibody test is available to test for acute hepatitis E.[7]

Pathophysiology

Liver

In viral hepatitis, hepatocytes become targets of the virus in 1 of 2 ways: through direct action of the virus (as in HCV infection) or through a cell-mediated immune response to the virus (as in HBV and HCV infection).

During acute viral hepatitis, large numbers of infected hepatocytes are destroyed. Hepatocyte destruction leads to a wide range of liver-related dysfunction. Bile production, coagulation, blood glucose, and protein metabolism can be affected. Detoxification and processing of drugs, hormones, and metabolites (e.g., ammonia from protein catabolism) may be disrupted.

After acute infection resolves, liver cells can regenerate. If no complications occur, the liver can resume its normal appearance and function. In some patients, the acute hepatitis can become so severe and irreversible that they develop liver failure or die.

Chronic viral hepatitis can be insidious and silent, causing persistent and continual destruction of infected hepatocytes. Over time scar tissue can develop, which leads to fibrosis, cirrhosis, and compromised liver function. Fibrosis can lead to cirrhosis and liver failure. Cirrhosis is a generally irreversible condition that can increase one's risk for liver dysfunction, portal hypertension, and primary liver cancer.

Systemic Effects

In the early phases of hepatitis infection, antigen-antibody complexes between the virus and its corresponding antibody may form circulating immune complexes. The circulating immune complexes activate the complement system (see Chapter 12). The manifestations of this activation are rash, angioedema, arthritis, fever, and malaise. *Cryoglobulinemia* (abnormal proteins found in the blood), glomerulonephritis, vasculitis, and involvement of other organs can occur from immune complex activation.

Clinical Manifestations and Complications

We classify the manifestations of the different viral hepatitis infections into acute hepatitis and chronic hepatitis (Table 48.2).

Acute Hepatitis

Many patients with acute hepatitis have no symptoms. They may not even know they are infected. Others may have anorexia, lethargy, nausea, vomiting, skin rashes, diarrhea or constipation, malaise, fatigue, muscle pain, joint pain, other flu-like symptoms, and right upper quadrant (RUQ) tenderness (caused by liver inflammation).

Although the acute phase of viral hepatitis varies depending on the type of hepatitis, it usually lasts from 1 to 6 months. During this time, the patient may have a decreased sense of smell and find food repugnant. Smokers may have distaste for

cigarettes. Physical assessment often reveals hepatomegaly, lymphadenopathy, abdominal tenderness, and sometimes splenomegaly. The acute phase is the period of maximal infectivity.

A patient in the acute phase of hepatitis may be *icteric* (jaundiced) or anicteric. **Jaundice**, a yellowish discoloration of body tissues, results from a change in normal bilirubin metabolism or disruption of the flow of bile into the hepatic or biliary duct systems. Table 48.3 describes the types of jaundice. The urine may appear darker due to the kidneys excreting excess bilirubin. If conjugated bilirubin cannot pass into the intestines from the liver because of obstruction or inflammation of the bile ducts, the stools will be clay colored.

TABLE 48.2 Manifestations of Hepatitis

Acute Hepatitis	Chronic Hepatitis
• Anorexia	• ↑ ALT, AST (may be normal in some people)
• Clay-colored stools	• Ascites and lower extremity edema
• Dark urine	• Asterixis ("liver flap")
• Diarrhea, constipation	• ↑ Bilirubin
• Fatigue, lethargy, malaise	• Bleeding problems (thrombocytopenia, easy bruising, prolonged clotting time)
• Flu-like symptoms (e.g., headache)	• Fatigue, malaise
• Hepatomegaly	• Hepatic encephalopathy: confusion, problems concentrating, easy agitation
• Jaundice	• Hepatomegaly
• Joint and muscle pain	• Jaundice
• Low-grade fever	• Joint and muscle pain
• Lymphadenopathy	• Palmar erythema
• Nausea, vomiting	• Spider angiomas
• Pruritus	
• RUQ tenderness	
• Splenomegaly	
• ↓ Taste and smell	
• Weight loss	

Pruritus (intense generalized itching) sometimes accompanies jaundice. It occurs from the accumulation of bile salts beneath the skin. Itching can be intolerable to the patient.

As jaundice fades, the convalescent phase begins. The convalescent phase can last for weeks to months, with an average of 2 to 4 months. During this period, patients often have malaise and fatigue. Hepatomegaly remains for several weeks. Splenomegaly (if present) subsides during this period.

Most patients with acute viral hepatitis recover completely. Almost all cases of acute hepatitis A resolve. However, some patients may have a relapse in the first 2 to 3 months after the infection. The disappearance of jaundice does not mean the patient has totally recovered. Some HBV infections and most HCV infections result in chronic hepatitis.

The overall mortality rate for acute hepatitis is less than 1%. The mortality rate is higher in older adults and those with underlying debilitating illnesses (including chronic liver disease).

Complications of acute hepatitis include chronic hepatitis, cirrhosis, portal hypertension, and liver cancer. Sometimes, acute liver failure (fulminant hepatic failure) may occur. It is a serious condition with a poor prognosis. Manifestations include encephalopathy, coagulation problems, and jaundice. Multiple complications can develop. A liver transplant may cure these patients.

Chronic Hepatitis

Table 48.2 shows the manifestations of chronic hepatitis. Chronic HBV is more likely to develop if the person acquired the infection at birth or during childhood. Chronic HBV can remain asymptomatic for years. Complications such as cirrhosis, liver failure, and liver cancer develop in 15% to 40% of people with HBV.[3]

HCV infection is more likely than HBV to become chronic. Many patients with chronic HCV infection develop chronic

TABLE 48.3 Classification of Jaundice

	Hemolytic Jaundice	Hepatocellular Jaundice	Obstructive Jaundice
Causes	• Blood transfusion reactions, hemolytic anemia, sickle cell crisis	• Cirrhosis, hepatitis, liver cancer	• Cirrhosis, hepatitis, liver cancer • Common bile duct obstruction from stone(s), biliary strictures, pancreatic cancer, sclerosing cholangitis
Description	• Caused by increased breakdown of RBCs, which produces an increased amount of unconjugated bilirubin in blood • Liver is unable to handle increased load	• Results from liver's altered ability to take up bilirubin from blood or to conjugate or excrete it • In hepatocellular disease, damaged hepatocytes leak bilirubin	• Results from decreased or obstructed flow of bile through liver or biliary duct system • Obstruction may occur in intrahepatic or extrahepatic bile ducts • Intrahepatic obstructions are due to swelling or fibrosis of the liver's canaliculi and bile ducts
Diagnostic Findings			
Serum Bilirubin			
Unconjugated (indirect)	↑	↑	↑
Conjugated (direct)	Normal	↑ or ↓ (severe disease)	↑
Urine Bilirubin	Negative	↑	↑
Urobilinogen			
Stool	↑	Normal, ↓	↓
Urine	↑	Normal, ↑	↓

TABLE 48.4 Diagnostic Studies

Viral Hepatitis

Virus	Tests	Significance
A (HAV)	HAV immunoglobulin M (IgM)	Acute infection
	HAV immunoglobulin G (IgG)	Previous infection or immunization
		Not routinely done in clinical practice
B (HBV)	HBsAg (hepatitis B surface antigen)	Marker of infectivity
		Present in acute or chronic infection
		Positive in chronic carriers
	Anti-HBs (hepatitis B surface antibody)	Indicates previous infection with HBV or immunization
	HBeAg (hepatitis B e antigen)	Indicates high infectivity
		Used to determine the clinical management of patients with chronic HBV
	Anti-HBe (hepatitis B e antibody)	Indicates previous infection
		In chronic HBV, indicates a low viral load and low degree of infectivity
	Anti-HBc (antibody to hepatitis B core antigen) IgM	Indicates acute infection
		Does not appear after vaccination
	Anti-HBc IgG	Indicates previous infection or ongoing infection with HBV
		Does not appear after vaccination
	HBV DNA quantitation	Indicates active ongoing viral replication
		Best indicator of viral replication and effectiveness of therapy in patient with chronic HBV
	HBV genotyping	Indicates the genotype of HBV
C (HCV)	Anti-HCV (antibody to HCV)	Marker for acute or chronic infection with HCV
	HCV RNA quantitation	Indicates active ongoing viral replication
	HCV genotyping	Indicates the genotype of HCV
D (HDV)	Anti-HDV	Present in past or current infection with HDV
	HDV Ag (hepatitis D antigen)	Present within a few days after infection
E (HEV)	Anti-HEV IgM and IgG	Present 1 week to 2 months after illness onset
	HEV RNA quantitation	Indicates active ongoing viral replication

liver disease, cirrhosis, portal hypertension, and liver cancer if untreated. In some patients, co-infection with HIV may cause complications or require treatment modification.

Skin manifestations may include spider angiomas, palmar erythema, and gynecomastia. Some patients with advanced fibrosis have spleen, liver, or cervical lymph node enlargement.

In patients with decompensated cirrhosis, *hepatic encephalopathy*, a potentially life-threatening spectrum of neurologic, psychiatric, and motor disturbances can occur. Hepatic encephalopathy results from the liver's inability to remove toxins (especially ammonia) from the blood.

Ascites is the accumulation of excess fluid in the peritoneal cavity. It is a common manifestation of hepatitis (especially from cirrhosis due to chronic hepatitis). Fluid accumulates due to reduced protein levels in the blood, which reduces the plasma oncotic pressure.

Diagnostic Studies

The only definitive way to distinguish among the types of viral hepatitis is by testing the patient's blood for the specific antigen or antibody (Table 48.4). In some types of viral hepatitis, we can test the blood for the viral load (viral level). Many liver function tests show significant abnormalities, as shown in Table 48.5.

Several tests are available to determine the presence of HCV. The screening test for HCV infection is HCV antibody testing. Antibodies can be detected within 4 weeks of infection. If the antibody test is positive, HCV RNA testing assesses for chronic

TABLE 48.5 Diagnostic Findings in Acute Hepatitis

Test	Abnormal Finding	Cause
Alkaline phosphatase	Moderately ↑	Impaired excretory function of liver
γ-Glutamyl transpeptidase (GGT)	↑	Liver cell injury
Aminotransferases		
• Aspartate aminotransferase (AST)	↑ in acute phase Decreases as jaundice disappears	Liver cell injury
• Alanine aminotransferase (ALT)	↑ in acute phase Decreases as jaundice disappears	Liver cell injury
Prothrombin time	Prolonged	↓ Prothrombin production by liver
Serum proteins		
• Albumin	Normal or ↓	Liver cell injury
• γ-Globulin	Normal or ↓	Impaired clearance from liver
Total bilirubin (serum)	↑ to about 8–15 mg/dL (137–257 μmol/L)	Liver cell injury
Urinary bilirubin	↑	Conjugated hyperbilirubinemia
Urinary urobilinogen	↑ 2–5 days before jaundice	↓ Urobilinogen reabsorption

infection and quantifies viral load. A positive result confirms chronic infection. A few patients may have a false-positive HCV antibody result with a negative HCV RNA test. If we suspect recent HCV infection, HCV RNA testing is usually done because it may take several weeks or longer for HCV antibodies to develop.

HCV RNA testing may be used for immunocompromised patients (e.g., patients with HIV). Because of altered or delayed antibody response to HCV, these patients may not have detectable antibody levels even if they are infected with HCV.

Viral genotype testing is done in patients receiving drug therapy for HBV or HCV infection. HBV has at least 8 different genotypes (A to H). In some centers, we do HBV genotyping before starting treatment. HBV genotype may be useful in predicting disease course and treatment outcomes. HBV core Ab (HBVcAb) IgG shows if the patient has a history of recovered HBV infection. HBV may reactivate in these patients if they become immunosuppressed.

HCV has 6 genotypes and more than 50 subtypes. In the United States, HCV genotype 1 causes 70% of HCV infections. For patients who test positive for HCV, we do genotyping before starting drug therapy. The genotype determines the choice and duration of therapy. It is one of the strongest predictors of a patient's response to drug therapy.

A liver biopsy is done in acute hepatitis if the diagnosis is in doubt. In chronic hepatitis, a liver biopsy allows for histologic examination of liver cells and determination of the degree of inflammation, fibrosis, or cirrhosis that may be present. A patient who has a bleeding disorder may not be able to have a percutaneous liver biopsy because of the risk for bleeding. In these patients, a transjugular biopsy may be done. This type of biopsy consists of obtaining liver tissue through a rigid cannula introduced into a hepatic vein, normally using jugular venous access.

Noninvasive assessment of liver fibrosis is increasingly replacing the need for liver biopsy. One option is the use of ultrasound elastography (e.g., FibroScan), which uses an ultrasound transducer to determine the degree of liver fibrosis. Magnetic resonance elastography (MRE) is another noninvasive imaging technique to measure liver fibrosis. FibroSure (FibroTest) is an example of one of several biomarkers that uses the results of serum tests to assess the extent of hepatic fibrosis.[8]

Interprofessional Care

There is no specific treatment for acute viral hepatitis. Most patients are managed at home. Emphasis is on providing adequate nutrition and measures to rest the body and help the liver to regenerate and repair (Table 48.6). Rest reduces the metabolic demands on the liver and promotes liver cell regeneration. The degree of rest depends on the severity of symptoms. Usually, alternating periods of activity and rest are adequate. Teaching should include the importance of avoiding alcohol and notifying contacts for testing and prophylaxis, if needed.

In patients with chronic viral hepatitis, care may involve liver specialists, infectious disease specialists, pharmacists, dietitians, and mental health or substance use specialists. The role and extent of involvement of team members is based on the patient's specific needs.

TABLE 48.6 Interprofessional Care

Viral Hepatitis

Diagnostic Assessment

- History and physical assessment
- Liver function tests (Table 48.5)
- PT time and INR
- Hepatitis testing (Table 48.4)
  - *Hepatitis A (HAV):* HAV IgM, HAV IgG, HAV total antibody
  - *Hepatitis B (HBV):* HBsAg, anti-HBs, HBeAg, anti-HBe, anti-HBc IgM and IgG, HBV DNA quantitation, HBV genotyping
  - *Hepatitis C (HCV):* Anti-HCV, HCV RNA quantitation, HCV genotyping
  - *Hepatitis D (HDV):* Anti-HDV, HDV Ag, HDV RNA
  - *Hepatitis E (HEV):* Anti-HEV IgM, anti-HEV IgG
- FibroScan
- FibroSure (FibroTest)

Management

Acute and Chronic

- Well-balanced diet
- Vitamin supplements
- Rest (degree of strictness varies)
- Avoiding alcohol and drugs detoxified by liver

Chronic HBV and HCV

- Drug therapy (Table 48.7)

Drug Therapy

Acute hepatitis. There are no drug therapies for treating acute HAV infection. Treatment of acute HBV may be indicated only in patients with severe hepatitis and liver failure.

In acute HCV, some patients may choose to be monitored for spontaneous clearance of the infection. Patients who choose treatment may receive one of the DAAs. DAAs are discussed later in the section on chronic hepatitis.

Supportive drug therapy may include antihistamines for generalized itching and antiemetics for nausea.

Chronic hepatitis B. Drug therapy for chronic HBV focuses on decreasing viral load and liver enzymes, and in turn, slowing the rate of disease progression. Long-term goals are preventing the development of cirrhosis, portal hypertension, liver failure, and liver cancer. Current drug therapies do not eradicate the virus. They suppress viral replication and prevent complications. First-line therapies primarily include nucleoside and nucleotide analogs (Table 48.7) and sometimes interferon therapy.

Nucleoside and nucleotide analogs. Nucleoside and nucleotide analogs inhibit viral DNA replication. HBV reproduces by making copies of its viral DNA nucleosides and nucleotides. The nucleoside and nucleotide analog drugs mimic normal building blocks for DNA but are actually faulty viral DNA building blocks. Once they become included in the viral DNA, they halt DNA synthesis.

Nucleoside and nucleotide analogs do not prevent all viral reproduction. They can substantially lower viral load or the amount of virus in the body. These drugs include lamivudine (Epivir), adefovir (Hepsera), entecavir (Baraclude), telbivudine (Tyzeka), and tenofovir (Viread). They are used to treat chronic

TABLE 48.7 Drug Therapy

Viral HBV and HCV

Drug Class	Examples	Mechanism of Action	Indication
Immune modulator	pegylated interferon (Pegasys, PegIntron)	Has antiviral, antiproliferative, immune-regulating actions	Chronic HBV
Nucleoside and nucleotide analogs	adefovir[a] entecavir (Baraclude) lamivudine (Epivir HBV) telbivudine (Tyzeka)[a] tenofovir (Vemlidy, Viread)	Inhibits HBV DNA polymerase enzyme by competing with natural substrates. Prevents viral replication	Chronic HBV
Direct-acting antivirals for HCV			
NS3/4A protease inhibitors	glecaprevir[b] grazoprevir[c] voxilaprevir[b]	Blocks viral protease enzyme. Prevents viral replication in genotype 1 HCV	Chronic HCV
NS5A inhibitors	elbasvir[b] ledipasvir[c] pibrentasvir[b] velpatasvir[b]	Blocks nonstructural protein 5A (NS5A) at early stage in RNA HCV replication	Chronic HCV
NS5B polymerase inhibitors	sofosbuvir (Sovaldi)	Nucleotide inhibitor and non-nucleoside inhibitor of HCV polymerase. Prevent replication of RNA HCV	Chronic HCV
Combination therapies	elbasvir + grazoprevir (Zepatier) ledipasvir + sofosbuvir (Harvoni) Pibrentasvir + glecaprevir (Mavyret) velpatasvir + sofosbuvir (Epclusa) velpatasvir + sofosbuvir + voxilaprevir (Vosevi)	Drugs are combined in 1 tablet. Drugs may be from the same or different classes.	Chronic HCV

[a]Not preferred
[b]Used only in combination therapy.
[c]CYP3A inhibitor used to enhance the pharmacokinetics of the other agents.

HBV when there is evidence of significant active viral replication and liver inflammation.[9]

These drugs also decrease liver damage and decrease serum liver enzyme levels. Most patients with HBV need long-term treatment. When these drugs are stopped, many patients' (except those who have seroconverted) HBV DNA and liver enzyme levels return to pretreatment levels.

Severe exacerbations can develop after ending treatment. If these drugs are stopped for any reason, we monitor the patient's liver enzymes for several months.

Interferon. Interferon is a naturally occurring immune protein made by the body during an infection to recognize and respond to pathogens. It has antiviral, antiproliferative, and immune-modulating effects (see Chapter 14). Pegylated interferon (PEG-Intron, Pegasys) is given by subcutaneous injection. The many side effects of therapy, including flu-like symptoms (e.g., fever, malaise, fatigue), make adherence hard for some patients. The availability of better tolerated and more effective oral treatments limits interferon use. However, it is still used to treat some patients with HBV because it can have an increased viral response.

Patients receiving interferon should have blood counts and liver function tests every 4 to 6 weeks. Depression is a side effect of therapy. We must screen patients for depression and other mood disorders before starting treatment and monitor them frequently while on therapy.

Chronic hepatitis C. Treatment of chronic HCV is patient specific. It is based on the genotype of the HCV, severity of liver disease, and presence of other health problems (e.g., HIV). The goal of drug therapy is eradicating the virus and preventing HCV-related complications.

Treatment for HCV primarily includes the use of DAAs (Table 48.7), which block proteins needed for HCV replication. Patients normally complete 12 weeks of DAA therapy. Almost all (>95%) of those who complete DAA treatment see a cure of their chronic HCV infection.[4,5]

Many patients with HIV also have HCV. Patients who have stable HIV and intact immune systems ($CD4^+$ counts greater than 200/μL) receive HCV treatment with the goal of eradicating HCV and reducing the risk for progression to cirrhosis. HCV treatment plans are equally effective for HCV/HIV coinfected and HCV mono-infected patients.

Patients with advanced fibrosis or cirrhosis can receive drug therapy if liver decompensation (e.g., ascites, variceal rupture, jaundice, wasting, encephalopathy) is not present.

Nutrition Therapy

No special diet is part of the treatment of viral hepatitis. Emphasize a well-balanced diet that the patient can tolerate. During acute viral hepatitis, adequate calories are important because the patient usually loses weight. If the patient does not tolerate fat content because of decreased bile production, it should be reduced. The patient may receive vitamin supplements, particularly B-complex and vitamin K. If anorexia, nausea, and vomiting are severe, we may give IV glucose solutions or supplemental enteral nutrition (EN). Fluid and electrolyte balance must be maintained.

TABLE 48.8 NURSING ASSESSMENT

Hepatitis

Subjective Data

Important Health Information

Health history: Hemophilia, cancer, exposure to infected persons, ingestion of contaminated food or water. Exposure to benzene, carbon tetrachloride, or other hepatotoxic agents. Crowded, unsanitary living conditions. Exposure to contaminated needles. Recent travel, organ transplant recipient, exposure to new drug regimens, hemodialysis, transfusion of blood or blood products before 1992. HIV status (if known)

Medications: Use and misuse of acetaminophen, new medications or supplements

Functional Health Patterns

Health perception–health management: IV drug and chronic alcohol use. Malaise, distaste for cigarettes (in smokers), high-risk sexual behaviors

Nutritional-metabolic: Weight loss, anorexia, nausea, vomiting. Feeling of RUQ fullness

Elimination: Dark urine, light-colored stools, constipation or diarrhea, skin rashes, hives

Activity-exercise: Fatigue, muscle pain, joint pain

Cognitive-perceptual: RUQ pain, liver tenderness, headache, itching

Role-relationship: Exposure as health care worker, resident in long-term care institution, incarceration, homelessness

Objective Data

General

Low-grade fever, lethargy, lymphadenopathy

GI

Hepatomegaly, splenomegaly

Skin

Rash or other skin changes, jaundice, icteric sclera, injection sites

Possible Diagnostic Findings

↑ Liver enzyme levels. ↑ Serum total bilirubin, hypoalbuminemia, anemia, bilirubin in urine and urobilinogen. Prolonged PT time. Positive tests for hepatitis, including HAV IgM, HBsAg, anti-HBs, HBeAg, anti-HBe, anti-HBc IgM and IgG, HBV DNA quantitation, anti-HCV, HCV RNA quantitation, anti-HDV, HDV Ag. Abnormal liver scan, abnormal results on liver biopsy

HAV, Hepatitis A virus; *HBcAg,* hepatitis B core antigen; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HDV Ag,* hepatitis D antigen; *HDV,* hepatitis D virus.

❖ NURSING MANAGEMENT: VIRAL HEPATITIS

◆ Assessment

Subjective and objective data that you should obtain from a person with hepatitis are outlined in Table 48.8.

◆ Clinical Problems

Clinical problems for the patient with viral hepatitis may include:

- Nutritionally compromised
- Activity intolerance
- Risk for bleeding

Additional information on clinical problems and interventions for the patient with hepatitis is presented in eNursing Care Plan 48.1 available on the website for this chapter.

◆ Planning

The overall goals are that the patient with viral hepatitis will (1) have relief of discomfort, (2) be able to resume normal activities, and (3) return to normal liver function without complications.

◆ Implementation

◆ Health Promotion

Viral hepatitis is a public health problem. Your role is important in the prevention and control of this disease. It is helpful to understand the epidemiology of the different types of viral hepatitis when considering appropriate control measures. Preventive and control measures for hepatitis A, B, and C are outlined in Table 48.9.

A suggested guideline for general practice to prevent you from contracting viral hepatitis from diagnosed and undiagnosed patients and carriers is for you to wear personal protective equipment (PPE) when fecal or blood contamination is likely in handling (1) soiled bedpans, urinals, and catheters and (2) when the patient's bed linens are soiled by body excreta or secretions.

Hepatitis A. Viral hepatitis outbreaks are usually due to HAV. Preventive measures include personal and environmental hygiene and health education to promote good sanitation. Hand washing is the most important precaution. Teach about careful hand washing after bowel movements and before eating.

Isolation is not needed for HAV infection. For a patient with HAV infection, use infection control precautions. Place the patient who is incontinent of stool or has poor personal hygiene in a private room.

Vaccination is the best protection against HAV. All children at 1 year of age should receive the vaccine. Adults at risk should also receive the vaccine. These include travelers to areas with increased rates of hepatitis A, MSM, IV and noninjecting drug users, and homelessness. Others who should receive the vaccine include persons with clotting factor disorders (e.g., hemophilia) and chronic liver disease.

HAV vaccine is inactivated HAV protein. There are 2 forms of HAV vaccine in the United States: Havrix and Vaqta. Primary immunization consists of 1 dose given IM in the deltoid muscle. A booster is recommended 6 to 12 months after the first dose to ensure adequate antibody titers and long-term protection. Primary immunization provides immunity within 30 days after 1 dose in more than 97% to 100% of those vaccinated.[2]

Twinrix, a combined HAV and HBV vaccine, is available for people over 18 years of age. It consists of 3 doses, given on a 0-, 1-, and 6-month schedule (the same schedule as the single HBV vaccine). Twinrix may be given to high-risk persons, including patients with chronic liver disease, IV drug users, patients on hemodialysis, MSM, and people with clotting factor disorders who receive therapeutic blood products. The side effects are mild. They include soreness and redness at the injection site.

Both HAV vaccine and immune globulin (IG) are used to prevent HAV infection after exposure to an infected person *(postexposure prophylaxis).* The vaccine is used for preexposure prophylaxis. We can give IG either before or after exposure. IG gives temporary (1 to 2 months) passive immunity. It is effective

TABLE 48.9 Prevention of Viral Hepatitis

Hepatitis A

General Measures

- Hand washing
- Proper personal hygiene
- Environmental sanitation
- Control and screening (signs, symptoms) of food handlers
- Serologic screening for those carrying virus
- Active immunization: HAV vaccine

Use of Immune Globulin

- Early administration (1–2 weeks after exposure) to those exposed
- Prophylaxis for travelers to areas where hepatitis A is common if not vaccinated with HAV vaccine

Special Considerations for Health Care Personnel

- *HAV,* Hepatitis A virus; *HBcAg,* hepatitis B core antigen; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HDV Ag,* hepatitis D antigen; *HDV,* hepatitis D virus.
- *HAV,* Hepatitis A virus; *HBcAg,* hepatitis B core antigen; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HDV Ag,* hepatitis D antigen; *HDV,* hepatitis D virus.

Hepatitis B and C

Percutaneous Transmission

- Screening of donated blood
- *HBV:* HBsAg
- *HCV:* Anti-HCV
- Use of disposable needles and syringes

Sexual Transmission

- Acute exposure: HBIG administration to sexual partner of HBsAg-positive person
- Give HBV vaccine series uninfected sexual partners
- Use condoms for sexual intercourse

General Measures

- Hand washing
- Avoid sharing toothbrushes and razors
- HBIG administration for one-time exposure (needle stick, contact of mucous membranes with infectious material)
- Active immunization: HBV vaccine

Special Considerations for Health Care Personnel

- Use infection control precautions
- Reduce contact with blood or blood-containing secretions
- Handle the blood of patients as potentially infective
- Dispose of needles properly
- Use needleless IV access devices when available

for preventing HAV if given within 2 weeks after exposure. IG is given to persons who do not have HAV antibodies and were exposed by close (household, daycare center) contact with persons who have HAV or foodborne exposure. Because patients with HAV are most infectious just before the onset of symptoms, those exposed through household contact or foodborne outbreaks should receive the HAV vaccine. They may receive IG based on risk factors. Although IG may not prevent infection, it may lessen the illness to a subclinical infection.

Hepatitis B. The best way to reduce HBV infection is to identify those at risk, screen them for HBV, and vaccinate those who are not infected. Teach those at high risk for contracting HBV to reduce risks by following good hygienic practices, including hand washing and using gloves when expecting contact with blood. Patients should not share razors, toothbrushes, and other personal items. Teach patients to use a condom for sexual intercourse. In addition, the partner should be vaccinated.

The HBV vaccine is the best means of prevention. The HBV vaccines (Recombivax HB, Engerix-B) contain HBsAg. HBsAg promotes the synthesis of specific antibodies directed against HBV. The vaccine is given in a series of 3 IM injections in the deltoid muscle. It is given on a 0-, 1-, and 6-month schedule. The vaccine is 95% effective. Minor reactions include transient fever and soreness at the injection site. The vaccine can be given in pregnancy. A newer formulation of the HBV vaccine (Heplisav-B) is approved for persons 18 years or older. It is given in 2 doses, spaced 4 weeks apart. Use is not approved in pregnancy.

The traditional HBV vaccine of 3 doses is normally given in childhood. The first dose of HBV vaccine should be given at birth. The vaccine series is completed by age 6 to 18 months. Older children and adolescents who did not receive the HBV vaccine should be vaccinated.[9] It is important to vaccinate adults who are in the at-risk groups and are not immune. Household members of the patient with HBV should be tested and vaccinated if they are HBsAg and antibody negative. HBV vaccination is recommended for patients with chronic kidney disease before they start dialysis. Dialysis patients should routinely have their antibody titer levels checked to determine the need for revaccination.

For postexposure prophylaxis, the HBV vaccine series and hepatitis B immune globulin (HBIG) are given. HBIG has antibodies to HBV and confers temporary passive immunity. HBIG is prepared from the plasma of donors with a high titer of anti-HBs. HBIG is recommended for postexposure prophylaxis in cases of needle stick, mucous membrane contact, or sexual exposure and for infants born to mothers who are positive for HBsAg. Ideally, we should give HBIG within 24 hours of exposure. Giving antiviral therapy (e.g., tenofovir) to pregnant women in the third trimester with viral levels over 200,000 IU/mL can prevent the small risk for neonatal infection that may occur even with postnatal immunization and vaccination.

The Centers for Disease Control and Prevention (CDC) recommends following standard precautions for the patient with HBV (see Table 15.9). This includes using disposable needles and syringes and disposing of them in puncture-resistant units without recapping, bending, or breaking.

Hepatitis C. No vaccine is currently available for HCV. So, it is important to identify those at high risk for contracting HCV and teach them how to reduce their risks. Measures to prevent HCV transmission include (1) screening of blood, organ, and tissue donors; (2) using infection control precautions; and (3) modifying high-risk behavior.

BOX 48.2 EVIDENCE-BASED PRACTICE

Screening and Testing of Hepatitis C Virus

You are caring for S.B., a 32-year-old man who often visits the community clinic with health concerns. He arrives today saying he feels "tired." He tells you a friend was recently diagnosed with hepatitis C virus (HCV), and he wants "a shot" to keep from "getting it." You see on the medical record that he injects drugs and has not been tested for HCV.

Making Clinical Decisions

Best Available Evidence

Currently, most HCV-infected persons are undiagnosed and therefore untreated. We recommend testing for patients with known risk factors for HCV. Rapid diagnostic tests (RDTs), including oral HCV antibody (Ab) RDTs, have excellent sensitivity and specificity for HCV Ab detection.

Clinician Expertise

You know a major risk factor for HCV is IV drug use. You understand early diagnosis of HCV is important for best patient outcomes and preventing transmission to others.

Patient Preferences and Values

S.B. tells you he is "busy today," but he can come back tomorrow for HCV testing.

Implications for Nursing Practice

1. What information would you provide to S.B. on HCV testing, symptoms, and transmission?
2. Since S.B. is now willing to be tested for HCV, how would you determine barriers to the informed consent process?
3. Should S.B. test positive for HCV, what other information will you provide him?

Reference for Evidence

Center for Disease Control and Prevention: Viral hepatitis: hepatitis C FAQs for health professionals. Retrieved from www.cdc.gov/hepatitis/hcv/hcvfaq.htm.

In the United States, many people have undiagnosed HCV. The US current screening guidelines recommend one time opt-out HCV testing for everyone 18 years and older. Annual HCV screening is recommended for IV drug users (Box 48.2).

Acute Care

In patients with hepatitis, assess for the presence and degree of jaundice. In light-skinned persons, jaundice is usually seen first in the sclera of the eyes and later in the skin. In dark-skinned persons, jaundice is seen in the hard palate of the mouth and inner canthus of the eyes. The urine may have a dark-brown or brownish-red color from bilirubin excretion from the kidneys. Comfort measures to relieve itching, headache, and joint pain are helpful.

CHECK YOUR PRACTICE

You are caring for a patient with acute hepatitis. He has decreased appetite from severe nausea and vomiting. He is admitted to the hospital for IV hydration and monitoring. The patient says, "I'm so weak, and I feel like I'm going to vomit all the time. Isn't there something you can do to help me?"

- How would you handle this situation?
- What information and teaching will you give him?

Ensuring that the patient receives adequate nutrition is not always easy. The anorexia and distaste for food may cause nutrition problems. Assess the patient's tolerance of specific foods and eating pattern. Small, frequent meals may be preferable to 3 large ones and may help prevent nausea. Often a patient with hepatitis finds that anorexia is not as severe in the morning, so it is easier to eat a good breakfast than a large dinner. Include measures to stimulate the appetite, such as mouth care, antiemetics, and attractively served meals in pleasant surroundings. Drinking carbonated beverages and avoiding very hot or cold foods may help ease anorexia. Adequate fluid intake (2500 to 3000 mL/day) is important.

Rest is a critical factor in promoting hepatocyte regeneration. Assess the patient's response to the rest and activity plan. Modify it as needed based on liver function tests and symptoms.

Psychologic and emotional rest is as essential as physical rest. Limited activity may produce anxiety and restlessness in some patients. Diversion activities, such as reading and hobbies, may help a patient cope with the plan of care and ensure adequate rest.

Ambulatory Care

Most patients with viral hepatitis are cared for at home. Assess the patient's knowledge of nutrition and provide any needed dietary teaching. Caution the patient about overexertion and the need to follow the HCP's advice about when to return to work. For patients who have fatigue, tell them to plan activities after periods of rest when energy levels are highest. Teach the patient and caregiver how to prevent transmission to other family members and symptoms to report to the HCP.

Assess the patient for any complications. These include bleeding tendencies with increasing prothrombin (PT) time values, encephalopathy, bloody or tarry stools, vomiting of blood, or high liver enzymes. Note a sudden increase in weight and abdominal girth, which may indicate fluid retention and/or ascites.

Teach the patient to have regular follow-ups for at least 1 year after the diagnosis of hepatitis. Because relapses occur with HBV and HCV, teach the patient the symptoms of recurrence and the need for follow-up care. All patients with chronic HBV or HCV should avoid alcohol as it can accelerate disease progression. Remind patients who are positive for HBsAg (chronic carrier status) or HCV antibody that they cannot be blood donors.

Evaluation

Expected outcomes are that the patient with hepatitis will

- Maintain food and fluid intake adequate to meet nutrient needs
- Avoid alcohol and other hepatotoxic agents
- Show gradual increase in activity tolerance
- Perform daily activities with scheduled rest periods

DRUG- AND CHEMICAL-INDUCED LIVER DISEASES

Excessive alcohol use can cause injury and necrosis of liver tissue. The manifestations can range from a mild elevation in liver enzymes to acute alcoholic hepatitis. Advanced fibrosis and cirrhosis can occur after decades of excess alcohol use. Patients

may have serious liver disease caused by another chronic disease (e.g., chronic viral infection) in combination with alcoholic liver disease, which can compound the problem.

Acute alcoholic hepatitis is a syndrome of hepatomegaly, jaundice, increased liver enzymes (AST, ALT, alkaline phosphate), and low-grade fever. Ascites and prolonged PT time are possible. These manifestations may improve if alcohol intake ceases.

Even at the end-stage of cirrhosis, abstinence can result in significant reversal in some patients. If liver function does not recover after abstaining from alcohol for 6 months or longer, liver transplantation may be an option.[10]

Chemical hepatotoxicity is liver injury caused by exposure to certain compounds (e.g., carbon tetrachloride, gold compounds). Some agents can cause hepatotoxicity, while others may induce cholestasis, necrosis, or liver cancer. Fortunately, because of the decreased use of these agents, the incidence of chemically induced liver toxicity has decreased since the 1980s.

Drug-induced liver injury (DILI) can present similarly to other forms of liver disease. The pattern of injury depends on the drug causing the reaction. Many drugs can cause an increase in liver enzymes and in severe cases jaundice and acute liver failure. The main cause of DILI is antimicrobial agents, especially amoxicillin-clavulanate. The most common cause of acute liver failure is acetaminophen. In patients with chemical hepatotoxicity or DILI, all drugs identified as the cause of liver injury should be stopped.[11]

DRUG ALERT

Acetaminophen

- Safe when taken at recommended levels.
- Its prevalence in a variety of pain relievers, fever reducers, and cough medicines may mean that patients do not know they are taking several drugs that all contain acetaminophen. This can cause an overdose.
- Acute liver failure can occur because of overdosing, either intentionally or unintentionally.
- Combining the drug with alcoholic beverages increases the risk for liver damage.

AUTOIMMUNE, GENETIC, AND METABOLIC LIVER DISEASES

Autoimmune Hepatitis

Autoimmune hepatitis is a chronic inflammatory liver disorder in which the patient's own immune system attacks the liver. The cause is unknown. It is characterized by the presence of autoantibodies and high levels of serum immunoglobulins. It often occurs with other autoimmune diseases.

Most patients with autoimmune hepatitis are women. Laboratory tests useful in the diagnosis include antinuclear antibody (ANA), anti-smooth muscle antibody (ASMA), and antimitochondrial antibody (AMA) testing. A liver biopsy can confirm the diagnosis and guide the treatment decision.

Although autoimmune hepatitis can cause acute liver failure, the spectrum of disease is variable. Most patients develop chronic hepatitis. Untreated autoimmune hepatitis can progress to cirrhosis. Prednisone with or without azathioprine (Imuran) is the recommended treatment for active autoimmune hepatitis. Cyclosporine, tacrolimus (Prograf), budesonide (Entocort), methotrexate, mercaptopurine, and mycophenolate mofetil (CellCept) are options in those who do not respond to prednisone and azathioprine. Mycophenolate is most often used for those who are intolerant to azathioprine.[12]

Wilson Disease

Wilson disease is an autosomal recessive disorder involving cellular copper transport. A defect in biliary excretion leads to copper accumulation in the liver. This causes progressive liver injury and cirrhosis.

Once cirrhosis occurs, copper leaks into the plasma, leading to multiple problems, including neurologic and psychiatric symptoms. The hallmark of Wilson disease is corneal Kayser-Fleischer rings. These are brownish-red rings seen in the cornea near the limbus on eye examination. Low serum ceruloplasmin levels and markedly elevated copper concentrations from liver biopsy samples are present. Diagnosis is based on clinical findings. First-degree relatives of patients with Wilson disease need to be screened for the disease.[13]

The recommended first treatment of symptomatic patients or those with active disease is chelating agents, such as D-penicillamine or trientine (Syprine). They promote the excretion of urinary copper. Zinc acetate (Galzin), another therapy, interferes with copper absorption. Once we have reduced the amount of copper in the body, treatment focuses on preventing copper from building up again. Liver transplantation may be an option with severe liver damage.

Hemochromatosis

Hemochromatosis is a condition in which excess iron accumulates in the body. It is mainly caused by a genetic defect *(hereditary hemochromatosis)*. Iron accumulation in the liver can also be caused by liver disease and chronic blood transfusions used to treat thalassemia and sickle cell disease.[14] Hemochromatosis is discussed in Chapter 34.

Alpha-1 antitrypsin (AAT) deficiency is a genetic disorder that causes an accumulation of AAT in the liver that leads to fibrosis and lung disease. There is no treatment. We recommend patients avoid other causes of liver injury such as alcohol use and fatty liver.[15]

Primary Biliary Cholangitis

Primary biliary cholangitis (PBC), also known as primary biliary cirrhosis, is a chronic disease of the small bile ducts of the liver. In PBC, there is a T cell-mediated attack of the small bile duct cells. This causes a loss of bile ducts and cholestasis (blockage of bile flow). Over time, this leads to liver fibrosis and cirrhosis.

Most patients diagnosed with PBC are middle-aged women. The disease is associated with other autoimmune disorders, such as rheumatoid arthritis, Sjögren syndrome, and scleroderma. High serum alkaline phosphatase, AMA, ANA, and serum lipid levels are present.

The goals of treatment are suppressing ongoing liver damage, preventing complications, and symptom management.

Drugs for PBC include ursodiol, a bile acid, and obeticholic acid (Ocaliva). These drugs decrease bile in the liver. Care focuses on preventing or minimizing malabsorption, hyperlipidemia, vitamin deficiencies, anemia, and fatigue. Care is taken to manage skin disorders, such as itching and xanthomas (cholesterol deposits in the skin). Cholestyramine is used to treat itching. Patients are monitored for progression to cirrhosis. Liver transplantation is an option for end-stage liver disease in patients with PBC.[16]

Primary Sclerosing Cholangitis

Primary sclerosing cholangitis (PSC) is characterized by chronic inflammation, fibrosis, and narrowing of the medium and large bile ducts both inside and outside the liver. We do not know the cause. Most patients with PSC also have ulcerative colitis or, less often, Crohn disease. Complications include cholangitis, cholestasis with jaundice, bile duct cancer, and cirrhosis.

Drug therapy has no proven benefit, although many HCPs use ursodiol. Treatment is directed at reducing the incidence of biliary complications and screening for bile duct and colorectal cancer, which is related to the high incidence of ulcerative colitis. Patients with advanced liver disease may need liver transplantation.

Nonalcoholic Fatty Liver Disease and Nonalcoholic Steatohepatitis

Nonalcoholic fatty liver disease (NAFLD) refers to a wide spectrum of liver diseases ranging from a fatty liver (steatosis) to **nonalcoholic steatohepatitis (NASH)** to cirrhosis.[17] The term *nonalcoholic* is used because NAFLD and NASH occur in people who do not consume excess amounts of alcohol.

The fundamental characteristic of NAFLD is the accumulation of fatty infiltration in the hepatocytes. In NASH, the fat accumulation is associated with varying degrees of inflammation and fibrosis of the liver. If NASH is untreated, it can lead to cirrhosis, liver cancer, and liver failure.

NASH occurs in 3% to 6% of the US population. It is more prevalent in patients with metabolic disease and obesity. About 20% of patients with NASH progress to cirrhosis. NASH should be considered in patients with risk factors, including obesity, diabetes, hyperlipidemia, and hypertension (or *metabolic syndrome*).

Elevated liver function tests (ALT, AST) are often the first sign of NAFLD. Ultrasound and CT scans can be used to diagnose NAFLD. Definitive diagnosis is by a liver biopsy.

There is no currently approved drug for NAFLD. The goal of therapy is weight loss of at least 10% of body weight, if overweight or obese, and exercise. Bariatric surgery for morbidly obese persons reduces the risk of NAFLD. Reducing other risk factors, including hyperlipidemia, hypertension, and diabetes, is important.

CIRRHOSIS

Cirrhosis is the end stage of liver disease.[18] It is characterized by extensive degeneration and destruction of the liver cells. This results in the replacement of liver tissue by fibrosis (scar tissue) and regenerative nodules that occur from the liver's attempt to repair itself (Fig. 48.4). The development of cirrhosis usually happens after decades of chronic liver disease.

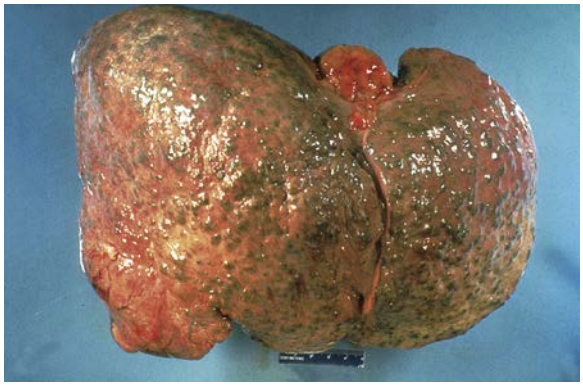

Fig. 48.4 Cirrhosis from alcohol use. The characteristic diffuse nodularity of the surface is due to the combination of regeneration and scarring of the liver. (From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

Etiology and Pathophysiology

Any chronic liver disease can cause cirrhosis. The most common causes in the United States are chronic HCV infection, NASH, and alcohol-induced liver disease. In patients with alcohol-induced liver disease, malnutrition adds to the damage caused by the alcohol itself. Some cases of nutrition-related cirrhosis have resulted from extreme dieting, malabsorption, and obesity. Environmental factors and genetic predisposition may lead to the development of cirrhosis.

Chronic inflammation and cell necrosis from viral hepatitis can result in progressive fibrosis and cirrhosis. Chronic hepatitis combined with alcohol use has a synergistic effect in accelerating liver damage. Biliary causes include PBC and PSC.

Cardiac cirrhosis includes a spectrum of liver problems that result from long-standing, severe, right-sided heart failure. It causes hepatic venous congestion, parenchymal damage, necrosis of liver cells, and fibrosis over time. Treatment is aimed at managing the patient's underlying heart failure.

In cirrhosis, the liver cells try to regenerate, but the regenerative process is disorganized. This results in abnormal blood vessel and bile duct architecture. The overgrowth of new and fibrous connective tissue distorts the liver's normal lobular structure, resulting in lobules of irregular size and shape with impeded blood flow. Eventually, irregular and disorganized liver regeneration, poor cell nutrition, and hypoxia (from inadequate blood flow and scar tissue) result in decreased liver function.

Clinical Manifestations

Early Manifestations

Patients may be unaware of their liver condition because there are few symptoms in early-stage disease. If a person does have symptoms, these may include fatigue or an enlarged liver. Blood tests may show normal liver function (compensated cirrhosis). The diagnosis of cirrhosis is often made later when a patient presents with symptoms of more advanced liver disease.

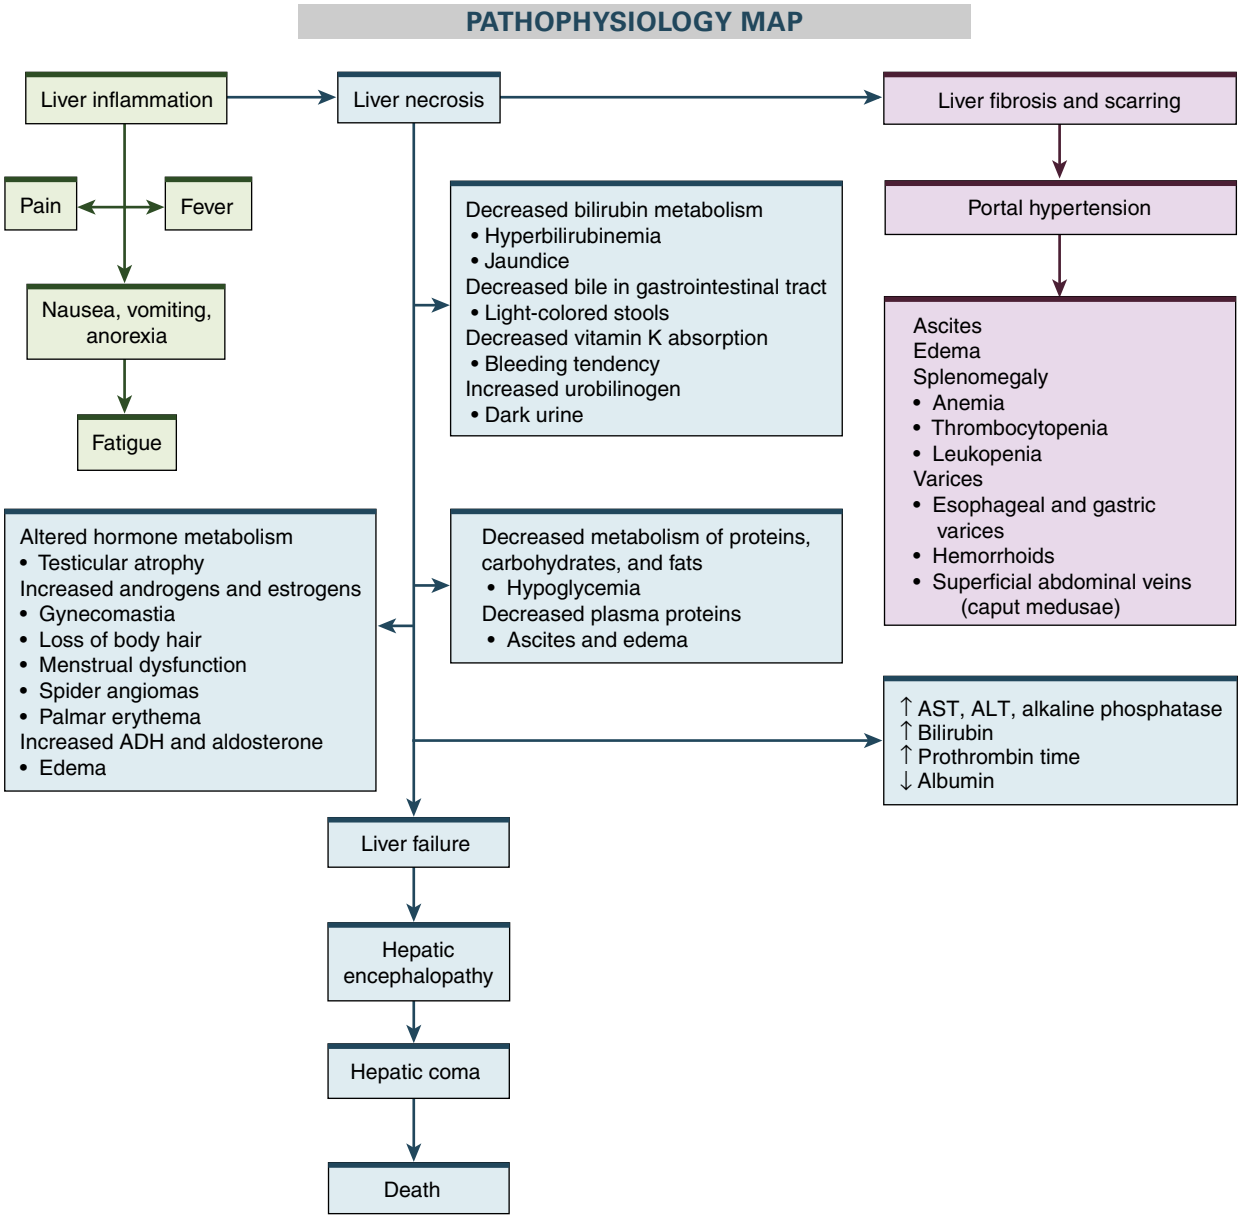

Fig. 48.5 Continuum of liver dysfunction in cirrhosis and resulting manifestations. (Adapted from Huether SE, McCance KL: *Understanding pathophysiology,* ed 5, St Louis, 2012, Mosby.)

Late Manifestations

Late manifestations result from liver failure and portal hypertension (Fig. 48.5). Jaundice, peripheral edema, and ascites develop gradually. Other late manifestations include skin lesions, hematologic problems, endocrine problems, and peripheral neuropathies (Fig. 48.6). In the advanced stages, the liver becomes small and nodular. Liver function is dramatically impaired.

Jaundice. Jaundice results from decreased ability to conjugate and excrete bilirubin into the small intestines (Table 48.3). There is an overgrowth of connective tissue in the liver, which compresses the bile ducts and leads to an obstruction. This results in an increase in the bilirubin in the vascular system, and jaundice occurs. The jaundice may be minimal or severe, depending on the degree of liver damage.

Skin lesions. Various skin manifestations often occur with cirrhosis. *Spider angiomas* (telangiectasia or spider nevi) are small, dilated blood vessels with a bright red center point and spiderlike branches. They occur on the nose, cheeks, upper trunk, neck, and shoulders. *Palmar erythema* (a red area that blanches with pressure) occurs on the palms of the hands. Both lesions are due to an increase in circulating estrogen due to the damaged liver's inability to metabolize steroid hormones.

Hematologic problems. Hematologic problems include thrombocytopenia, leukopenia, anemia, and coagulation problems. We think thrombocytopenia, leukopenia, and anemia are caused by the splenomegaly that results from the backup of blood from the portal vein into the spleen (portal hypertension). Overactivity of the enlarged spleen results in increased removal of blood cells from circulation. Anemia can result from inadequate red blood cell (RBC) production and survival, poor diet, poor folic acid absorption, and bleeding from varices.

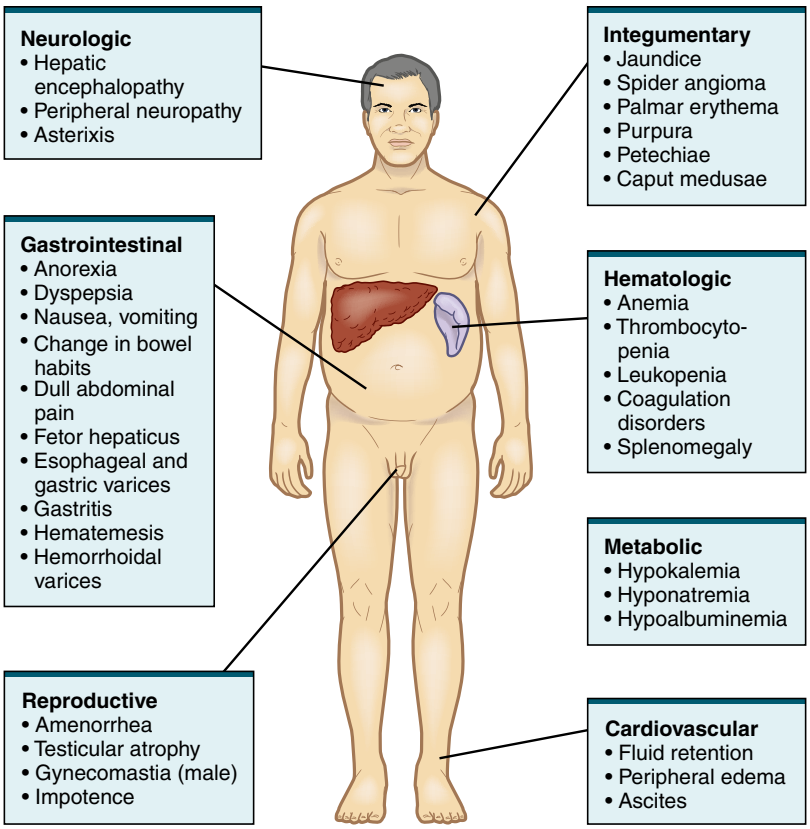

Fig. 48.6 Systemic manifestations of cirrhosis.

Coagulation problems result from the liver's inability to make prothrombin and other factors essential for blood clotting. Manifestations include nosebleeds, purpura, petechiae, easy bruising, gingival bleeding, and heavy menses.

Endocrine problems. The liver plays a vital role in the metabolism of hormones, such as estrogen and testosterone. In men with cirrhosis, gynecomastia, loss of axillary and pubic hair, testicular atrophy, and impotence with loss of libido may occur because of increased estrogen levels. Younger women with cirrhosis may develop amenorrhea. Older women may have vaginal bleeding. If the liver does not metabolize aldosterone properly, it can lead to hyperaldosteronism with sodium and water retention and potassium loss.

Peripheral neuropathy. Peripheral neuropathy is a common finding in alcoholic cirrhosis. It is probably due to a diet deficiency of thiamine, folic acid, and cobalamin. The neuropathy usually results in sensory and motor symptoms, but sensory symptoms may dominate.

Complications

Complications include portal hypertension, esophageal and gastric varices, peripheral edema, abdominal ascites, hepatic encephalopathy, and hepatorenal syndrome. Patients who are cirrhotic but have no obvious complications have *compensated cirrhosis.* Those who have 1 or more complications have *decompensated cirrhosis.*

Portal Hypertension and Esophageal and Gastric Varices

In patients with cirrhosis, the liver undergoes structural changes. These changes lead to obstruction of blood flow in and out of the liver. This results in increased pressure within the liver's circulatory system (portal hypertension). **Portal hypertension** is characterized by increased venous pressure in the portal circulation, splenomegaly, large collateral veins, ascites, and gastric and esophageal varices.[19]

To reduce pressure, the body develops alternate circulatory pathways, referred to as *collateral circulation.* The collateral channels often form in the lower esophagus, anterior abdominal wall, parietal peritoneum, and rectum. Varicosities (distended veins) develop in areas where the collateral and systemic circulations communicate, resulting in esophageal and gastric varices, *caput medusae* (ring of varices around the umbilicus), and hemorrhoids.

Esophageal varices are a complex of tortuous, enlarged veins at the lower end of the esophagus. **Gastric varices** are found in the upper part of the stomach. These varices are fragile and do not tolerate high pressure, so they can bleed easily. Large varices are more likely to bleed. Esophageal varices can cause variceal hemorrhages with a 5-year mortality of 20%. The patient may present with melena or hematemesis. Ruptured esophageal varices are the most life-threatening complication of cirrhosis and considered a medical emergency.

Peripheral Edema and Ascites

Peripheral edema occurs in the lower extremities and presacral area. Peripheral edema can occur before, concurrently with, or after ascites development. Edema results from decreased colloidal oncotic pressure from impaired liver synthesis of albumin and increased portacaval pressure from portal hypertension.

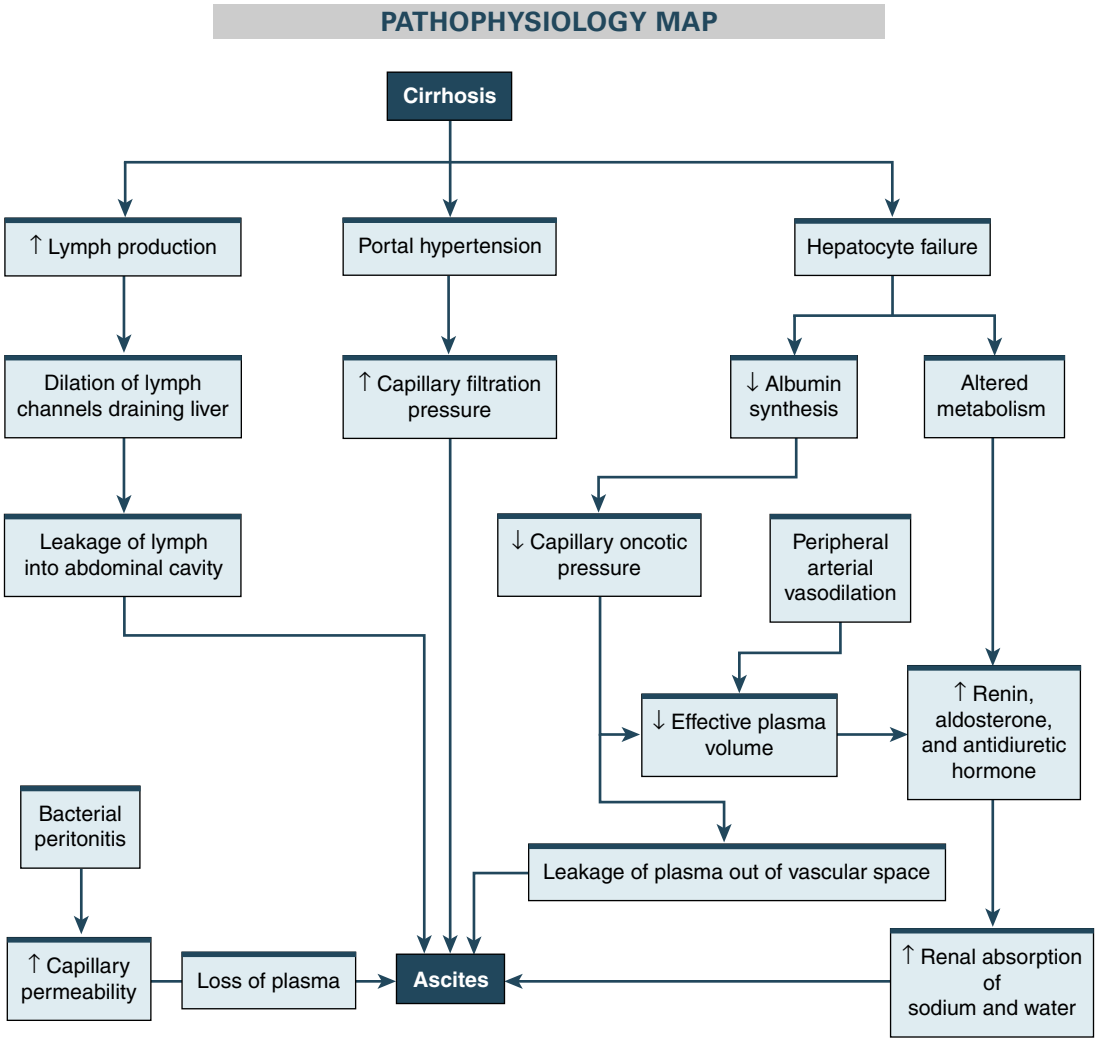

Fig. 48.7 Mechanisms for development of ascites. (Adapted from Huether SE, McCance KL: *Understanding pathophysiology,* ed 5, St Louis, 2012, Mosby.)

Ascites is the accumulation of serous fluid in the peritoneal or abdominal cavity. It is a common manifestation of cirrhosis. Several mechanisms lead to ascites. One mechanism occurs with portal hypertension, which causes proteins to shift from the blood vessels into the lymph space (Fig. 48.7). When the lymphatic system is unable to carry off the excess proteins and water, they leak into the peritoneal cavity. The osmotic pressure of the proteins pulls more fluid into the peritoneal cavity (Table 48.10).

A second mechanism of ascites formation is hypoalbuminemia resulting from the liver's decreased ability to synthesize albumin. Hypoalbuminemia results in decreased colloidal oncotic pressure.

A third mechanism of ascites is hyperaldosteronism, which occurs when the damaged hepatocytes metabolize aldosterone. The increased aldosterone level causes increased sodium reabsorption by the renal tubules. Sodium retention, combined with an increase in antidiuretic hormone in blood, leads to further water retention and edema. Edema decreases intravascular volume with decreased renal blood flow and glomerular filtration.

TABLE 48.10 Factors Involved in Ascites

Factor	Mechanism
↑ Hepatic lymph flow	Leaking of protein-rich lymph from surface of cirrhotic liver
Hyperaldosteronism	↑ Aldosterone secretion stimulated by ↓ renal blood flow ↓ Liver catabolism of circulating aldosterone
Impaired water excretion	↑ Antidiuretic hormone stimulated by ↓ renal blood flow
Portal hypertension	↑ Resistance of blood flow through liver
↓ Serum colloidal oncotic pressure	Impaired liver synthesis of albumin Loss of albumin into peritoneal cavity

Ascites is manifested by abdominal distention with weight gain (Fig. 48.8). If the ascites is severe, the increase in abdominal pressure from the fluid accumulation may cause eversion of the umbilicus. Abdominal striae with distended abdominal wall veins may be present. Patients may have signs of dehydration and a decrease in urine output. Hypokalemia is common. It is due to an excessive loss of potassium caused by hyperaldosteronism.

Low potassium levels can also result from diuretic therapy used to treat the ascites. Those with severe ascites are at risk for pleural effusion.

Because of decreased immune function with cirrhosis, patients with ascites are at risk for *spontaneous bacterial peritonitis* (SBP). SBP is a bacterial infection of the ascitic fluid. In SBP, bacteria normally found in the intestines move into the peritoneal space. The bacteria most often responsible for the infection are a gram-negative enteric pathogen, such as *Escherichia coli*. SBP is a common complication of hospitalized patients with cirrhosis and ascites. Worsening vasodilation contributes to the development of SBP.

Hepatic Encephalopathy

Hepatic encephalopathy is a neuropsychiatric manifestation of liver disease. The pathogenesis is multifactorial.[20] It includes the neurotoxic effects of ammonia, abnormal neurotransmission, astrocyte swelling, and inflammatory cytokines. A major source of ammonia is the bacterial and enzymatic deamination of amino acids in the intestines. The ammonia that results from deamination normally goes to the liver via the portal circulation where it is converted to urea. The kidneys then excrete urea. When blood is shunted past the liver via the collateral vessels or the liver is so damaged that it is unable to convert ammonia to urea, the ammonia levels in the systemic circulation increase. The ammonia crosses the blood-brain barrier and produces neurologic manifestations.

Fig. 48.8 Gross ascites. (From Butcher GP: *Gastroenterology: an illustrated colour text,* London, 2004, Churchill Livingstone.)

Factors that increase ammonia may precipitate hepatic encephalopathy (Table 48.11). Hepatic encephalopathy can occur after placement of a transjugular intrahepatic portosystemic shunt (TIPS). TIPS reduces portal hypertension by diverting blood flow around the liver.

Manifestations include neurologic and mental status changes. These include impaired consciousness and inappropriate behavior, ranging from sleep problems to trouble concentrating to deep coma. Changes may occur suddenly from an increase in ammonia in response to bleeding varices or infection or gradually as blood ammonia levels slowly increase. We often use a grading system to classify the stages of hepatic encephalopathy (Table 48.12).

A characteristic manifestation is **asterixis** (flapping tremors). This may take several forms, with the most common involving the arms and hands. When asked to hold the arms and hands stretched out, the patient is unable to hold this position and performs a series of rapid flexion and extension movements of the hands.

TABLE 48.11 Risk Factors for Hepatic Encephalopathy

Factor	Mechanism
Cerebral depressants (e.g., opioids)	↓ Metabolism by liver, causing ↑ drug levels and cerebral depression
Constipation	↑ Ammonia production from bacterial action on feces
Dehydration	Potentiates ammonia toxicity
GI bleeding	↑ Ammonia in GI tract
Hypokalemia	Potassium needed by brain to metabolize ammonia
Hypovolemia	↑ Ammonia because of hepatic hypoxia Impaired cerebral, liver, and renal function because of ↓ blood flow
Infection	↑ Metabolic rate and cerebral sensitivity to toxins
Metabolic alkalosis	Facilitate transport of ammonia across blood-brain barrier ↑ Renal production of ammonia
↑ Metabolism	↑ Workload of liver
Paracentesis	Loss of sodium and potassium ions ↓ Blood volume
Uremia (renal failure)	Retention of nitrogenous metabolites

TABLE 48.12 Grading Scale for Hepatic Encephalopathy

Grade	Level of Consciousness	Intellectual Function	Neurologic Findings
0	Normal to minimal change	Subtle to no change in personality, behavior, memory, concentration	Asterixis absent May have abnormal psychometric test
1	Lack of awareness, sleep disturbance	Short attention span, impaired computational skills, personality change, impaired short-term memory, mild confusion, depression	Incoordination, asterixis may be absent
2	Lethargy, drowsiness	Disoriented to time, inappropriate behavior, deficits in executive function	Asterixis, abnormal reflexes
3	Somnolent, arousable	Disoriented to time, loss of meaningful conversation, marked confusion, incomprehensible speech	Asterixis, abnormal reflexes
4	Not arousable, comatose	Absent	Decerebrate May be responsive to painful stimuli

Writing impairments include difficulty moving the pen or pencil from left to right and *apraxia* (inability to construct simple figures). Other signs include hyperventilation, hypothermia, twitching of the tongue, and grimacing and grasping reflexes. *Fetor hepaticus* (musty, sweet odor of the patient's breath) occurs in some patients. This odor is from the accumulation of digestive by-products that the liver is unable to degrade.

Hepatorenal Syndrome

Hepatorenal syndrome is a type of renal failure with azotemia, oliguria, and intractable ascites. In this syndrome, the kidneys have no structural problems. The cause is complex. The final common pathway is likely to be portal hypertension along with liver decompensation, resulting in splanchnic and systemic vasodilation and decreased arterial blood volume. As a result, renal vasoconstriction occurs, and renal failure follows. Liver transplantation can reverse renal failure. In the patient with cirrhosis, hepatorenal syndrome can follow diuretic therapy, GI bleeding, or paracentesis.

Diagnostic Studies

Patients with cirrhosis have abnormalities in most of their liver function tests. Enzyme levels, including alkaline phosphatase, AST, ALT, and γ-glutamyl transpeptidase (GGT), are initially high due to their release from inflamed liver cells. However, in end-stage liver disease, AST and ALT levels may be normal due to the death and loss of hepatocytes. Patients will also have low serum total protein and albumin, increased serum bilirubin (Table 48.3) and globulin levels, and prolonged PT time. Low cholesterol levels reflect changes in fat metabolism.

A liver biopsy can identify liver cell changes. It is the gold standard for a definitive diagnosis of cirrhosis. Although a liver ultrasound may be able to detect cirrhosis, it is not a reliable diagnostic test for cirrhosis. Ultrasound elastography (Fibroscan) is a noninvasive test used to quantify the degree of liver fibrosis.

Interprofessional Care

The goal of treatment is to slow the progression of cirrhosis and to prevent and treat any complications. Interprofessional care measures are listed in Table 48.13. Management of specific problems from cirrhosis is described next.

Ascites

Management of ascites focuses on sodium restriction, diuretics, and fluid removal. Patients may need to limit sodium intake to 2 g/day. Very low-sodium intake can result in reduced nutrient intake and malnutrition. The patient is usually not on restricted fluids unless severe ascites develops. Monitor fluid and electrolyte balance. An albumin infusion may help maintain intravascular volume and adequate urine output by increasing plasma colloid oncotic pressure.

Diuretic therapy is an important part of management. Often a combination of drugs that work at multiple sites of the nephron is more effective than a single agent. Spironolactone (Aldactone) is an effective diuretic, even in patients with severe ascites. Spironolactone is an aldosterone antagonist and potassium sparing. A high-potency loop diuretic (e.g., furosemide) is often used with a potassium-sparing drug. Hyponatremia is a common problem in patients with cirrhosis on diuretics. It causes an increase in water excretion, resulting in an increase in serum sodium concentration.

A *paracentesis* is a sterile procedure in which a catheter is used to withdraw fluid from the abdominal cavity. This procedure can diagnose a medical condition or relieve pain, pressure, or problems breathing. In the patient with cirrhosis, this procedure is done for the patient with impaired respiration or abdominal discomfort caused by severe ascites who does not respond to diuretic therapy. It is only a temporary measure because the fluid tends to reaccumulate rapidly.

TIPS is used to treat ascites that does not respond to diuretics. A peritoneovenous shunt is a surgical procedure that provides continuous reinfusion of ascitic fluid into the venous system. It is rarely used due to the high rate of complications.

TABLE 48.13 Interprofessional Care

Cirrhosis

Diagnostic Assessment

- History and physical assessment
- Liver function tests
- Serum albumin
- Serum electrolytes
- PT time
- Complete blood count
- Liver biopsy (percutaneous needle)
- Liver ultrasound (e.g., FibroScan)
- Upper endoscopy (esophagogastroduodenoscopy)
- CT scan, MRI

Management

Conservative Therapy

- Rest
- B-complex vitamins
- Avoiding alcohol
- Minimizing or avoiding aspirin, acetaminophen, and NSAIDs

Ascites

- Low-sodium diet
- Diuretics
- Paracentesis (if needed)

Esophageal and Gastric Varices

- Endoscopic band ligation or sclerotherapy
- Balloon tamponade
- TIPS

Drug Therapy

- Nonselective β-blocker (e.g., propranolol)
- octreotide (Sandostatin)
- vasopressin

Hepatic Encephalopathy

Drug Therapy

- Antibiotics (rifaximin [Xifaxan])
- lactulose

Esophageal and Gastric Varices

The main therapeutic goal for esophageal and gastric varices is to prevent bleeding and variceal rupture by reducing portal pressure.[21] The patient who has esophageal and/or gastric varices should avoid alcohol, aspirin, and nonsteroidal antiinflammatory drugs (NSAIDs).

All patients with cirrhosis should have an upper endoscopy (esophagogastroduodenoscopy [EGD]) to screen for varices. Patients with varices who are at risk for bleeding often receive a nonselective β-blocker (nadolol, propranolol) to reduce bleeding risk. β-Blockers decrease high portal pressure, which decreases the risk for rupture.[22]

When variceal bleeding occurs, the first step is to stabilize the patient and manage the airway. IV therapy is started and may include giving blood products. Care then moves toward stopping the bleeding, identifying the source, and applying interventions to prevent further bleeding. Management that involves a combination of drug therapy, and endoscopic therapy is more successful than either approach alone.

Drug therapy for bleeding varices may include the somatostatin analog octreotide (Sandostatin) or vasopressin. Both produce vasoconstriction of the splanchnic arterial bed, decrease portal blood flow, and decrease portal hypertension. Octreotide is used more often because it has fewer side effects than vasopressin.

At the time of endoscopy, band ligation or sclerotherapy of varices may be used to prevent rebleeding. Endoscopic variceal ligation (EVL, or "banding") is done by placing a small rubber band (elastic O-ring) around the base of the *varix* (enlarged vein). Sclerotherapy involves injecting a sclerosing solution into the swollen veins through a needle placed through the endoscope.

Balloon tamponade is an option when endoscopy does not control acute esophageal or gastric variceal hemorrhage. Balloon tamponade controls the bleeding by mechanical compression of the varices. Several types of tubes are available. The Sengstaken-Blakemore tube has 2 balloons, gastric and esophageal, with 3 lumens: 1 for the gastric balloon, 1 for the esophageal balloon, and 1 for gastric aspiration.

! SAFETY ALERT

Balloon Tamponade

- Label each lumen to avoid confusion.
- Secure the tube to prevent movement of the tube that could result in airway occlusion.
- Deflate balloons for 5 min every 8–12 hr per agency policy to prevent tissue necrosis.

Supportive measures during an acute variceal bleed include giving fresh frozen plasma and packed RBCs, vitamin K, and proton pump inhibitors (PPIs; e.g., pantoprazole). Lactulose and rifaximin (Xifaxan) may be given to prevent hepatic encephalopathy from breakdown of blood and the release of ammonia in the intestine. Antibiotics are given to prevent bacterial infection.

Because of the high incidence of recurrent bleeding with each bleeding episode, continued therapy is necessary. Long-term management of patients who have had an episode of bleeding includes nonselective β-blockers, repeated band ligation of the varices, and portosystemic shunts in patients who develop recurrent bleeding.

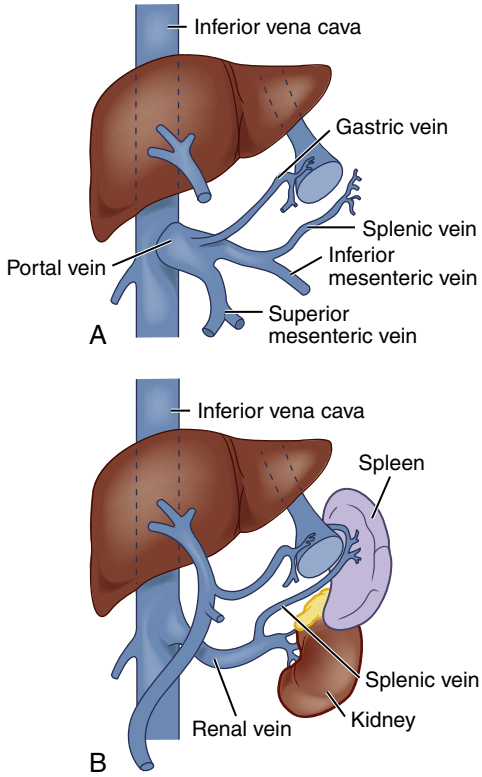

Fig. 48.9 Portosystemic shunts. (A) Portacaval shunt. The portal vein is anastomosed to the inferior vena cava, diverting blood from the portal vein to the systemic circulation. (B) Distal splenorenal shunt. The splenic vein is anastomosed to the renal vein. The portal venous flow stays intact while esophageal varices are selectively decompressed. (The short gastric veins are decompressed.) The spleen conducts blood from the high pressure of the esophageal and gastric varices to the low-pressure renal vein.

Shunting procedure. Nonsurgical and surgical methods of shunting blood away from the varices are available. Shunting procedures tend to be done more after a second major bleeding episode than during an initial bleeding episode. *TIPS* is a nonsurgical procedure in which a tract (shunt) between the systemic and portal venous systems is created to redirect portal blood flow. A catheter is placed in the jugular vein and then threaded through the superior and inferior vena cava to the hepatic vein. The wall of the hepatic vein is punctured, and the catheter is directed to the portal vein. Stents are positioned along the passageway, overlapping in the liver tissue and extending into both veins.

This procedure reduces portal venous pressure and decompresses the varices, thus controlling bleeding. TIPS does not interfere with a future liver transplantation. Limitations of TIPS include the increased risk for hepatic encephalopathy (toxin-containing blood bypasses the liver) and stenosis of the stent. TIPS is contraindicated in patients with severe hepatic encephalopathy, liver cancer, severe hepatorenal syndrome, and portal vein thrombosis.

Various surgical shunting procedures can decrease portal hypertension by diverting some of the portal blood flow while allowing adequate liver perfusion. Currently, the surgical shunts most often used are the portacaval shunt and the distal splenorenal shunt (Fig. 48.9).

TABLE 48.14 Drug Therapy

Cirrhosis

Drug	Mechanism of Action
Diuretics	
furosemide (Lasix)	Acts on distal tubule and loop of Henle to ↓ reabsorption of sodium and water
spironolactone (Aldactone)	Blocks actions of aldosterone, potassium sparing
Other Therapy	
lactulose	Acidifies feces in bowel and traps ammonia, causing its elimination in feces
magnesium sulfate	Corrects hypomagnesemia that may occur with liver dysfunction
nadolol propranolol	↓ Portal venous pressure and esophageal variceal bleeding
neomycin sulfate rifaximin (Xifaxan)	↓ Bacterial flora, thus reducing ammonia formation
octreotide (Sandostatin) vasopressin	Hemostasis and control of bleeding in esophageal and gastric varices, constricts splanchnic arterial bed
PPIs (e.g., pantoprazole)	↓ Gastric acidity
Vitamin K	Corrects clotting problems from decreased vitamin K levels

Hepatic Encephalopathy

The goal of management of hepatic encephalopathy is to reduce ammonia formation. Lactulose, a drug that traps ammonia in the gut, reduces ammonia formation in the intestines. We can give it orally, as an enema, or through a nasogastric (NG) tube. The drug's laxative effect expels the ammonia from the colon. Antibiotics, such as rifaximin, may be given, especially in patients who do not respond to lactulose. Regular and frequent bowel movements are necessary to minimize ammonia buildup, so use measures to prevent constipation.

Control of hepatic encephalopathy also involves treating risk factors (Table 48.10). This includes preventing and controlling GI bleeds and, in the case of a bleed, removing the blood promptly from the GI tract to decrease the protein accumulation in the gut.

Drug Therapy

There is no specific drug therapy for cirrhosis. However, several drugs are used to treat symptoms and complications of advanced liver disease (Table 48.14).

Nutrition Therapy

The diet for the patient who has cirrhosis without complications is high in calories (3000 cal/day). It is high in carbohydrate content with moderate to low levels of fat.

A patient with alcoholic cirrhosis often has protein-calorie malnutrition. Oral supplements containing protein from branched-chain amino acids that are metabolized by the muscles may be needed. These supplements provide protein that the liver can more easily metabolize. Parenteral nutrition (PN) or EN are given for severe malnutrition (see Chapter 44).

The patient with ascites and edema receives a low-sodium diet. The degree of sodium restriction depends on the patient's condition.

TABLE 48.15 NURSING ASSESSMENT

Cirrhosis

Subjective Data

Important Health Information

Health history: Viral, toxic, or idiopathic hepatitis. Alcohol use, metabolic syndrome, chronic biliary obstruction and infection, severe right-sided heart failure

Medications: Adverse reaction to any medication. Use of anticoagulants, aspirin, NSAIDs, acetaminophen

Functional Health Patterns

Health perception–health management: Chronic alcohol use. Weakness, fatigue

Nutritional-metabolic: Anorexia, weight loss, dyspepsia, nausea and vomiting, gingival bleeding. Dry, yellow skin, bruising

Elimination: Dark urine, decreased urine output, light-colored or black stools, flatulence, change in bowel habits.

Cognitive-perceptual: Dull, RUQ or epigastric pain. Numbness, tingling of extremities. Itching

Sexuality-reproductive: Impotence, amenorrhea

Objective Data

General

Fever, cachexia, wasting of extremities

GI

Abdominal distention, ascites, distended abdominal wall veins, palpable liver and spleen, foul breath. Hematemesis. Black, tarry stools. Hemorrhoids

Neurologic

Altered mentation, asterixis

Reproductive

Gynecomastia, testicular atrophy, and impotence (men); loss of libido (men and women); amenorrhea or heavy menses (women)

Respiratory

Shallow, rapid respirations. Nosebleeds

Skin

Icteric sclera, jaundice, petechiae, bruising, spider angiomas, palmar erythema, alopecia, loss of axillary and pubic hair, peripheral edema

Possible Diagnostic Findings

Anemia, thrombocytopenia; leukopenia. ↓ Serum albumin, potassium. Abnormal liver function studies. ↑ INR, ↓ platelets, ↑ ammonia, ↑ bilirubin levels. Abnormal abdominal ultrasound, CT, or MRI

Teach the patient and caregiver about the degree of restriction. Review which foods are high in sodium. Teach the patient to read labels for sodium content (see Fig. 44.5). Offer suggestions about how to make the diet more palatable. Seasonings, like garlic, parsley, onion, lemon juice, and spices may make food more appetizing. Collaborate with a dietitian about dietary strategies.

❖ NURSING MANAGEMENT: CIRRHOSIS

◆ Assessment

Subjective and objective data that you should obtain from a person with cirrhosis are outlined in Table 48.15.

Clinical Problems

Clinical problems for the patient with cirrhosis may include:

- Nutritionally compromised
- Ineffective tissue perfusion
- Activity intolerance
- Fluid imbalance

Additional information on clinical problems and interventions for the patient with cirrhosis is presented in eNursing Care Plan 48.2 available on the website for this chapter.

Planning

The overall goals are that the patient with cirrhosis will (1) have relief of discomfort, (2) have minimal to no complications, and (3) return to as normal a lifestyle as possible.

Implementation

Health Promotion

Common risk factors include alcohol use, malnutrition, viral hepatitis, biliary obstruction, obesity, and right-sided heart failure. Prevention and early treatment of cirrhosis focus on reducing or eliminating these risk factors. Urge patients to abstain from alcohol. Encourage those with chronic alcohol use to enroll in support programs that help patients maintain sobriety. The treatment of alcohol use is discussed in Chapter 11.

Adequate nutrition, especially for the person who uses alcohol and other people at risk for cirrhosis, is essential to promote normal liver regeneration. Identify and treat acute hepatitis early so that it does not progress to chronic hepatitis and cirrhosis.

Acute Care

Care for the patient with cirrhosis focuses on conserving the patient's strength while maintaining muscle strength and tone. When the patient needs complete bed rest, implement measures to prevent pneumonia, thromboembolic problems, and pressure injuries. Modify the activity and rest schedule according to signs of improvement (e.g., decreasing jaundice, improved liver function studies).

Anorexia, nausea and vomiting, pressure from ascites, and poor eating habits interfere with adequate nutrient intake. Oral hygiene before meals may improve the patient's taste sensation. Make between-meal snacks available so that the patient can eat them at times when food is best tolerated. Offer preferred foods whenever possible. Explain the reason for any dietary restrictions to the patient and caregiver.

Assess the patient's physical status. Is jaundice present? Where is it seen—sclera, skin, hard palate? What is the progression of jaundice? If the pruritis accompanies jaundice, use measures to relieve itching. Cholestyramine or hydroxyzine (Atarax) may help. Cholestyramine is a resin that binds bile salts in the intestine, increasing their excretion in the feces. It comes in powder form that you mix with milk or juice. Side effects include nausea, vomiting, diarrhea or constipation, and skin reactions. It may bind with other medications, so check drug-to-drug interactions. Other measures to relieve itching include baking soda or moisturizing bath oils (Alpha Keri), lotions containing calamine, antihistamines, soft or old linens, and control of the temperature (not too hot and not too cold). Keep the patient's nails short and clean. Teach patients to rub with their knuckles rather than scratch with their nails when they cannot resist scratching.

Note the color of urine and stools and assess for improvement or normalization of color. When jaundice is present, the urine is often dark brown, and the stool is gray or tan.

Edema and ascites require your assessment and intervention. Accurate calculation and recording of intake and output, daily weights, and measurements of extremities and abdominal girth help in the ongoing assessment of the location and extent of the edema. Mark the abdomen with a permanent marker so that you measure the girth at the same location each time.

Provide appropriate care for the patient having a paracentesis (Table 48.16).

TABLE 48.16 NURSING MANAGEMENT

Care of the Patient Undergoing Paracentesis

Preprocedure

- Have the patient void or insert an indwelling catheter.
- Obtain baseline vital signs and pulse oximetry. Weigh patient, inspect and palpate abdomen, and assess abdominal girth. Assess bladder for distention and determine last voiding.
- Assess baseline laboratory values (e.g., CBC, electrolytes, coagulation studies).
- Give any sedation or analgesia, if ordered.
- Teach patient to remain immobile during the procedure.
- Help the patient to a high-Fowler (sitting) position with feet on the floor.

Postprocedure

- Perform assessment and compare with baseline: vital signs, pulse oximetry, abdominal girth, abdominal pain. Note any signs of hypovolemia.
- Have the patient sit on the side of the bed or place in high-Fowler's position.
- Label and send the fluid for laboratory analysis.
- Check the dressing for bleeding and/or leakage of ascitic fluid.
- Give IV fluid and/or albumin as ordered.
- Measure any drainage and describe the collected fluid.
- Reweigh the patient and monitor intake and output.
- Maintain bedrest per agency protocol.

CHECK YOUR PRACTICE

You are caring for a patient with advanced cirrhosis and ascites. The patient tells you that he is having increased shortness of breath.

- What is your concern?
- What would you do?

Dyspnea is a frequent problem for the patient with severe ascites. A semi-Fowler's or Fowler's position allows for maximal respiratory efficiency. Use pillows to support the arms and chest to increase the patient's comfort and ability to breathe. Monitor the patient's O_2 level and vital signs.

Meticulous skin care is essential because the edematous tissues are prone to break down. Use an alternating-air pressure mattress or other special mattress. Adhere to a turning schedule (minimum of every 2 hours). Support the abdomen with

pillows. If the abdomen is taut, cleanse it gently. The patient will tend to avoid moving because of abdominal discomfort and dyspnea. Range-of-motion exercises are helpful. Implement measures such as coughing and deep breathing to prevent respiratory problems. The lower extremities may be elevated. If scrotal edema is present, a scrotal support gives some comfort.

When the patient is taking diuretics, monitor serum sodium, potassium, chloride, and bicarbonate levels. Monitor renal function (blood urea nitrogen [BUN], serum creatinine) routinely and with any change in the diuretic dosage. Observe for signs of fluid and electrolyte imbalance, especially hypokalemia. Dysrhythmias, hypotension, tachycardia, and generalized muscle weakness may occur with hypokalemia. Muscle cramping, weakness, lethargy, and confusion may be present with hyponatremia from water excess.

Observe for and provide nursing care for any hematologic problems. These include bleeding tendencies, anemia, and increased susceptibility to infection.

Assess the patient's response to altered body image resulting from jaundice, spider angiomas, palmar erythema, ascites, and gynecomastia. The patient may have anxiety and embarrassment about these changes. Explain these phenomena and be a supportive listener. Provide nursing care with concern and encouragement to help the patient maintain their self-esteem.

Bleeding varices. If the patient has esophageal or gastric varices, observe for any signs of bleeding from the varices, such as hematemesis and melena. If hematemesis occurs, assess the patient for bleeding and call the HCP. Be ready to transfer the patient to the endoscopy suite and/or assist with equipment to control the bleeding. Maintain the patient's airway. Patients with bleeding varices are usually admitted to the intensive care unit (ICU).

Balloon tamponade is an option for patients who have bleeding that is unresponsive to band ligation or sclerotherapy. When balloon tamponade is used, explain to the patient and caregiver the use of the tube and how the balloon is inserted. Check the balloons for patency. It is usually the HCP's responsibility to insert the tube by either the nose or mouth. Then, the gastric balloon is inflated with 250 mL of air, and the tube is retracted until resistance (lower esophageal sphincter) is felt. The tube is secured by placing a piece of sponge or foam rubber at the nostrils (nasal cuff). For continued bleeding, the esophageal balloon is then inflated. A sphygmomanometer is used to measure and maintain the desired pressure at 20 to 40 mm Hg. An x-ray confirms the balloon's position.

Monitor for complications of rupture or erosion of the esophagus, regurgitation and aspiration of gastric contents, and occlusion of the airway by the balloon. If the gastric balloon breaks or deflates, the esophageal balloon will slip upward, obstructing the airway and causing asphyxiation. If this happens, cut the tube or deflate the esophageal balloon. Keep scissors at the bedside. Minimize regurgitation by oral and pharyngeal suctioning and keeping the patient in a semi-Fowler's position.

The patient is unable to swallow saliva because the inflated esophageal balloon occludes the esophagus. Encourage the patient to expectorate. Provide an emesis basin and tissues. Frequent oral and nasal care offers relief from the taste of blood and irritation from mouth breathing.

Hepatic encephalopathy. Nursing care focuses on maintaining a safe environment, sustaining life, and assisting with measures to reduce the formation of ammonia. Patients with hepatic encephalopathy may be confused and at risk for falls or other injuries. Assess the patient's level of responsiveness (e.g., reflexes, pupillary reactions, orientation). Note any sensory and motor problems (e.g., hyperreflexia, asterixis, motor coordination). Assess for fluid, electrolyte, and acid-base imbalances. Evaluate the response to treatment measures.

Assess neurologic status at least every 2 hours. Include an exact description of the patient's behavior. Plan your care of the patient based on the severity of the encephalopathy. In patients with altered levels of consciousness or whose airway may become compromised, have emergency equipment readily available. Any GI bleeding may worsen encephalopathy. Institute measures to prevent falls or injuries.

Control factors known to precipitate encephalopathy as much as possible. Measures to minimize constipation are important to reduce ammonia production. Give drugs, laxatives, and enemas as ordered. Encourage fluids, if not contraindicated. Assess the patient taking lactulose for diarrhea and excessive fluid and electrolyte losses.

◆ Ambulatory Care

The patient with cirrhosis may be faced with a prolonged course and the chance of life-threatening problems and complications. The patient and caregiver need to understand the importance of continual health care and medical supervision. Supportive measures include proper diet, rest, avoiding potentially hepatotoxic drugs, such as acetaminophen in high doses, and abstaining from alcohol. Abstinence from alcohol is important and results in improvement in most patients. However, some patients find abstinence difficult and need emotional support. Explore your own attitude toward the patient whose cirrhosis is from chronic alcohol use (Box 48.3). Always provide care without being condescending or judgmental. Treat patients with respect and concern for their well-being (see Chapter 11).

Cirrhosis is a chronic disease. People can live many years with symptoms and complications from cirrhosis. Cirrhosis affects all aspects of the patient's life. They may need to make major lifestyle changes, especially if chronic alcohol use is the primary cause. Provide information about community support programs, such as Alcoholics Anonymous, for help with chronic alcohol use.

Teach the patient and caregiver about complications and when to seek medical attention (Table 48.17). Include instructions about adequate rest periods, how to detect early signs of complications, skin care, drug therapy side effects, observation for bleeding, and protection from infection.

Referral to a community or home health nurse may help ensure patient adherence to prescribed therapy. Home care for the patient with cirrhosis focuses on helping the patient with activities of daily living while maintaining the highest level of wellness possible.

◆ Evaluation

Expected outcomes are that the patient with cirrhosis will:

- Maintain food and fluid intake adequate to meet nutrient needs

BOX 48.3 ETHICAL/LEGAL DILEMMAS

Rationing

Situation

T.H., a 43-year-old female patient with cirrhosis, is frequently admitted to the hospital. She has been told that her continued alcohol use will inevitably lead to her death. She now has GI bleeding and needs blood transfusions. She has a rare blood type that is hard to match. Should you ask for an ethics consult?

Ethical/Legal Points for Consideration

- *Rationing,* or the controlled distribution of scarce resources, is a difficult ethical problem. The needs of an individual patient or group of patients are weighed against the needs of many patients, who may have a greater chance of recovery, and the availability of resources.
- Health interests can supersede the interests or rights of a person. For example, in anticipation of an anthrax attack, the government could confiscate all relevant antibiotics and restrict their use to treat the disease.
- Two individual rights that must be considered are the (1) constitutional right to privacy and (2) right to consent to or refuse medical procedures and therapy.
- The competent adult is the only person who may consent to or refuse treatment for their health care problems.
- If T.H. consents to a blood transfusion, an intervening party may be allowed to refuse that treatment only given substantial intervening circumstances and not as a threat to compel adherent future behavior.
- If involved parties cannot reach an agreement, legal intervention by way of a court order may become necessary.

Discussion Questions

1. Do you think patients with diseases that have a behavioral component, like substance use, deserve aggressive treatment?
2. Would you request an ethics consult in T.H.'s case?

TABLE 48.17 PATIENT & CAREGIVER TEACHING

Cirrhosis

When teaching the patient and caregiver about management of cirrhosis, do the following:

1. Explain that cirrhosis is a chronic illness and requires continual health care.
2. Teach the symptoms of complications and when to seek medical attention to enable prompt treatment.
3. Teach the patient to avoid potentially hepatotoxic over-the-counter drugs, because the diseased liver is unable to metabolize them.
4. Encourage abstinence from alcohol. Continued use increases the rate of liver disease progression and risk for liver complications.
5. Teach the patient with esophageal or gastric varices to avoid aspirin and NSAIDs to prevent bleeding.
6. Teach the patient with portal hypertension and varices that straining at stool, coughing, sneezing, and retching and vomiting may increase the risk for variceal hemorrhage.

- Maintain skin integrity with relief of edema and itching
- Have normal fluid and electrolyte balance
- Acknowledge and get treatment for a substance use problem

ACUTE LIVER FAILURE

Acute liver failure, or *fulminant hepatic failure,* is a potentially life-threatening clinical syndrome.[22] It is characterized by a rapid onset of severe liver dysfunction in someone with no history of liver disease. It is often accompanied by hepatic encephalopathy.

The most common cause is drugs, usually acetaminophen. Other drugs that can cause acute liver failure include isoniazid, sulfa-containing drugs, and anticonvulsants. Herbal and dietary supplements can also cause acute liver failure. Drugs can cause hepatocyte damage by disrupting essential intracellular processes or causing an accumulation of toxic metabolic products. Other causes can include autoimmune hepatitis, viral hepatitis, especially HBV. HAV is a less common cause.

Outcomes depend on the cause. Cerebral edema, cerebellar herniation, and brainstem compression are the most common causes of death. Liver transplantation has a significant survival benefit in patients with a low probability of spontaneous recovery.

Clinical Manifestations and Diagnostic Studies

Manifestations include jaundice, coagulation problems, and encephalopathy. Changes in cognitive function are often the first clinical sign. Patients are susceptible to a wide variety of complications. These include cerebral edema, renal failure, hypoglycemia, metabolic acidosis, sepsis, and multiorgan failure.

Serum bilirubin is high. The PT time is prolonged. Liver enzyme levels (AST, ALT) are often markedly increased. Other laboratory tests include blood chemistries (especially glucose, since hypoglycemia may be present and need correction), complete blood count (CBC), acetaminophen level, screening for other drugs and toxins, viral hepatitis serology (especially HAV and HBV), serum ceruloplasmin (enzyme synthesized in liver) and α_1-antitrypsin levels, iron levels, ammonia levels, and autoantibodies (ANAs and ASMAs).

CT or MRI can provide information about the liver size and contour, presence of ascites or tumors, and patency of the blood vessels.

Interprofessional and Nursing Care

Acute liver failure may progress rapidly, with hour-by-hour changes in consciousness. The patient is usually transferred to the ICU once the diagnosis is made. Planning for transfer to a transplant center should begin in patients with grade 1 or 2 encephalopathy because they may worsen rapidly. Early transfer is important because the risks involved with patient transport may increase or even prevent transfer if stage 3 or 4 encephalopathy develops (Table 48.12).

Renal failure is a frequent complication. It may be due to dehydration, hepatorenal syndrome, or acute tubular necrosis. The frequency of renal failure is greater with acetaminophen overdose or other toxins with which direct renal toxicity occurs. Although few patients die of renal failure alone, it often increases the mortality risk and may worsen the prognosis. Protect renal function by maintaining adequate fluid balance, avoiding nephrotoxic agents (e.g., aminoglycosides, NSAIDs), and promptly identifying and treating infection.

Monitoring and management of hemodynamic and renal function, as well as glucose, electrolytes, and acid-base status, are critical. Conduct frequent neurologic evaluations for signs

of increased intracranial pressure. Position the patient with the head elevated at 30 degrees. Avoid excessive patient stimulation. Maneuvers that cause straining or Valsalva-like movements may increase intracranial pressure (ICP). See more about ICP monitoring in Chapter 61.

Assess the patient regularly for baseline level of consciousness and orientation. Report any changes to the HCP. Avoid the use of any sedatives due to their effects on mental status. The effects can be confused with worsening encephalopathy. Use only minimal doses of benzodiazepines due to their delayed metabolism by the failing liver. Closely observe the patient to prevent injuries and pad bedrails to avoid injury from possible seizures. Monitor intake and output for renal function. Provide good skin and oral care to avoid breakdown and infection.

Changes in level of consciousness may compromise oral intake. Many patients receive vitamin supplementation. Other factors, such as coagulation problems, may influence whether we start EN. An NG tube may be irritating to the nasal and esophageal mucosa and cause bleeding.

LIVER CANCER

Primary liver cancer starts in the liver. The most common types of liver cancer are hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (bile duct cancer). In 2018, there were about 42,220 cases of liver cancer with 30,200 liver cancer deaths in the United States.[23] Worldwide liver cancer is the 5th most common cancer and 2nd most common cause of cancer death.

Liver cancer is the most common cause of death in patients with cirrhosis. Cirrhosis caused by HCV is the most common cause of HCC in the United States, followed by NAFLD. About 2% of patients with cirrhosis develop liver cancer each year.

In primary liver cancer, lesions may be singular or numerous and nodular or diffusely spread over the entire liver. Some tumors infiltrate other organs, such as the gallbladder, or move into the peritoneum or the diaphragm. Primary liver cancer often metastasizes to the lung.

Metastatic cancer in the liver is more common than primary liver cancer (Fig. 48.10). The liver is a common site of metastatic growth because of its high rate of blood flow and extensive capillary network. Cancer cells in other parts of the body are often carried to the liver via the portal circulation.

Clinical Manifestations and Diagnostic Studies

The manifestations of early liver cancer can be absent or subtle. They are often a result of the underlying cirrhosis rather than from the actual liver tumor(s). The patient may present with hepatomegaly, splenomegaly, fatigue, peripheral edema, ascites, and other complications from portal hypertension. In late stages, patients will often have fever/chills, jaundice, anorexia, weight loss, palpable mass, and RUQ pain.

Diagnostic and screening tests for liver cancer are ultrasound, CT, and MRI. Recent advancements in MRI scanning have allowed for accurate diagnosis and staging of liver cancers without the need for a percutaneous biopsy. Sometimes, a biopsy is only done when diagnostic imaging studies are inconclusive or tissue is needed to guide treatment. Risks of a biopsy include bleeding and potential tumor cell seeding along the needle tract. Serum α-fetoprotein (AFP) levels combined with ultrasound have a high rate of detection of early-stage HCC.

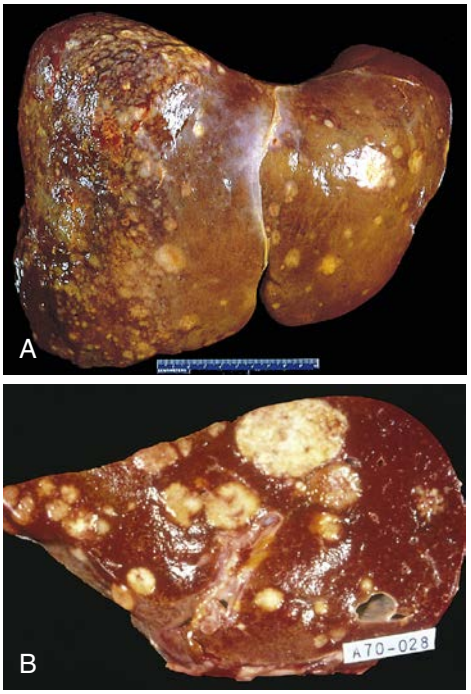

Fig. 48.10 Multiple hepatic metastases from a primary colon cancer. (A) Gross specimen showing outside of liver. (B) Liver section showing metastatic lesions. (*A,* From Kumar V, Abbas AK, Fausto N: *Robbins and Cotran pathologic basis of disease,* ed 7, Philadelphia, 2005, Saunders. *B,* From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

Interprofessional and Nursing Care

Prevention of liver cancer focuses on identifying and treating chronic HBV and HCV infections. Treatment of chronic alcohol use may lower the risk for liver cancer. Screening for at-risk patients (e.g., those with cirrhosis) usually involves a combination of serum AFP and CT, MRI, or ultrasound imaging of the liver.

Treatment depends on the stage of cancer: number, size, and location of tumors; involvement of any blood vessels; patient age and overall health; and extent of underlying liver disease. Liver resection (partial hepatectomy) offers the best chance for a cure. However, only about 15% of people have enough healthy liver tissue for this to be an option. The underlying cirrhosis and portal hypertension often compromise liver function and may cause liver failure after surgery. Many patients are diagnosed at an advanced stage of cancer when surgery is not an option. For those patients who have early-stage liver cancer and impaired liver function, liver transplantation offers a good prognosis.

Nonsurgical therapies include percutaneous ablation, chemoembolization, radioembolization, and systemic therapies. In ablation, a thin needle is inserted into the core of the tumor. Then, various substances can be injected (ethanol, acetic acid) and the temperature of the probe (radiofrequency, microwave, cryotherapy) can be altered to destroy the tumor. This

procedure is done percutaneously, laparoscopically, or through an open incision. It is limited by the number, size, and location of liver tumors. It is usually offered to patients with early-stage liver cancer. Complications are uncommon but include infection, bleeding, dysrhythmias, and skin burn.

In patients with multinodular HCC or intermediate-stage liver cancer, embolization of the tumors is another intervention. There are 2 usual options: transarterial chemoembolization (TACE) or transarterial radioembolization (TARE). TACE and TARE are minimally invasive procedures done by interventional radiologists. A catheter is placed via the femoral artery or radial artery and advanced to the arterial blood supply of the tumors. Either a chemotherapy drug (TACE) or radioactive beads (TARE) along with embolizing agents are then injected into the arteries of the tumor(s) region. TACE works by shutting off the blood supply to the tumors and exposing the tumor cells to the chemotherapy drug. TARE destroys the tumor(s) by slowly releasing radioactive material directly to the site of the tumor. It can take up to 3 months for complete results.

Systemic therapy options include chemotherapy and immune-based therapy, such as monoclonal antibodies, tyrosine kinase inhibitors, and immune checkpoint inhibitors (see Table 16.13).[24] These drugs have the potential to slow tumor progression and prolong life. Nursing care focuses on keeping the patient as comfortable as possible. Since these patients have the same problems as any patient with advanced liver disease, the interventions discussed for cirrhosis apply to these patients.

Although the prognosis for patients with liver cancer is poor, it is improving with early screening and surveillance programs for those with chronic hepatitis and/or cirrhosis. The cancer often progresses rapidly, with patients having complications from the advancing cancer and declining liver function. Without treatment, death may occur within 6 to 12 months, most often from hepatic encephalopathy or massive blood loss from GI bleeding.

LIVER TRANSPLANTATION

Liver transplantation has become an option for many people with end-stage liver disease or localized HCC. Liver disease related to errors of metabolism, specifically NAFLD, is the leading reason for liver transplantation followed by chronic viral hepatitis.[25] Other reasons include congenital biliary abnormalities (biliary atresia), inborn errors of metabolism, sclerosing cholangitis, acute liver failure, and chronic end-stage liver disease. In 2018, 11,514 patients were listed for a liver transplant in the United States with 8250 patients receiving a transplant.

Liver transplant candidates must go through a rigorous transplant evaluation prior to being placed on the transplant list. This is done to confirm the diagnosis of end-stage liver disease and to assess for other co-morbid conditions (e.g., cardiovascular disease, chronic kidney disease) that may affect the patient's surgical outcome. The evaluation includes physical assessment, laboratory tests (CBC, liver function tests), cardiac and pulmonary evaluations, endoscopy, CT scan, and psychologic testing. Potential recipients receive counseling about cigarette smoking and alcohol abstinence. Contraindications include severe extrahepatic disease, advanced HCC or other cancer, ongoing drug or chronic alcohol use, and inability to understand or adhere with the rigorous posttransplant care.

Liver transplantation is done using both deceased (cadaver) and live donor livers. The live donor liver transplant was first developed for children whose parents wanted to serve as donors. Today, some liver transplant centers are performing live liver transplant procedures for adults. In this procedure, the living person donates a part of their liver to another. However, live liver donation poses potential risks to the donor, including biliary problems, hepatic artery thrombosis, wound infection, postoperative ileus, and pneumothorax.

Because of the limited number of donor livers, when a liver becomes available for transplant, it may be divided into 2 parts (split liver transplant) and implanted into 2 recipients. The decision to use a split donor liver is based on the donor's size and health. The recipients of the split liver generally are smaller than the donor. The success rate of split liver transplantation is lower than that of whole organ transplantation.

Postoperative complications include bleeding, infection, and rejection. However, the liver is subject to a less aggressive immunologic attack than other organs, like the kidneys. Transplants and immunosuppressive therapy are discussed in Chapter 14.

Immunosuppressive therapy generally involves a combination of corticosteroids, a calcineurin inhibitor (cyclosporine or tacrolimus), and an antiproliferative agent (e.g., azathioprine). Tacrolimus is superior to cyclosporine in liver transplants. Standard immunosuppressive regimens often change over the course of the recipient's life. Corticosteroid withdrawal is relatively safe to do in liver transplant recipients.

About 80% of patients live more than 5 years after liver transplant. Long-term survival depends on the cause of liver failure (e.g., localized HCC, chronic HBV or HCV, biliary disease). Patients who have liver disease from HBV or HCV often have reinfection of the transplanted liver. For patients with HBV, treatment after surgery with IV HBIG and a nucleoside or nucleotide analog (used to treat HBV infection) has reduced the rates of reinfection of the transplanted liver. For patients with HCV, treatment with the new DAAs that can cure HCV infection has provided the opportunity to use HCV-positive liver grafts. The need for liver transplant may decrease in the HCV population. Research is ongoing to decide if DAAs should be started before or after transplant.

The patient who had a liver transplant needs highly skilled nursing care, either in an ICU or other specialized unit. After surgery, we monitor electrolyte levels, neurologic status, and urine output and note signs of bleeding, infection, and rejection. Common respiratory problems are pneumonia, atelectasis, and pleural effusions. To prevent these complications, encourage the patient to cough, deep breathe, use incentive spirometry, and frequently reposition. Measure the drainage from the Jackson–Pratt drain, NG tube, and T tube and note the color and consistency of the drainage at regular intervals.

The first 2 months after surgery are critical for monitoring for infection. Causes of infection can be viral, fungal, or bacterial. Fever may be the only sign of infection. Adhering to

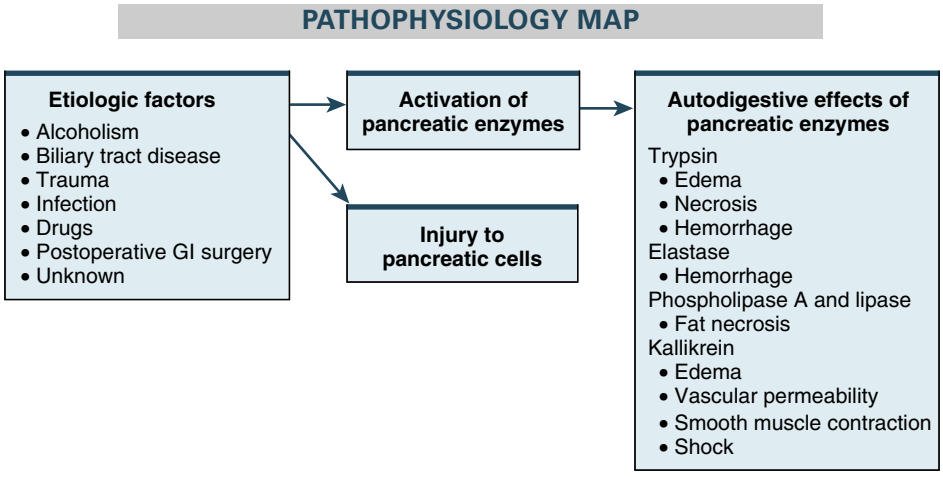

Fig. 48.11 Pathogenic process of acute pancreatitis.

the medication plan can be hard, especially in the beginning. Emotional support and teaching for the patient and caregiver are essential to the success of the patient with a liver transplant.

Gerontologic Considerations: Liver Disease in the Older Adult

The incidence of liver disease increases with age. The liver's size and metabolic breakdown of drugs decrease, and hepatobiliary function changes. The liver has a decreased capacity to respond to injury. This especially applies to regeneration after injury. Transplanted livers take longer to regenerate in the older adult.

Older adults are particularly vulnerable to DILI. This is due to several factors, including the increased use of multiple prescription and OTC drugs, which can lead to drug interactions and potential drug toxicity. Age-related decreases in liver function result in decreased drug metabolism and a decreased ability to recover from drug-induced injury.

A growing number of older adults have chronic HCV and the resulting cirrhosis. We may find antibodies to HCV and high liver enzymes during a routine health assessment in asymptomatic patients.

Lifetime health behaviors may influence the development of chronic liver disease in the older adult. Chronic alcohol use and obesity can contribute to cirrhosis, fatty liver inflammation (NASH), and liver failure. Because of many older adults' concomitant cardiovascular and lung diseases and possible anticoagulant therapy, variceal bleeding can cause significant morbidity and mortality and needs immediate medical intervention. In the older adult with liver disease, we sometimes misdiagnose hepatic encephalopathy as dementia.

Because older adults tend to have more comorbid conditions, transplantation may have more risks for complications. Therefore, older adults may not be good candidates for liver transplants.

PANCREAS PROBLEMS

ACUTE PANCREATITIS

Acute pancreatitis is an acute inflammation of the pancreas.[26] Spillage of pancreatic enzymes into surrounding pancreatic tissue causes autodigestion and severe pain. The degree of inflammation varies from mild edema to severe hemorrhagic necrosis.

Etiology and Pathophysiology

Many factors can cause injury to the pancreas. In the United States, the most common cause is gallbladder disease (gallstones), which is more common in women. The second most common cause is chronic alcohol use. This is more common in men.

Other less common causes include drug reactions, pancreatic cancer, and hypertriglyceridemia (serum levels over 1000 mg/dL). Biliary sludge and microlithiasis, a mix of cholesterol crystals and calcium salts, can be present in patients with acute pancreatitis.

The most common pathogenic mechanism in acute pancreatitis is autodigestion of the pancreas (Fig. 48.11). The causative factors injure pancreatic cells or activate the pancreatic enzymes in the pancreas rather than in the intestine. This may be due to reflux of bile acids into the pancreatic ducts through an open or distended sphincter of Oddi. This reflux may be caused by blockage created by gallstones. Obstruction of pancreatic ducts results in pancreatic ischemia.

The exact mechanism by which chronic alcohol use predisposes a person to pancreatitis is not known. We think that alcohol increases the production of digestive enzymes in the pancreas.

The pathophysiologic involvement of acute pancreatitis is either *mild pancreatitis* (*edematous* or *interstitial pancreatitis*) or *severe pancreatitis* (*necrotizing pancreatitis*) (Fig. 48.12). In severe pancreatitis, about half the patients have permanent decreases in pancreatic endocrine and exocrine function. Patients with severe pancreatitis are at high risk for developing pancreatic necrosis, organ failure, and septic complications. This results in an overall fatality rate of 9%.

Clinical Manifestations

Abdominal pain is the main manifestation. The pain is due to distention of the pancreas, peritoneal irritation, and biliary tract obstruction. It is usually in the left upper quadrant but may be

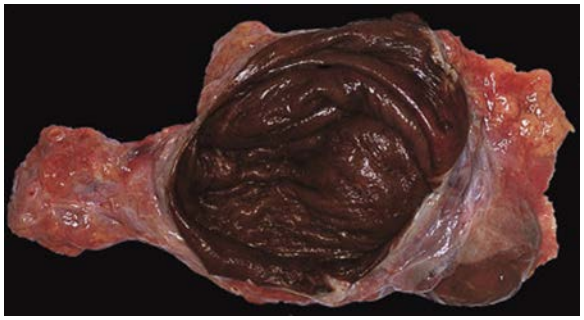

Fig. 48.12 Pancreatitis with large pseudocyst. (From Connolly A, Finkbeiner W, Ursell P, et al.: *Atlas of gross autopsy pathology*, ed 3, Philadelphia, 2016, Elsevier.)

mid-epigastric. It often radiates to the back due to the retroperitoneal location of the pancreas. The pain has a sudden onset. It is described as severe, deep, piercing, and continuous or steady. Eating worsens the pain. Pain is not relieved by vomiting and may be accompanied by flushing, cyanosis, and dyspnea. It often starts when the patient is recumbent. The patient may assume various positions involving flexion of the spine to try to relieve the severe pain.

Other manifestations include nausea and vomiting, low-grade fever, leukocytosis, hypotension, tachycardia, and jaundice. Abdominal tenderness with muscle guarding is common.

Bowel sounds may be decreased or absent. Paralytic ileus may occur and causes marked abdominal distention. The lungs are often involved with crackles present. Intravascular damage from circulating trypsin (a proteolytic enzyme) may cause areas of cyanosis or greenish to yellow-brown discoloration of the abdominal wall. Other areas of bruising are the flanks (*Grey Turner spots* or *sign,* a bluish flank discoloration) and the periumbilical area (*Cullen sign,* a bluish periumbilical discoloration). These result from seepage of bloodstained exudate from the pancreas and may occur in severe cases.

Shock may occur from bleeding into the pancreas, toxemia from the activated pancreatic enzymes, or hypovolemia due to fluid shift into the retroperitoneal space (massive fluid shifts).

Complications

The severity of acute pancreatitis depends on the extent of pancreatic destruction. Acute pancreatitis can be life threatening. Some patients recover completely. Others have recurring attacks, and some develop chronic pancreatitis.

Two significant local complications are pseudocyst and abscess. A *pancreatic pseudocyst* is an accumulation of fluid, pancreatic enzymes, tissue debris, and inflammatory exudates surrounded by a wall next to the pancreas. Manifestations are abdominal pain, palpable epigastric mass, nausea, vomiting, and anorexia. The serum amylase level is often high. CT, MRI, and endoscopic ultrasound (EUS) may detect a pseudocyst. The cysts usually resolve spontaneously within a few weeks but may perforate, causing peritonitis or rupture into the stomach or the duodenum. Treatment options include surgical drainage, percutaneous catheter placement and drainage, and endoscopic drainage.

When a pseudocyst gets infected, a *pancreatic abscess* results from extensive necrosis in the pancreas. It may rupture or perforate into adjacent organs. Manifestations of an abscess include upper abdominal pain, abdominal mass, high fever, and leukocytosis. Pancreatic abscesses need prompt surgical drainage to prevent sepsis.

The main systemic complications are cardiovascular and pulmonary (pleural effusion, atelectasis, pneumonia, and acute respiratory distress syndrome [ARDS]). Pulmonary complications are due to the passage of exudate-containing pancreatic enzymes from the peritoneal cavity through transdiaphragmatic lymph channels. Enzyme-induced inflammation of the diaphragm occurs, with the result being atelectasis caused by reduced diaphragm movement. Trypsin can activate prothrombin and plasminogen, increasing the patient's risk for intravascular thrombi, pulmonary emboli, and DIC. Hypotension can occur from fluid shifts and sepsis.

Tetany, which can be caused by hypocalcemia, is a sign of severe disease. It is due in part to the combining of calcium and fatty acids during fat necrosis. We do not understand the exact mechanisms of how or why hypocalcemia occurs. Patients with severe acute pancreatitis are at risk for abdominal compartment syndrome from intraabdominal hypertension and edema.

TABLE 48.18 Diagnostic Findings

Acute Pancreatitis

Laboratory Test	Abnormal Finding
Serum amylase	↑
Serum lipase	↑
Urinary amylase	↑
Blood glucose	↑
Serum calcium	↓
Serum triglycerides	↑

Diagnostic Studies

The primary diagnostic tests for acute pancreatitis are serum amylase and lipase (Table 48.18). The serum amylase level is usually high early and stays high for 24 to 72 hours. Serum lipase level is high in acute pancreatitis. It is an important test because other disorders (e.g., mumps, cerebral trauma) may increase serum amylase levels. Other serum findings include an increase in liver enzymes, triglycerides, glucose, and bilirubin and a decrease in calcium.

Diagnostic testing is aimed at determining the cause. An abdominal ultrasound, x-ray, or contrast-enhanced CT scan may identify pancreatic problems. CT scan is the best imaging test for pancreatitis and related complications, such as pseudocysts and abscesses. ERCP is an option (although ERCP can cause acute pancreatitis), along with EUS, magnetic resonance cholangiopancreatography (MRCP), and angiography. Chest x-rays may show atelectasis and pleural effusions.

Interprofessional Care

Goals of interprofessional care include (1) pain relief, (2) prevent or alleviate shock, (3) reduce pancreatic secretions, (4) correct fluid and electrolyte imbalances, (5) prevent or treat infection, and (6) remove the precipitating cause, if possible (Table 48.19).

TABLE 48.19 Interprofessional Care

Acute Pancreatitis

Diagnostic Assessment

- History and physical assessment
- Serum amylase and lipase
- Blood glucose
- Serum calcium
- Serum triglycerides
- Flat plate of the abdomen
- Abdominal ultrasound
- Endoscopic ultrasound (EUS)
- MRCP
- ERCP
- Contrast-enhanced CT of pancreas
- Chest x-ray

Management

- NPO with NG tube to suction
- Albumin (if shock present)
- IV calcium gluconate (10%) (if tetany present)
- Lactated Ringer's solution

Drug Therapy

- Pain medication (e.g., morphine)
- PPI (e.g., omeprazole)
- Antibiotics (if necrotizing pancreatitis)

TABLE 48.20 Drug Therapy

Acute and Chronic Pancreatitis

Drug	Mechanism of Action
Acute Pancreatitis	
Antacids	Neutralize gastric hydrochloric (HCl) acid secretion ↓ Production and secretion of pancreatic enzymes and bicarbonate
Antispasmodics (e.g., dicyclomine)	↓ Vagal stimulation, motility, pancreatic outflow (↓ volume and concentration of bicarbonate and enzyme secretion) Contraindicated in paralytic ileus
Carbonic anhydrase inhibitor (acetazolamide)	↓ Volume and bicarbonate concentration of pancreatic secretion
Morphine	Pain relief
PPIs (e.g., omeprazole)	↓ HCl acid secretion (HCl acid stimulates pancreatic activity)
Chronic Pancreatitis	
Insulin	Treat diabetes or hyperglycemia, if needed
Pancreatic enzyme products (pancrelipase [Pancrease, Zenpep, Creon, Viokace])	Replacement therapy for pancreatic enzymes

Conservative Therapy

Treatment focuses on supportive care. This includes aggressive hydration, pain management, managing metabolic complications, and minimizing pancreatic stimulation. Treatment and control of pain are very important. We may give IV opioid analgesics. Pain medications may be given with an antispasmodic agent. Atropine and other anticholinergic drugs are avoided when paralytic ileus is present because they can decrease GI mobility, making the problem worse. Other drugs that relax smooth muscles (spasmolytics), such as nitroglycerin or papaverine, may be used. Supplemental O_2 is used to maintain O_2 saturation greater than 95%. In patients with severe pancreatitis, we monitor serum glucose levels for hyperglycemia.

If shock is present, we give blood volume replacements. The patient may receive plasma or plasma volume expanders, such as dextran or albumin. Lactated Ringer's solution or other electrolyte solutions can correct fluid and electrolyte problems. Central venous pressure readings can help determine fluid replacement requirements. Vasoactive drugs, such as dopamine, may be needed to increase systemic vascular resistance in those with hypotension.

It is important to reduce or suppress pancreatic enzymes to decrease stimulation of the pancreas and allow it to rest. We do this in several ways. First, the patient is NPO. Second, NG suction may be used to reduce vomiting and gastric distention and to prevent gastric acidic contents from entering the duodenum. Certain drugs are given to suppress gastric acid secretion (Table 48.20).

The inflamed and necrotic pancreatic tissue is a good medium for bacterial growth. In patients with acute necrotizing pancreatitis, infection is the leading cause of morbidity and mortality. Therefore, it is important to prevent infections. Because many of the organisms come from the intestine, EN reduces the risk for necrotizing pancreatitis. Monitor the patient closely so that antibiotic therapy can be started early if necrosis and infection occur. Endoscopic- or CT-guided percutaneous aspiration with Gram stain and culture may be done.

Surgical Therapy

When the acute pancreatitis is related to gallstones, an urgent ERCP plus endoscopic *sphincterotomy* (severing of the muscle layers of the sphincter of Oddi) may be done. Laparoscopic cholecystectomy may follow ERCP to reduce the potential for recurrence. Surgery may be done when the diagnosis is uncertain or for the patient does not respond to conservative therapy.

A patient may need drainage of necrotic fluid collections. This is done surgically, under CT guidance, or endoscopically. Percutaneous drainage of a pseudocyst can be done, and a drainage tube left in place.

Drug Therapy

Several different drugs are used to prevent and treat problems associated with pancreatitis (Table 48.20). Currently, there are no drugs that cure pancreatitis.

Nutrition Therapy

Initially, the patient with acute pancreatitis is NPO to reduce pancreatic secretion. Depending on the severity of the pancreatitis, we start EN. Because of infection risk, PN is reserved for patients who cannot tolerate EN (see Chapter 44). If the patient receives IV lipids, monitor blood triglyceride levels.

As pancreatitis resolves, the patient resumes oral intake. When food is allowed, start with small, frequent feedings.

The diet is high in carbohydrate content because that is the least stimulating to the exocrine part of the pancreas. Suspect intolerance to oral foods when the patient reports pain, has increasing abdominal girth, or has increased serum amylase and lipase levels. Supplemental fat-soluble vitamins may be given.

CHECK YOUR PRACTICE

The family member of your patient approaches you and is upset that her mother has not been given any food. The patient is admitted for acute pancreatitis. "My mother has been here for 8 hours and she is starving. Why can't you give her something to eat?"

- How would you respond?
- What information and teaching would you provide?

NURSING MANAGEMENT: ACUTE PANCREATITIS

Assessment

Subjective and objective data that should be obtained from a person with acute pancreatitis are outlined in Table 48.21.

Clinical Problems

Clinical Problems for the patient with acute pancreatitis may include:

- Pain
- Fluid imbalance
- Electrolyte imbalance
- Nutritionally compromised

Additional information on clinical problems and interventions for the patient with acute pancreatitis is presented in eNursing Care Plan 48.3 available on the website for this chapter.

Planning

The overall goals are that the patient with acute pancreatitis will have (1) pain relief, (2) normal fluid and electrolyte balance, (3) minimal to no complications, and (4) no recurrent attacks.

Implementation

Health Promotion

The major factors involved in health promotion are (1) assessing the patient for risk factors and (2) encouraging early treatment of these factors to prevent acute pancreatitis. Encourage the patient to cease alcohol intake, especially if they have had pancreatitis before. Recurrent attacks of pancreatitis may become milder or disappear if they stop alcohol use. Encourage early diagnosis and treatment of biliary tract disease, such as gallstones.

Acute Care

During the acute phase, it is important to monitor vital signs. Hypotension, fever, and tachypnea may compromise hemodynamic stability. Monitor the response to IV fluids. Closely assess fluid and electrolyte balance. Frequent vomiting, along with gastric suction, may result in decreased chloride, sodium, and potassium levels.

TABLE 48.21 NURSING ASSESSMENT

Acute Pancreatitis

Subjective Data

Important Health Information

Health history: Biliary tract disease, alcohol use, abdominal trauma, duodenal ulcers, infection, metabolic disorders

Medications: Thiazides, NSAIDs

Surgery or other treatments: Surgery on the pancreas, stomach, duodenum, or biliary tract. Endoscopic retrograde cholangiopancreatography (ERCP)

Functional Health Patterns

Health perception–health management: Chronic alcohol use, fatigue

Nutritional-metabolic: Nausea and vomiting, anorexia

Activity-exercise: Dyspnea

Cognitive-perceptual: Severe midepigastric or left upper quadrant pain that may radiate to the back, worsened by food and alcohol intake, unrelieved by vomiting

Objective Data

Cardiovascular

Tachycardia, hypotension

GI

Abdominal distention, tenderness, and muscle guarding. Decreased bowel sounds

General

Restlessness, anxiety, low-grade fever

Respiratory

Tachypnea, basilar crackles

Skin

Flushing, diaphoresis, discoloration of abdomen and flanks, cyanosis, jaundice. Decreased skin turgor, dry mucous membranes

Possible Diagnostic Findings

- ↑ Serum amylase and lipase, leukocytosis, hyperglycemia, hypocalcemia. Abnormal ultrasound and CT scans of pancreas, abnormal ERCP or MRCP

Respiratory failure may develop in the patient with severe acute pancreatitis. Assess respiratory function (e.g., lung sounds, O_2 saturation levels). If ARDS develops, the patient may need intubation and mechanical ventilation support.

SAFETY ALERT

Respiratory Distress in Acute Pancreatitis

- Assess for respiratory distress in the patient with severe acute pancreatitis.
- Listen to lung sounds and monitor O_2 saturation on a regular basis.

Because hypocalcemia can occur, observe for symptoms of tetany, including jerking, irritability, and muscular twitching. Numbness or tingling around the lips and in the fingers is an early sign of hypocalcemia. Assess the patient for a positive Chvostek sign or Trousseau sign (see Fig. 17.15). Give calcium gluconate as ordered to treat symptomatic hypocalcemia. Monitor serum magnesium levels since hypomagnesemia may develop.

A major focus of your care is pain relief. Pain and restlessness can increase the metabolic rate and contribute to hemodynamic instability. Opioids may be used for pain relief. Assess and document the duration of pain relief. Comfortable positioning, frequent changes in position, and relief of nausea and vomiting help reduce the restlessness that usually accompanies the pain. Assuming positions that flex the trunk and draw the knees up to the abdomen may decrease pain. A side-lying position with the head elevated 45 degrees decreases tension on the abdomen and may help.

For the patient who is on NPO status or has an NG tube, provide frequent oral and nasal care to relieve the dryness of the mouth and nose. Oral care is essential to prevent parotitis. If the patient is taking anticholinergics to decrease GI secretions, the mouth will be especially dry. If the patient is taking antacids to neutralize gastric acid secretion, they should be sipped slowly or inserted in the NG tube.

Observe for fever and other signs of infection in the patient with acute pancreatitis. Respiratory tract infections are common and cause the patient to take shallow, guarded abdominal breaths. Measures to prevent respiratory tract infections include turning, coughing, deep breathing, and assuming a semi-Fowler's position.

Assess for signs of paralytic ileus, renal failure, and mental changes. Determine the blood glucose level to assess damage to the β cells of the islets of Langerhans in the pancreas.

Patients who had surgery to drain necrotic fluid or treat a cyst may need special wound care for an anastomotic leak or a fistula. To prevent skin irritation, use skin barriers (e.g., Stomahesive, Karaya Paste), pouching, and drains. In addition to protecting the skin, pouching allows a more accurate determination of fluid losses and increases patient comfort. Sterile pouching systems are available. Consult with a clinical specialist or wound, ostomy, and continence nurse (WOCN).

Ambulatory Care

After acute pancreatitis, the patient may need home care follow-up. Because of loss of physical and muscle strength, physical therapy may be needed. Continued care to prevent infection and detect any complications is important. Counseling about abstinence from alcohol is important to prevent the patient from experiencing future attacks of acute pancreatitis and developing chronic pancreatitis. Because nicotine can stimulate the pancreas, they should avoid smoking.

Teach the patient and caregiver about the treatment plan, including the importance of taking the required medications and following the recommended diet. Diet teaching should include fat restriction. Fats stimulate cholecystokinin secretion, which then stimulates the pancreas. Encourage carbohydrates as they are less stimulating to the pancreas. Teach the patient to avoid crash and binge dieting because they can precipitate attacks.

Teach the patient and caregiver to recognize and report symptoms of infection, diabetes, or steatorrhea (foul-smelling, fatty stools). These changes indicate ongoing destruction of pancreatic tissue and pancreatic insufficiency. The patient may need exogenous enzyme supplementation.

Evaluation

The expected outcomes are that the patient with acute pancreatitis will:

- Have adequate pain control
- Maintain adequate fluid and electrolyte balance
- Be knowledgeable about the treatment plan to restore health
- Get help for alcohol use and smoking cessation (if needed)

CHRONIC PANCREATITIS

Chronic pancreatitis is a continuous, prolonged, inflammatory, and fibrosing process of the pancreas. The pancreas is progressively destroyed as it is replaced by fibrotic tissue. Strictures and calcifications may occur in the pancreas.

Etiology and Pathophysiology

The most common cause of nonobstructive pancreatitis (the most common type of chronic pancreatitis) is chronic alcohol use. There is inflammation and sclerosis, mainly in the head of the pancreas and around the pancreatic duct. In some people who drink alcohol, a genetic factor may predispose them to the direct toxic effect of the alcohol on the pancreas.

The most common cause of obstructive pancreatitis is inflammation of the sphincter of Oddi from gallstones. Cancer of the ampulla of Vater, duodenum, or pancreas can also cause this type of chronic pancreatitis.

Chronic pancreatitis may follow acute pancreatitis. It may occur with systemic diseases (e.g., systemic lupus erythematosus), autoimmune pancreatitis, and cystic fibrosis. Some patients may not have an identifiable risk factor (idiopathic pancreatitis).

Clinical Manifestations

As with acute pancreatitis, a major manifestation of chronic pancreatitis is abdominal pain. The patient may have episodes of acute pain, but it usually is chronic (recurrent attacks at intervals of months or years). The attacks may become more frequent until they are almost constant. Sometimes they decrease as pancreatic fibrosis develops. The pain occurs in the same areas as in acute pancreatitis. It is usually described as a heavy, gnawing feeling or sometimes as burning and cramp-like. Food or antacids do not relieve the pain.

Other manifestations include symptoms of pancreatic insufficiency. These include malabsorption with weight loss, constipation, mild jaundice with dark urine, steatorrhea, and diabetes. The steatorrhea may become severe, with voluminous, foul-smelling, fatty stools. Some abdominal tenderness may be present.

Chronic pancreatitis can cause a variety of complications. These include pseudocyst formation, bile duct or duodenal obstruction, pancreatic ascites or pleural effusion, splenic vein thrombosis, pseudoaneurysms, and pancreatic cancer.

Diagnostic Studies

Confirming the diagnosis of chronic pancreatitis can be hard. The diagnosis is based on the patient's signs and symptoms, laboratory studies, and imaging. In chronic pancreatitis, serum

amylase and lipase levels may be increased slightly or not at all, depending on the degree of pancreatic fibrosis. Serum bilirubin and alkaline phosphatase levels may be increased. There is usually mild leukocytosis and a high sedimentation rate.

ERCP can visualize the pancreatic and common bile ducts. Imaging studies, such as CT, MRI, MRCP, and abdominal ultrasound, can show a variety of changes, including calcifications, ductal dilation, pseudocysts, and enlargement of the pancreas.

Stool samples are examined for fecal fat content. Deficiencies of fat-soluble vitamins and cobalamin, glucose intolerance, and diabetes may occur. A secretin stimulation test can assess the degree of pancreatic dysfunction.

Interprofessional and Nursing Care

When the patient with chronic pancreatitis has an acute attack, the therapy is identical to that for acute pancreatitis. At other times, the focus is on preventing further attacks, pain relief, and controlling pancreatic exocrine and endocrine insufficiency. It sometimes takes frequent doses of analgesics (morphine, fentanyl patch) to relieve the pain if diet measures and enzyme replacement are not effective.

Diet, pancreatic enzyme replacement, and diabetes control are ways to control pancreatic insufficiency. Small, bland, frequent meals that are low in fat decrease pancreatic stimulation. Smoking can accelerate progression of chronic pancreatitis. Teach the patient not to consume alcohol and caffeinated beverages. If the patient is dependent on alcohol, refer the patient to other resources as needed (see Chapter 11).

Pancreatic enzyme products, such as pancrelipase, contain amylase, lipase, and trypsin. They are used to replace the deficient pancreatic enzymes. The enzymes are usually enteric coated to prevent their breakdown or inactivation by gastric acid. They are usually taken with meals and snacks. Teach the patient and caregiver to monitor stools for steatorrhea to help determine the effectiveness of the enzymes. Bile salts may be given to help with fat-soluble vitamin (A, D, E, and K) absorption and prevent further fat loss.

If diabetes develops, the patient needs insulin (most often) or oral hypoglycemic agents. Teach the patient about testing blood glucose levels and drug therapy (see Chapter 53). While acid-neutralizing drugs (e.g., antacids) and acid-inhibiting drugs (e.g., H_2-receptor blockers, PPIs) may be given to control gastric acidity, they have little overall effect on patient outcomes. Antidepressants can reduce any neuropathic pain.

Treatment sometimes requires endoscopic therapy or surgery. When biliary disease is present or obstruction or pseudocyst develops, surgery may be needed. Surgical procedures can divert bile flow or relieve ductal obstruction. A choledochojejunostomy diverts bile around the ampulla of Vater, where there may be spasm or hypertrophy of the sphincter. In this procedure, the common bile duct is anastomosed into the jejunum. Another surgical diverting procedure is the Roux-en-Y pancreatojejunostomy. The pancreatic duct is opened, and an anastomosis made with the jejunum. Pancreatic drainage procedures can relieve ductal obstruction and are often done with ERCP. Some patients may have an ERCP with sphincterotomy and/or stent placement at the site of obstruction. These patients need follow-up procedures, such as ERCP, to either exchange or remove the stent.

PANCREATIC CANCER

Most pancreatic tumors are adenocarcinomas that begin in the epithelium of the ductal system. More than half of the tumors occur in the head of the pancreas. As the tumor grows, the common bile duct becomes obstructed and obstructive jaundice develops. Tumors starting in the body or tail often remain silent until their growth is advanced. Most cancers have metastasized at the time of diagnosis. Pancreatic cancer has a low incidence rate of around 1.6%. The median age at diagnosis is around 68 years of age.[27] The prognosis of a patient with cancer of the pancreas is poor. Most patients die within 5 to 12 months of diagnosis. The 5-year survival rate is only 9%.

Etiology and Pathophysiology

The cause of pancreatic cancer is unknown. The most established risk factor is cigarette smoking. Smokers are 2 to 3 times more likely to develop pancreatic cancer than nonsmokers. The risk is related to both the duration and number of cigarettes smoked. Other risk factors include chronic pancreatitis, diabetes, age, family history of pancreatic cancer, high-fat diet, and exposure to chemicals, such as benzidine. Blacks have the highest incidence of pancreatic cancer.

Clinical Manifestations

The signs and symptoms of pancreatic cancer are similar to those of chronic pancreatitis.[28] They include abdominal pain (dull, aching), anorexia, rapid and progressive weight loss, nausea, and jaundice. Common manifestations with cancer of the head of the pancreas are pain, jaundice, and weight loss. In general, pain is common and is related to the cancer's location. The pain is often in the upper abdomen or left hypochondrium and often radiates to the back. It is often related to eating and occurs at night. Extreme, unrelenting pain is related to extension of the cancer into the retroperitoneal tissues and nerve plexuses. Pruritus may accompany obstructive jaundice. Weight loss is due to poor digestion and absorption caused by a lack of digestive enzymes from the pancreas.

Diagnostic Studies

Abdominal ultrasound or EUS, spiral CT scan, ERCP, MRI, and MRCP are the most often used diagnostic imaging techniques for pancreatic cancer. EUS involves imaging the pancreas with the use of an endoscope positioned in the stomach and duodenum. EUS also allows for fine-needle aspiration of the tumor for biopsy. CT scan is often the first study and gives information on metastasis and vascular involvement of the tumor. ERCP allows us to see the pancreatic duct and biliary system. With ERCP, pancreatic secretions and tissue can be obtained for biopsy and analysis of tumor markers. MRI, PET, PET/CT scans, and MRCP may be done to confirm a cancer diagnosis and determine staging. They can also monitor progress and response to therapy.

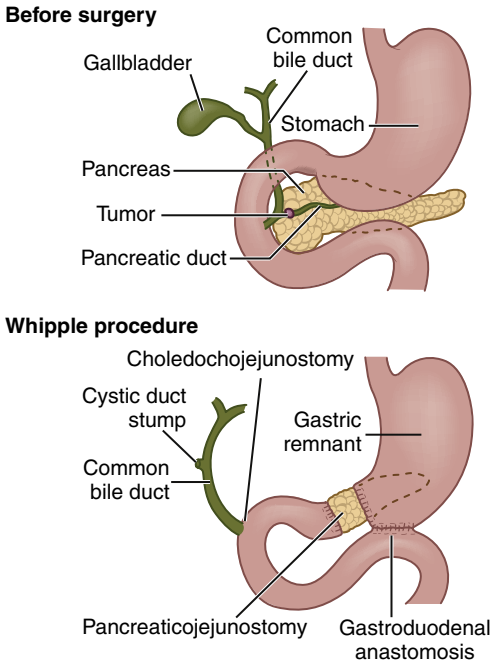

Fig. 48.13 Whipple procedure or radical pancreaticoduodenectomy. This surgery involves resecting the proximal pancreas, adjoining duodenum, distal part of the stomach, and distal part of the common bile duct. An anastomosis of the pancreatic duct, common bile duct, and stomach to the jejunum is done. (From Butcher GP: *Gastroenterology: an illustrated colour text,* London, 2004, Churchill Livingstone.)

Tumor markers are used both for diagnosing pancreatic cancer and monitoring the response to treatment. Cancer-associated antigen 19-9 (CA 19-9) is increased in pancreatic cancer. It is the most commonly used tumor marker. However, CA 19-9 also can be increased in gallbladder cancer and benign conditions, such as acute and chronic pancreatitis, hepatitis, and biliary obstruction.

Interprofessional Care

Surgery is the most effective treatment for pancreatic cancer. Only 15% to 20% of patients have resectable tumors at the time of diagnosis. With the use of neoadjuvant chemotherapy (treatment before surgery), more patients can eventually become surgical candidates. The type of surgery depends on the size and location of the tumor. Pancreatic head tumors require the classic Whipple procedure or pancreaticoduodenectomy (Fig. 48.13). In the Whipple surgery, the proximal pancreas (proximal pancreatectomy), along with duodenum (duodenectomy), distal segment of the common bile duct, and distal part of the stomach (partial gastrectomy) are removed. The pancreatic duct, common bile duct, and stomach are anastomosed to the jejunum. Pancreatic body and/or tail tumors require a distal pancreatectomy procedure. Sometimes, a total pancreatectomy is done. It causes diabetes and the patient must receive insulin therapy and pancreatic enzyme supplements for life. If the pancreatic tumor cannot be removed surgically, palliative measures, such as a cholecystojejunostomy, to relieve biliary obstruction and/or endoscopically placed biliary stents, can be done.

Radiation therapy alone has little effect on survival but may help with pain relief. External radiation is most common, but implanting internal radiation seeds into the tumor has been used. The role of chemotherapy is limited and can have a significant side effect profile. Chemotherapy usually consists of fluorouracil and gemcitabine (Gemzar) either alone or in combination with agents such as capecitabine (Xeloda), paclitaxel (Abraxane), erlotinib (Tarceva), or irinotecan (Onivyde). Erlotinib is a targeted therapy drug (see Chapter 16).

❖ NURSING MANAGEMENT: PANCREATIC CANCER

Because the patient with pancreatic cancer has many of the same problems as the patient with pancreatitis, nursing care includes many of the same measures. Provide symptomatic and supportive nursing care. This includes giving medications and providing comfort measures to relieve pain. Psychologic support is essential, especially during times of distress.

Adequate nutrition is important. Frequent and supplemental feedings may be needed. Include measures to stimulate the appetite as much as possible and to manage anorexia, nausea, and vomiting. If the patient is receiving radiation therapy, observe for adverse reactions, such as anorexia, nausea, vomiting, and skin irritation.

The prognosis for a patient with pancreatic cancer is poor. Help the patient and caregiver cope with the diagnosis and prognosis. Chapter 10 provides information on palliative and end-of-life care.

BILIARY TRACT PROBLEMS

CHOLELITHIASIS AND CHOLECYSTITIS

The most common disorder of the biliary system is **cholelithiasis** (stones in the gallbladder) (Fig. 48.14). The gallstones may lodge in the neck of the gallbladder or in the cystic duct. **Cholecystitis** (inflammation of the gallbladder wall) is usually associated with gallstones. They usually occur together, although a person can have gallstones without cholecystitis. Cholecystitis may be acute or chronic.

Gallbladder disease is a common health problem in the United States. Up to 10% of American adults have cholecystitis caused by gallstones. The actual number is not known because many persons with stones are asymptomatic. *Cholecystectomy* (removal of the gallbladder) is among the most common surgeries done in the United States.

Gallstones are more common in women, especially multiparous women and women over 40 years of age (Box 48.4). Postmenopausal women on estrogen replacement therapy and younger women on oral contraceptives are at an increased risk for gallbladder disease. Oral contraceptives affect cholesterol production and increase gallbladder cholesterol saturation. Other factors are a sedentary lifestyle, a familial tendency, and obesity. Obesity causes increased secretion of cholesterol in bile. The incidence of gallbladder disease is especially high in the Native American population.

Fig. 48.14 Cholesterol gallstones in a gallbladder that was removed. (From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

BOX 48.4 BIOLOGIC SEX CONSIDERATIONS

Cholelithiasis

Men
- Incidence is lower in men

Women
- Pregnancy and estrogen replacement therapy increase risk
- Obesity increases the risk, especially for women

Etiology and Pathophysiology

Cholelithiasis

We do not know the cause of gallstones. They develop when the balance that keeps cholesterol, bile salts, and calcium in solution is changed so that these substances precipitate. Other components of bile that precipitate into stones are bilirubin and protein. Mixed cholesterol stones, which are mainly cholesterol, are the most common gallstones.

Conditions that lead to gallstone formation include supersaturation of bile with cholesterol, decreased bile acids that dissolve cholesterol, excess mucus production, and gallbladder dysmotility and stasis. Normally, bile contains enough chemicals to dissolve the cholesterol the liver excretes. If the liver excretes more cholesterol than bile can dissolve, the excess cholesterol may form into crystals and eventually stones. The bile secreted by the liver may be supersaturated with cholesterol (lithogenic bile). The bile in the gallbladder then becomes supersaturated with cholesterol and precipitation of cholesterol occurs in the gallbladder. Bile stasis can promote the progression of supersaturation and changes in the chemical composition of the bile (biliary sludge). Immobility, pregnancy, and inflammatory or obstructive lesions in the biliary system decrease bile flow. Hormonal factors during pregnancy may cause delayed emptying of the gallbladder, resulting in bile stasis.

The stones may stay in the gallbladder or migrate to the cystic duct or the common bile duct. They cause pain as they pass through the ducts. Stones can lodge in the ducts and cause an obstruction. Small stones are more likely to move into a duct and cause obstruction. Table 48.22 describes the changes and manifestations that occur when the stones obstruct the common bile duct. If the blockage occurs in the cystic duct, the bile can continue to flow into the duodenum directly from the liver. However, when the bile in the gallbladder cannot escape, bile stasis may lead to cholecystitis.

Cholecystitis

Cholecystitis is most often associated with obstruction caused by gallstones or biliary sludge. Cholecystitis in the absence of obstruction *(acalculous cholecystitis)* occurs most often in older adults and in patients who are critically ill. Acalculous cholecystitis is also associated with prolonged immobility and fasting, prolonged PN, and diabetes. We think the main cause of this illness is bile stasis. Critically ill patients are more predisposed because of increased bile viscosity due to fever and dehydration and because of prolonged absence of oral feeding resulting in a decrease or absence of cholecystokinin-induced gallbladder contraction. Other risk factors include adhesions, cancer, anesthesia, and opioids.

Once acalculous cholecystitis is present, secondary infection with enteric pathogens, including *E. coli, Enterococcus faecalis, Klebsiella, Pseudomonas,* and *Proteus,* is common. Perforation occurs in severe cases.

Inflammation is the major issue. It may be confined to the mucous lining or involve the entire wall of the gallbladder. During an acute attack of cholecystitis, the gallbladder is edematous and hyperemic. It may be distended with bile or pus. The cystic duct is also involved and may become occluded. The wall of the gallbladder becomes scarred after an acute attack. Decreased functioning will occur if large amounts of tissue become fibrotic.

Clinical Manifestations

Gallstones may cause a range of symptoms. The severity depends on whether the stones are stationary or mobile and whether obstruction is present. When a stone is lodged in the ducts or when stones are moving through the ducts, spasms may result in response to the stone. This sometimes causes severe pain, which is termed *biliary colic,* even though the pain is rarely colicky. The pain is more often steady. The pain can be excruciating and accompanied by tachycardia, diaphoresis, and prostration. The severe pain may last up to an hour, and when it subsides, there is residual RUQ tenderness. Pain often occurs 3 to 6 hours after a high-fat meal or when the patient lies down.

When total obstruction occurs, symptoms related to bile blockage occur (Table 48.22). If the common bile duct is obstructed, no bilirubin will reach the small intestine to be converted to urobilinogen. Thus, the kidneys will excrete bilirubin, causing dark amber to brown urine.

Manifestations of cholecystitis vary from indigestion to moderate to severe pain, fever, chills, and jaundice. Initial symptoms of acute cholecystitis include indigestion and acute pain and RUQ tenderness. Pain may be referred to the right shoulder and scapula. There may be nausea and vomiting, restlessness, and diaphoresis. Inflammation results in leukocytosis and fever. Physical findings include RUQ or epigastrium tenderness and abdominal rigidity. Chronic cholecystitis may present with a history of fat intolerance, dyspepsia, heartburn, and flatulence.

Complications

Complications of gallstones and cholecystitis include gangrenous cholecystitis, subphrenic abscess, pancreatitis, *cholangitis*

TABLE 48.22 Manifestations of Obstructed Bile Flow

Manifestation	Cause
Bleeding tendencies	Lack of or ↓ Vitamin K absorption, resulting in ↓ prothrombin production
Clay-colored stools	No bilirubin reaching small intestine to be converted to urobilinogen
Dark amber to brown urine, which foams when shaken	↑ Water-soluble (conjugated) bilirubin elimination in urine
Fever and chills	Bacterial reflux from biliary tract to systemic circulation
Intolerance for fatty foods	No bile in small intestine for fat digestion
Jaundice	No bile flow into duodenum, bilirubin accumulates in blood
Pruritus	Deposition of bile salts in skin tissues
Steatorrhea	Undigested fatty components of food are eliminated in stool. Occurs because no bile in small intestine, thus preventing emulsion, digestion, and absorption of fat
Urobilinogen absent in urine	No bilirubin reaching small intestine to be converted to urobilinogen

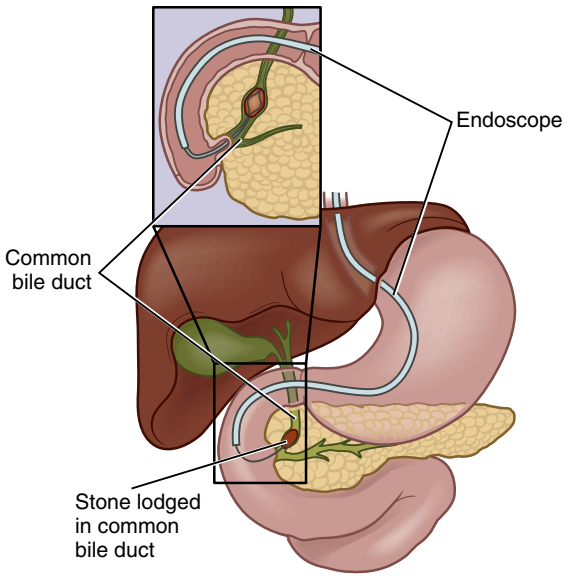

Fig. 48.15 During endoscopic sphincterotomy, an endoscope is advanced through the mouth and stomach until its tip sits in the duodenum opposite the common bile duct. *Inset,* After widening the duct mouth by incising the sphincter muscle, the HCP advances a basket attachment into the duct and snags the stone.

(inflammation of biliary ducts), biliary cirrhosis, fistulas, and rupture of the gallbladder, which can cause bile peritonitis. In older adults and those with diabetes, gangrenous cholecystitis and bile peritonitis are the most common complications of cholecystitis. *Choledocholithiasis* (stone in the common bile duct) may occur, producing symptoms of obstruction.

Diagnostic Studies

Ultrasound is often used to diagnose gallstones (see Table 43.11). It is especially useful for patients with jaundice (because it does not depend on renal function) and those who are allergic to contrast medium. ERCP allows for visualization of the gallbladder, cystic duct, common hepatic duct, and common bile duct. Bile taken during ERCP is sent for culture to identify possible infecting organisms.

Percutaneous transhepatic cholangiography is the insertion of a needle directly into the gallbladder duct followed by injection of contrast materials. It is generally done after ultrasound shows a bile duct blockage.

Laboratory tests may show an increased WBC count because of inflammation. Serum enzymes (e.g., alkaline phosphatase, ALT, and AST), direct and indirect bilirubin levels, and urinary bilirubin levels may be increased if an obstructive process is present (Table 48.3). Serum amylase is increased if the pancreas is involved.

Interprofessional Care

Once gallstones become symptomatic, a cholecystectomy is usually done. However, in some cases, conservative therapy may be considered.

Conservative Therapy

Cholelithiasis. The treatment of gallstones depends on the stage of disease. Bile acids (cholesterol solvents), such as ursodiol and chenodiol, are used to dissolve stones. However, the gallstones may recur. We usually do not treat gallstones with drugs because of the high use and success of laparoscopic cholecystectomy.

ERCP with endoscopic sphincterotomy (papillotomy) may be used to remove stones (Fig. 48.15). ERCP allows for visualization of the biliary system, dilation (balloon sphincteroplasty), and placement of stents and sphincterotomy. Special catheters with wire baskets or inflatable balloon tip may be used for stone removal.[29] When a stent is placed, it is generally removed or changed after a few months.

Extracorporeal shock-wave lithotripsy (ESWL) is an alternative treatment used when endoscopic approaches cannot remove stones. In ESWL, a lithotripter uses high-energy shock waves to disintegrate gallstones. It usually takes 1 to 2 hours to disintegrate the stones. The stone fragments pass through the common bile duct and into the small intestine. Usually, ESWL and oral dissolution therapy are used together.

Cholecystitis. During an acute episode of cholecystitis, treatment focuses on pain control, control of infection with antibiotics, and maintaining fluid and electrolyte balance (Table 48.23). Treatment is supportive and focused on symptom management. If nausea and vomiting are severe, NG tube insertion and gastric decompression may be used to prevent further gallbladder stimulation. A cholecystostomy may be used to drain purulent material from the obstructed gallbladder. Opioids are given for pain management. Anticholinergics can decrease GI secretions and counteract smooth muscle spasms.

Surgical Therapy

Laparoscopic cholecystectomy is the treatment of choice for symptomatic gallstones. About 90% of cholecystectomies are done laparoscopically. In this procedure, the gallbladder is

TABLE 48.23 Interprofessional Care

Cholelithiasis and Acute Cholecystitis

Diagnostic Assessment

- History and physical assessment
- Ultrasound
- ERCP
- Percutaneous transhepatic cholangiography
- Liver function tests
- WBC count
- Serum bilirubin

Management

Conservative Therapy

- IV fluid
- NPO with NG tube, later progressing to low-fat diet
- Antiemetics
- Analgesics
- Fat-soluble vitamins (A, D, E, and K)
- Anticholinergics (antispasmodics)
- Antibiotics (for secondary infection)
- Transhepatic biliary catheter
- ERCP with sphincterotomy (papillotomy)
- Extracorporeal shock-wave lithotripsy

Dissolution Therapy

- Chenodiol
- Ursodiol

Surgical Therapy

- Laparoscopic cholecystectomy
- Incisional (open) cholecystectomy

removed through 1 to 4 small punctures in the abdomen. The HCP makes a small cut below the umbilicus and inserts a needle into the area. CO_2 gas is passed into the abdomen to expand the area. This allows the HCP to see the organs more clearly and gives more room to work. The HCP inserts the laparoscope, which has a camera attached, and grasping forceps into the abdomen through the punctures. Using closed-circuit monitors to view the abdominal cavity, the HCP retracts and dissects the gallbladder and removes it with the forceps. The few contraindications to laparoscopic cholecystectomy include peritonitis, cholangitis, gangrene or perforation of the gallbladder, portal hypertension, and serious bleeding disorders.

This is a safe and routine procedure with minimal morbidity and quick recovery time. Most patients have minimal postoperative pain. They are discharged the day of surgery or the day after. They can usually resume normal activities and return to work within 1 week. The main complication is injury to the common bile duct.

Some patients may need an incisional (open) cholecystectomy. This involves removing the gallbladder through a right subcostal incision. A T tube may be placed in the common bile duct during a common bile duct exploration surgery (Fig. 48.16). It keeps the duct patent until the edema from the trauma of exploring and probing the duct subsides. It allows excess bile to drain while the small intestine is adjusting to receiving a continuous flow of bile.

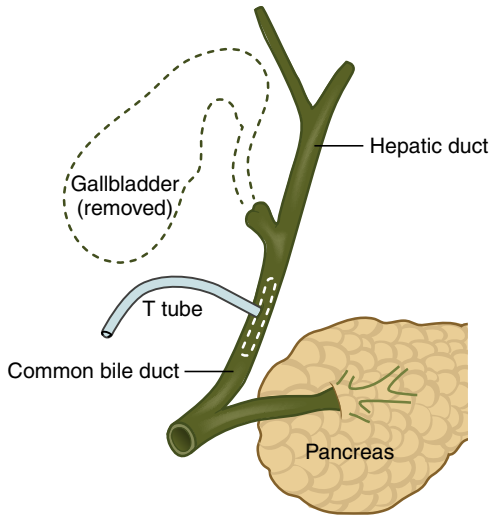

Fig. 48.16 Placement of T tube. *Dotted lines* show parts removed.

Transhepatic Biliary Catheter

The transhepatic biliary catheter can be used preoperatively in biliary obstruction and in liver dysfunction from obstructive jaundice. It also can be part of palliative care when inoperable liver, pancreatic, or bile duct cancer obstructs bile flow. The catheter is used when endoscopic drainage has been unsuccessful. The catheter is inserted percutaneously and allows for decompression of obstructed extrahepatic bile ducts so that bile can flow freely. After placement of the catheter into the obstructed duct internally, the external catheter is connected to a drainage bag. Encourage patients to replace fluids lost in the drainage bag with electrolyte-rich drinks. Cleanse the skin around the catheter insertion site daily with an antiseptic. Observe for bile leakage at the insertion site and any signs or symptoms of an occluded or malfunctioning drain. These include sudden abdominal pain, nausea, fever, or chills.

Drug Therapy

The most common drugs used in the treatment of gallbladder disease are analgesics, anticholinergics (antispasmodics), fat-soluble vitamins, and bile salts. Morphine may be used initially for pain management. Anticholinergics, such as atropine and other antispasmodics, may be used to relax the smooth muscle and decrease ductal tone.

The patient with chronic gallbladder disease or any biliary tract obstruction may need fat-soluble vitamin (A, D, E, and K) replacement. Bile salts can help with digestion and vitamin absorption. Cholestyramine may provide relief from itching.

Nutrition Therapy

People have fewer gallbladder problems if they eat smaller, more frequent meals with some fat at each meal to promote gallbladder emptying. If obesity is a problem, recommend a reduced-calorie diet. The diet should be low in saturated fats (e.g., butter, shortening, lard) and high in fiber and calcium. Avoid rapid weight loss because it can promote gallstone formation.

After a laparoscopic cholecystectomy, teach the patient to have liquids for the rest of the day and eat light meals for a few days.

TABLE 48.24 NURSING ASSESSMENT

Cholecystitis or Cholelithiasis

Subjective Data

Important Health Information

Health history: Obesity, multiparity, infection, cancer, extensive fasting, pregnancy

Medications: Estrogen or oral contraceptives

Surgery or other treatments: Abdominal surgery

Functional Health Patterns

Health perception–health management: Positive family history, sedentary lifestyle

Nutritional-metabolic: Weight loss, anorexia, indigestion, fat intolerance, nausea and vomiting, dyspepsia, chills

Elimination: Clay-colored stools, steatorrhea, flatulence. Dark urine

Cognitive-perceptual: Moderate to severe RUQ pain that may radiate to the back or scapula. Itching

Objective Data

Cardiovascular

Tachycardia

GI

Palpable gallbladder, abdominal guarding, and distention

General

Fever, restlessness

Respiratory

Tachypnea, splinting during respirations

Skin

Jaundice, icteric sclera, diaphoresis

Possible Diagnostic Findings

↑ Serum liver enzymes, alkaline phosphatase, and bilirubin. Absence of urobilinogen in urine, ↑ urinary bilirubin, leukocytosis. Abnormal gallbladder ultrasound

After an incisional cholecystectomy, the patient will progress from liquids to a regular diet once bowel sounds have returned. The amount of fat in the postoperative diet depends on the patient's tolerance of fat. A low-fat diet may be helpful if the flow of bile is reduced (usually only in the early postoperative period) or if the patient is overweight. Sometimes the patient must restrict fats for 4 to 6 weeks. Otherwise, no special diet is needed other than to eat nutritious meals and avoid excess fat intake.

❖ NURSING MANAGEMENT: GALLBLADDER DISEASE

◆ Assessment

Subjective and objective data that should be obtained from a person with gallbladder disease are outlined in Table 48.24.

◆ Clinical Problems

Clinical problems for the patient having gallbladder surgery may include:

- Pain
- Impaired GI function

◆ Planning

The overall goals are that the patient with gallbladder disease will have (1) relief of pain and discomfort, (2) no complications, and (3) no recurrent attacks of cholecystitis or gallstones.

◆ Implementation

◆ Health Promotion

Be aware of predisposing factors for gallbladder disease in health screening. Teach patients at risk the early manifestations and to see their HCP if these manifestations occur. Patients with chronic cholecystitis may not have acute symptoms and may not seek help until jaundice and biliary obstruction occur. Earlier detection in these patients is important so that they can be managed with a low-fat diet and monitored more closely.

◆ Acute Care

Nursing goals for the patient receiving conservative therapy include (1) treat pain, (2) relieve nausea and vomiting, (3) provide comfort and emotional support, (4) maintain fluid and electrolyte balance and nutrition, and (5) observe for complications.

The patient with acute cholecystitis or gallstones often has severe pain. Give the drugs ordered to relieve the pain as needed before pain becomes severe. Observe for side effects of the drugs as part of the continued assessment. Nursing comfort measures, such as comfortable positioning and oral care, are appropriate.

Some patients have more severe nausea and vomiting than others. For these patients, an NG tube and gastric decompression may be needed. Eliminating intake of food and fluids prevents further stimulation of the gallbladder. Maintain accurate intake and output NG suction. For patients with less severe nausea and vomiting, antiemetics are usually adequate. When the patient is vomiting, provide comfort measures, such as frequent mouth rinses. Remove any vomitus at once from the patient's view. Provide oral hygiene and care of nares. If itching occurs with jaundice, use measures to relieve itching. These can include antihistamines or other treatments as previously discussed.

Assess for symptom progression and complications. Observe for signs of obstruction of the ducts by stones. These include jaundice; clay-colored stools; dark, foamy urine; steatorrhea; fever; and increased WBC count.

When manifestations of obstruction are present (Table 48.22), bleeding may result from decreased prothrombin production by the liver. Common sites to observe for bleeding are the mucous membranes of the mouth, nose, gingivae, and injection sites. When giving injections, use a small-gauge needle and apply gentle pressure afterward. Know the patient's PT time and use it to guide your assessment.

Assess for infections. Monitor vital signs. A temperature elevation with chills and jaundice may indicate choledocholithiasis.

Your care of the patient after ERCP with papillotomy includes assessing for complications, such as pancreatitis, perforation, infection, and bleeding. Monitor the patient's vital signs. Abdominal pain, fever, and increasing amylase and lipase may indicate acute pancreatitis. The patient should be on bed rest

for several hours and NPO until the gag reflex returns. Teach the patient the need for follow-up if the stent is to be removed or changed.

Postoperative care. Postoperative nursing care after a laparoscopic cholecystectomy includes monitoring for complications, such as bleeding, making the patient comfortable, and preparing the patient for discharge. Patients may report referred pain to the shoulder because of the CO_2 that the HCP uses to inflate the abdominal cavity during surgery. It may not be released or absorbed by the body. The CO_2 can irritate the phrenic nerve and diaphragm, causing some difficulty breathing. Place the patient on their left side with right knee flexed to move the gas pocket away from the diaphragm. Encourage deep breathing along with movement and ambulation. NSAIDs or codeine can usually relieve pain. The patient starts clear liquids and can walk to the bathroom to void. Most patients go home the same day.

Postoperative nursing care for incisional cholecystectomy focuses on promoting ventilation and preventing respiratory complications. Other nursing care is the same as general postoperative nursing care (see Chapter 20).

If the patient has a T tube (Fig. 48.16), maintain the system, and monitor T-tube function and drainage. The T tube is usually connected to a closed gravity drainage system. If the Penrose or Jackson-Pratt drain or the T tube is draining large amounts of bile, it is helpful to use a sterile pouching system to protect the skin. Encourage the patient to replace any lost fluids and electrolytes.

Ambulatory Care

When the patient has conservative therapy, nursing care depends on the patient's symptoms and on whether surgery is planned. Provide any diet teaching. The diet is usually low in fat. The patient may need to take fat-soluble vitamin supplements. If needed, review a weight-reduction diet. Teach the patient signs and symptoms of obstruction (e.g., stool and urine changes, jaundice, itching). Explain the importance of continued health care follow-up.

The patient who had a laparoscopic cholecystectomy is discharged soon after the surgery, so home care and teaching are important (Table 48.25).

After an incisional cholecystectomy, tell the patient to avoid heavy lifting for 4 to 6 weeks. Usual sexual activities, including intercourse, can be resumed as soon as the patient feels ready, unless otherwise instructed by the HCP.

Sometimes, the patient needs to remain on a low-fat diet for 4 to 6 weeks. Provide patient-centered diet teaching. A weight-reduction program may be helpful if the patient is overweight. Most patients tolerate a regular diet with no problems but should avoid excess fats.

TABLE 48.25 PATIENT & CAREGIVER TEACHING

Postoperative Laparoscopic Cholecystectomy

Postoperative teaching should include:

1. Remove the bandages on the puncture sites the day after surgery and you can shower.
2. Notify your HCP if any of the following signs and symptoms occurs:
   - Redness, swelling, bile-colored drainage or pus from any incision
   - Severe abdominal pain, nausea, vomiting, fever, chills
3. You can gradually resume normal activities.
4. Return to work within 1 week of surgery.
5. You can resume your usual diet. Many tolerate a low-fat diet better for several weeks after surgery.

Evaluation

The overall expected outcomes are that the patient with gallbladder disease will:

- Appear comfortable and have pain relief
- Remain free from complications

GALLBLADDER CANCER

Gallbladder cancer has an incidence rate of 1.4 per 100,000 in women and 0.8 per 100,000 in men in the United States.[30] Most gallbladder cancers are adenocarcinomas. Many patients are asymptomatic. The early symptoms are insidious and similar to those of chronic cholecystitis and gallstones. This makes the diagnosis difficult. Most cancers are found incidentally. Many have advanced disease at the time of diagnosis leading to high mortality rates. Later symptoms are usually those of biliary obstruction.

Diagnosis and staging of gallbladder cancer are done using EUS, abdominal ultrasound, CT, MRI, and/or MRCP. When found early, surgery can be curative. Several factors influence successful surgical outcomes. These include the depth of cancer invasion, extent of liver involvement, venous or lymphatic invasion, and lymph node metastasis. Extended cholecystectomy with lymph node dissection has improved outcomes for those with gallbladder cancer.

When surgery is not an option, endoscopic stenting of the biliary tract can reduce obstructive jaundice. Adjuvant therapies, including radiation therapy and chemotherapy, may be used depending on the disease state. Overall, gallbladder cancer has a poor prognosis.

Nursing management involves palliative care with special attention to nutrition, hydration, skin care, and pain relief. Nursing care measures used for patients with cholecystitis and gallstones and for the patient with cancer (see Chapter 16) are appropriate.

Case Study

Cirrhosis

(© sbeagle/iStock/Thinkstock.)

Patient Profile

M.B. has cirrhosis. He has been vomiting for 2 days and noticed blood in the toilet when he vomited. He lives 40 miles from the nearest hospital. He had one of his ranch hands drive him to the hospital. His medical history includes chronic HCV, depression, and stage II chronic kidney disease.

Subjective Data

- Estranged from his 2 children since his divorce 3 years ago
- Has had cirrhosis for 12 years
- States he drank heavily for 20 years but has been sober for the past 2 years
- Reports anorexia, nausea, and abdominal discomfort

Objective Data

Physical Assessment

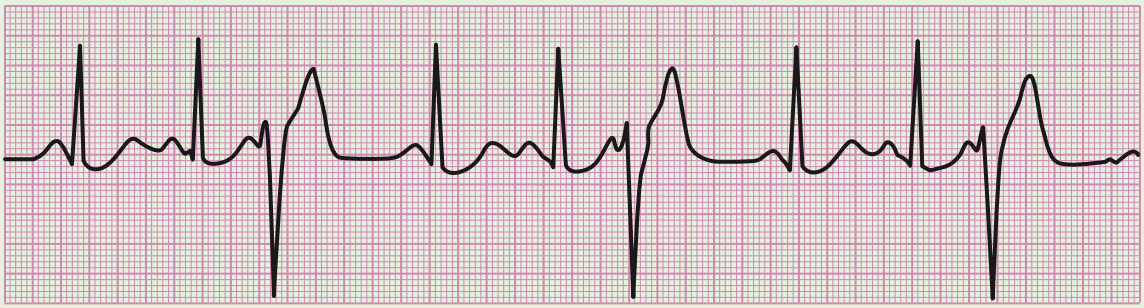
- Has moderate ascites
- Has jaundice of sclera and skin
- Has 4+ pitting edema of the lower extremities
- Liver and spleen are palpable

Laboratory Values

- Total bilirubin: 15 mg/dL (257 mmol/L)
- AST: 190 U/L (3.2 μkat/L)
- ALT: 210 U/L (3.5 μkat/L)
- Platelets: 45,000/μL
- eGFR: 62 mL/min
- ECG is below

Discussion Questions

1. ***Recognize***: Based on the history, what type of cirrhosis does M.B. likely have?
2. ***Recognize***: Describe the pathophysiologic changes that occur in the liver as cirrhosis develops.
3. ***Analyze***: Explain the significance of the results of his laboratory values and ECG findings.
4. ***Analyze***: What are possible causes of his GI bleeding?
5. ***Plan***: If M.B. begins to show signs and symptoms of hepatic encephalopathy, what would you monitor? What measures would be used to control or decrease the encephalopathy?
6. ***Prioritize:*** Based on the assessment data, what are the priority clinical problems?
7. ***Act:*** What interventions do you need to implement in this situation?
8. ***Act:*** M.B. discusses his prognosis with you. He says, "There is no hope. I might as well keep drinking." How would you respond to his statement?
9. ***Evaluate:*** What would you need to monitor to decide if care was effective?
10. ***Safety:*** Given M.B.'s bleeding history and current laboratory values, identify areas of injury risk and specify actions you will take to ensure patient safety.
11. Develop a conceptual care map for M.B.



Answers and a corresponding conceptual care map available at evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter

1. The nurse anticipates the preferred treatment for a patient with acute hepatitis A infection will include
   - **a.** interferon.
   - **b.** supportive care.
   - **c.** hepatitis A vaccine.
   - **d.** direct-acting antivirals.
2. A person needs postexposure prophylaxis for hepatitis B with hepatitis B immune globulin (HBIG). When should HBIG be given after exposure?
   - **a.** Within 24 hours
   - **b.** Between 1 and 2 weeks
   - **c.** At 1 month and 6 months
   - **d.** At 1 month, 4 months, and 6 months
3. A patient with late-stage cirrhosis develops portal hypertension. Which complications can develop from this condition? (*select all that apply*)
   - **a.** Ascites
   - **b.** Esophageal varices
   - **c.** Decreased bilirubin
   - **d.** Decreased spleen size
   - **e.** Increased albumin levels
4. A patient with cancer that has metastasized to the liver has symptoms of fluid retention, including edema and ascites. To determine the effectiveness of diuretic therapy on ascites, what should the nurse assess?
   - **a.** Bowel sounds
   - **b.** Abdominal girth
   - **c.** Recent blood work
   - **d.** Mucous membranes

5. Which intervention would the nurse expect for a patient admitted with acute pancreatitis?
   a. Keep the patient NPO
   b. Abdominal paracentesis
   c. Start enteral feedings to prevent malnutrition
   d. Administer acetaminophen every 4 hours for pain relief
6. The patient diagnosed with pancreatic cancer underwent a Whipple procedure 2 days ago. Which clinical problem has the highest priority?
   a. Anticipatory grieving
   b. Fluid volume imbalance
   c. Impaired tissue integrity
   d. Nutritionally compromised
7. Which finding can indicate gallstones and gallbladder obstruction?
   a. Dark colored stools
   b. Pain in the left lower abdomen
   c. Referred pain to the right shoulder
   d. Improved symptoms with high-fat meals
8. Discharge teaching for the patient who underwent laparoscopic cholecystectomy should include the need to
   a. abstain from alcohol.
   b. avoid eating low-fat meals.
   c. obtain hepatitis A vaccine.
   d. call if there are changes in stool or urine color.

1. b; 2. a; 3. a, b; 4. b; 5. a; 6. b; 7. c; 8. d.

Case Study

Applying Clinical Judgment With Multiple Patients

The following 4 patients are among the 7 you are assigned to care for today on the medical unit. You have 1 LPN and 1 AP who are assigned to help you.

(© iStockphoto/Thinkstock.)	M.S. is a 70-year-old woman who was admitted with weakness and malnutrition. She is 5 ft, 4 in tall and weighs 100 lb, with a 30-lb weight loss in past 2 months. Her history includes a recent stroke with hemiparesis and dysphagia. She has been NPO for the past 24 hours and started EN via PEG tube placed yesterday afternoon.
(© Christa Brunt/iStock/Thinkstock.)	S.R. is a 48-year-old woman admitted with chest pain. She has a history of type 2 diabetes, hypertension, and osteoarthritis. She is 5 ft, 6 in tall and weighs 230 lb. Her last 2 glucose levels were over 250 mg/dL and she received sliding scale insulin. Cardiac enzymes and ECG are all normal. She is scheduled to have a cardiac stress test at 10 AM. Vital signs: 160/110, 102, RR 22, O_2 saturation 94% with O_2 2 L/min via nasal cannula.
(© iStockphoto/Thinkstock.)	F.H., a 40-year-old man, was admitted yesterday with upper GI bleeding. He had just finished treatment with omeprazole, clarithromycin, and amoxicillin for a duodenal ulcer and *H. pylori*. He came to the ED yesterday with severe epigastric pain and melena. He is on a pantoprazole IV infusion and scheduled for a repeat EGD today.
(© sbeagle/iStock/Thinkstock.)	M.B. is a 58-year-old man admitted early this morning with upper GI bleeding. He has had cirrhosis for 12 years. He reports vomiting for 2 days. He currently has anorexia, nausea, and abdominal discomfort with severe ascites, jaundice, and 4+ pitting edema. His liver enzymes are high and platelet count is 45,000/μL. Vital signs: 102/54, 102, RR 22, O_2 saturation 94% with O_2 2 L/min via nasal cannula.

1. Highlight all the findings above that require your follow-up.
2. After receiving report, which patient should you see first?
3. Which tasks could you delegate to the LPN? *(Select all that apply.)*
   a. Administer a bolus enteral tube feeding to M.S.
   b. Assess M.S.'s PEG tube dressing and bowel sounds.
   c. Administer a scheduled dose of oral lactulose solution to M.B.
   d. Teach F.H.'s wife about his disease because she speaks English.
   e. Perform bedside glucose reading and administer sliding scale insulin to S.R.
4. Which diagnostic finding would you report to the HCP immediately?
   a. Blood glucose level 220 mg/dL for S.R.
   b. Hemoglobin 6.9 g/dL and hematocrit 21% for F.H.
   c. Serum sodium 134 mEq/L and potassium 3.4 mEq/L for M.S.
   d. Total bilirubin 3.2 mg/dL with positive urine bilirubin for M.B.
5. As you are assessing M.B., the LPN tells you that F.H. just vomited a large amount of bright red blood. What initial action would be *most* appropriate?
   a. Have the LPN administer an antiemetic to F.H.
   b. Ask the LPN to notify F.H.'s HCP immediately.
   c. Leave M.B.'s room to perform a focused assessment on F.H.
   d. Ask the AP to obtain a unit of packed RBCs from the blood bank.

Case Study Progression

When you enter F.H.'s room, he tells you that his pain actually feels somewhat relieved since he vomited. However, you note that his skin is cool and clammy, his BP is 90/54 mm Hg, and his heart rate is 116 bpm. You notify his HCP.

6. Which interventions would you expect the HCP to order for F.H.? *(select all that apply)*
   a. Stat hemoglobin and hematocrit
   b. Emergent endoscopy with band ligation
   c. Discontinue the pantoprazole (Protonix) infusion
   d. Start a second IV site and administer a 500 mL normal saline bolus
   e. Contact HCP and notify operating room that patient is unstable and needs surgery
7. You see that you need to complete M.B.'s medication reconciliation for the new HCP orders. Choose the most likely options for the information missing from the table below by selecting from the lists of options provided.

Medication	Dose, Route, Frequency	Drug Class	Indication
Propranolol	1	β-blocker	Decrease portal venous pressure
2	100 mg PO daily	Potassium-sparing diuretic	Excrete fluid with ascites
Lactulose	15 mL PO twice daily	Laxative	3
Vasopressin	10 units subcut 3 times daily	4	Decrease portal blood flow

Case Study—cont'd

Options for 1	Options for 2	Options for 3	Options for 4
20 mg IV every 12 hours 320 mg PO twice daily 640 mg PO daily	acetazolamide chlorothiazide spironolactone	Decrease bacterial flora Decrease gastric acidity Fecal elimination of ammonia	Anticoagulant Antihypertensive Hormone analog

8. Which intervention to treat ascites would you expect the HCP to order for M.B.? *(select all that apply)*
   a. Thoracentesis
   b. 2 g sodium diet
   c. Diuretic therapy
   d. 1800 mL/day fluid restriction
   e. Shunt insertion from peritoneum to heart
9. While you are administering M.S.'s bolus feeding of EN, you perform her assessment. For each assessment finding, use an X to indicate whether the interventions were Effective (helped to meet expected outcomes), Ineffective (did not help to meet expected outcomes), or Unrelated (not related to the expected outcomes).

Assessment Finding	Effective	Ineffective	Unrelated
Swallowing without difficulty			
Weight gain of 2 lb in 1 week			
Periodic diarrheal stools			
Improved activity intolerance			
Increased muscle strength			
Wound around PEG tube not healing properly			

10. After giving M.S. the bolus feeding, it would be *most* important to
    a. assess for gastric residual.
    b. obtain an abdominal x-ray.
    c. keep head of bed elevated 30–45 degrees.
    d. record the total amount of fluid administered.
11. As you enter the nurse's station, you overhear derogatory comments made by the AP to the LPN about S.R.'s weight. Which response would be *most* appropriate?
    a. Report the incident to charge nurse for follow-up.
    b. Talk to the AP to discuss a possible HIPAA violation.
    c. Talk to S.R. about the impact of AP's bias on the patient's self-image.
    d. Set up an in-service to teach staff members to recognize obesity as a disease process.

Assessment: Urinary System

Teresa Turnbull

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Elimination

Fluids and Electrolytes

LEARNING OUTCOMES

1. Identify the anatomic location and functions of the kidneys, ureters, bladder, and urethra.
2. Explain the physiologic events involved in the formation and passage of urine from glomerular filtration to voiding.
3. Obtain significant subjective and objective data related to the urinary system from a patient.
4. Link the age-related changes of the urinary system to the differences in assessment findings.
5. Perform a physical assessment of the urinary system using appropriate techniques.
6. Distinguish normal from abnormal findings of a physical assessment of the urinary system.
7. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the urinary system.
8. Evaluate findings of a urinalysis.

KEY TERMS

costovertebral angle (CVA)
creatinine
cystoscopy, Table 49.12
glomerular filtration rate (GFR)
glomerulus
nephron
renal biopsy, Table 49.12
urinalysis

Adequate kidney function is essential to health. If a person has complete kidney failure and treatment is not provided, death is inevitable. This chapter discusses the structures and functions, assessment, and diagnostic studies of the urinary system.

STRUCTURES AND FUNCTIONS OF URINARY SYSTEM

The *upper urinary system* consists of 2 kidneys and 2 ureters. The *lower urinary system* consists of a urinary bladder and urethra (Fig. 49.1). Urine is formed in the kidneys, drains through the ureters to be stored in the bladder, and then passes out of the body through the urethra.

Kidneys

The kidneys are the principal organs of the urinary system. The primary functions of the kidneys are to (1) regulate the volume and composition of extracellular fluid (ECF) and (2) excrete waste products from the body. The kidneys also function to control BP, make erythropoietin, activate vitamin D, and regulate acid-base balance.

Macrostructure

The paired kidneys are bean-shaped organs located retroperitoneally (behind the peritoneum) on either side of the vertebral column at about the level of the 12th thoracic (T12) vertebra to the 3rd lumbar (L3) vertebra. Each kidney weighs 4 to 6 oz (113 to 170 g) and is about 5 in (12.5 cm) long. The right kidney, positioned at the level of the twelfth rib, is lower than the left. An adrenal gland lies on top of each kidney.

Each kidney is surrounded by a significant amount of fat and connective tissue that cushion, support, and help the kidney to maintain its position. A thin, smooth layer of fibrous membrane called the *capsule* covers the surface of each kidney. The capsule protects the kidney and serves as a shock absorber if this area is traumatized from a sudden force or strike. The *hilus* on the medial side of the kidney serves as the entry site for the renal artery and nerves and as the exit site for the renal vein and ureter.

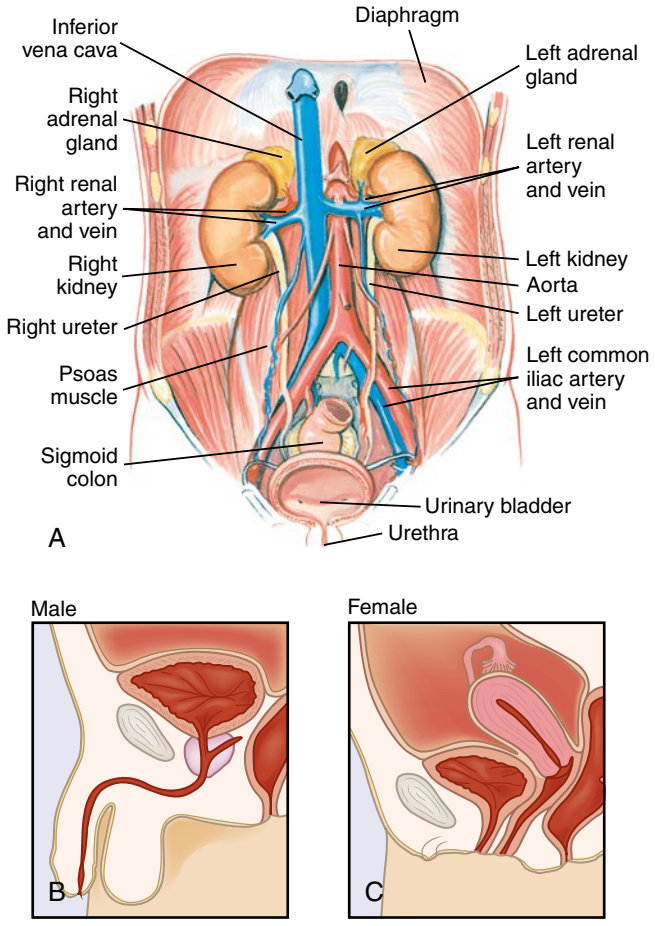

Fig. 49.1 Organs of the urinary system. (A) Upper urinary tract in relation to other anatomic structures. (B) Male urethra in relation to other pelvic structures. (C) Female urethra.

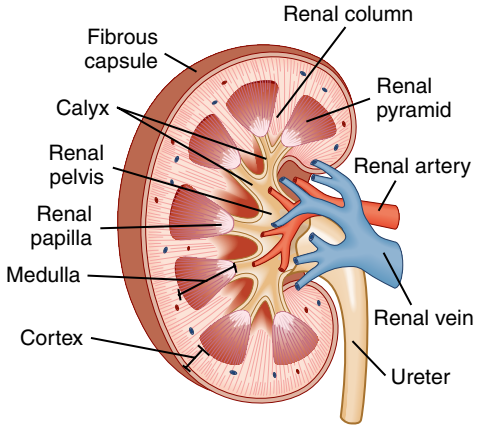

Fig. 49.2 Longitudinal section of the kidney.

The *parenchyma* is the actual tissue of the kidney (Fig. 49.2). The outer layer of the parenchyma is the *cortex*. The inner layer is the *medulla*. The medulla consists of a number of pyramids. The apices (tops) of these pyramids are the *papillae,* through which urine passes to enter the calyces. The minor calyces widen and merge to form major calyces, which form a funnel-shaped sac called the *renal pelvis*. The minor and major calyces transport urine to the renal pelvis, from there it drains through the ureter to the bladder. The renal pelvis can store a small volume of urine (3 to 5 mL).

Microstructure

The **nephron** is the functional unit of the kidney. Each kidney has around 1 million nephrons. Each nephron is composed of the glomerulus, Bowman capsule, and a tubular system. The tubular system consists of the proximal convoluted tubule, loop of Henle, distal convoluted tubule, and collecting tubules (Fig. 49.3). The glomerulus, Bowman capsule, proximal tubule, and distal tubule are in the cortex of the kidney. The loop of Henle and collecting tubules are in the medulla. Several collecting tubules join to form a single collecting duct. The collecting ducts eventually merge into a pyramid that empties via the papilla into a minor calyx.

Blood Supply

Blood flow to the kidneys, around 1200 mL/min, accounts for 20% to 25% of the cardiac output. Blood reaches the kidneys via the renal artery, which arises from the aorta and enters the kidney through the hilus. The renal artery divides into secondary branches and then into still smaller branches, each of which forms an afferent arteriole. The afferent arteriole divides into a capillary network, the **glomerulus**, which is a collection of up to 50 capillaries (Fig. 49.3). The capillaries of the glomerulus unite in the efferent arteriole. This efferent arteriole splits to form a capillary network, the peritubular capillaries, which surround the tubular system. All peritubular capillaries drain into the venous system. The renal vein empties into the inferior vena cava.

Physiology of Urine Formation

Urine formation is the outcome of a complex, multistep process of filtration, reabsorption, secretion, and excretion of water, electrolytes, and metabolic waste products. Although urine formation is the result of this process, the primary functions of the kidneys are to filter the blood and maintain the body's internal homeostasis.

Glomerular function. Urine formation begins at the glomerulus, where blood is filtered. The glomerulus is a semipermeable membrane that allows filtration (Fig. 49.3). The hydrostatic pressure of the blood within the glomerular capillaries causes a portion of blood to be filtered across the semipermeable membrane into Bowman capsule. There, the filtered portion of the blood (glomerular filtrate) begins to pass down to the tubule. Filtration is more rapid in the glomerulus than in ordinary tissue capillaries because the glomerular membrane is porous. The glomerular filtrate is similar in composition to blood except that it lacks blood cells, platelets, and large plasma proteins. Under normal conditions, capillary pores are too small to allow the loss of these large blood components. However, in many kidney diseases, capillary permeability increases, which allows plasma proteins and blood cells to pass into the urine.

The amount of blood filtered each minute by the glomeruli is the **glomerular filtration rate (GFR)**. The normal GFR is about 125 mL/min. The peritubular capillary network reabsorbs most of the glomerular filtrate before it reaches the end

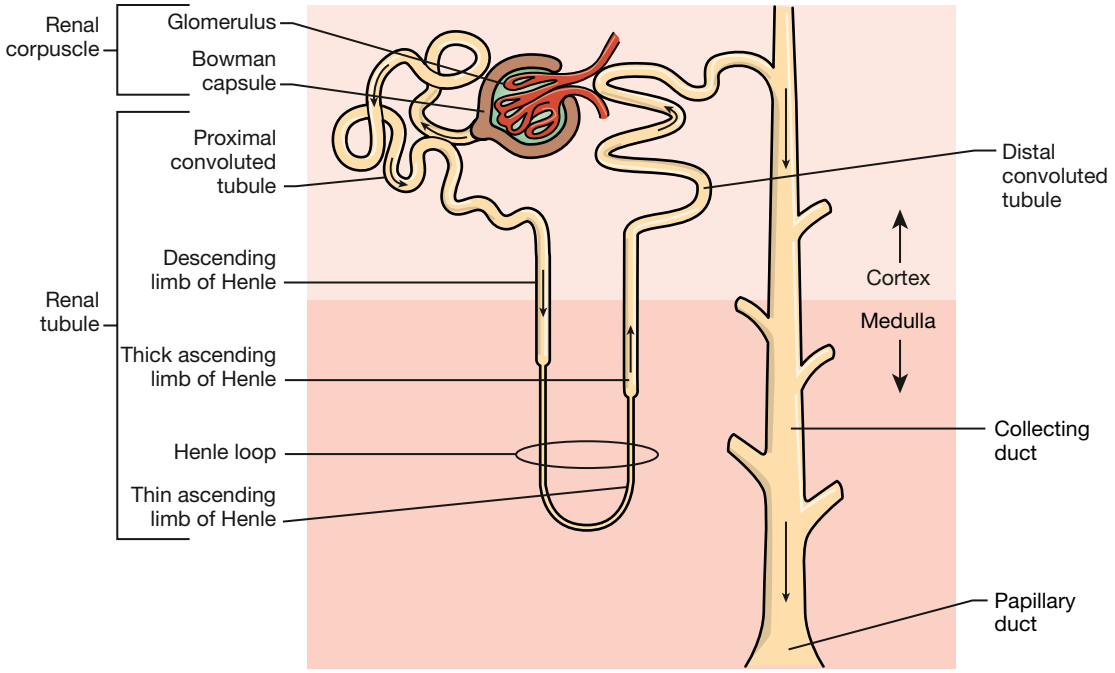

Fig. 49.3 The nephron is the basic functional unit of the kidney. This illustration of a single nephron unit shows the surrounding blood vessels. (Modified from Thibodeau GA, Patton KT: *The human body in health and disease,* ed 4, St Louis, 2005, Mosby.)

TABLE 49.1 Functions of Nephron Segments

Segment	Function
Glomerulus	Selective filtration
Proximal tubule	Reabsorption of 80% of electrolytes and water, glucose, amino acids, HCO_3^-
	Secretion of H^+ and creatinine
Loop of Henle	Concentration of filtrate
	Reabsorption of Na^+ and Cl^- in ascending limb and water in descending loop
Distal tubule	Reabsorption of water (regulated by ADH) and HCO_3^-
	Regulation of Ca^{2+} and PO_4^{2}—by parathyroid hormone
	Regulation of Na^+ and K^+ by aldosterone
	Secretion of K^+, H^+, ammonia
Collecting duct	Reabsorption of water (requires ADH)

of the collecting duct. Therefore only 1 mL/min (on average) is excreted as urine.

Tubular function. The tubules and collecting ducts are responsible for the reabsorption of essential materials and excretion of nonessential ones (Table 49.1). They carry out these functions by reabsorption and secretion. *Reabsorption* is the passage of a substance from the lumen of the tubules through the tubule cells and into the capillaries. This process involves both active and passive transport mechanisms. Tubular *secretion* is the passage of a substance from the capillaries through the tubular cells into the lumen of the tubule. Reabsorption and secretion cause many changes in the composition of the glomerular filtrate as it moves through the entire length of the tubule.

In the proximal convoluted tubule, about 80% of the electrolytes are reabsorbed. Normally, this includes all glucose, amino acids, and small proteins. As reabsorption continues in the loop of Henle, water is conserved, which is important for concentrating the filtrate. The descending loop is permeable to water and moderately permeable to sodium, urea, and other solutes. In the ascending limb, chloride ions (Cl^-) are actively reabsorbed, followed by passive reabsorption of sodium ions (Na^+). About 25% of the filtered sodium is reabsorbed in the ascending limb.

Two key functions of the distal convoluted tubules are final regulation of water balance and acid-base balance. Antidiuretic hormone (ADH) is needed for water reabsorption in the kidney. It is important in water balance. ADH makes the distal convoluted tubules and collecting ducts permeable to water. This allows water to be reabsorbed into the peritubular capillaries and eventually returned to the circulation.

Osmoreceptors in the anterior hypothalamus detect decreases in plasma osmolality. These osmoreceptors send neural input to *superoptic nuclei cells* in the hypothalamus. These superoptic nuclei cells have neuronal axons that end in the posterior pituitary gland and act to inhibit ADH secretion. In the absence of ADH, the tubules are essentially impermeable to water. Thus, any water in the tubules leaves the body as urine.

Aldosterone (released from the adrenal cortex) acts on the distal tubule to cause reabsorption of Na^+ and water. In exchange for Na^+, potassium ions (K^+) are excreted. Circulating blood volume and plasma concentrations of Na^+ and K^+ influence aldosterone secretion.

Acid-base regulation involves reabsorbing and conserving most of the bicarbonate (HCO_3^-) and secreting excess hydrogen ions (H^+). The distal tubule has different ways to keep the pH of ECF within a range of 7.35 to 7.45 (see Chapter 17).

Myocyte cells in the right atrium secrete atrial natriuretic peptide (ANP) in response to atrial distention from an increase in plasma volume. ANP acts on the kidneys to increase sodium excretion. At the same time, ANP inhibits renin, ADH, and the action of angiotensin II on the adrenal glands, thereby suppressing aldosterone secretion. These combined effects of ANP result in the production of a large volume of dilute urine. ANP also causes relaxation of the afferent arteriole, thus increasing the GFR.

The renal tubules are involved in calcium balance. The parathyroid gland releases parathyroid hormone (PTH) in response to low serum calcium levels. PTH maintains serum calcium levels by causing increased tubular reabsorption of calcium ions (Ca^{2+}) and decreased tubular reabsorption of phosphate ions (PO_4^{2-}). In kidney disease, the effects of PTH may have a major effect on bone metabolism.

Vitamin D is a hormone that we obtain in the diet or make by the action of ultraviolet radiation on cholesterol in the skin. These forms of vitamin D are inactive. They go through 2 more steps to become metabolically active. The first step occurs in the liver; the second step occurs in the kidneys. Active vitamin D is essential for the absorption of calcium from the gastrointestinal (GI) tract. The patient with kidney failure (also called *renal failure*) will have a deficiency of the active metabolite of vitamin D and problems with calcium and phosphate balance (see Chapter 52).

In summary, the basic function of nephrons is to cleanse blood plasma of unnecessary substances. After the glomerulus has filtered the blood, the tubules select the unwanted from the wanted portions of tubular fluid. Essential constituents are returned to the blood, and dispensable substances pass into urine.

Other Functions of Kidneys

The kidneys participate in red blood cell (RBC) production and BP regulation. Erythropoietin is a hormone made in the kidneys. It is secreted in response to hypoxia and decreased renal blood flow. Erythropoietin stimulates RBC production in the bone marrow. A deficiency of erythropoietin occurs in kidney failure, leading to anemia.

Renin is important in BP regulation. Renin is made and secreted by the kidney's juxtaglomerular cells (Fig. 49.4). Renin is released into the bloodstream in response to decreased renal perfusion, decreased arterial BP, decreased ECF, decreased serum Na^+ concentration, and increased urinary Na^+ concentration. The plasma protein angiotensinogen (from the liver) is activated to angiotensin I by renin. Angiotensin I is then converted to angiotensin II by angiotensin-converting enzyme (ACE). ACE is found on the inner surface of all blood vessels, with especially high levels in the vessels of the lungs. Angiotensin II stimulates the release of aldosterone from the adrenal cortex.

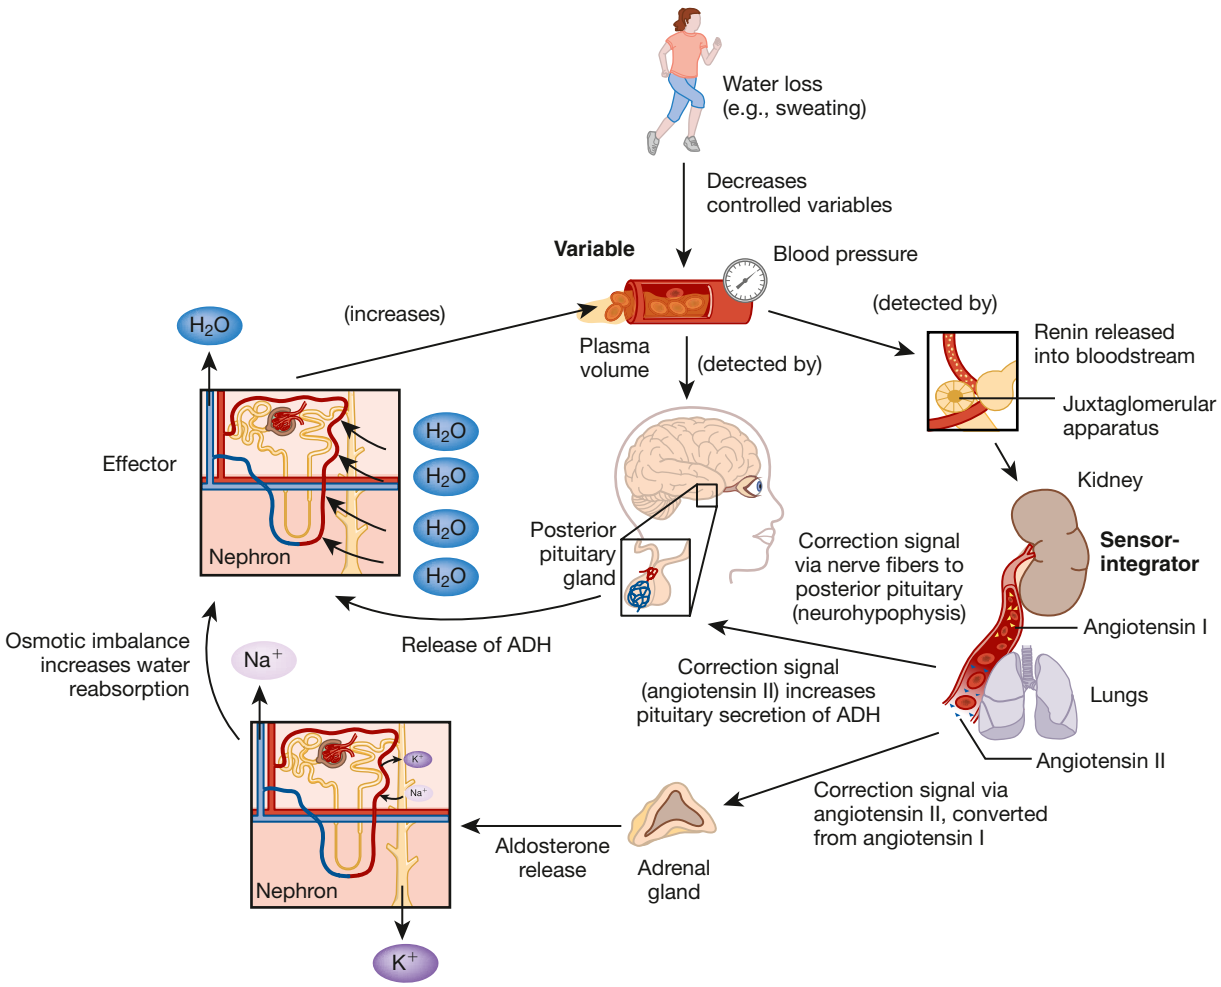

Fig. 49.4 Feedback renin-angiotensin-aldosterone system to fluid loss.

This causes Na^+ and water retention, leading to increased ECF volume. Angiotensin II also causes increased peripheral vasoconstriction. An elevated BP inhibits renin release. Excessive renin production caused by impaired renal perfusion may be a contributing factor in causing hypertension (see Chapter 36).

Most body tissues make prostaglandins (PGs) from the precursor arachidonic acid in response to appropriate stimuli. (See Chapter 12 and Fig. 12.2 for more about PGs.) In the kidney, PG synthesis (mainly PGE_2 and PGI_2) occurs mainly in the medulla. These PGs have a vasodilating action, thus increasing renal blood flow and promoting Na^+ excretion. They counteract the vasoconstrictive effect of substances such as angiotensin and norepinephrine. Renal PGs may have a systemic effect in lowering BP by decreasing systemic vascular resistance. The significance of renal PGs is related to the kidneys' role in causing hypertension. In renal failure with a loss of functioning tissue, these renal vasodilator factors are also lost, which may contribute to hypertension (see Chapter 36).

Ureters

The ureters are tubes that carry urine from the renal pelvis to the bladder (Fig. 49.1). Each ureter is about 10 to 12 inches (25 to 30.5 cm) long and 0.08 to 0.3 inches (0.2 to 0.8 cm) in diameter. Arranged in a mesh-like outer layer, circular and longitudinal smooth muscle fibers contract to promote the peristaltic, 1-way flow of urine through the ureters. Distention, neurologic and endocrine influences, and drugs can affect these muscle contractions.

The narrow area where each ureter joins the renal pelvis is the *ureteropelvic junction* (UPJ). The ureters insert into either side of the bladder base at the *ureterovesical junctions* (UVJs). Because the ureteral lumens are narrowest at these junctions, the UPJ and UVJ are often sites of obstruction. The narrow ureteral lumens can be easily obstructed internally (e.g., urinary stones) or externally (e.g., tumors, adhesions, inflammation). Sympathetic and parasympathetic nerves, along with the vascular supply, surround the mucosal lining of the ureters. Stimulation of these nerves during passage of a stone may cause acute, severe pain, termed *renal colic.*

Because the renal pelvis holds only 3 to 5 mL of urine, kidney damage can result from a backflow of more than that amount of urine. The UVJ relies on the ureter's angle of bladder insertion and muscle fiber attachments with the bladder to prevent the backflow *(reflux)* of urine, which predisposes a person to an ascending infection. The distal ureter enters the bladder laterally at its base. It then courses along obliquely through the bladder wall for about 1.5 cm and intermingles with muscle fibers of the bladder base. Circular and longitudinal bladder muscle fibers adjacent to the imbedded ureter help secure it. When bladder pressure rises (e.g., during voiding or coughing), muscle fibers that the ureter shares with the bladder base contract first, promoting ureteral lumen closure. Next, the bladder contracts against its base, ensuring UVJ closure and preventing urine reflux through the junction.

Bladder

The urinary bladder is located behind the symphysis pubis and anterior to the vagina and rectum (Fig. 49.5). Its primary functions are to serve as a reservoir for urine and to eliminate waste products from the body. Like the stomach, the bladder is a stretchable, saclike organ that contracts when it is empty.

The *trigone* is the triangular area formed by the 2 ureteral openings and bladder neck at the base of the bladder. The trigone is attached to the pelvis by many ligaments. It does not change its shape during bladder filling or emptying. The bladder muscle *(detrusor)* is composed of layers of intertwined smooth muscle fibers. These fibers are capable of considerable distention during bladder filling and contraction during emptying. It is attached to the abdominal wall by an umbilical ligament, the *urachus.* Because of this attachment, as the bladder fills, it rises toward the umbilicus. The dome and the anterior and lateral aspects of the bladder expand and contract.

Normal adult urine output is around 1500 mL/day, which varies with food and fluid intake. The volume of urine at night is less than half of that formed during the day because of hormonal influences (e.g., ADH). This diurnal pattern of urination is normal. Typically, a person will urinate 5 or 6 times during the day and sometimes at night.

On average, 200 to 250 mL of urine in the bladder cause moderate distention and the urge to urinate. When the quantity of urine reaches 400 to 600 mL, the person feels uncomfortable. Bladder capacity varies with the person, but generally ranges from 600 to 1000 mL. Evacuation of urine is termed *urination, micturition,* or *voiding.*

The bladder has the same mucosal lining as that of the renal pelvises, ureters, and bladder neck. The bladder is lined by transitional cell epithelium referred to as the *urothelium*. Unique to the urinary tract, the urothelium is resistant to absorption of urine. This means that after waste products (made by the kidneys) have left the kidneys, they cannot be reabsorbed in the

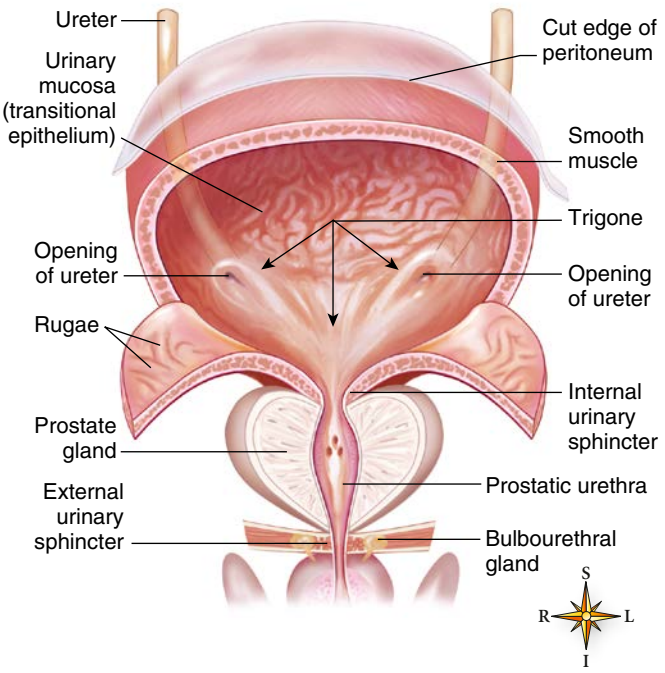

Fig. 49.5 Distended male urinary bladder. (From Patton KT, Thibodeau GA: *The human body in health & disease*, ed 7, St Louis, 2018, Mosby.)

urinary system. Microscopically, urothelium is only several cells deep. However, as urine enters the bladder, these cells can stretch to accommodate filling. As the bladder empties, the urothelium resumes its multicellular layer formation.

Urethra

The urethra is a small tube that incorporates the smooth muscle of the bladder neck and extends to the striated muscle of the external meatus. The urethra's primary functions are to (1) control voiding and (2) serve as a conduit for urine from the bladder to the outside of the body during voiding.

The female urethra is 1 in to 2 in (2.5 cm to 5 cm) long and lies behind the symphysis pubis but anterior to the vagina (Fig. 49.1C). The male urethra, which is about 8 in to 10 in (20 cm to 25 cm) long, starts at the bladder neck and extends the length of the penis (Fig. 49.1B).

Urethrovesical Unit

Together, the bladder, urethra, and pelvic floor muscles form the *urethrovesical unit*. Voluntary control of this unit is defined as *continence*. Stimulating and inhibiting impulses are sent from the brain through the thoracolumbar (T11 to L2) and sacral (S2 to S4) areas of the spinal cord to control voiding. Bladder distention stimulates stretch receptors within the bladder wall. Impulses are transmitted to the sacral spinal cord and then to the brain, causing a desire to urinate.

If you cannot void at a given time, inhibitor impulses in the brain are stimulated and transmitted back through the thoracolumbar and sacral nerves innervating the bladder. In a coordinated fashion, the detrusor muscle accommodates to the pressure (does not contract) while the sphincter and pelvic floor muscles tighten (contract) to resist bladder pressure.

If you can void, cerebral inhibition is voluntarily suppressed. Impulses are transmitted via the spinal cord for the bladder neck, sphincter, and pelvic floor muscles to relax and for the bladder to contract. The sphincter closes, and the detrusor muscle relaxes when the bladder is empty.

Any disease or trauma that affects the function of the brain, spinal cord, or nerves that directly innervate the bladder, bladder neck, external sphincter, or pelvic floor can affect bladder function. These conditions include diabetes, multiple sclerosis, paraplegia, and quadriplegia. Drugs affecting nerve transmission can affect bladder function.

Gerontologic Considerations: Effects of Aging on Urinary System

Anatomic changes in the aging kidney include a 10% decrease in size, weight, and blood flow each decade starting at age 30. There is a similar decline in glomerular function starting at age 40.[1] Atherosclerosis accelerates the decrease of renal size with age.

Physiologic changes in the aging kidney include decreased renal blood flow, due in part to atherosclerosis, resulting in a decreased GFR. Changes in hormone levels (including ADH, aldosterone, ANP) result in decreased urinary concentrating ability and changes in water, sodium, potassium, and acid excretion. Despite these changes, older adults maintain homeostasis unless they have other problems. After abrupt changes in blood volume, acid load, or other insults, the kidney may not be able to function effectively because much of its renal reserve has been lost.[1]

Physiologic changes occur in the aging urethra and bladder. The female urethra, bladder, vagina, and pelvic floor lose elasticity and muscle support. Consequently, older women are more prone to bladder infections and incontinence. The prostate surrounds the proximal urethra. As men age, the prostate enlarges. This can affect urinary patterns, causing hesitancy, retention, slow stream, and bladder infections.

Constipation, often experienced by older adults, can affect urination. Partial urethral obstruction may occur because the rectum is close to the urethra. Age-related changes in the urinary system and differences in assessment findings are outlined in Table 49.2.

ASSESSMENT OF URINARY SYSTEM

Subjective Data

Important Health Information

Health history. Ask the patient about the presence or history of kidney disease or other urologic problems. Note specific urinary problems, such as cancer, infections, benign prostatic hyperplasia (BPH), and stones. Are there other health problems that may affect kidney function? These include hypertension, diabetes, gout, connective tissue disorders (e.g., systemic lupus erythematosus), hepatitis, human immunodeficiency virus (HIV) infection, neurologic problems (e.g., stroke, back injury), and trauma.[2]

TABLE 49.2 GERONTOLOGIC ASSESSMENT DIFFERENCES

Urinary System

Gerontologic Changes	Differences in Assessment Findings
Kidney	
• ↓ Amount of renal tissue	• Less palpable
• ↓ Number of nephrons and renal blood vessels. Thickened basement membrane of Bowman capsule and glomeruli	• ↓ Creatinine clearance, ↑ BUN level, ↑ serum creatinine
• ↓ Function of loop of Henle and tubules	• Changes in drug excretion, nocturia, loss of normal diurnal excretory pattern because of ↓ ability to concentrate urine; less concentrated urine
Ureter, Bladder, and Urethra	
• ↓ Elasticity and muscle tone	• Palpable bladder after urination because of retention
• Weakening of urinary sphincter	• Stress incontinence (especially during Valsalva maneuver), dribbling of urine after urination
• ↓ Bladder capacity and sensory receptors	• Frequency, urgency, nocturia, overflow incontinence
• Estrogen deficiency leading to thin, dry vaginal tissue	• Stress or overactive bladder, dysuria
• ↑ Prevalence of unstable bladder contractions	• Overactive bladder
• Prostate enlargement	• Hesitancy, frequency, urgency, nocturia, straining to urinate, retention, dribbling

Medications. Assess the patient's current and past use of medications. Include over-the-counter drugs, prescription drugs, and herbal therapies. Drugs affect the urinary tract in several ways. Many drugs can be nephrotoxic (Table 49.3). Certain drugs may alter the quantity and character of urine output (e.g., diuretics). Several drugs change the color of urine. Phenazopyridine (Pyridium) turns urine orange. Nitrofurantoin turns urine dark yellow to brown. Anticoagulants may cause hematuria. Many antidepressants, calcium channel blockers, antihistamines, and drugs used for neurologic and musculoskeletal problems affect the ability of the bladder or sphincter to contract or relax normally.

Surgery or other treatments. Ask the patient about hospitalizations related to renal or urologic problems. Were there any urinary problems during past pregnancies? Ask about the duration, severity, and patient's perception of any problem and its treatment. Have they had surgery, especially pelvic surgery, and urinary tract instrumentation (e.g., catheterization)? Ask the patient about any radiation or chemotherapy treatment for cancer.

Case Study

Patient Introduction

(© iStockphoto/ Thinkstock.)

A.K. is a 28-year-old man who comes to the emergency department (ED) in acute distress with severe abdominal pain. The pain began about 6 hours ago after he finished a 10-mile run as part of his training for a marathon. He says that the pain has steadily increased, and he is nauseous. His urine is a dark, smoky color.

Discussion Questions

1. What are the possible causes of A.K.'s abdominal pain, nausea, and urine color?
2. What type of assessment would be most appropriate for A.K.: comprehensive, focused, or emergency? On what basis did you make that decision?
3. What assessment questions will you ask him?

You will learn more about A.K. and his condition as you read through this assessment chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

TABLE 49.3 Potentially Nephrotoxic Agents

Antimicrobials	Other Drugs	Other Agents
• aminoglycosides • amphotericin B • antivirals • cephalosporins • polymyxin B • sulfonamides • vancomycin	• ACE inhibitors • captopril • cimetidine • cisplatin • cocaine • cyclosporine • heroin • lithium • methotrexate • nitrosoureas (e.g., carmustine) • NSAIDs (e.g., ibuprofen, indomethacin) • quinine • rifampin • salicylates (large quantities) • statins	• Gold • Heavy metals

Functional Health Patterns

Table 49.4 lists key questions to ask a patient with problems related to the renal system.

Health perception–health management pattern. Ask about the patient's general health. Abnormal kidney function may be suspected if the patient reports changes in weight or appetite, excess thirst, fluid retention, headache, pruritus, blurred vision, or "feeling tired all the time." An older adult may report malaise and nonlocalized abdominal discomfort as the only symptoms of a urinary tract infection (UTI). In older adults with a UTI, family members may report the patient is disoriented, has fallen, or has increased confusion.

Obtain a smoking history. Cigarette smoking is a major risk factor for bladder and kidney cancer. Smokers who work with cancer-causing chemicals have an especially high risk for bladder cancer.

Exposure to certain chemicals can affect the urinary system. Aromatic amines and some organic chemicals increase the risk for bladder cancer. Phenol and ethylene glycol are examples of nephrotoxic chemicals. Obtain an occupational history. Machinists, painters, hairdressers, printers, and truck drivers have an increased risk for bladder cancer.[3]

Information about places where a patient has lived is important. Persons living in the U.S. Southeast have the highest incidence of urinary stones (referred to as "stone belt"). This may be caused by differences in temperature, humidity, and sunlight.[4] A person living in Middle Eastern countries or Africa can acquire certain parasites that can cause cystitis or bladder cancer (Box 49.1).

Nutritional-metabolic pattern. The usual quantity and types of fluid a patient drinks are important in relation to urinary tract disease. Dehydration may contribute to UTIs, stone formation, and kidney failure. Large intake of specific foods, such as dairy products or foods high in proteins, may lead to stone formation. Asparagus may cause the urine to smell musty. Red urine caused by beet ingestion may be mistaken for bloody urine. Caffeine, alcohol, carbonated beverages, some artificial sweeteners, or spicy foods often worsen urinary inflammatory diseases. Green tea and some herbal teas cause diuresis. An unexplained weight gain may be the result of fluid retention from a kidney problem. Anorexia, nausea, and vomiting can dramatically affect fluid status and require careful monitoring.

Elimination pattern. Questions about urine elimination patterns are the cornerstone of the health history in the patient with a lower urinary tract disorder. Begin with asking how the patient manages urine elimination. Ask about daytime (diurnal) voiding frequency and the frequency of nocturia. Pelvic organ prolapses, particularly advanced anterior vaginal prolapse, may cause suprapubic pressure, frequency, urgency, and incontinence from urinary retention. Ask about other bothersome lower urinary tract symptoms, including urgency, incontinence, or urinary retention. Table 49.5 lists some common manifestations of urinary tract disorders.

Changes in the color and appearance of urine are often significant and need evaluated. If blood is visible in the urine, determine if it occurs at the beginning of, throughout, or at the end of urination. This is harder for the female patient.

TABLE 49.4 HEALTH HISTORY

Urinary System

Health Perception–Health Management
- How is your energy level compared with 1 year ago?
- Do you have any vision changes?[a]
- Have you ever smoked? If yes, how many packs per day?
- Tell me about the types of jobs you have had.

Nutritional-Metabolic
- How is your appetite?
- Has your weight changed over the past year?[a]
- Do you take vitamins, herbs, or any other supplements?[a]
- How much and what kinds of fluids do you drink daily?
- How many dairy products and how much meat do you eat?
- Do you drink coffee? Colas? Tea?
- Do you spice your food heavily?[a]

Elimination
- Are you able to sit through a 2-hr meeting or ride in a car for 2 hr without urinating?
- Do you awaken at night to urinate? If so, how many times does this occur during an average night?
- Do you ever have blood in your urine?[a] If so, at what point in the urination does it occur?
- Have you noticed any change in the color or smell of your urine?[a]
- Do you ever pass urine when you do not intend to? When?
- Do you use special devices or supplies for urine elimination or control?[a]
- How often do you move your bowels?
- Do you ever have constipation or diarrhea?[a]
- Do you ever have problems controlling your bowels?[a]

Activity-Exercise
- Have you noticed any changes in your ability to perform your usual daily activities?[a]
- Do certain activities worsen your urinary problem?[a]
- Has your urinary problem caused you to alter or stop any activity or exercise?[a]
- Do you need help getting to the bathroom?[a]

Sleep-Rest
- Do you awaken at night from an urge to urinate?[a] How does this disturb your sleep?
- Do you awaken at night from pain or other problems and urinate as a matter of routine before returning to sleep?[a]
- Do you have daytime sleepiness and fatigue because of nighttime urination?[a]

Cognitive-Perceptual
- Do you ever have pain when you urinate?[a] If so, where is the pain?

Self-Perception–Self-Concept
- How does your urinary problem make you feel about yourself?
- Do you perceive your body differently since you have developed a urinary problem?

Role-Relationship
- Does your urinary problem interfere with your relationships with family or friends?[a]
- Has your urinary problem caused a change in your job status or affected your ability to work?[a]

Sexuality-Reproductive
- Has your urinary problem caused any change in your sexual pleasure or performance?
- Do hygiene concerns interfere with sexual activities?

Coping–Stress Tolerance
- Do you feel able to manage your urinary problem? If not, explain.
- What strategies are you using to cope with your urinary problem?

Values-Beliefs
- Has your present illness affected your belief system?[a]
- Are your treatment decisions related to your urinary problem in conflict with your value system?[a]

[a]If yes, describe.

BOX 49.1 GENETIC RISK ALERT

- Polycystic kidney disease and congenital urinary tract abnormalities (e.g., Alport syndrome [congenital nephritis]) are genetic disorders.
- A family history of certain renal or urologic problems increases the chance of similar problems occurring in the patient.
- For any disease reported in the health history, ask if other family members also have/had the same or similar diseases.

Assess bowel function. Problems with fecal incontinence may signal neurologic causes for bladder problems because of shared nerve pathways. Constipation and fecal impaction can partially obstruct the urethra, causing inadequate bladder emptying, overflow incontinence, and infection.

Determine the patient's method of managing a urinary problem. A patient may already be using a catheter or collection device. Sometimes, a patient must assume a specific position to urinate or perform maneuvers, such as pressing on the lower abdomen (Credé's method) or straining (Valsalva maneuver), to empty the bladder.

Activity-exercise pattern. Assess the patient's level of activity. A sedentary person is more likely to have stasis of urine than an active person and, thus, is predisposed to infection and stones. Bone demineralization in a person with limited physical activity can cause increased urine calcium precipitation.

An active person may find that increasing activity worsens the urinary problem. The patient who has had prostate surgery or who has weakened pelvic floor muscles may leak urine when trying certain activities, such as running. Some men develop chronic inflammatory prostatitis or epididymitis after heavy lifting or long-distance driving.

Sleep-rest pattern. Nocturia is a common and a particularly bothersome symptom that often leads to sleep deprivation, daytime sleepiness, and fatigue. It occurs in multiple problems affecting the lower urinary tract. These include urinary incontinence, urinary retention, and interstitial cystitis. Nocturia may be related to polyuria from kidney disease, poorly controlled diabetes, alcohol use, excess fluid intake, liver disease, heart failure, or obstructive sleep apnea.

TABLE 49.5 Manifestations of Urinary System Disorders

General Manifestations	SPECIFIC MANIFESTATIONS RELATED TO URINARY SYSTEM				
	Edema	Pain	Patterns of Urination	Urine Output	Urine Composition
• Anorexia • ↑ BP • Blurred vision • Change in weight • Chills • Cognitive changes • Fatigue • Headaches • Nausea and vomiting • Thirst	• Ankle • Ascites • Facial (periorbital) • Generalized • Sacral	• Dysuria • Flank or costovertebral angle • Groin • Suprapubic	• Change in stream • Dribbling • Dysuria • Frequency • Hesitancy of stream • Incontinence • Nocturia • Retention • Stress incontinence • Urgency	• Anuria • Oliguria • Polyuria	• Color (red, brown, yellowish green) • Concentrated • Dilute • Hematuria • Pyuria

When assessing nocturia, determine if the need to urinate causes the person to arise from sleep or if pain or other symptoms interrupt sleep. Ask if the person urinates as a matter of habit before returning to bed. Up to 1 episode of nocturia is normal in younger adults, and up to 2 episodes are acceptable in adults ages 65 years or older. If an older adult has more than 2 episodes during the night, assess the amount and timing of fluid intake. This information will help determine if further assessment is needed.

Cognitive-perceptual pattern. Assess the level of mobility, visual acuity, and dexterity. These are important factors to evaluate, especially when urine retention or incontinence is a problem. Determine if the patient is alert, understands instructions, and can recall instructions when needed.

If urinary incontinence is present, ask how the patient is managing the problem. Recognize that incontinence is often distressing and embarrassing. Discuss the problem with the patient with sensitivity.

Pain is a frequent symptom of renal and urologic problems. The patient may report dysuria, groin pain, costovertebral pain, or suprapubic pain. Assess pain and document the location, character, and duration. The absence of pain when other urinary symptoms exist is significant. Many urinary tract cancers are painless in the early stages.

Self-perception–self-concept pattern. Some problems, such as incontinence, urinary diversion procedures, and chronic fatigue (may occur with anemia), can result in loss of self-esteem and a negative body image.

Role-relationship pattern. Urinary problems can affect many aspects of a person's life, including the ability to work and relationships with others. These factors have implications for treatment and management of the patient's condition.

Urinary system problems may be serious enough to cause problems in job-related and social situations. Chronic dialysis therapy often makes regular employment or management of home and family responsibilities difficult. Concurrent poor health and negative body image can seriously affect existing roles.

Sexuality-reproductive pattern. Assess the effect of renal problems on the patient's sexual satisfaction. Problems related to personal hygiene and fatigue can negatively affect sexual relationships. Although urinary incontinence is not directly related to sexual problems, it often has a devastating effect on self-esteem and social and intimate relationships. Counseling both the patient and partner may be needed.

Case Study

Subjective Data

(© iStockphoto/Thinkstock.)

A focused subjective assessment of A.K. revealed the following:

Medical History: History of 1 isolated incidence of gout 6 years ago. He stopped drinking alcohol with no further occurrence. Appendectomy 12 years ago.

Medications: None.

Health Perception–Health Management: A.K. states that he is usually healthy. He does not smoke or drink alcohol. He has never had this type of pain before. Describes the pain as being sharp and colicky (coming in waves). Rates the pain as 9 on a scale of 0 to 10.

Nutritional-Metabolic: A.K. is currently on a high-protein diet as he trains for the marathon. He eats a lot of chicken, beef, and seafood. He drinks milk-based protein shakes and water after exercising but admits that he does not think he drinks enough to replace fluid loss from perspiration. He drinks coffee for energy but denies eating chocolate or other sweets. He avoids sodas.

Elimination: Denies any history of problems with urination, constipation, or diarrhea. This is the first time he has ever noticed a change of color in his urine.

Activity-Exercise: Prides himself on his ability to exercise and run without difficulty.

Sleep-Rest: Does not awaken at night to urinate.

Cognitive-Perceptual: Denies pain on urination.

Self-Perception–Self-Concept: Believes he can monitor himself and maintain a healthy lifestyle.

Coping–Stress Tolerance: Worried that this pain may interfere with his marathon training.

Discussion Questions

1. Which subjective assessment findings concern you most?
2. What would be your priority assessment of A.K.?
3. What should be included in the physical assessment? What would you be looking for?

You will learn more about the physical assessment of the urinary system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Fig. 49.6 Palpating the right kidney. (From Jarvis C: *Physical examination and health assessment,* ed 8, St Louis, 2020, Elsevier.)

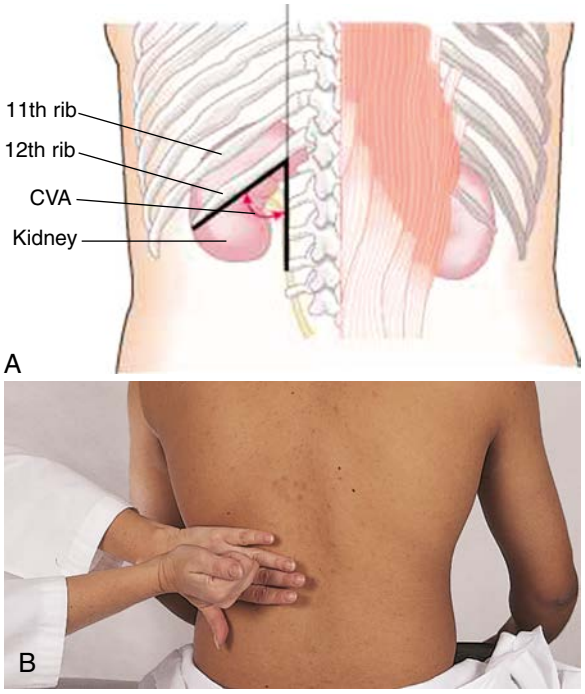

Fig. 49.7 (A) Costovertebral angle. (B) Indirect fist percussion of the costovertebral angle *(CVA).* To assess the kidney, place one hand over the twelfth rib at the CVA on the back. Thump that hand with the ulnar edge of the other fist. (From Jarvis C: *Physical examination and health assessment,* ed 8, St Louis, 2020, Elsevier.)

Objective Data

Physical Assessment

Inspection. Assess for changes in the following:

- *Skin:* Pallor, yellow-gray cast, excoriations, changes in turgor, bruises, texture (e.g., rough, dry skin)
- *Mouth:* Stomatitis, ammonia breath odor
- *Face and extremities:* Generalized edema, peripheral edema
- *Abdomen:* Abdominal contour for midline mass in lower abdomen (may indicate bladder distention and urinary retention) or unilateral mass (sometimes seen in adults, indicating kidney enlargement from large tumor or polycystic kidney)
- *Weight:* Weight gain from edema. Weight loss and muscle wasting in kidney failure
- *General health:* Fatigue, lethargy, and decreased alertness

Palpation. The kidneys are posterior organs protected by the abdominal organs, ribs, and heavy back muscles. A landmark useful in locating the kidneys is the **costovertebral angle (CVA)** formed by the rib cage and the vertebral column. The normal-sized left kidney is rarely palpable because the spleen lies directly on top of it. Occasionally, the lower pole of the right kidney is palpable.

To palpate the right kidney, place your left (anterior) hand behind and support the patient's right side between the rib cage and the iliac crest (Fig. 49.6). Elevate the right flank with the left hand. Use your right hand to palpate deeply for the right kidney. The lower pole of the right kidney may be felt as a smooth, rounded mass that descends on inspiration. If the kidney is palpable, note its size, contour, and tenderness. Kidney enlargement is suggestive of cancer or other serious renal problems.

The urinary bladder is normally not palpable unless it is distended with urine. If the bladder is full, it may be felt as a smooth, round, firm organ and is sensitive to palpation.

Percussion. Tenderness in the flank area may be detected by fist percussion *(kidney punch).* Perform fist percussion by striking the fist of one hand against the dorsal surface of the other hand, which is placed flat along the posterior CVA margin (Fig. 49.7). Normally, this action should not elicit pain. If CVA tenderness and pain are present, it may indicate a kidney infection or polycystic kidney disease.[5]

A bladder does not percuss until it contains at least 150 mL of urine. If the bladder is full, dullness is heard above the symphysis pubis. A distended bladder may be percussed as high as the umbilicus.

Auscultation. Use the diaphragm of the stethoscope to auscultate bowel sounds, since the bowels can affect the urinary system.

TABLE 49.6 Normal Physical Assessment of Urinary System

- No costovertebral angle tenderness
- Nonpalpable kidney and bladder
- No palpable masses

Table 49.6 shows how to record the normal physical assessment findings of the urinary system. Table 49.7 describes assessment abnormalities of the urinary system. Assessment findings may vary in the older adult. Table 49.2 presents the age-related changes in the urinary system and differences in assessment findings. Use a *focused assessment* to evaluate the status of previously identified urinary system problems and monitor for signs of new problems (Table 49.8).

TABLE 49.7 ASSESSMENT ABNORMALITIES

Urinary System

Finding	Description	Possible Etiology and Significance
Anuria	Technically no urination (24-h urine output <100 mL)	Acute kidney injury, end-stage renal disease (ESRD), bilateral ureteral obstruction
Burning on urination	Stinging pain in urethral area	Urethral irritation, UTI, urethral stones
Dysuria	Painful or difficult urination	UTI, interstitial cystitis, urethral stones, and wide variety of pathologic conditions
Enuresis	Involuntary nocturnal urination	Lower urinary tract disorder
Frequency	↑ Incidence of urination	Acutely inflamed bladder, retention with overflow, excess fluid intake, intake of bladder irritants, urethral stones
Hematuria	Blood in the urine	Cancer of genitourinary tract, blood dyscrasias, kidney disease, UTI, stones in kidney or ureter, anticoagulants
Hesitancy	Delay or difficulty in initiating urination	Partial urethral obstruction, BPH
Incontinence	Inability to voluntarily control discharge of urine	Neurogenic bladder, bladder infection, injury to external sphincter
Nocturia	Frequent urination at night	Kidney disease with impaired concentrating ability, bladder obstruction, heart failure, diabetes, post renal transplant, excess evening and nighttime fluid intake
Oliguria	↓ Amount of urine in a time period (24-hr urine output of 100–400 mL)	Severe dehydration, shock, transfusion reaction, kidney disease, ESRD
Pain	Suprapubic pain (related to bladder), urethral pain (irritation of bladder neck), flank pain, CVA tenderness	Infection, urinary retention, foreign body in urinary tract, urethritis, pyelonephritis, renal colic, stones
Pneumaturia	Passage of urine containing gas	Fistula connections between bowel and bladder, gas-forming UTI
Polyuria	Large volume of urine in a time period	Diabetes, diabetes insipidus, chronic kidney disease, diuretics, excess fluid intake, obstructive sleep apnea
Retention	Inability to urinate even though bladder contains excess amount of urine	Finding after pelvic surgery, childbirth, catheter removal, anesthesia; urethral stricture or obstruction; neurogenic bladder
Stress incontinence	Involuntary urination with ↑ pressure (sneezing or coughing)	Weakness of sphincter control, lack of estrogen, urinary retention

TABLE 49.8 FOCUSED ASSESSMENT

Urinary System

Use this checklist to ensure that you complete key assessment steps.

Subjective

Ask the patient about any of the following and note responses.

Painful urination	Y	N
Changes in color of urine (blood, cloudy)	Y	N
Change in characteristics of urination (decreased, excessive)	Y	N
Problems with frequent nighttime urination (nocturia)	Y	N

Objective: Diagnostic

Check the following laboratory results for critical values.

Blood urea nitrogen	✓
Serum creatinine	✓
Urinalysis	✓
Urine culture and sensitivity	✓

Objective: Physical Assessment

Inspect

Abdomen	✓
Urinary meatus for inflammation or discharge	✓

Palpate

Abdomen for bladder distention, masses, or tenderness	✓

Percuss

Costovertebral angle for tenderness	✓

Case Study

Objective Data: Physical Assessment

(© iStockphoto/Thinkstock.)

A focused assessment of A.K. reveals the following:

A.K. is lying with his knees bent and drawn to his abdominal area. He appears restless and keeps moving from back to side to reduce his discomfort. Vital signs are as follows: BP 156/70, apical pulse 108, respiratory rate 24, temperature 37.4°C, O_2 saturation 96% on room air. Awake, alert, and oriented × 3. Lungs are clear to auscultation. Apical pulse is regular. Abdomen nondistended with + bowel sounds in all 4 quadrants. No rebound tenderness. Positive left costovertebral tenderness. Voiding small amounts of dark, smoky urine.

Discussion Questions

1. Which physical assessment findings concern you most?
2. Based on the results of the subjective and physical assessment findings, what diagnostic studies do you think may be ordered for A.K.?

You will learn more about diagnostic studies related to the urinary system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

DIAGNOSTIC STUDIES OF URINARY SYSTEM

Many diagnostic studies are used to assess urinary system problems. Tables 49.9, 49.10, 49.11, and 49.12 describe the most common studies. Select studies are described in more detail here.

Urine Studies

Urinalysis

Urinalysis is one of the first studies done to evaluate disorders of the urinary tract (Table 49.9). Results from the urinalysis

TABLE 49.9 Urinalysis

General examination of urine to establish baseline information or provide data to establish a tentative diagnosis and determine if further studies are needed.
Before: Wash perineal area before collecting specimen.
During: Try to obtain first urinated morning specimen.
After: Ensure specimen is examined within 1 hr of urinating.

Test	Normal	Abnormal Finding	Possible Cause and Significance
Bilirubin	None	Present	Liver problems. May appear before jaundice is visible (see Chapter 48).
Casts	None Occasional hyaline	Present	Molds of the renal tubules that may contain protein, WBCs, RBCs, or bacteria. Noncellular casts (hyaline in appearance) occasionally found in normal urine.
Color	Amber yellow	Dark, smoky color Yellow-brown to olive green Orange-red or orange-brown Cloudiness of freshly voided urine Colorless urine	Hematuria. Excess bilirubin. phenazopyridine (Pyridium), rifampin. UTI Excess fluid intake, kidney disease, or diabetes insipidus.
Culture for organisms	No organisms in bladder <10^4 organisms/mL result of normal urethral flora	Bacteria counts >10^5/mL	UTI; most common organisms are *E. coli,* enterococci, *Klebsiella, Proteus,* streptococci.
Glucose	None	Glycosuria	Diabetes, low renal threshold for glucose reabsorption (if blood glucose level is normal). Pituitary problems.
Ketones	None	Present	Altered carbohydrate and fat metabolism in diabetes and starvation; dehydration, vomiting, severe diarrhea.
Odor	Aromatic	Ammonia-like odor Unpleasant odor	Urine allowed to stand. UTI.
Osmolality	50–1200 mOsm/kg (50–1200 mmol/kg)	<50 mOsm/kg >1200 mOsm/kg	Tubular dysfunction. Kidney lost ability to concentrate or dilute urine.
pH	4.6–8.0 (average, 6.0)	>8.0	UTI. Urine allowed to stand at room temperature (bacteria decompose urea to ammonia).
Protein	Random protein (dipstick): 0–trace 24-h protein (quantitative): 50–80 mg/day	Persistent proteinuria	Characteristic of acute and chronic kidney disease, especially involving glomeruli. Heart failure. In absence of disease: high-protein diet, strenuous exercise, dehydration, fever, stress, contamination by vaginal secretions.
RBCs	0–4/hpf	<4.0 >4/hpf	Respiratory or metabolic acidosis. Stones, cystitis, cancer, glomerulonephritis, tuberculosis, kidney biopsy, UTI, trauma.
Specific gravity	1.005–1.030 Maximum concentrating ability of kidney in morning urine (1.025–1.030)	Low High Fixed at about 1.010	Dilute urine, excess diuresis, diabetes insipidus. Dehydration, albuminuria, glycosuria. Renal inability to concentrate urine; end-stage renal disease.
WBCs	0–5/hpf	5/hpf	UTI, inflammation.

hpf, High-powered field.

TABLE 49.10 Diagnostic Studies

Urine

Study	Description and Purpose	Nursing Responsibility
Composite urine collection	Measures specific components, such as electrolytes, glucose, protein, 17-ketosteroids, catecholamines, creatinine, and minerals. Composite urine specimens collected over a period ranging from 2 to 24 hr.	*During:* Have patient urinate and discard this 1st urine specimen. Note this time as the start of the test. Save all urine from subsequent urinations in a container for designated period. At end of period, ask patient to urinate, and add this urine to container. Remind patient to save all urine during study period. Specimens may need refrigerated or preservatives added to container used for collecting urine.
Concentration test	Evaluates renal concentration ability. Measured by specific gravity readings. *Reference interval*: 1.005–1.030.	*Before:* Have patient fast after given time in evening (in usual procedure). *During:* Collect 3 urine specimens at hourly intervals in morning.

TABLE 49.10 Diagnostic Studies—cont'd

Urine

Study	Description and Purpose	Nursing Responsibility
Creatinine clearance	Creatinine is a waste product of protein breakdown (primarily body muscle mass). Clearance of creatinine by kidney approximates the GFR. Calculated as follows: $\text{Creatinine clearance} = \frac{\text{Urine creatinine (mg/dL)} \times \text{Urine volume (mL/min)}}{\text{Serum creatinine (mg/dL)}}$ Reference interval: *Male*: 107–139 mL/min/1.73 m^2 *Female:* 87–107 mL/min/1.73 m^2 (corrected for body surface area).	*During:* Collect 24-hr urine specimen. Discard 1st urination when test is started. Save urine from all subsequent urinations for 24 hr. Have patient urinate at end of 24 hr and add specimen to collection. Measure serum creatinine during 24-hr period.
Protein determination		
• Dipstick (Albustix, Combistix)	Detects protein (primarily albumin) in urine. *Reference interval:* 0 to trace.	*During:* Dip end of stick in urine and read result by comparison with color chart on label as directed. Grading is from 0 to 4+. Interpret with caution. Positive result may not indicate significant proteinuria. Some drugs may give false-positive readings.
• Quantitative protein test	24-hr collection gives a more accurate indication of amount of protein in urine. Persistent proteinuria usually indicates glomerular kidney disease. *Reference interval:* 50–80 mg/day (mainly albumin).	*During:* Perform 24-hr urine collection as above.
Residual urine	Determines amount of urine left in bladder after urinating. Finding may be abnormal in problems with bladder innervation, sphincter impairment, BPH, urethral strictures. *Reference interval:* ≤50 mL urine (↑ with age).	*During:* Immediately after patient urinates, catheterize patient or use bladder ultrasound equipment. If a large amount of residual urine is obtained, HCP may want catheter left in bladder.
Urine culture ("clean catch," "midstream")	Confirms suspected UTI and identifies causative organisms. Normally, bladder is sterile, but urethra contains bacteria and a few WBCs. *Reference interval:* If properly collected, stored, and handled: $<10^3$ organisms/mL usually indicates no infection. 10^3–10^5/mL is usually not diagnostic. Test may need repeated. $>10^5$/mL indicates infection.	*During:* Use sterile container for collection of urine. Touch only outside of container. *For women:* Wipe the periurethral area from front to back, dry the area thoroughly with sterile swab, separate labia with one hand. *For men:* Retract foreskin (if present), cleanse glans around urethra, replace foreskin after cleaning. After cleaning, have patient start voiding, and collect the specimen 1–2 sec after voiding starts. The initial voided urine flushes out most contaminants in the urethra and perineal area. Catheterization may be needed if patient is unable to cooperate with procedure.
Urine cytologic study	Identifies abnormal cellular structures that occur with bladder cancer. Used to follow the progress of bladder cancer after treatment.	*During:* Obtain specimens by voiding, catheterization, or bladder irrigation. Do not use morning's 1st voided specimen because epithelial cells may change in appearance in urine held in bladder overnight. *After:* Specimen should be fresh or brought to laboratory within the hour. An alcohol-based fixative is then added to preserve the cellular structure.

TABLE 49.11 Blood Studies

Urinary System

Test	Reference Interval	Significance
Bicarbonate	22–26 mEq/L (22–26 mmol/L).	Most patients in renal failure have metabolic acidosis and low serum HCO_3^- levels.
Blood urea nitrogen (BUN)	10–20 mg/dL (3.6–7.1 mmol/L)	Used to detect renal problems. Concentration of urea in blood is regulated by rate at which kidney excretes urea. Nonrenal factors may ↑ BUN (e.g., cell destruction from infections, fever, GI bleeding, trauma, athletic activity, excessive muscle breakdown).
BUN/creatinine ratio	12:1–20:1	Increased ratio may be due to conditions that ↓ blood flow to kidneys (e.g., heart failure, dehydration, GI bleeding) or increased protein intake. Decreased ratio may occur with liver disease (from ↓ urea formation) and malnutrition.
Calcium (total)	9.0–10.5 mg/dL (2.25–2.62 mmol/L)	Main mineral in bone and aids in muscle contraction, neurotransmission, and clotting. In kidney disease, ↓ Ca^{2+} reabsorption leads to renal osteodystrophy.
Creatinine	*Male*: 0.6–1.2 mg/dL (53–106 μmol/L) *Female:* 0.5–1.1 mg/dL (49.97 μmol/L)	More reliable than BUN as a determinant of renal function. Creatinine is a product of muscle and protein metabolism. It is released at a constant rate.
Phosphorus	3.0–4.5 mg/dL (0.97–1.45 mmol/L)	Phosphorus balance is inversely related to Ca^{2+} balance. In kidney disease, phosphorus levels are high because the kidney is the primary excretory organ.
Potassium	3.5–5.0 mEq/L (3.5–5.0 mmol/L)	Kidneys excrete majority of body's potassium. In kidney disease, K^+ determinations are critical because K^+ is one of the first electrolytes to become abnormal. High K^+ levels >6 mEq/L can lead to muscle weakness and dysrhythmias.
Sodium	136–145 mEq/L (136–145 mmol/L)	Main extracellular electrolyte determining blood volume. Values usually stay within normal range until late stages of renal failure.
Uric acid	*Male:* 4.0–8.5 mg/dL (0.24–0.51 mmol/L) *Female:* 2.7–7.3 mg/dL (0.16–0.43 mmol/L)	Used as screening test for disorders of purine metabolism. Can indicate kidney disease. Values depend on renal function, rate of purine metabolism, and diet intake of food rich in purines.

TABLE 49.12 Diagnostic Studies

Urinary System

Study	Description and Purpose	Nursing Responsibility
Endoscopy		
Cystoscopy	Inspects interior of bladder with a tubular lighted scope (cystoscope) (Fig. 49.8). Can be used to insert ureteral catheters, remove stones, obtain biopsy specimens of bladder lesions, treat bleeding lesions. Lithotomy position is used. Done under local or general anesthesia, depending on patient's needs and condition. Complications include urinary retention, urinary tract hemorrhage, bladder infection, and bladder perforation.	*Before:* Give IV fluids if general anesthesia is to be used. Ensure consent form is signed. Explain procedure to patient. Give preoperative medication. *After:* Explain that burning on urination, pink-tinged urine, and urinary frequency are expected effects. Observe for bright red bleeding, which is not normal. Help with ambulation because orthostatic hypotension may occur. Offer warm sitz baths, heat, mild analgesics to relieve discomfort.
Radiologic Procedures		
Computed tomography (CT) scan (CT urogram)	Visualizes kidneys, ureters, and bladder. Can detect tumors, abscesses, suprarenal masses (e.g., adrenal tumors), and obstructions. Done with or without contrast media. Contrast is iodine based.	*Before:* Before contrast medium used, evaluate renal function. Assess if patient is allergic to shellfish, since the contrast is iodine based. Patient may need to be NPO 4 hr prior to study. *During:* Warn patient that contrast injection may cause a feeling of being warm and flushed. Patient must lie completely still during scan. *After:* Encourage patient to drink fluids to avoid renal problems with any contrast.
Cystogram	Visualizes bladder and evaluates vesicoureteral reflux. Evaluates patients with neurogenic bladder and recurrent UTIs. Can delineate abnormalities of bladder (e.g., diverticula, stones, tumors). Contrast media instilled into bladder via cystoscope or catheter.	*Before:* Explain procedure to patient. *During:* If done via cystoscope, follow nursing care related to cystoscopy.
Intravenous pyelogram (IVP)	Visualizes urinary tract after IV injection of contrast media. Evaluates size and shape of kidneys, ureters, and bladder. Cysts, tumors, and ureteral obstructions distort normal appearance of these structures. Patient with decreased renal function should not have IVP because contrast media can be nephrotoxic.	*Before:* Cathartic or enema given night before. Assess patient for iodine sensitivity to avoid anaphylactic reaction. *During:* Warn patient that contrast injection may cause a feeling of being warm and flushed. *After:* Force fluids to avoid renal problems with contrast.
Kidneys, ureters, bladder (KUB)	X-ray examination of abdomen and pelvis. Delineates size, shape, and position of kidneys, ureter, and bladder. Can see radiopaque stones and foreign bodies.	*Before:* No special preparation needed.
Loopogram	Detects obstructions, anastomotic leaks, stones, and reflux when patient has a urinary pouch or ileal conduit. Because urinary diversions are created with bowel, there is risk for absorption of contrast media.	*Before:* Explain procedure to patient. *During:* Monitor patient for reactions to the contrast media.
Magnetic resonance angiography	Visualizes renal vasculature. Gadolinium-enhanced studies allow visualization of renal artery.	Same as renal arteriogram. Does not require femoral artery puncture.
Magnetic resonance imaging (MRI)	Visualizes kidneys. Not proven useful for detecting urinary stones or calcified tumors.	*Before:* Oral and/or IV contrast injection may be used. Check for pregnancy, allergies, and renal function before test. Have patient remove all metal objects. Remove metallic foil patches. Contraindicated for persons with implanted metallic devices or other metal fragments unless noted to be MRI safe. Ask about any staples, plates, dental bridges, or other metal appliances. Patient may need to be fasting. Assess for claustrophobia and the need for antianxiety medication. *During*: Patient must lie completely still during scan.
Nephrostogram (antegrade pyelogram)	Evaluates upper urinary tract when patient has allergy to contrast media, decreased renal function, or abnormalities that prevent passage of a ureteral catheter. Contrast media may be injected percutaneously into renal pelvis or via a nephrostomy tube that is already in place when determining tube function or ureteral integrity after trauma or surgery.	*Before:* Explain procedure and prepare patient as for IVP. *During and after:* Watch for signs of complications (e.g., hematuria, infection, hematoma).
Renal arteriogram (angiogram)	Visualizes renal blood vessels. Can aid in diagnosing renal artery stenosis (Fig. 49.9), extra or missing renal blood vessels, and renovascular hypertension. Can aid in distinguishing between a renal cyst and renal tumor. Included in workup of a potential renal transplant donor. A catheter is inserted into the femoral artery and passed up the aorta to the level of renal arteries (Fig. 49.10). Contrast media is injected to outline renal blood supply.	*Before:* Cathartic or enema may be used the night before. Before injection of contrast material, assess for iodine sensitivity. Tell patient they may feel a transient warm feeling along the course of blood vessel when contrast media is injected. *After:* Place a pressure dressing over femoral artery injection site. Observe site for bleeding and inflammation. Have patient maintain bed rest with affected leg straight. Take peripheral pulses in the involved leg every 30–60 min to detect occlusion of blood flow (from thrombus or emboli).

TABLE 49.12 Diagnostic Studies—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Renal biopsy	Obtains renal tissue for examination to determine type of kidney disease or to follow progress of kidney disease. Usually done as a skin (percutaneous) biopsy through needle insertion into lower lobe of kidney under CT or ultrasound guidance. Absolute contraindications are bleeding disorders, single kidney, and uncontrolled hypertension. Relative contraindications include suspected renal infection, hydronephrosis, and possible vascular lesions.	*Before:* Type and crossmatch patient for blood. Ensure consent form is signed. Assess coagulation status through patient history, medication history, CBC, hematocrit, prothrombin time, and bleeding and clotting time. Patient should not be taking aspirin or warfarin. *After:* Apply pressure dressing and keep patient on affected side for 30–60 min. Bed rest for 24 hr. Vital signs every 5–10 min, first hour. Assess for flank pain, hypotension, decreasing hematocrit, fever, chills, urinary frequency, dysuria, and gross or microscopic hematuria. Inspect biopsy site for bleeding. Teach patient to avoid lifting heavy objects for 5–7 days and to not take anticoagulant drugs until allowed by HCP.
Renal scan	Evaluates anatomic structures, perfusion, and function of kidneys. IV radioactive isotopes are injected. Radiation detector probes are placed over kidney and scintillation counter monitors radioactive material in kidney. Radioisotope distribution in kidney is scanned and mapped. Shows location, size, and shape of kidney and assesses blood flow, glomerular filtration, tubular function, and urinary excretion. Abscesses, cysts, and tumors may appear as cold spots because of nonfunctioning tissue. Monitors function of a transplanted kidney.	*Before:* No diet or activity restriction. Tell patient that there should not be any pain or discomfort during test.
Renal ultrasound	Detects renal or perirenal masses (tumors, cysts) and obstructions. Small external ultrasound probe is placed on patient's skin. Conductive gel applied to skin. Noninvasive procedure involves passing sound waves into body structures and recording images as they are reflected. Computer interprets tissue density based on sound waves and displays it in picture form. Safe for patients with renal failure.	*Before:* Explain procedure to patient. No bowel preparation needed. *During:* Because radiation exposure is avoided, can obtain repeated images over a brief period.
Retrograde pyelogram	X-ray of urinary tract taken after injection of contrast material into kidneys. May be done if an IVP does not visualize the urinary tract or has decreased renal function. A cystoscope is inserted, and ureteral catheters are inserted through it into renal pelvis. Contrast media is injected through catheters.	*Before:* Prepare patient as for IVP. Tell patient that there may be pain from distention of pelvis and discomfort from cystoscope. Anesthesia may be given for procedure. *After:* Complications similar to those for cystoscopy.
Urethrogram	Similar to a cystogram. Contrast media is injected retrograde into urethra to identify strictures, diverticula, or other urethral pathologic conditions. When urethral trauma is suspected, a urethrogram is done before catheterization.	*Before:* Explain procedure to patient.
Voiding cystourethrogram (VCUG)	Voiding study of bladder opening (bladder neck) and urethra. Bladder is filled with contrast media. Fluoroscopic films are taken to visualize bladder and urethra. After urination, another film is taken to assess for residual urine. Can detect abnormalities of lower urinary tract, urethral stenosis, bladder neck obstruction, vesicoureteral reflux, and prostatic enlargement.	*Before:* Explain procedure to patient.
Urodynamic Studies		
Cystometrogram	Evaluates bladder's capacity to contract and expel urine. Involves insertion of catheter and instillation of water or saline solution into bladder. Measurements of pressure exerted against bladder wall are recorded. If measuring abdominal pressure, a 2nd tube is inserted into rectum or vagina. This tube is attached to a small fluid-filled balloon to allow pressure recording.	*Before:* Explain procedure to patient. *During:* Ask patient about sensations of bladder filling, usually including the first desire (urge) to urinate, a strong desire to urinate, and perception of bladder fullness. *After:* Observe patient for manifestations of UTI after procedure.
Radionuclide cystography (RNC)	Detects and grades vesicoureteral reflux. Like VCUG with a small dose of radioisotope tracer instilled into the bladder via urethral catheter. More sensitive than VCUG, and radiation dose is 1/1000 that of the VCUG.	*Before:* Explain procedure to patient as in VCUG.

Continued

TABLE 49.12 Diagnostic Studies—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Sphincter electromyography (EMG)	Recording of electrical activity created when nervous system stimulates muscle tissue. By placing needles, percutaneous wires, or patches near the urethra, pelvic floor muscle activity can be assessed. During the cystometrogram, sphincter EMG is used to identify voluntary pelvic floor muscle contractions and response of these muscles to bladder filling, coughing, and other provocative maneuvers.	*Before:* Explain procedure to patient.
Urine flow study (uroflow)	Measures urine volume in a single voiding expelled in a period. Used to (1) assess the degree of outflow obstruction caused by such conditions as BPH, (2) assess bladder or sphincter dysfunction effects on voiding, and (3) evaluate effects of treatment for lower urinary tract problems. Graphic displays can illustrate straining and intermittent flow patterns or other abnormal voiding disorders. *Normal maximum flow rate:* Men: 20–25 mL/sec; women: 25–30 mL/sec. Volume voided and patient's age can affect the flow rate.	*Before:* Explain procedure to patient. *During:* Ask the patient to start the test with a comfortably full bladder, urinate into a designated container, and try to empty completely. *After:* Measure residual urine volume immediately after a urinary flow study because this will help identify degree of chronic urinary retention that often occurs with abnormal flow patterns.
Videourodynamics	Combination of cystometrogram, sphincter EMG, and/or urinary flow study with anatomic imaging of the lower urinary tract, typically via fluoroscopy. Used in selected cases to identify an obstructive lesion and characterize anatomic changes in bladder and lower urinary tract.	*Before:* Explain procedure to patient.
Voiding pressure flow study	Combines a urinary flow rate, cystometric pressures (intravesical, abdominal, and detrusor pressures), and sphincter EMG for detailed evaluation of micturition. Completed by assisting the patient to a specialized toilet to urinate while the various pressure tubes and EMG apparatus remain in place.	*Before:* Explain procedure to patient.
Whitaker study	Measures the pressure differential between renal pelvis and bladder. Ureteral obstruction can be assessed. Percutaneous access to renal pelvis obtained by placing a catheter in renal pelvis. A catheter is placed in bladder. Fluid is perfused through the percutaneous tube or needle at a rate of 10 mL/min. Pressure data are then collected. Pressure measurements are combined with fluoroscopic imaging to find the level of obstruction.	*Before:* Explain procedure to patient.

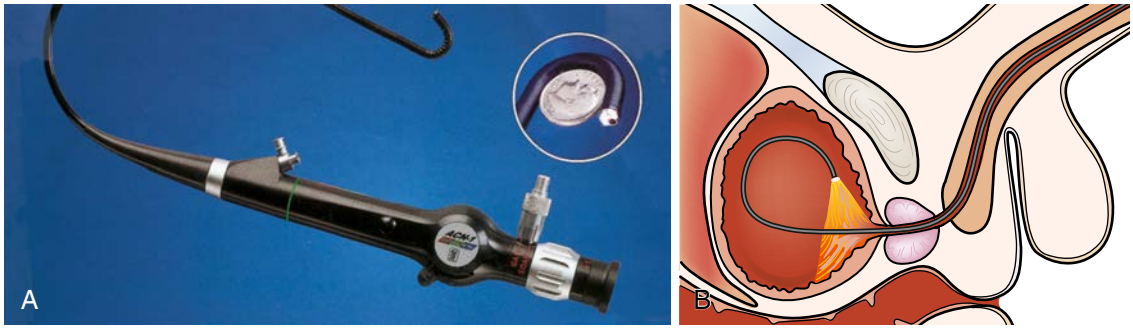

Fig. 49.8 Cystoscopic examination of the bladder in a man. (A) Flexible cystonephroscope. (B) Scope inserted into bladder. (A, Courtesy Circon Corporation, Santa Barbara, CA.)

may show abnormalities, suggest the need for further studies, or show progression in a previously diagnosed disorder.

Although a specimen may be collected at any time of the day for a routine urinalysis, it is best to obtain the first specimen urinated in the morning. This concentrated specimen is more likely to contain abnormal constituents if they are present in the urine. The specimen should be examined within 1 hour of urinating. Otherwise, bacteria multiply rapidly, RBCs hemolyze, *casts* (molds of renal tubules) disintegrate, and the urine becomes alkaline because of urea-splitting bacteria. If it is not

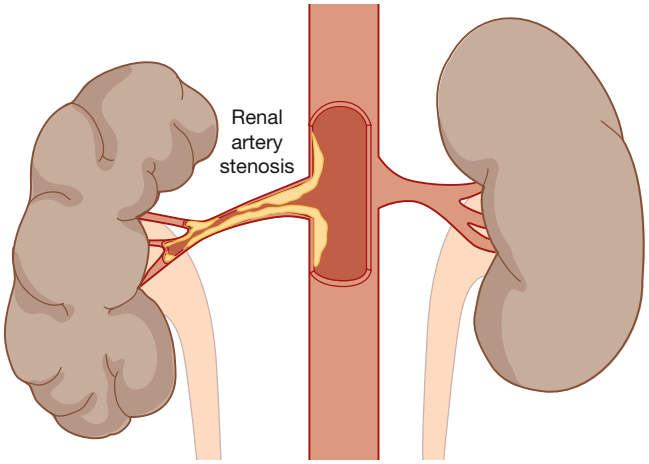

Fig. 49.9 Left renal artery stenosis *(arrow)*.

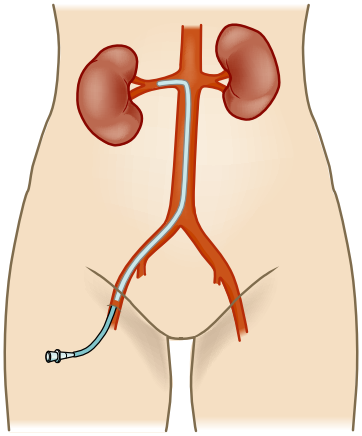

Fig. 49.10 Catheter insertion for a renal arteriogram.

possible to send the specimen to the laboratory immediately, refrigerate it. However, for the best results, coordinate specimen collection with routine laboratory hours.

Creatinine Clearance

A common test used to analyze urinary system disorders is creatinine clearance. **Creatinine** is a waste product made by muscle breakdown. Urinary excretion of creatinine is a measure of the amount of active muscle tissue in the body, not of body weight. Therefore, people with larger muscle mass have higher values. Creatinine levels stay remarkably constant for each person because they are not significantly affected by protein ingestion, exercise, water intake, or rate of urine production.

Since almost all creatinine is excreted by the kidneys, creatinine clearance is the most accurate indicator of renal function. The result of a creatinine clearance test closely approximates that of the GFR. Normal creatinine clearance values range from 87 to 139 mL/min (Table 49.11). After age 40, the creatinine clearance rate decreases at a rate of about 1 mL/min/year. We should obtain a blood specimen to measure serum creatinine during the period of urine collection.

Urodynamic Studies

Urodynamic studies measure urinary tract function. Urodynamic tests study the storage of urine within the bladder and the flow of urine through the urinary tract to the outside of the body. A combination of techniques may be used for a detailed assessment of urinary function (Table 49.12).

Radiologic Studies

Many radiologic studies require a bowel preparation the evening before the study to clear the lower GI tract of feces and flatus. Because the kidneys lie in a retroperitoneal location, colon contents can obstruct visualization of the urinary tract. If the bowel preparation does not adequately clear the lower GI tract, the study may be unsuccessful and need rescheduled. Common bowel preparations include enemas, magnesium citrate, and bisacodyl (Dulcolax) tablets or suppositories. Patients with kidney failure should not receive some bowel preparations, such as magnesium citrate and saline laxative enema, because the kidneys cannot excrete the magnesium (see Chapter 51).

Iodine-based contrast media used in some diagnostic studies may cause contrast-induced kidney injury (CIN) and allergic reactions. Keeping the patient hydrated is important. Some patients may need IV fluids started hours before the procedure. N-acetylcysteine—a renal vasodilator and antioxidant—is sometimes given to reduce the incidence of CIN. It can be given by oral or IV route.

When a patient has multiple diagnostic studies, it is important to maintain hydration. The patient is at risk for dehydration when they have had nothing by mouth for consecutive days, extended time in the radiology department, and bowel preparations. Severe dehydration, especially in debilitated or older patients and patients with diabetes, may lead to acute kidney injury. Ensure that the patient is hydrated and given adequate nourishment between studies. Check with the HCP about insulin dosage for patients with diabetes who are NPO.

Case Study

Objective Data: Diagnostic Studies

(© iStockphoto/Thinkstock.)

The HCP orders the following initial diagnostic studies for A.K.:

- CBC, basic metabolic panel (electrolytes, BUN, creatinine)
- Urinalysis, culture if indicated
- Renal ultrasound

A.K.'s CBC and metabolic panel results are within normal limits. His urinalysis shows moderate hematuria. A renal ultrasound shows several stones in the left ureter. There is no hydronephrosis at present. The HCP prescribes IV opioids for pain management and admits A.K. to a medical unit.

Discussion Questions

1. Which diagnostic study results are abnormal?
2. Which diagnostic study results are of most concern to you?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A renal stone in the pelvis of the kidney will change the patient's kidney function by interfering with the
   - **a.** structural support of the kidney.
   - **b.** regulation of the concentration of urine.
   - **c.** entry and exit of blood vessels at the kidney.
   - **d.** collection and drainage of urine from the kidney.
2. A patient with kidney disease has oliguria and a creatinine clearance of 40 mL/min. These findings most directly reflect abnormal function of
   - **a.** tubular secretion.
   - **b.** glomerular filtration.
   - **c.** capillary permeability.
   - **d.** concentration of filtrate.
3. The nurse identifies a risk for urinary stones in a patient who relates a health history that includes
   - **a.** dehydration.
   - **b.** hyperaldosteronism.
   - **c.** serotonin deficiency.
   - **d.** adrenal insufficiency.
4. Diminished ability to concentrate urine, associated with aging of the urinary system, is due to
   - **a.** a decrease in bladder sensory receptors.
   - **b.** a decrease in the number of functioning nephrons.
   - **c.** decreased function of the loop of Henle and tubules.
   - **d.** thickening of the basement membrane of Bowman capsule.
5. During physical assessment of the urinary system, the nurse
   - **a.** performs fist percussion to detect tenderness in the flank area.
   - **b.** expects a dull percussion sound when 100 mL of urine is present in the bladder.
   - **c.** percusses above the symphysis pubis to determine the level of urine in the bladder.
   - **d.** palpates the lower pole of the right kidney as a smooth mass that descends on expiration.
6. Normal findings expected on physical assessment of the urinary system include *(select all that apply)*
   - **a.** nonpalpable bladder.
   - **b.** nonpalpable left kidney.
   - **c.** auscultation of renal artery bruit.
   - **d.** no CVA tenderness elicited by a kidney punch.
   - **e.** full bladder percusses as dullness above the symphysis pubis.
7. A diagnostic study that evaluates renal blood flow, glomerular filtration, tubular function, and excretion is a(n)
   - **a.** IVP.
   - **b.** VCUG.
   - **c.** renal scan.
   - **d.** loopogram.
8. On reading the urinalysis results of a dehydrated patient, the nurse would expect to find
   - **a.** a pH of 8.4.
   - **b.** RBCs of 4/hpf.
   - **c.** color: yellow, cloudy.
   - **d.** specific gravity of 1.035.

1. d; 2. b; 3. a; 4. c; 5. a; 6. a, b, d, e; 7. c; 8. d.

CONCEPTUAL FOCUS

Elimination
Fluids and Electrolytes
Infection
Pain

LEARNING OUTCOMES

1. Discuss the pathophysiology, clinical manifestations, and interprofessional and nursing management of urinary tract infections, cystitis, urethritis, and pyelonephritis.
2. Distinguish the etiology, clinical manifestations, and nursing and interprofessional management of acute poststreptococcal glomerulonephritis, Goodpasture syndrome, and chronic glomerulonephritis.
3. Describe the common causes, clinical manifestations, and interprofessional and nursing management of nephrotic syndrome.
4. Compare and contrast the etiology, clinical manifestations, and interprofessional and nursing management of various types of urinary calculi.
5. Distinguish the common causes and management of renal trauma, renal vascular problems, and hereditary kidney diseases.
6. Describe the clinical manifestations and nursing and interprofessional management of kidney and bladder cancers.
7. Describe the common causes and management of urinary incontinence and urinary retention.
8. Distinguish among urethral, ureteral, suprapubic, and nephrostomy catheters regarding indications for use and nursing responsibilities.
9. Explain the nursing management of the patient undergoing nephrectomy or urinary diversion surgery.

stricture
urethritis
urinary incontinence (UI)
urinary retention
urinary tract infection (UTI)
urosepsis

A wide range of renal and urologic problems contribute to impaired elimination. This chapter discusses problems of the upper urinary tract (kidneys and ureter) and lower urinary tract (bladder and urethra). Many patients are at risk for fluid, electrolyte, and acid-base imbalances because of the kidneys' vital role in homeostasis. The person may have discomfort, incontinence, disrupted sleep, and impaired skin integrity.

INFECTIOUS AND INFLAMMATORY URINARY PROBLEMS

URINARY TRACT INFECTION

Urinary tract infections (UTIs) are infections of the urinary tract. They are the most common outpatient infection. *Escherichia coli* is the most common pathogen causing a UTI. It causes 75% of cases without urinary tract structural

TABLE 50.1 Common Causes of UTIs

- *Candida* species
- *Enterobacter*
- *Enterococcus*
- *Escherichia coli*
- *Klebsiella pneumoniae*
- *Proteus mirabilis*
- *Pseudomonas aeruginosa*
- *Serratia*
- *Staphylococcus aureus*
- *Streptococci*, Group B

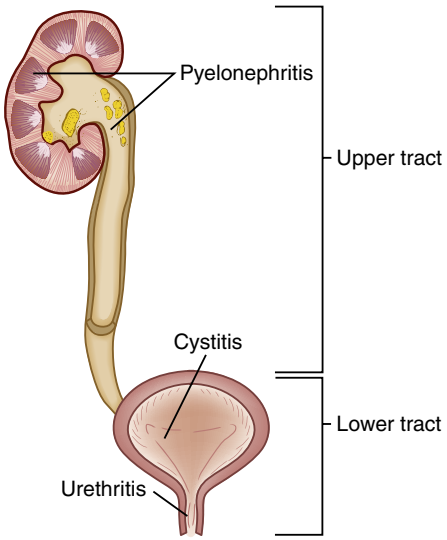

Fig. 50.1 Sites of infections in the upper and lower urinary tracts.

abnormalities or stones and 65% of complicated UTIs (Table 50.1).[1]

Fungal and parasitic infections sometimes cause UTIs. These are more common in patients who are immunosuppressed, have diabetes or kidney problems, or received multiple courses of antibiotic therapy. They may also occur in persons who live in or have traveled to certain developing countries.

Classification of Urinary Tract Infection

UTIs can be broadly described as an upper or lower UTI according to its location within the urinary system (Fig. 50.1). We use specific terms to describe the location of a UTI. For example, **pyelonephritis** implies inflammation (usually caused by infection) of the renal parenchyma and collecting system. **Cystitis** is an inflammation of the bladder. **Urethritis** is an inflammation of the urethra. **Urosepsis** is a UTI that has spread systemically. It is a life-threatening condition requiring emergency treatment.

We also classify a UTI as complicated or uncomplicated. *Uncomplicated UTIs* occur in an otherwise normal urinary tract. They usually only involve the bladder. *Complicated UTIs* occur in a person with an underlying disease or with a structural or functional problem in the urinary tract. Examples include obstruction, stones, catheters, abnormal genitourinary (GU) tract, acute kidney injury (AKI), chronic kidney disease (CKD), kidney transplant, diabetes, or neurologic disease. They can also occur when a person has developed antibiotic resistance, is immunocompromised, has pregnancy-induced changes, or has recurrent infection. The person with a complicated infection is at risk for pyelonephritis, urosepsis, and renal damage.

TABLE 50.2 Risk Factors for UTIs

Anatomic Factors
- Congenital defects leading to obstruction or urinary stasis
- Fistula exposing urinary stream to skin, vagina, or fecal stream
- Obesity
- Shorter female urethra and colonization from normal vaginal flora

Factors Compromising Immune Response
- Aging
- Diabetes
- HIV infection

Factors Increasing Urinary Stasis
- Extrinsic obstruction (tumor, fibrosis compressing urinary tract)
- Intrinsic obstruction (stone, tumor of urinary tract, urethral stricture, BPH)
- Renal impairment
- Urinary retention (e.g., neurogenic bladder)

Foreign Bodies
- Catheters (indwelling, external condom catheter, ureteral stent, nephrostomy tube, intermittent catheterization)
- Urinary tract instrumentation (cystoscopy)
- Urinary tract stones

Functional Disorders
- Constipation
- Voiding dysfunction with detrusor sphincter muscle incoordination

Other Factors
- Habitual delay of urination ("nurse's bladder," "teacher's bladder")
- Pregnancy
- Menopause
- Sexual activity (women)
- Poor personal hygiene
- Use of spermicidal agents, contraceptive diaphragm (women), bubble baths, feminine sprays

Etiology and Pathophysiology

The urinary tract above the urethra is normally sterile. Several mechanical and physiologic defense mechanisms aid in maintaining sterility and preventing UTIs. These defenses include normal voiding with complete bladder emptying, ureterovesical junction (UVJ) competence, and ureteral peristaltic activity that propels urine toward the bladder. The antibacterial properties of urine are maintained by a slightly acidic pH (6.0 to 7.5) and abundant antimicrobial proteins and peptides that interfere with the bacterial growth. A change in any of these defense mechanisms increases the risk for a UTI (Table 50.2).

The organisms that usually cause UTIs originate in the perineum. They are introduced via the ascending route from the urethra. Most infections are caused by gram-negative bacilli normally found in the gastrointestinal (GI) tract. However, gram-positive organisms, such as streptococci, enterococci, and *Staphylococcus saprophyticus,* can also cause UTIs.

TABLE 50.3 Lower Urinary Tract Symptoms (LUTS)

Symptoms	Description
Emptying Symptoms	
Dysuria	• Painful or difficult urination
Hesitancy	• Difficulty starting urine stream • Delay between initiation of urination (because of urethral sphincter relaxation) and beginning of flow of urine • Diminished urinary stream
Intermittency	• Interruption of urinary stream while voiding
Postvoid dribbling	• Urine loss after completing voiding
Urinary retention or incomplete emptying	• Inability to empty urine from bladder • Caused by atonic bladder or obstruction of urethra • Can be acute or chronic
Storage Symptoms	
Incontinence	• Involuntary or accidental urine loss or leakage
Nocturia	• Awakened by urge to void 2 or more times during sleep • May be diurnal or nocturnal depending on sleep schedule
Nocturnal enuresis	• Adults: loss of urine during sleep
Urgency	• Sudden, strong, or intense desire to void immediately • Often accompanied by frequency
Urinary frequency	• More than 8 times in 24-h period • Often <200 mL each voiding

A common factor contributing to ascending infection is urologic instrumentation (e.g., catheterization, cystoscopic examinations). Instrumentation allows bacteria that are normally present at the opening of the urethra to enter the urethra or bladder. Sexual intercourse promotes "milking" of bacteria from the vagina and perineum. It may cause minor urethral trauma that predisposes women to UTIs.

UTIs can result from hematogenous transmission, in which blood-borne bacteria invade the kidneys, ureters, or bladder from elsewhere in the body. For a kidney infection to occur this way, there must be prior injury to the urinary tract, such as obstruction of the ureter, damage caused by stones, or renal scars.

UTIs are the most common health care–associated infection (HAI). They are mainly due to the use of an indwelling catheter. *Catheter-associated urinary tract infections (CAUTIs)* are often caused by *E. coli* and, less often, *Pseudomonas* organisms. CAUTIs lead to extended hospital stays, increased health care costs, and increased mortality.[2]

Clinical Manifestations

Manifestations of UTIs range from painful urination in uncomplicated urethritis or cystitis to severe systemic illness with abdominal or back pain, fever, and sepsis.

Lower urinary tract symptoms (LUTS) occur in patients who have UTIs of the upper urinary tract, as well as those confined to the lower tract. Symptoms are related to either bladder storage or bladder emptying (Table 50.3). These include dysuria, frequency (voiding more than every 2 hours), urgency, and suprapubic discomfort or pressure. The urine may have grossly visible blood (hematuria) or sediment, giving it a cloudy appearance. Upper UTIs (involving the renal parenchyma, pelvis, and ureters) typically causes fever, chills, and flank pain. A UTI confined to the lower urinary tract does not usually have systemic manifestations. People with significant bacteriuria may have no symptoms or may have nonspecific symptoms, such as fatigue or anorexia.

Remember that the common manifestations of a UTI are often absent in older adults. Older adults tend to have general abdominal discomfort rather than dysuria and suprapubic pain. They may have impaired cognition or overall clinical deterioration. Because older adults are less likely to have a fever with a UTI, temperature is an unreliable sign of a UTI.[3]

Multiple problems may produce LUTS similar to the symptoms of a UTI. For example, patients with bladder tumors or those receiving intravesical chemotherapy or pelvic radiation usually have urinary frequency, urgency, and dysuria. Interstitial cystitis/painful bladder syndrome produces urinary symptoms that are similar to and sometimes confused with a UTI.

A small number of healthy persons have some bacteria colonizing the bladder. We call this asymptomatic bacteriuria. It does not justify screening or treatment except in pregnant women, those with a recent kidney transplant, or those having a urologic procedure.

Diagnostic Studies

In a patient suspected of having a UTI, first obtain a dipstick urinalysis. This test can identify the presence of nitrites (indicating bacteriuria), white blood cells (WBCs), and leukocyte esterase (an enzyme present in WBCs, indicating pyuria). Microscopic urinalysis can confirm these findings. Bacterial counts of 10^5 colony-forming units per milliliter (CFU/mL) or higher typically indicate a clinically significant UTI. However, counts as low as 10^2 to 10^3 CFU/mL in a person with signs and symptoms are indicative of UTI.

After confirmation of bacteriuria and pyuria, we may do a urine culture. A urine culture is needed in persistent bacteriuria, recurring UTIs (more than 2 or 3 per year), or complicated, CAUTI, or HAI UTIs. We may culture urine when the infection is not responsive to empiric therapy or the diagnosis is questionable.

A voided midstream technique *(clean-catch urine sample)* is best for obtaining a urine culture in most circumstances (see Table 49.8). When we cannot obtain an adequate clean-catch specimen, we may do catheterization. A specimen from catheterization gives more accurate results than a clean-catch specimen.

A urine culture with *sensitivity testing* can determine the bacteria's susceptibility to a variety of antibiotic drugs. The results allow the HCP to choose an antibiotic known to be capable of destroying the bacteria causing a UTI in a specific patient.

Some patients need imaging studies of the urinary tract. An ultrasound or CT scan may be done if we suspect an obstruction or UTIs recur.

Interprofessional Care

The interprofessional care and drug therapy of UTIs are outlined in Table 50.4. Once a UTI has been diagnosed, appropriate antimicrobial therapy is started. An antibiotic may be chosen

TABLE 50.4 Interprofessional Care

UTI

Diagnostic Assessment
- History and physical assessment
- Urinalysis (midstream, "clean-catch" voided specimen)
- Urine for culture and sensitivity (if indicated)
- Imaging studies of urinary tract (if indicated): CT scan, ultrasound, cystoscopy

Management

Uncomplicated UTI
- Patient teaching
- Adequate fluid intake (8 to 9 8-oz glasses/day)

Drug Therapy
- Antibiotics
  - fluconazole (in patients with fungal UTI)
  - fosfomycin (Monurol)
  - nitrofurantoin (Macrodantin, Macrobid)
  - TMP/SMX (Bactrim, Bactrim DS)
  - trimethoprim alone (in patients with sulfa allergy)
  - cephalexin

Recurrent UTI
- Repeat urinalysis
- Urine culture and sensitivity testing
- Adequate fluid intake (8 to 9 8-oz glasses/day)
- Repeat patient teaching
- Imaging studies of urinary tract (if indicated): see above

Drug Therapy
- Antibiotic: nitrofurantoin, TMP/SMX
- Sensitivity-guided antibiotic therapy: ampicillin, amoxicillin, 1st- or 2nd-generation cephalosporin, fluoroquinolones
- 3- to 6-month trial of suppressive or prophylactic antibiotic therapy
- Postcoital antibiotic prophylaxis: cephalexin, nitrofurantoin, TMP/SMX, fosfomycin, trimethoprim

based on the HCP's best judgment *(empiric therapy)* or the results of sensitivity testing.

Uncomplicated UTIs are treated with a short-term course of antibiotics, typically for 3 days. In contrast, complicated UTIs need a longer period of treatment, lasting 7 to 14 days or more.[4] Many residents of long-term care facilities, especially women, have chronic asymptomatic bacteriuria. However, we usually only treat symptomatic UTIs.

First-choice drugs to treat uncomplicated or initial UTIs are trimethoprim/sulfamethoxazole (TMP/SMX), nitrofurantoin, cephalexin, and fosfomycin.[4] TMP/SMX has the advantages of being inexpensive and taken twice daily. Nitrofurantoin is taken 3 or 4 times daily, but a twice-daily formulation is available.

DRUG ALERT

Nitrofurantoin (Macrodantin)
- Avoid use if the creatinine clearance <30 mL/min.
- Notify HCP at once if fever, chills, cough, chest pain, dyspnea, rash, or numbness or tingling of fingers or toes develops.

Other antibiotics used in the treatment of uncomplicated UTI include ampicillin, amoxicillin, and cephalosporins. Fluoroquinolones (e.g., levofloxacin, ciprofloxacin) are given to treat complicated UTIs. *E. coli* resistance to TMP/SMX, β-lactams, and ciprofloxacin is an increasing problem in the United States. In patients with UTIs from fungi, fluconazole (Diflucan) is the preferred therapy.

A urinary analgesic, such as oral phenazopyridine, may relieve discomfort caused by severe dysuria. Phenazopyridine is an azo dye excreted in urine. There it exerts a topical analgesic effect on the urinary tract mucosa. It is taken up to 2 concurrent days. Teach patients that this drug causes the urine to turn orange or red.

Patients who have repeated UTIs may receive prophylactic or suppressive antibiotics. A low dose of TMP/SMX, nitrofurantoin, or another antibiotic taken daily may prevent recurring UTIs. A single dose may be taken after an event likely to provoke a UTI, such as sexual intercourse. While suppressive therapy is often effective short term, use is limited because of the risk for antibiotic resistance, which leads to breakthrough infections with increasingly virulent pathogens.

NURSING MANAGEMENT: URINARY TRACT INFECTION

Assessment

Subjective and objective data that you should obtain from a patient with a UTI are shown in Table 50.5.

Clinical Problems

Clinical problems for the patient with a UTI may include:
- Impaired urinary elimination
- Infection
- Pain
- Deficient knowledge

More information on clinical problems and interventions for the patient with a UTI is presented in eNursing Care Plan 50.1 (available on the website for this chapter).

Planning

The overall goals are that the patient with a UTI will have (1) relief from bothersome symptoms, (2) no upper urinary tract involvement, and (3) no recurrence.

Implementation

Health Promotion

It is important to recognize people who are at risk for a UTI. These include debilitated persons, older adults, patients who are immunocompromised (e.g., cancer, diabetes), and patients treated with immunosuppressive drugs or corticosteroids. Health promotion measures can help decrease the frequency of UTIs and support early detection of infection. These activities include teaching preventive measures, including (1) emptying the bladder regularly and completely, (2) evacuating the bowel regularly, (3) wiping the perineal area from front to back after voiding and defecation, and (4) drinking an adequate amount of liquid each day.

TABLE 50.5 NURSING ASSESSMENT

UTI

Subjective Data

Important Health Information

Health history: Previous UTI. Urinary stones, reflux, strictures, or retention. Neurogenic bladder, pregnancy, BPH, bladder cancer, sexually transmitted infection.

Medications: Antibiotics, anticholinergics, antispasmodics

Surgery or other treatments: Recent urologic instrumentation (catheterization, cystoscopy)

Functional Health Patterns

Cognitive-perceptual: Suprapubic or low back pain, bladder spasms, dysuria, burning on urination

Elimination: Urinary frequency, urgency, hesitancy, dysuria, nocturia

Health perception–health management: Urinary hygiene practices. Lassitude, malaise

Nutritional-metabolic: Nausea, vomiting, anorexia. Chills and fever

Sexuality-reproductive: Sexual activity, use of spermicidal agents or contraceptive diaphragm (women)

Objective Data

General

Fever, chills, dysuria

Atypical presentation in older adults: afebrile, absence of dysuria, loss of appetite, altered mental status

Urinary

Hematuria. Cloudy, foul-smelling urine

Possible Diagnostic Findings

Leukocytosis. Urinalysis positive for bacteria, pyuria, RBCs, WBCs, and nitrites. Positive urine culture. Ultrasound, CT scan, MRI, voiding cystourethrogram (VCUG), cystoscopy showing urinary tract abnormalities

BOX 50.1 EVIDENCE-BASED PRACTICE

Nurse-Driven Protocol for Catheter Removal

You are caring for M.B., a 42-year-old patient who had a total vaginal hysterectomy for dysfunctional uterine bleeding. She had an indwelling urinary catheter placed before surgery. On the 1st postoperative day, M.B. asks you when the catheter will be removed.

Making Clinical Decisions

Synthesis of Best Available Evidence

CAUTI still represents a notable source of infection in hospitalized patients. A single CAUTI can increase cost of care by $600 to $20,000. Because the Centers for Medicare and Medicaid Services requires public reporting of CAUTI as an indicator for hospital reimbursement, hospital leaders have led efforts to develop CAUTI prevention bundles. Traditionally, physicians have been responsible for ordering urinary catheter removal. However, research has shown physicians tend to leave catheters in place without appropriate indications and may be unaware the patient continues to have an indwelling urinary catheter. Nurse-driven protocols for directed assessment of catheter need and decision for removal may be a way to decrease catheter days and CAUTI occurrence.

Clinician Expertise

As part of the unit's efforts to decrease occurrence of CAUTI, you have received education on daily assessment of specific indications for continued catheterization. In your agency, use of an indwelling catheter typically does not exceed 24 hours after a hysterectomy. You have assessed M.B. based on identified criteria and found the time appropriate for urinary catheter removal. You explain the process to M.B. and prepare to remove the indwelling urinary catheter.

Patient Preferences and Values

M.B. expresses concern about getting a UTI related to catheterization.

Implications for Nursing Practice

1. How would you explain the catheter removal protocol and its rationale to M.B.?
2. How can you demonstrate engagement with and ownership of this unit practice?

Reference for Evidence

Tyson AF, Campbell EF, Spangler LR, et al.: Implementation of a nurse-driven protocol for catheter removal to decrease catheter-associated urinary tract infection rate in a surgical trauma ICU, *J Intensiv Care Med* 35:738, 2020.

Routine and thorough perineal hygiene is important for all hospitalized patients, especially after using a bedpan, after a bowel movement, or if fecal incontinence is present. Answer call lights quickly. Offer the bedpan or urinal to bedridden patients at frequent intervals. These measures can prevent incontinence and decrease the number of incontinence episodes.

Prevention of CAUTI. All patients undergoing catheterization of the urinary tract are at risk for developing CAUTI. You play a key role in preventing CAUTI. Avoiding unnecessary catheterization and early removal of indwelling catheters are the most effective means for reducing CAUTI (Box 50.1). Always follow aseptic technique during these procedures. Wash your hands before and after contact with each patient. Wear gloves for care of urinary catheters. The American Nurses Association offers an evidence-based clinical tool for decreasing CAUTI.[5]

◆ Acute Care

Acute care for a patient with a UTI includes ensuring adequate fluid intake unless contraindicated. Maintaining adequate fluid intake may be hard because of the patient feeling that fluid intake will make the pain and urinary frequency worse. Tell patients that fluids will increase frequency of urination but will also dilute the urine, making the bladder less irritable. Fluids will help flush out bacteria before they have a chance to colonize in the bladder. Teach them to avoid caffeine, alcohol, citrus juices, chocolate, and highly spiced foods or beverages because they are bladder irritants.

Applying heat to the suprapubic area or lower back may relieve the discomfort. Have the patient apply a heating pad (turned to its lowest setting) against the back or suprapubic area. A warm shower or sitting in a tub of warm water filled above the waist can give temporary relief.

Teach the patient about the prescribed drug therapy, including side effects. Emphasize the importance of taking the full course of antibiotics. Often patients stop antibiotic therapy once symptoms disappear. This can lead to inadequate treatment, recurrent infection, or bacterial resistance to antibiotics.

Sometimes a second drug or a reduced dosage of drug is given after the first course to suppress bacterial growth in patients

TABLE 50.6 PATIENT & CAREGIVER TEACHING

UTI

When teaching a patient and caregiver measures to prevent a recurrence of a UTI, include:

1. Take all antibiotics as prescribed. Symptoms may improve after 1–2 days of therapy, but organisms may still be present.
2. Practice appropriate hygiene, including:
   - Carefully clean the perineal region by separating the labia in females, or in males pulling back the foreskin if present when cleansing.
   - Wipe from front to back after urinating.
   - Cleanse with warm soapy water after each bowel movement.
3. Empty the bladder before and after sexual intercourse.
4. Void regularly, about every 3–4 hours during the day.
5. Maintain adequate fluid intake.
6. Avoid vaginal douches and harsh soaps, bubble baths, powders, and sprays in the perineal area.
7. Report to the HCP symptoms or signs of recurrent UTI (e.g., fever, cloudy urine, pain on urination, urgency, frequency).

susceptible to recurrent UTI. Teach the patient to monitor for signs of improvement (e.g., cloudy urine becomes clear) as well as a decrease in or cessation of symptoms. Tell patients to report to their HCP any (1) persistence of bothersome LUTS beyond the antibiotic treatment course, (2) onset of flank pain, or (3) fever.

◆ Ambulatory Care

Teach the patient and caregiver about the need for ongoing care (Table 50.6). This includes (1) taking antimicrobial drugs as ordered, (2) maintaining adequate daily fluid intake, (3) voiding regularly (every 3 to 4 hours), and (4) voiding before and after intercourse. Have the patient temporarily stopping using a diaphragm.

If treatment is complete and the symptoms are still present, teach the patient to get follow-up care. Recurrent symptoms typically occur within 1 to 2 weeks after completing therapy. If the patient has followed the treatment plan, a relapse indicates the need for further evaluation.

◆ Evaluation

The expected outcomes are that the patient with a UTI will

- Have normal urinary elimination patterns
- Report relief of bothersome urinary tract symptoms
- State knowledge of the treatment plan

ACUTE PYELONEPHRITIS

Etiology and Pathophysiology

Pyelonephritis is an inflammation of the renal parenchyma and collecting system, including the renal pelvis (Fig. 50.2). The most common cause is bacterial infection. Fungi, protozoa, or viruses can also infect the kidney.[6]

Urosepsis is a systemic infection arising from a urologic source. Its prompt diagnosis and effective treatment are critical because it can lead to septic shock and death unless promptly treated. Septic shock is discussed in Chapter 42.

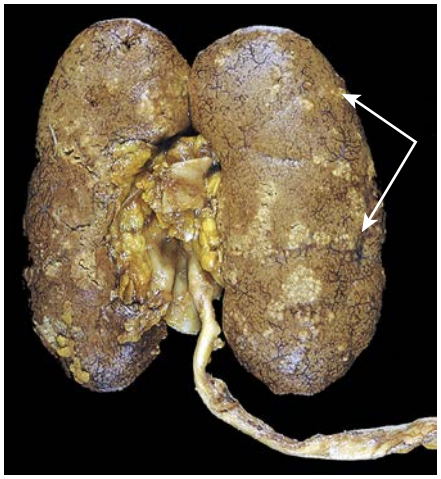

Fig. 50.2 Acute pyelonephritis. Cortical surface shows grayish-white areas of inflammation and abscess formation *(arrows)*. (From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

Pyelonephritis usually begins with colonization and infection of the lower urinary tract via the ascending urethral route. Bacteria normally found in the GI tract, including *E. coli* or *Proteus, Klebsiella*, or *Enterobacter* species, often cause pyelonephritis. A preexisting factor can be present, like *vesicoureteral reflux* (retrograde [backward] movement of urine from lower to upper urinary tract) or dysfunction of the lower urinary tract (e.g., obstruction from benign prostatic hyperplasia [BPH], stricture, stones).

Acute pyelonephritis often starts in the renal medulla and spreads to the adjacent cortex. Pregnancy-induced physiologic changes in the urinary system are an important risk factor for acute pyelonephritis. Recurring episodes of pyelonephritis, especially in the presence of obstructive abnormalities, can lead to chronic pyelonephritis (discussed later).

Clinical Manifestations and Diagnostic Studies

The classic manifestations include (1) fever/chills, (2) nausea/vomiting, (3) malaise, and (4) flank pain. There may be LUTS, such as dysuria, urgency, and frequency. *Costovertebral angle tenderness* to percussion (costovertebral angle [CVA] pain) is typically present on the affected side. In some cases of pyelonephritis, renal scarring and decreased kidney function can occur. Potentially life-threatening urosepsis can occur.

Urinalysis results may show pyuria, bacteriuria, and varying degrees of hematuria. WBC casts in the urine may indicate renal parenchyma involvement. Urine cultures with sensitivities are done when pyelonephritis is suspected. Blood cultures may be done on hospitalized patients with more severe illness.

Ultrasound can identify anatomic abnormalities, hydronephrosis, renal abscesses, or an obstructing stone. CT scans are the preferred imaging studies. They can assess for signs of infection in the kidney and complications of pyelonephritis, such as impaired renal function, scarring, chronic pyelonephritis, or abscesses.

Interprofessional Care

The diagnostic tests and interprofessional care of acute pyelonephritis are outlined in Table 50.7. Patients with severe infections

TABLE 50.7 Interprofessional Care

Acute Pyelonephritis

Diagnostic Assessment

- History and physical assessment
- Urinalysis
- Urine for culture and sensitivity
- Imaging studies: ultrasound (initially), CT scan, MRI, cystoscopy, voiding cystourethrogram (VCUG)
- CBC count with WBC differential
- Blood culture (if bacteremia is suspected)
- Percussion for flank (CVA) pain

Management

Mild Symptoms

- Outpatient management or short hospitalization
- Adequate fluid intake
- NSAIDs or antipyretic drugs
- Follow-up urine culture and imaging studies

Drug Therapy

- Empirically selected broad-spectrum antibiotics: fluoroquinolones (ciprofloxacin, levofloxacin), cephalosporins preferred. TMP/SMX or an oral β-lactam can be used if infection expected to be susceptible
- Short course of IV antibiotics, such as an extended spectrum cephalosporin or penicillin, fluroquinolone (e.g., ciprofloxacin, levofloxacin), or an aminoglycoside without or with amoxicillin
- Switch to sensitivity-guided therapy when urine and blood culture results available

Severe Symptoms

- Hospitalization
- Adequate fluid intake (IV initially; switch to oral fluids as nausea, vomiting, and dehydration subside)
- NSAIDs or antipyretic drugs to reverse fever and relieve discomfort
- Follow-up urine culture and imaging studies

Drug Therapy

- IV antibiotics
  - Empirically selected broad-spectrum antibiotics: carbapenem (e.g., imipenem, meropenem), vancomycin, daptomycin, linezolid
  - Switch to sensitivity-guided antibiotic therapy when results of urine and blood culture are available
- Oral antibiotics when patient tolerates oral intake

or complicating factors, such as nausea and vomiting with dehydration, need hospitalized.

The patient with mild symptoms may be treated as an outpatient with antibiotics for 5 to 14 days (Table 50.7). IV antibiotics are often given initially in the hospital to rapidly establish high serum and urinary drug levels.[6] When initial treatment resolves acute symptoms and the patient can tolerate oral fluids and drugs, they can be discharged on oral antibiotics for 14 more days. Symptoms and signs typically improve or resolve within 48 to 72 hours after starting therapy.

Relapses may be treated with a different course of antibiotics. Antibiotic prophylaxis also may be used for recurrent infections. The effectiveness of therapy is based on bacterial growth on urine culture.

Urosepsis is characterized by bacteriuria and bacteremia (bacteria in blood). Close observation and vital sign monitoring are essential. Prompt recognition and treatment of septic shock may prevent irreversible damage or death.

❖ NURSING MANAGEMENT: ACUTE PYELONEPHRITIS

◆ Assessment

Subjective and objective data that you should obtain from a patient with pyelonephritis are similar to those for the patient with a UTI (Table 50.5).

◆ Clinical Problems

Clinical problems for the patient with pyelonephritis include those for the patient with a UTI.

◆ Planning

The overall goals are that the patient with pyelonephritis will have (1) normal renal function, (2) no complications, (3) relief of pain, and (4) no recurrence of symptoms.

◆ Implementation

Health promotion and maintenance measures are similar to those for cystitis. Early treatment for cystitis can prevent ascending infections. Because patients with structural abnormalities of the urinary tract are at high risk for infection, stress the need for regular medical care.

Interventions vary depending on the severity of symptoms. Teach the patient about the disease process. Emphasize (1) taking antibiotic therapy as prescribed, (2) having a follow-up urine culture, and (3) recognizing signs of recurrence or relapse (Table 50.6). Encourage the patient to drink at least 8 glasses of fluid every day, even after the infection has been treated. Rest will increase patient comfort.

The patient who has frequent relapses or reinfections may receive long-term, low-dose antibiotics. Making certain the patient understands the reason for therapy is important to increase adherence.

◆ Evaluation

The expected outcomes for the patient with pyelonephritis are the same as for UTI.

CHRONIC PYELONEPHRITIS

In *chronic pyelonephritis,* the kidneys are continually infected. This leads to inflammation and fibrosis (scarring). There may be a loss of renal function and renal atrophy (shrinkage). Chronic pyelonephritis is usually the result of significant anatomic abnormalities, such as vesicoureteral reflux or recurring infections involving the upper urinary tract. It can rarely occur due to a substantial inflammatory response from an infection.

Radiologic imaging studies can confirm the diagnosis of chronic pyelonephritis and possible contributing factors. A

renal biopsy can show the loss of functioning nephrons, infiltration of the parenchyma with inflammatory cells, and fibrosis.

The level of renal function in chronic pyelonephritis depends on whether 1 or both kidneys are affected, the extent of scarring, and the presence of coexisting infection. Chronic pyelonephritis can progress to end-stage renal disease (ESRD). Monitoring and treating infection and correcting any underlying contributing factors are important. Care of the patient with CKD is discussed in Chapter 51.

URETHRITIS

Urethritis is inflammation of the urethra. Causes include a bacterial or viral infection (e.g., herpes simplex virus), *Trichomonas,* monilial infection (especially in women), chlamydial infection, *Mycoplasma*, and gonorrhea.

In men, the causes of urethritis are usually sexually transmitted. Purulent discharge can indicate a gonococcal urethritis. A clear or mucoid discharge typically signifies a nongonococcal urethritis. Sexually transmitted infections are discussed in Chapter 57. Urethritis can cause bothersome LUTS, including dysuria, urgency, and frequency, similar to those seen with cystitis. Men may have penile burning.

In women, urethritis can be hard to diagnose. It should be considered when WBCs are present on urinalysis but there are no bacteria. It often produces bothersome LUTS, but urethral discharge may not be present.

Treatment of urethritis is based on identifying and treating the cause and providing symptomatic relief. Drugs used for bacterial infections include TMP/SMX, doxycycline (Vibramycin), ceftriaxone, and nitrofurantoin. Metronidazole (Flagyl) and tinidazole (Tindamax) are options for treating *Trichomonas* infection. Drugs used to treat monilial infections include nystatin, clotrimazole, or fluconazole. In chlamydial infections, doxycycline or azithromycin are options. Women with negative urine cultures and no pyuria usually do not respond to antibiotics.

Warm sitz baths may temporarily relieve bothersome symptoms. Teach the patient to (1) avoid using vaginal deodorant sprays and contraceptive gels, (2) cleanse the perineal area after bowel movements and voiding, and (3) avoid sexual intercourse for at least 7 days. Tell patients with sexually transmitted urethritis to refer their sex partners for evaluation and testing if they had sexual contact in the 60 days before the onset of the patient's symptoms or diagnosis.

URETHRAL DIVERTICULA

Urethral diverticula are localized outpouchings of the urethra. Women have a much higher incidence than men. The rare cases in males usually are associated with congenital lower urinary tract anomalies or surgical trauma.

Risk factors include obstructed periurethral glands or infection. The periurethral glands are found along the distal two-thirds of the urethra. Other risk factors include urethral trauma, vaginal delivery, urethral instrumentation, and urethral dilation.

Classic symptoms include dysuria, postvoid dribbling, and dyspareunia (painful intercourse). Other symptoms include frequency (voiding more often than every 2 hours), urgency, suprapubic discomfort or pressure, pelvis or urethral pain, and a feeling of incomplete bladder emptying. Urinary incontinence (UI) is often present. However, women can also be asymptomatic.

The urine may have gross blood (hematuria) or sediment, which gives it a cloudy appearance. The diverticula can protrude into the anterior vaginal wall, causing an anterior wall mass. The mass may be felt on assessment. When palpated, the mass is often quite tender and can express urine and/or purulent discharge through the urethra.

Radiographic studies, such as ultrasound and MRI, are helpful in determining the size of the diverticulum in relation to the urethral lumen. A urethroscopy may be of benefit. It is done as an adjunct to radiologic studies.

Surgical options include transvaginal diverticulectomy, marsupialization (creation of a permanent opening) of the diverticular sac into the vagina *(Spence procedure),* and urethroscopic surgical excision. Stress UI, infection, bleeding, and urethral-vaginal fistula are potential complications of the surgery.

INTERSTITIAL CYSTITIS/PAINFUL BLADDER SYNDROME

Interstitial cystitis (IC) is a chronic, painful disease of the bladder characterized by urgency, frequency, and pain in the bladder and/or pelvis. IC is also called bladder pain syndrome or painful bladder syndrome (PBS). The term *IC/PBS* refers to cases of urinary pain that we cannot attribute to other causes, such as UTI or urinary stones. IC/PBS is more common in women. It affects about 3 to 8 million women and 1 to 4 million men each year.[7]

The cause of IC/PBS is unknown. It is likely multifactorial. Possible causes include neurogenic hypersensitivity of the lower urinary tract, changes in mast cells in the muscle and/or mucosal layers of the bladder, bladder attacked by the immune system, or production of a toxic substance in the urine.

Clinical Manifestations and Diagnostic Studies

The 2 primary manifestations of IC/PBS are pain and bothersome LUTS (e.g., frequency, urgency). People with severe cases may void as often as 60 times in a day, including nighttime urination. The pain is usually in the suprapubic area, but may involve the vagina, labia, or entire perineal region, including the rectum and anus. The pain varies from mild to severe. The pain may get worse with bladder filling, postponed urination, physical exertion, pressure against the suprapubic area, certain foods, exercise, or prolonged sitting. Voiding temporarily relieves pain. Bothersome LUTS are similar to a UTI. The condition may be misdiagnosed as a recurring or chronic UTI or, in men, chronic prostatitis.

The patient may have periods of remission and exacerbation. Women often report pain that occurs before menstruation. Sexual intercourse or emotional stress can worsen pain. Some patients have symptoms that disappear altogether after a period of weeks to months. Others have persistent symptoms over months to years.

IC/PBS is a diagnosis of exclusion. A history and physical assessment can rule out other problems that have similar

symptoms, such as cancer, infection, or pelvic abnormalities. Urine cultures do not find any bacteria or other organisms in the urine. Cystoscopic examination may reveal a small bladder capacity, Hunner lesions (distinct inflammatory areas on the bladder wall), and glomerulations (superficial ulcerations with pinpoint bleeding). These findings, though, are not always present.

Interprofessional Care

No single treatment consistently reverses or relieves symptoms. Various therapies have been effective, including nutrition and drug therapy. People with IC/PBS do not respond to antibiotic therapy. They rarely need surgery.

Eliminating foods and beverages that are likely to irritate the bladder may give some symptom relief. Common bladder irritants include coffee and tea (caffeinated and decaffeinated); alcohol; citrus products; carbonated drinks; chocolate; foods containing vinegar, curries, or hot peppers; and foods or beverages likely to lower urinary pH, including fruits such as cranberries. An over-the-counter (OTC) supplement called *calcium glycerophosphate* (Prelief) or 1 tablespoon of baking soda mixed with water alkalinizes the urine. It may provide relief from the irritating effects of some foods. Recipes and menus for a well-balanced diet that avoids bladder-irritating foods and beverages are available at the website for the Interstitial Cystitis Association (www.ichelp.org).

The tricyclic antidepressants, amitriptyline (preferred) and nortriptyline, may reduce burning and urinary frequency. Pentosan polysulfate sodium (Elmiron) is the only oral agent approved for treating IC symptoms. It enhances the protective effects of the glycosaminoglycan layer of the bladder and relieves pain by reducing the irritative effects of urine on the bladder wall. This drug provides relief over time (weeks to months). It does not give immediate relief for acute symptoms. Due to reports of macular eye changes, this medication has an FDA approved warning label regarding eye toxicity.

Pelvic physical therapy and bladder hydrodistention therapy may be useful. Dimethyl sulfoxide (DMSO) can be directly instilled into the bladder through a small catheter. DMSO improves inflammation and desensitizes pain receptors in the bladder wall. Heparin, lidocaine, or sodium bicarbonate can also be instilled into the bladder to relieve acute symptoms. Intradetrusor botulinum toxin and cyclosporine A may be of some help.

Surgery is an option to improve severe, debilitating pain. Sacral neuromodulation or fulguration (using high-frequency energy to destroy a lesion) and resection of Hunner lesions are options. Urinary diversion, such as an ileal conduit, without or with removal of the bladder, is an option when other measures fail. Unfortunately, some patients have pain within the urinary diversion, which means that some factor in the urine may contribute to IC/PBS in some cases.

NURSING MANAGEMENT: IC/PBS

Assess the characteristics of the pain with IC/PBS. Ask the patient about specific diet or lifestyle factors that relieve pain or make it worse. Teach the patient to keep a bladder log or voiding diary over a period of at least 3 days to determine voiding frequency and patterns of nocturia. Keeping a pain record at the same time may be useful.

A UTI may occur during IC/PBS management because of diagnostic instrumentation and frequent bladder instillations. A UTI is likely to cause an acute exacerbation of bothersome LUTS and urinary frequency, as well as dysuria (not typically present with IC/PBS), odorous urine, and hematuria.

Because stress can worsen symptoms or cause flare-ups, stress management techniques such as relaxation breathing and imagery (see Chapter 7) may be helpful. Using lubrication or changing positions may decrease pain from sexual intercourse.

Discuss proper nutrition, especially considering the broad diet restrictions often needed to control IC-related pain. Tell the patient to take a multivitamin containing no more than the recommended daily allowance for essential vitamins. They should avoid high-potency vitamins because they may irritate the bladder. The patient should avoid clothing that creates suprapubic pressure, such as pants with tight belts or waistlines. Information about diet, coping with the need for frequent urination, and coping with the emotional burden of IC/PBS are available from the Interstitial Cystitis Association (www.ichelp.org). Reassurance that IC/PBS is a real condition experienced by others and that it can be treated may relieve the anxiety, anger, guilt, and frustration related to having chronic pain and voiding dysfunction in the absence of a clear-cut diagnosis and treatment strategy.

GENITOURINARY TUBERCULOSIS

Genitourinary tuberculosis (GUTB) is the 3rd most common type of extrapulmonary tuberculosis. Between 2% and 20% of patients with pulmonary TB develop GUTB. Onset can occur 1 to 33 years after the primary lung infection.[8,9] When the kidney is first infected with bacilli, the patient is often asymptomatic and may have incidental microscopic hematuria and/or pyuria. With progression of the infection to involve the bladder, symptoms of urgency, frequency, dysuria, and/or nocturia develop in about 50% of patients. A third of patients have back pain and gross hematuria.

A diagnosis of GUTB is based on finding *Mycobacterium tuberculosis* bacilli in the urine. A CT scan with contrast and ultrasound can help determine the extent and severity of the disease. A TB skin test should be done.

Long-term complications of GUTB depend on the duration of the disease. Scarring of the renal parenchyma, calcifications, hydronephrosis, and ureteral strictures can occur. The earlier treatment is started, the less likely renal failure will develop. The patient may need long-term urologic follow-up. Care of the patient with TB is discussed in Chapter 30.

IMMUNOLOGIC KIDNEY PROBLEMS

GLOMERULONEPHRITIS

Glomerulonephritis (inflammation of the glomeruli) affects both kidneys equally. It is the 3rd leading cause of ESRD in the

TABLE 50.8 Causes and Risk Factors for Glomerulonephritis (GN)

Cause or Risk Factor	Description
Conditions Causing Scarring of Glomeruli	
Diabetic nephropathy	• Primary cause of end-stage renal disease in the United States (see Chapter 51) • Microvascular changes of diffuse glomerulosclerosis involving thickening of the glomerular basement membrane
Focal segmental glomerulosclerosis	• Characterized by scattered scarring of glomeruli • May result from another disease or occur for unknown reasons
Hypertension	• Nephrosclerosis is a complication of hypertension • GN can cause hypertension
Immune Diseases	
Anti-GBM disease	• Autoimmune disorder that causes lung and kidney disease • Causes bleeding into lungs and GN
Immunoglobulin A (IgA) nephropathy	• Results from deposits of IgA in the glomeruli • Characterized by recurrent episodes of hematuria
Scleroderma	• Disease of unknown cause characterized by widespread changes in connective tissue and vascular lesions in many organs (see Chapter 69) • In the kidney, vascular lesions are associated with fibrosis • Severity of renal involvement varies
Systemic lupus erythematosus (SLE)	• Autoimmune disorder characterized by the involvement of several tissues and organs, especially joints, skin, and kidneys (see Chapter 69) • GN often occurs in SLE and has a poor prognosis
Infections	
Infective endocarditis	• Bacteria can cause an infection of 1 or more of the heart valves (see Chapter 40) • People at risk include those with a heart defect, such as a damaged or artificial heart valve • GN may be due to glomerular membrane deposits of complement and immunoglobulin
Poststreptococcal glomerulonephritis	• GN may develop 1–3 weeks after a streptococcal throat infection or 3–6 weeks after a skin infection • Antibodies (Ab) to strep antigen (Ag) develop and the Ag-Ab deposit in the glomeruli, causing inflammation
Viral infections	• Viral infections can trigger GN • Common viruses include HIV, hepatitis B, and hepatitis C viruses
Vasculitis	
Granulomatosis with Polyangiitis	• Form of vasculitis affecting small and medium blood vessels • Most often affects kidneys, lungs, and upper respiratory tract
Polyarteritis nodosa	• Rare disease, possibly autoimmune, that affects small and medium blood vessels • Can affect any organ but common in heart, kidneys, and intestines
Other Causes	
Amyloidosis	• Caused by infiltration of tissues with amyloid (hyaline substance) • Hyaline bodies consist largely of protein • Kidney involvement is common • Proteinuria is often the first clinical manifestation
Illegal drug use	• People who use these drugs are at increased risk for GN

United States. Although the glomerulus is the primary site of inflammation, tubular and interstitial changes with vascular scarring and hardening *(glomerulosclerosis)* in the kidney can occur.[10]

A variety of conditions are associated with glomerulonephritis. These range from kidney infections, drugs toxic to the kidneys, problems with the immune system, and systemic diseases (Table 50.8). Glomerulonephritis can be acute or chronic. With *acute glomerulonephritis,* symptoms come on suddenly. They may be temporary or reversible. An example of this is acute poststreptococcal glomerulonephritis (APSGN). *Chronic glomerulonephritis* typically progresses slowly and can lead to irreversible renal failure.

Diagnostic studies and the history, including any recent infection, such as a sore throat or upper respiratory tract infection, or a diagnosis of diabetes, aid in identifying the type of glomerulonephritis present.

Acute Poststreptococcal Glomerulonephritis

Acute poststreptococcal glomerulonephritis is the most common type of acute glomerulonephritis worldwide. It is most common in children aged 5 to 7 years old and adults older than 60 years. APSGN develops about 1 to 6 weeks after an infection of the tonsils, pharynx, or skin (e.g., streptococcal sore throat, impetigo) by nephrotoxic strains of group A β-hemolytic streptococci.[11] The person makes antibodies to the streptococcal antigen. Although the exact mechanism is not known, tissue injury occurs as the antigen-antibody complexes are deposited in the glomeruli, complement is activated (see Chapter 12), and inflammation results.

Manifestations vary. They include generalized edema, hypertension, oliguria, hematuria, and proteinuria. Fluid retention occurs because of decreased glomerular filtration. At first, edema appears in low-pressure tissues, such as those around the eyes *(periorbital edema)*. Later it progresses to involve the whole body. Red to brown urine occurs with bleeding in the upper urinary tract. The degree of proteinuria varies with the severity of the glomerulonephritis. Hypertension results from increased extracellular fluid volume. The patient may have abdominal or flank pain. Sometimes the patient may be asymptomatic. The problem is found on routine urinalysis.

The diagnosis of APSGN is based on a complete history and physical assessment. An immune response to the streptococci is often shown by the streptozyme test. It measures 5 different streptococcal antibodies, including antistreptolysin-O (ASO). The finding of decreased complement components (especially C3 and CH50) indicates an immune-mediated response. A renal biopsy can confirm the disease.

Dipstick urinalysis and urine sediment microscopy can show significant numbers of red blood cells (RBCs) with or without casts. Proteinuria may range from mild to severe. Blood tests include blood urea nitrogen (BUN) and serum creatinine to assess the extent of renal impairment.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: ACUTE POSTSTREPTOCOCCAL GLOMERULONEPHRITIS

More than 90% of patients with APSGN recover completely or improve rapidly with supportive management. Accurate recognition and assessment are critical. Chronic glomerulonephritis can develop if the patient is not treated appropriately.

Management focuses on symptomatic relief. Rest is recommended until the signs of glomerular inflammation (proteinuria, hematuria) and hypertension subside. Restricting sodium and fluid intake and giving diuretics can reduce edema. Severe hypertension is treated with antihypertensive drugs. We may restrict protein intake if there is evidence of an increase in nitrogenous wastes (e.g., increased BUN). The protein restriction varies with the degree of proteinuria. Low-protein, low-sodium, fluid-restricted diets are discussed in Chapter 51. Antibiotics are given if the streptococcal infection is still present.

One of the most important ways to prevent APSGN is to encourage early diagnosis and treatment of sore throats and skin lesions. If a culture is positive for streptococci, treatment with the appropriate antibiotic therapy is essential. Encourage the patient to take the full course of antibiotics to ensure that the bacteria are completely gone. Good personal hygiene is a key factor in preventing the spread of cutaneous streptococcal infections.

In most cases, recovery from the acute glomerulonephritis is complete. However, in rare cases, hypertension, proteinuria, and/or renal insufficiency can occur.

◆ Chronic Glomerulonephritis

Chronic glomerulonephritis is a syndrome of permanent and progressive renal fibrosis involving the glomeruli. It can progress to ESRD. Most types of glomerulonephritis and nephrotic syndrome can eventually lead to chronic glomerulonephritis. Some people who develop chronic glomerulonephritis have no history of kidney disease. We may not find the cause of chronic glomerulonephritis. An inherited disorder (e.g., Alport syndrome) or an autoimmune disorder may be the cause.

With chronic glomerulonephritis, symptoms develop slowly over time. Patients are often unaware that progressive kidney impairment is occurring, even if it is severe, until they have a diagnostic evaluation. Chronic glomerulonephritis is often discovered by finding an abnormality on a urinalysis, high BP, or increased serum creatinine.

The syndrome is characterized by proteinuria, hematuria, and the slow development of uremia (see Chapter 51) because of decreasing renal function. Chronic glomerulonephritis progresses insidiously toward ESRD over a course of several years.

Manifestations include varying degrees of hematuria (ranging from microscopic to gross), proteinuria, and urinary excretion of various formed elements, including RBCs, WBCs, and casts. Increased BUN and serum creatinine levels are common. Ultrasound and CT scans are the preferred radiologic studies. A renal biopsy may be done to determine the cause of the glomerulonephritis.

The history provides vital information. Assess exposure to drugs (e.g., nonsteroidal antiinflammatory drugs [NSAIDs]) and infections (e.g., hepatitis). Evaluate the patient for other immune disorders, such as systemic lupus erythematosus (SLE). The patient may not recall any history of renal problems.

Treatment depends on the cause of the chronic glomerulonephritis. It includes supportive and symptomatic care. Management of CKD is discussed in Chapter 51.

◆ Anti-Glomerular Basement Membrane Disease

Anti-glomerular basement membrane (GBM) disease (formerly called Goodpasture syndrome) is an autoimmune disease characterized by antibodies that attack the glomerular and alveolar basement membranes. Damage to the kidneys and lungs results when binding of the antibody causes an inflammatory reaction mediated by complement activation (see Chapter 12).

GBM is a rare disease that occurs mainly in older children and adults, especially those in their 30s and 60s to 70s. The manifestations can include weakness, pallor, and pulmonary symptoms, such as cough, mild shortness of breath, hemoptysis, crackles, and pulmonary insufficiency. Renal involvement includes hematuria, proteinuria, and anemia. It can proceed quickly to renal failure. Pulmonary involvement can occur before or at the same time as glomerular abnormalities.

Current management includes glucocorticoids, immunosuppressive drugs (e.g., cyclophosphamide, rituximab), plasmapheresis (see Chapter 14), and, if needed, dialysis. Plasmapheresis removes the circulating anti–GBM antibodies. Immunosuppressive therapy inhibits further antibody production. Those with ESRD due to the disease may be a candidate for a kidney transplant. GBM disease rarely occurs in the transplanted kidney.

Encourage smoking cessation. The patient receives care appropriate for a critically ill patient who has AKI (see Chapter 51) and respiratory distress (see Chapter 32). Death is often from bleeding in the lungs and respiratory failure.

◆ Rapidly Progressive Glomerulonephritis

Rapidly progressive glomerulonephritis (RPGN) is a type of glomerular disease with glomerular crescent formations. In contrast to chronic glomerulonephritis, which develops slowly and progresses over many years, RPGN is characterized by more rapid, progressive loss of renal function over days to months.

There are 3 types of RPGN: (1) anti-GBM disease, (2) due to immune complex disease (e.g., SLE, postinfectious), (3) or due to pauci-immune disease where no or few immune deposits are seen on electron or immunofluorescence microscopy.

Manifestations almost always include renal insufficiency. They include hypertension, edema, hematuria, and reduced urine output. Treatment aims include correcting fluid overload, hypertension, and uremia and reducing inflammatory injury to the kidney. Treatment often includes corticosteroids and cyclophosphamide. Plasmapheresis may be an option. Dialysis or a kidney transplant may be considered for the patient with RPGN who has progressed to ESRD. After a kidney transplant, RPGN may recur.

NEPHROTIC SYNDROME

Nephrotic syndrome results when the glomerulus is excessively permeable to plasma protein, causing proteinuria that leads to low plasma albumin and edema.

Etiology and Clinical Manifestations

Common causes of nephrotic syndrome are listed in Table 50.9. Minimal change disease is the most common cause in children. For adults, 30% of nephrotic syndrome cases are due to systemic disease such as diabetes, SLE, or amyloidosis.[12]

The common manifestations are peripheral edema, massive proteinuria, hyperlipidemia, hypoalbuminemia, and foamy urine. The increased glomerular membrane permeability is responsible for the massive excretion of protein in the urine. This results in decreased total serum protein and subsequent edema formation. Ascites and *anasarca* (massive, generalized edema) develop if there is severe hypoalbuminemia.

The diminished plasma oncotic pressure from the decreased serum proteins stimulates hepatic lipoprotein synthesis, which results in hyperlipidemia. Significant increases in the lipid profile (e.g., cholesterol, LDL triglycerides) can occur. Fat bodies (fatty casts) often appear in the urine, causing foamy urine.

Immune responses are impaired. As a result, there is an increased risk of infection. Calcium and skeletal abnormalities may occur, including hypocalcemia, blunted calcium response to parathyroid hormone, hyperparathyroidism, and osteomalacia.

TABLE 50.9 Causes of Nephrotic Syndrome

Primary Glomerular Disease
- Focal-segmental glomerulosclerosis
- Membranous glomerulopathy
- Minimal-change disease

Secondary Causes

Cancers
- Hodgkin lymphoma
- Leukemias
- Solid tumors of lungs, colon, stomach, breast, renal, prostate

Drugs
- Captopril
- Heroin
- Lithium
- NSAIDs
- Penicillamine

Infections
- Bacterial (streptococcal, syphilis)
- Protozoal (malaria)
- Viral (hepatitis, HIV, mononucleosis)

Multisystem Disease
- Amyloidosis
- Diabetes
- SLE

Hypercoagulability is a serious issue for those with nephrotic syndrome. Hypercoagulability increases the risk for arterial and venous thromboembolism, including pulmonary embolism and deep vein or renal thrombus.

Interprofessional and Nursing Care

Specific treatment of nephrotic syndrome depends on the cause. The goals are to cure or control the primary disease and relieve the symptoms. Corticosteroids and cyclophosphamide may be used. Prednisone has been effective to varying degrees for some causes of nephrotic syndrome (e.g., membranous glomerulonephritis, lupus nephritis). Managing diabetes is important when nephrotic syndrome is related to diabetes.

Angiotensin-converting enzyme inhibitor or angiotensin receptor blocker drugs may reduce urine protein losses. Diuretics (typically loop diuretics) can improve edema.

The treatment of hyperlipidemia includes lipid-lowering agents (see Table 37.6). Anticoagulant therapy may be given if thrombosis is present.

The patient is placed on a low-sodium (less than 2 g/day), low-moderate protein (1 g/kg/day) diet. If urine protein losses are high (more than 10 g/day), more protein may be needed. Patients are usually anorexic. They can become malnourished from the excess loss of protein in the urine. Serve small, frequent meals in a pleasant setting to encourage intake.

A major nursing focus is on managing edema. Assess edema by (1) weighing the patient daily, (2) recording intake and output, and (3) measuring abdominal girth or extremity size. Compare this information daily to assess the effectiveness of treatment. Clean edematous skin carefully. Avoid trauma to the skin.

Because the patient is susceptible to infection, teach the patient to avoid exposure to persons with known infections. Support for the patient, especially in helping cope with an altered body image, is essential. They may feel embarrassment and shame because of their edematous appearance.

OBSTRUCTIVE UROPATHIES

Urinary obstruction refers to any anatomic or functional condition that blocks or impedes the flow of urine (Fig. 50.3). It may be congenital or acquired. Damaging effects from an obstruction affect the urinary system above the level of the obstruction. The severity of these effects depends on the location, duration of obstruction, amount of pressure or dilation, and presence of urinary stasis or infection. Infection increases the risk for irreversible damage.[13]

When obstruction occurs at the level of the bladder neck or prostate, significant bladder changes can occur. Detrusor muscle fibers *hypertrophy* (increase in size) to contract harder to push urine out a narrower pathway. Over a long period, the detrusor loses its ability to compensate for this resistance, eventually leading to a large residual urine volume in the bladder.

When *bladder outlet obstruction* is present, pressure increases during bladder filling or storage. This pressure can be transmitted to the ureters. Pressure can lead to *reflux* (backflow, or backward movement, of urine), *hydroureter* (ureteral dilation and distention), vesicoureteral reflux (backflow of urine from

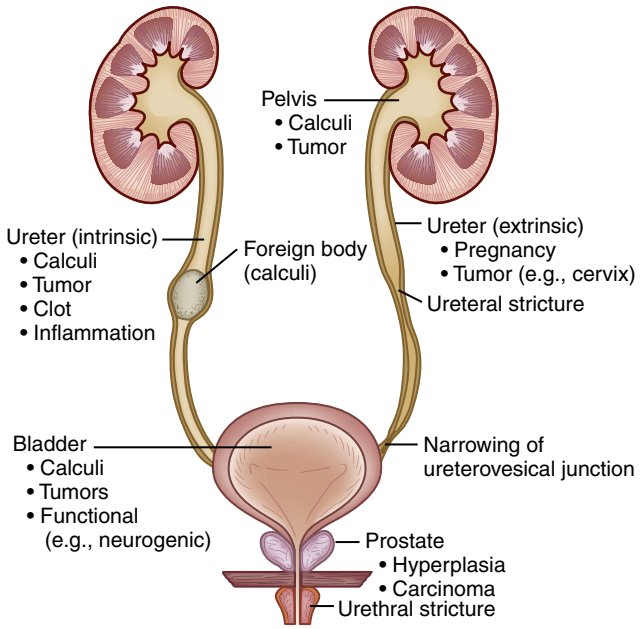

Fig. 50.3 Sites and causes of upper and lower urinary tract obstruction.

Fig. 50.4 Hydronephrosis of the kidney. Note the marked dilation of the pelvis and calyces and thinning of the renal parenchyma. (From Kumar V, Abbas AK, Aster JC, et al.: *Robbins and Cotran pathologic basis of disease,* ed 8, Philadelphia, 2010, Saunders.)

the lower to upper urinary tract), and **hydronephrosis** (dilation or enlargement of the renal pelvises and calyces) (Fig. 50.4). Chronic pyelonephritis and renal atrophy may develop. If only 1 kidney is obstructed, the other kidney may try to compensate by enlarging.

Partial obstruction may occur in the ureter or at the ureteropelvic junction (UPJ) (where the renal pelvis narrows into the ureter). If the pressure stays low or moderate, the kidney may continue to dilate with no noticeable loss of function. Urinary stasis and reflux increase the risk for pyelonephritis. If only 1 kidney is involved, and the other kidney is functioning, the patient may be asymptomatic.

If both kidneys or only 1 functioning kidney is involved (e.g., if the patient has only 1 kidney), changes in renal function (e.g., increased BUN and serum creatinine levels) occur. Progressive obstruction can lead to renal failure. Treatment involves finding and relieving the blockage. This can include insertion of a tube (e.g., urethral, ureteral), surgical correction of the primary problem, or diversion of the urinary stream above the level of blockage.

BOX 50.2 BIOLOGIC SEX CONSIDERATIONS

Urinary Tract Stones

Men
- More likely to have urinary stones, except for struvite stones

Women
- More likely to have struvite stones associated with UTI

URINARY TRACT CALCULI

In their lifetime, 11% of men and 7% of women in the United States will have **nephrolithiasis** (kidney stone disease, renal calculi) (Box 50.2). The term **calculus** refers to the stone, and *lithiasis* refers to stone formation.

Most patients are middle-aged adults. The risk for developing kidney stones increases with age.[14] Stone formation occurs more often in Whites and Asians. The incidence is higher in persons with a family history of stone formation. Stones recur in up to 50% of patients. In the United States, the incidence of stone disease is highest in the South and Southwest. Stone formation occurs more often in the summer months, supporting the possible contributing factors of a hot climate and dehydration.

Etiology and Pathophysiology

Many factors are involved in the incidence and type of stones. These factors include climate, diet, genetic, metabolic, and lifestyle (Table 50.10). No single theory accounts for stone formation in all cases. Crystals, when in a supersaturated concentration, can precipitate and unite to form a stone. Keeping urine dilute and free flowing reduces the risk for recurrent stone formation in many people.

We think kidney stones form when certain crystal-forming substances are not diluted by the kidney and/or the kidney's ability to keep crystals from sticking together is reduced. Urinary pH, solute load, and inhibitors in the urine affect stone formation. The higher the pH (alkaline), the less soluble are calcium and phosphate. The lower the pH (acidic), the less soluble are uric acid and cystine. When a substance is not very soluble in fluid, it is more likely to precipitate out of solution.

Other key factors in stone formation include obstruction with associated urinary stasis and UTI with urea-splitting bacteria (e.g., *Proteus, Klebsiella, Pseudomonas,* and some species of staphylococci). These bacteria cause the urine to become alkaline and contribute to the formation of struvite stones. Infected stones, trapped in the kidney (Fig. 50.5), may assume a staghorn configuration as the stone branches to occupy a larger part of the collecting system. These stones can lead to a renal infection, hydronephrosis, and loss of kidney function.

TABLE 50.10 Risk Factors for Urinary Tract Stones

Climate
- Warm climates that cause increased fluid loss, low urine volume, and increased urine solute concentration

Diet
- Excess amounts of tea or fruit juices that increase urinary oxalate level
- Large intake of diet proteins that increases uric acid excretion
- Large intake of salt, low calcium intake
- Low fluid intake that increases urine concentration

Genetic Factors
- Family history of stone formation, cystinuria, gout, or renal acidosis

Lifestyle
- Immobility
- Obesity
- Sedentary occupation

Metabolic
- Abnormalities that result in increased urine pH, calcium, oxalate, or uric acid levels, or low citrate

Genetic factors may contribute to stone formation. Cystinuria, an autosomal recessive disorder, causes a large increase in the urinary excretion of cystine.

Types of Urinary Stones

The 5 main types of stones are (1) calcium oxalate, (2) calcium phosphate, (3) cystine, (4) struvite (magnesium ammonium phosphate), and (5) uric acid (Table 50.11). Calcium stones are the most common. Stone composition may be mixed. For example, calcium stones can be calcium oxalate, calcium phosphate, or a mix of both. Stones occur in various locations in the urinary tract (Figs. 50.3 and 50.5).

Clinical Manifestations

The first symptom of a kidney stone is usually severe pain that begins suddenly. Typically, a person feels a sharp, severe pain in the flank area, back, or lower abdomen. People describe the pain as the most excruciating that a person can endure. We call this pain *renal colic*. It results from the stretching, dilation, and spasm of the ureter in response to the obstructing stone. Nausea and vomiting may occur due to the severe pain.

Urinary stones cause manifestations when they obstruct urinary flow. Common sites of obstruction are at the UPJ and UVJ. Pain can vary depending on the location of the stone. If the obstruction is in a calyx or at the UPJ, the patient may have costovertebral flank pain or renal colic. Pain resulting from the passage of a stone down the ureter can be intense, colicky, and can radiate into the genital region. If the stone is nonobstructing, pain may be absent.

Patients with renal colic have a hard time being still. They go from walking to sitting to lying down, and then they repeat the process. Some people refer to this as the "kidney stone dance."

The patient may be in mild shock with cool, moist skin. As a stone nears the UVJ, pain moves around toward the abdomen and down toward the lower quadrant. Men may have testicular pain, while women may have labial pain. Both men and women can have groin pain. The patient may have manifestations of a UTI with dysuria, fever, and chills.

Diagnostic Studies

We can easily diagnose stones with either a noncontrast CT scan or ultrasound. A complete urinalysis helps confirm the diagnosis of a urinary stone by assessing for hematuria and

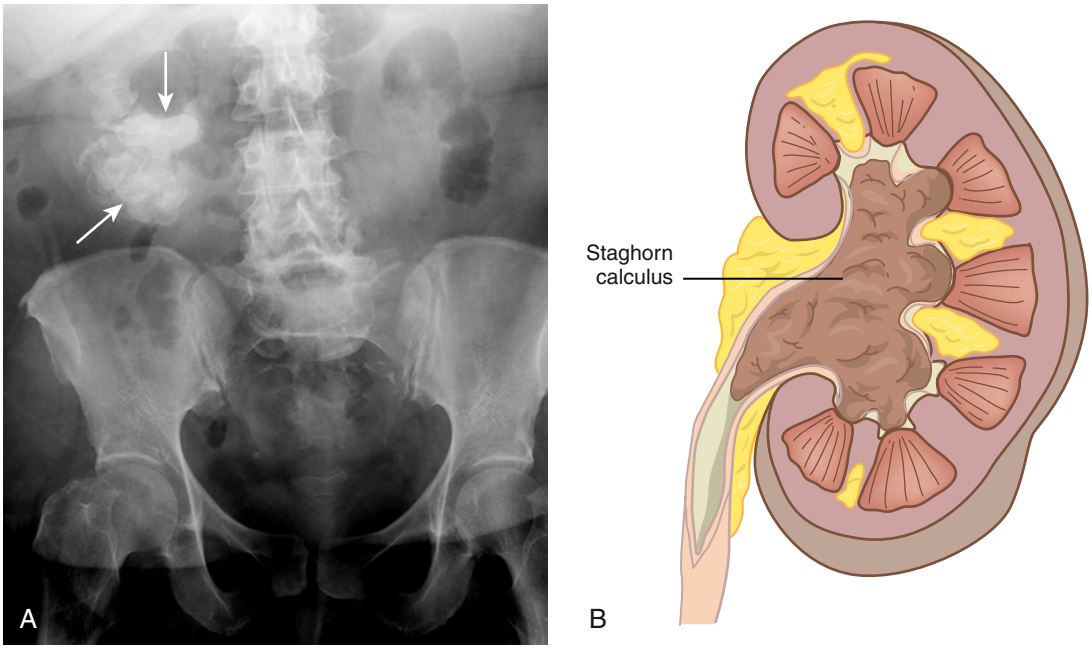

Fig. 50.5 (A) Bilateral staghorn stones *(arrows)* shown on x-ray. (B) Staghorn stone. The renal pelvis is filled with a large stone that is shaped to its contours, resembling the horns of a stag. (A, From Torigian DA, Ramchandani P: *Radiology secrets plus*, ed 4, Philadelphia, 2017, Elsevier.)

TABLE 50.11 Types of Urinary Tract Stones

Characteristics	Predisposing Factors	Treatment
Calcium Oxalate		
Most common type of stone. More frequent in men. *Incidence:* 70%–80%	Idiopathic hypercalciuria, hyperoxaluria, independent of urinary pH, family history	Increase hydration. Reduce oxalate intake, animal protein, and sodium. Increase intake of calcium, fruits, and vegetables. Give thiazide diuretics. Give potassium citrate to maintain alkaline urine. Avoid vitamin C and calcium supplements.
Calcium Phosphate		
Mixed stones (typically), with struvite or oxalate stones. *Incidence:* 15%	Alkaline urine, primary hyperparathyroidism	Increase hydration. Treat underlying causes and other stones. Reduce sodium and animal protein intake. Increase calcium intake.
Cystine		
Genetic autosomal recessive defect. Defective absorption of cystine in GI tract and kidney, excess concentrations causing stone formation. *Incidence:* 1%–2%	Acidic urine	Increase hydration. Give α-penicillamine, captopril, or tiopronin to prevent cystine crystallization. Give potassium citrate to keep urine alkaline.
Struvite (Magnesium Ammonium Phosphate)		
More common in women. Always associated with UTIs. Large staghorn type (usually) (Fig. 50.5). *Incidence:* 1%	UTIs (Urease-producing bacteria, usually *Proteus*)	Give antimicrobial agents, acetohydroxamic acid. Typically need surgery to remove stone. Take measures to acidify urine.
Uric Acid		
Predominant in men. *Incidence:* 5%–8%	Gout, acidic urine, high urinary uric acid	Increase hydration. Reduce urinary concentration of uric acid. Alkalinize urine with potassium citrate. Consider allopurinol. Reduce purine intake (Table 50.12).

crystalluria. Measuring urine pH is useful in the diagnosis of struvite stones (tendency to alkaline or high pH) and uric acid or cystine stones (tendency to acidic or low pH).

Retrieval and analysis of the stone(s) is important in diagnosing an underlying problem contributing to stone formation. We measure serum calcium, phosphorus, sodium, potassium, bicarbonate, uric acid, BUN, and creatinine levels. Patients who have recurrent stone formation have a 24-hour urinary measurement of calcium, phosphorus, magnesium, sodium, oxalate, citrate, cysteine, sulfate, potassium, uric acid, and total urine volume.

Interprofessional Care

Care of a patient with stones consists of 2 concurrent approaches. The first approach is aimed toward managing the acute attack by treating the pain, infection, and/or obstruction. Opioids and/or NSAIDS can relieve renal colic pain. Before using NSAIDs, make sure there is no contraindication because of renal function. Most stones are 4 mm or less in size and pass spontaneously. However, it may take weeks for a stone to pass.

α-Adrenergic blockers, such as tamsulosin (Flomax) or terazosin, which relax the smooth muscle in the ureter, can help stone passage. These drugs also relax the muscle tissue in the prostate in men with BPH.

The second approach is aimed toward determining the cause of the stone formation and preventing further stone development. Is there a history of prolonged illness with immobilization, dehydration, or disease or surgery involving the GI or GU tract? Is there a personal or family history of stone formation? What is their geographic residence? Obtain a nutrition assessment, including fluid intake and the intake of vitamins C and D. Review their activity pattern (active or sedentary). Obtain a complete medication history.

Therapy for active stone formers requires a comprehensive management approach, with an emphasis on teaching. Adequate hydration, sodium restrictions, diet changes, and drugs are used to minimize urinary stone formation (Table 50.11). Depending on the specific problem underlying the stone formation, various drugs are prescribed. These drugs prevent stone formation in several ways. These include altering urine pH, preventing excessive urinary excretion of a substance, or correcting a primary disease (e.g., hyperparathyroidism).

Treatment of struvite stones typically requires surgical intervention (e.g., percutaneous nephrolithotomy). Medical therapy alone is generally not effective in controlling infection of the urea-splitting bacterium. Chronic antibiotic therapy may be given to patients unable to tolerate surgery. It may also be given after surgically removing a stone. Acetohydroxamic acid may be used in those with a retained stone or with recurrent struvite stones. Acetohydroxamic acid inhibits urease produced by bacteria.

Endourology, lithotripsy, or open surgical stone removal may be used if (1) stones are too large for spontaneous passage (usually greater than 5 mm); (2) stones with bacteriuria

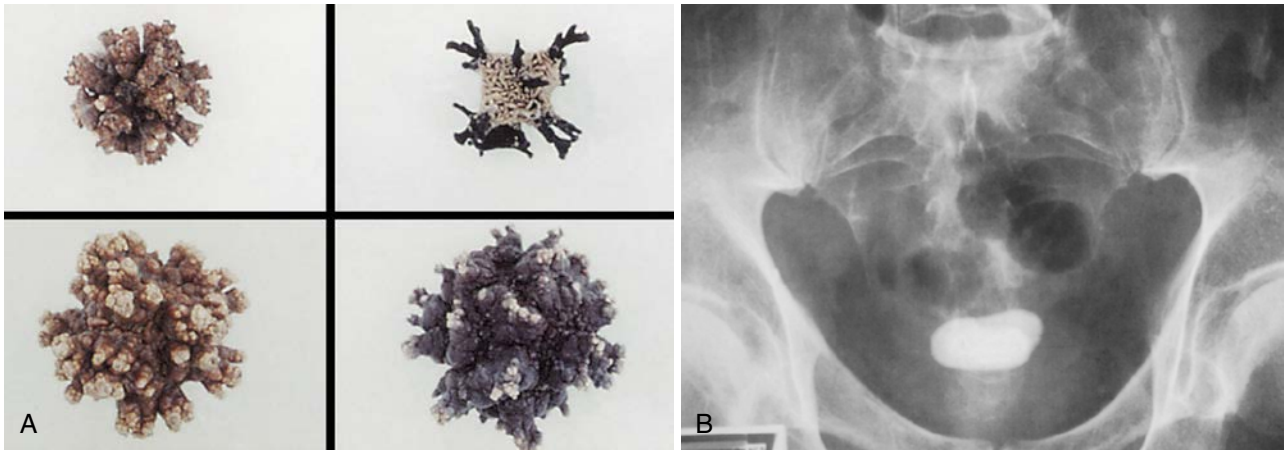

Fig. 50.6 (A) Calcium oxalate stones. (B) Abdominal x-ray showing large bladder stone. (From Bullock N, Doble A, Turner W, et al.: *Urology: an illustrated colour text,* London, 2008, Churchill Livingstone.)

or symptomatic infection are present; (3) stones are causing impaired renal function; (4) stones are causing persistent pain, nausea, or paralytic ileus; (5) patient is unable to be treated medically; and (6) patient has only 1 kidney.[15]

Endourologic Procedures

If the stone is in the bladder, a cystoscopy is done to remove small stones. For larger stones (Fig. 50.6), a *transurethral or percutaneous suprapubic cystolitholapaxy* is done. In this procedure, ultrasonic or laser energy or an instrument called a *lithotrite* (stone crusher) is used to break up the stone. The bladder is then irrigated, and the crushed stones washed out. A *cystoscopic lithotripsy* uses ultrasonic waves to break up stones. Sometimes, we may need to remove the stone with an open suprapubic cystotomy. Complications of these procedures include hemorrhage, retained stone fragments, and infection.

Flexible or rigid *ureteroscopes* can remove stones from the renal pelvis and upper urinary tract. Ultrasonic, laser, or electrohydraulic lithotripsy may be used in conjunction with ureteroscopy to break up the stone.

In *percutaneous nephrolithotomy,* a nephroscope is inserted into the kidney pelvis through a track (using a sheath) in the skin. The track is created in the patient's back. The kidney stones can be fragmented using ultrasound, electrohydraulic, or laser lithotripsy. The stone fragments are removed, and the pelvis is then irrigated. A percutaneous nephrostomy tube can be left in place to make sure that the ureter stays unobstructed. Complications include bleeding, injury to adjacent structures, and infection.

Lithotripsy

Lithotripsy is a procedure used to break up stones, thus allowing them to pass from the urinary tract. Lithotripsy techniques include (1) laser lithotripsy, (2) extracorporeal shock-wave lithotripsy (ESWL), (3) ultrasonic lithotripsy, and (4) electrohydraulic lithotripsy. *Laser lithotripsy* is used to shatter ureteral and large bladder stones. To access ureteral stones, a ureteroscope is used to get close to the stone. A small fiber is inserted up the scope so that the tip (which emits the laser energy) can come in contact with the stone. A holmium laser in direct contact with the stone is often used. The intense energy breaks the stone into small pieces. The pieces are then extracted or flushed out. This minimally invasive treatment usually requires general anesthesia.

In *extracorporeal shock-wave lithotripsy (ESWL),* the patient is anesthetized (spinal or general) to ensure they stay in the same position during the procedure. The HCP uses fluoroscopy or ultrasound to focus the lithotripter over the stone. Then, a high-voltage spark generator produces high-energy acoustic shock waves that shatters the stone. The small pieces of stone are then excreted in the urine. Complications of ESWL include incomplete breakup of the stone, which can lead to possible obstruction, kidney damage, decreased renal function, and elevated BP.

In *ultrasonic lithotripsy,* high-frequency sound waves are used to break the stone into sand-like particles. The patient receives general or spinal anesthesia. In *electrohydraulic lithotripsy,* electrical shock waves are used to break the stone into small fragments. The patient needs general anesthesia.

Complications of lithotripsy are rare. They include hemorrhage, infection, and obstruction. Hematuria is common and can last a few days to a few weeks. The first few times that the patient voids, the urine is often bright red. As the bleeding subsides, the urine can become dark red or a smoky color. Antibiotics are given afterward to reduce the risk for infection.

Afterward, the patient usually has mild to moderate pain. Severe colicky pain can occur as the pieces of stone pass. Most patients can return to their normal activities in a day or 2. For those with a large stone, a self-retaining ureteral stent may be placed to aid in passing the shattered stone. This helps prevent obstruction. The stent is typically removed within 2 weeks after lithotripsy. Encourage fluids to help dilute the urine and reduce the pain from passing stone fragments.

Surgical Therapy

A small group of patients need open surgical procedures. The primary indications for surgery include pain, infection, and obstruction. The type of surgery depends on the location of

TABLE 50.12 NUTRITION THERAPY

Urinary Tract Stones

Depending on the type of stone, modifying the diet can be helpful in preventing reoccurrence.

Calcium

High: Milk, cheese, ice cream, yogurt, sauces containing milk; all beans (except green beans), lentils; fish with fine bones (e.g., sardines, kippers, herring, salmon); dried fruits, nuts; Ovaltine, chocolate, cocoa

Oxalate

High: Dark roughage, spinach, rhubarb, asparagus, cabbage, tomatoes, beets, nuts, celery, parsley, runner beans; grapefruit, orange, raspberries; chocolate, cocoa, instant coffee, Ovaltine, tea; Worcestershire sauce

Purine

High: Sardines, anchovies, herring, mussels, scallops, organ meats, kidney, goose
Moderate: Chicken, salmon, crab, veal, mutton, bacon, pork, beef, ham

the stone. A *nephrolithotomy* is an incision into the kidney to remove a stone. A *pyelolithotomy* is an incision into the renal pelvis for stone removal. If the stone is in the ureter, a *ureterolithotomy* is done. A *cystotomy* may be indicated for bladder stones. For open surgery on the kidney or ureter, the patient often has a flank incision directly below the diaphragm and across their side. The most common complications after surgery for stone removal are bleeding and infection.

Nutrition Therapy

To manage an obstructing stone, the patient should drink adequate fluids to avoid dehydration. Do not force excess fluids because it does not promote the passage of stones in the urine. Forcing fluids may increase the pain or precipitate renal colic.

After an episode of urolithiasis, encourage a high fluid intake (around 3 L/day) to produce a urine output of at least 2.5 L/day unless contraindicated. High urine output prevents supersaturation of minerals (i.e., dilutes the concentration of urine) and promotes excretion of minerals within the urine, thus preventing stone formation. Increasing fluid intake is important for patients at risk for dehydration, including those who (1) are active in sports, (2) live in a dry climate, (3) perform physical exercise, (4) have a family history of stone formation, or (5) work outside or in an occupation that requires a great deal of physical activity. Water is the preferred fluid. Limit colas, coffee, and tea intake because they increase the risk for recurring urinary stones.

A low-sodium diet is best. High-sodium intake increases calcium excretion in the urine. Table 50.12 shows foods high in calcium, oxalate, and purines.

❖ NURSING MANAGEMENT: URINARY TRACT STONES

◆ Assessment

Subjective and objective data you should obtain from a patient with urinary tract stones are outlined in Table 50.13.

TABLE 50.13 NURSING ASSESSMENT

Urinary Tract Stones

Subjective Data

Important Health Information

Health history: Recent or chronic UTI. Immobilization. Previous urinary tract stones, obstruction, or kidney disease with urinary stasis. Gout, BPH, hyperparathyroidism, chronic diarrhea
Medications: Prior use of medication for prevention of stones or treatment of UTI, allopurinol, analgesics, loop diuretics, thiazide diuretics
Surgery or other treatments: External urinary diversion, long-term indwelling urinary catheter

Functional Health Patterns

Health perception–health management: Family history of urinary tract stones, sedentary lifestyle
Nutritional-metabolic: Nausea, vomiting. Intake of purines, calcium, salt, oxalates, phosphates, and OTC supplements. Low fluid intake. Chills
Elimination: Decreased urine output, urinary urgency, frequency, feeling of bladder fullness
Cognitive-perceptual: Acute, severe, colicky pain in flank, back, abdomen, groin, or genitalia. Burning on urination, dysuria. Anxiety

Objective Data

General

Guarding, back pain, fever, dehydration

GI

Abdominal distention, absence of bowel sounds

Skin

Warm, flushed skin or pallor with cool, moist skin (mild shock)

Urinary

Oliguria, hematuria, tenderness on palpation of renal areas, passage of stone or stones

Possible Diagnostic Findings

↑ BUN and serum creatinine levels. Urinalysis showing RBCs, WBCs, pyuria, crystals, casts, minerals, bacteria. ↑ Uric acid, calcium, phosphorus, oxalate, or cystine values on 24-h urine sample. Stones or anatomic changes on x-ray, CT scan, or renal/bladder US. Direct visualization of obstruction on cystourethroscopy

◆ Clinical Problems

Clinical problems for the patient with urinary tract stones include:

- Impaired urinary elimination
- Pain
- Deficient knowledge

More information on clinical problems and interventions for the patient with urinary tract stones is presented in eNursing Care Plan 50.2 (on the website for this chapter).

◆ Planning

The overall goals are that the patient with urinary tract stones will have (1) pain relief, (2) no urinary tract obstruction, and (3) knowledge of ways to prevent stone recurrence.

◆ Implementation

Most people who have had urinary stones can lower their risk for recurrence by changing their lifestyle and diet habits.

Adequate fluid intake is important to produce a urine output of around 2.5 L/day. Consult with the HCP about the patient's specific recommendations for fluid intake. The moderately active, ambulatory person should drink about 3 to 4 L/day. Fluid intake must be higher in the active person who works outdoors or who regularly engages in athletic activities.

Preventive measures for a person who is on bed rest or is immobile for a prolonged time include maintaining an adequate fluid intake, turning the patient every few hours, and helping the patient sit or stand, if possible, to maximize urinary flow.

Other preventive measures focus on reducing metabolic or secondary risk factors. For example, diet restriction of purines may be helpful for the patient at risk for developing uric acid stones. Teach the patient the dosage, scheduling, and potential side effects of drugs used to reduce the risk for stone formation (Table 50.11). You may teach some patients to monitor urinary pH or urine output.

Pain management is a key nursing responsibility when a patient has an obstructing stone and renal colic. To retrieve any spontaneously passed stones, strain all urine with a gauze or a urine strainer. Encourage ambulation to promote movement of the stone from the upper to the lower urinary tract. To ensure safety, tell the patient who has acute renal colic to ask for help when ambulating, especially if they are receiving opioid analgesics.

◆ Evaluation

The expected outcomes are that the patient with urinary tract stones will:

- Maintain free flow of urine with minimal hematuria
- Report satisfactory pain relief
- State understanding of disease process and ways to prevent recurrence

STRICTURES

A ureteral or urethral **stricture** is a narrowing of the lumen of the ureter or urethra.

Ureteral Strictures

Ureteral strictures can affect the entire length of the ureter, from the UPJ to UVJ. While these can be congenital, they are usually from adhesions or scar formation after surgery or radiation. They may be due to extrinsic factors, such as large tumors in the peritoneal cavity. Depending on its severity, ureteral obstruction can threaten kidney function.

Manifestations include mild to moderate colic, flank pain, and CVA tenderness. This pain may be moderate to severe in intensity, especially if the patient drinks a large volume of fluids, such as alcohol, over a brief period. Infection is unusual unless a stone or foreign object, such as a stent or nephrostomy tube, is present.

The obstruction of a ureteral stricture may be temporarily bypassed by placing a stent using endoscopy or by diverting urine flow through a nephrostomy tube placed in the renal pelvis of the affected kidney. Definitive correction requires surgery. Ureteral strictures under 1 cm can be treated using an endoscopic procedure *(endoureterotomy)*. In some patients, open surgery may be done to excise the stenotic area and reanastomose the ureter to the contralateral ureter *(ureteroureterostomy)* or to the renal pelvis. Alternatively, distal ureteral strictures may be treated by a *ureteroneocystostomy* (reimplantation of the ureter into the bladder wall).

Urethral Strictures

A *urethral stricture* is the result of fibrosis or inflammation of the urethral lumen. Causes of urethral strictures include trauma, urethritis (especially after gonococcal infection), surgical intervention or repeated catheterizations (iatrogenic), or a congenital defect of the urethra. Once the process of inflammation and fibrosis begins, the lumen of the urethra narrows and its compliance (ability to close or open in response to bladder filling or voiding) is compromised. Meatal stenosis, a narrowing of the urethral opening at the tip of the penis, develops due to irritation in this region. It is more common in circumcised patients.

Manifestations include a diminished force of the urinary stream, straining to void, sprayed stream, postvoid dribbling, or a split urine stream. The patient may report feelings of incomplete bladder emptying with urinary frequency and nocturia. Moderate to severe obstruction of the bladder outlet may lead to acute urinary retention. The patient may have a history of urethritis, difficulty with insertion of a urinary catheter, or trauma involving the penis or the perineum. However, many patients are unable to recall any such events, thus leading to a diagnosis of an idiopathic stricture. A history of UTI is common, especially if the stricture involves the distal urethra. Retrograde urethrography (RUG), ultrasound urethrography, voiding cystourethrogram, and cystourethroscopy are used to identify stricture length, location, and caliber.

Initial management can include dilation. With dilation, we place a metal instrument (urethral sound) or a series of progressively larger stents (followers) into the urethra to expand the lumen. Alternatively, the patient may have an endoscopic urethrotomy, a closed procedure involving an incision of the urethra. An open surgical procedure *(urethroplasty)* may be done for an obstructive urethral stricture. Shorter strictures may be treated by resecting the fibrotic area followed by reanastomosis of the urethra. Longer strictures may require the use of a skin flap as a substitute urethral segment.

RENAL TRAUMA

Renal trauma can be blunt or penetrating. *Blunt trauma* is the most common cause. Injury to the kidney can occur with sports injuries, motor vehicle accidents, and falls. Renal trauma is especially likely when the patient injures the abdomen, flank, or back. Around 10% of patients with abdominal trauma also have renal trauma. *Penetrating injuries* may result from violent encounters (e.g., gunshot, stabbing incidents).

The severity of renal trauma depends on the extent of the injury. Obtain a history of trauma to the area of the kidneys. Gross or microscopic hematuria may be present. Diagnostic studies include contrast-enhanced CT and CT pyelography. Both the injured kidney and the uninvolved kidney need

evaluated. Patients with renal trauma are often admitted for observation. Up to 60% to 70% need surgery.[16]

Nursing care depends on the type of trauma and the extent of any associated injuries. Interventions related to renal trauma include (1) assess cardiovascular status and monitor for shock, especially in a penetrating injury; (2) ensure adequate fluid intake and monitor intake and output; (3) provide for pain relief; (4) assess for hematuria and myoglobinuria; and (5) evaluate the patient and vital signs frequently.

RENAL VASCULAR PROBLEMS

Vascular problems involving the kidney include (1) nephrosclerosis, (2) renal artery stenosis, and (3) renal vein thrombosis.

NEPHROSCLEROSIS

Nephrosclerosis is sclerosis of the small arteries and arterioles of the kidney. The decreased blood flow results in ischemia, interstitial fibrosis, and necrosis of parts of the kidney. *Benign nephrosclerosis* usually occurs in adults over 60 years old. It is caused by vascular changes from hypertension and narrowing of blood vessels. Vascular changes account for most of the loss of renal function from aging. The degree of nephrosclerosis is related to the severity of hypertension. The patient with benign nephrosclerosis generally does not progress to significant loss of renal function or ESRD.

With accelerated nephrosclerosis (acute hypertensive or malignant nephrosclerosis), we see a significantly high BP (systolic BP ≥180 and/or diastolic BP ≥120 mm/Hg) with concurrent acute impairment of 1 of more organ systems. It can begin suddenly and is a medical emergency. With renal involvement, damage to the kidney can progress rapidly.

The availability and use of antihypertensive drugs have improved the prognosis for patients with nephrosclerosis. Treatment for benign nephrosclerosis is the same as that for essential hypertension (see Chapter 36). Malignant nephrosclerosis is treated with antihypertensive therapy. We generally lower the BP over a 24-hour period. The prognosis for a patient with untreated or refractive malignant hypertension is poor. These conditions can lead to death.

RENAL ARTERY STENOSIS

Renal artery stenosis is a partial occlusion of 1 or both renal arteries and their major branches. It can be due to atherosclerotic narrowing or fibromuscular hyperplasia. Renal artery stenosis can be a cause of secondary hypertension. When hypertension develops suddenly or is difficult to treat, renal artery stenosis should be considered.

Diagnostic tests used to assess for renal artery stenosis include a renal duplex Doppler ultrasonography, CT or MRI angiography, and renal arteriography.

The goals of therapy are to control BP and restore perfusion to the kidney. Percutaneous transluminal renal angioplasty, with or without stenting, for unilateral renal artery stenosis can be done but only if there is a high chance of success.

Surgical revascularization of the kidney is an option in complex cases. Revascularization may result in the patient's BP becoming normotensive. Surgery usually involves anastomosis between the kidney and another major artery, usually the splenic artery or aorta. In some cases of unilateral renal involvement, unilateral nephrectomy may be done.

RENAL VEIN THROMBOSIS

Renal vein thrombosis may occur unilaterally or bilaterally. It can develop acutely or chronically. Causes include trauma, extrinsic compression (e.g., tumor, aortic aneurysm), kidney cancer, pregnancy, contraceptive use, and nephrotic syndrome.

The patient can be asymptomatic, or have acute flank pain/tenderness, hematuria, fever, worsening renal function, and/or worsening proteinuria. Anticoagulation is used to prevent progression and the development of an embolus. The patient may undergo percutaneous thrombectomy. Other options include thrombolysis and placement of suprarenal IVC filters. Surgical thrombectomy is rarely needed.

HEREDITARY KIDNEY DISEASES

Hereditary kidney diseases involve developmental abnormalities of the renal parenchyma. Renal cysts occur with both inherited and non-inherited disorders. They can be simple or complex. In evaluating renal cysts, it is important to tell simple cyst(s) from those due to diseases such as PKD, kidney cancer, or a kidney abscess.

POLYCYSTIC KIDNEY DISEASE

Polycystic kidney disease (PKD) is a common genetic disorder. In PKD, cysts form in the kidneys that can cause the kidneys to change shape and enlarge over time. PKD affects 500,000 people in the United States. The disease usually progresses from loss of kidney function to ESRD by age 65 in 85% of patients.[17] It is the 4th leading cause of ESRD, affecting 5% of those with ESRD. A nongenetic PKD (acquired cystic kidney disease [ACKD]) can occur in those with severe kidney scarring and damage who typically receive dialysis. After 8 years on dialysis, 90% of patients will have ACKD.[17]

Genetic Link

PKD has 2 hereditary forms: one usually diagnosed in early childhood and one in adulthood. The childhood form of PKD is a rare autosomal recessive disorder that is often rapidly progressive (Box 50.3). The adult form of PKD is an autosomal dominant disorder (ADPKD) and accounts for 90% of all PKD cases. If 1 parent has the disease, there is a 50% chance that the disease will pass to the child.

ADPKD involves both kidneys. It occurs in both men and women. Large, thin-walled cysts that are several millimeters to several centimeters in diameter fill the cortex and medulla (Fig. 50.7). The cysts enlarge and destroy surrounding tissue by compression. They are filled with fluid and may contain blood or pus. ADPKD kidneys can become enlarged and look like they are filled with golf balls.

BOX 50.3 GENETICS IN CLINICAL PRACTICE

Polycystic Kidney Disease (PKD)

	Adult	Child
Genetic basis	Autosomal dominant	Autosomal recessive
Incidence	1 in 400–1000	1 in 20,000–40,000
Gene location	• *PKD1* gene on chromosome 16 or *PKD2* gene on chromosome 4 • Genes code for polycystins (proteins that promote normal kidney development and function) • Mutations in genes lead to formation of thousands of cysts that disrupt the normal function of kidneys and other organs	• Polycystic kidney and hepatic disease *(PKHD1)* gene on chromosome 6p21, DZIP1L gene may be affected • PKHD1 gene codes for fibrocystin • Mutations in gene leads to cyst formation
Genetic testing	DNA testing available	DNA testing available
Age of onset	Kidney function usually starts worsening in the 40s, but symptoms can start earlier	Infancy or childhood
Clinical implications	• Multisystem involvement • Systemic hypertension is common, occurs in 60% of patients before kidney function worsens • Increased risk for cerebral aneurysms • Those at risk should be screened	• Up to 30% of affected newborns die within one week after birth • If infant survives the newborn period, chances of survival are good • Often need dialysis or transplant by adulthood

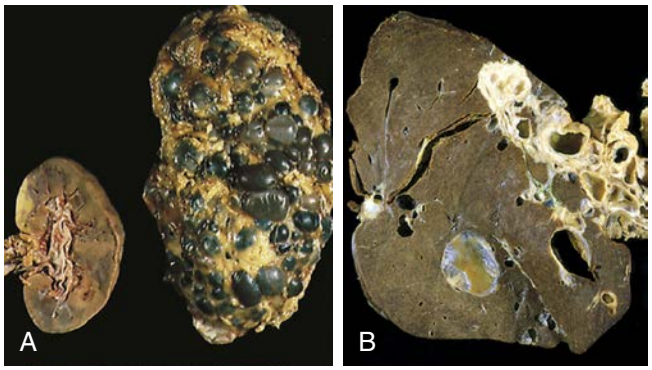

Fig. 50.7 (A) Comparison of polycystic kidney with normal kidney. (B) Cysts in the liver. (A, From Brundage DJ: *Renal disorders,* St Louis, 1992, Mosby. B, From Kumar V, Abbas AK, Fausto N: *Robbins and Cotran pathologic basis of disease,* ed 7, Philadelphia, 2005, Saunders.)

ADPKD can be symptomless for many years. Signs and symptoms usually develop between 30 and 50 years of age.[17] Symptoms can appear when the renal cysts begin to enlarge. Often the first manifestations are hypertension, hematuria, proteinuria, loss of kidney function, and/or a feeling of pain or heaviness in the back, side, or abdomen.

Both acute and chronic pain is a common problem. Acute pain can develop from kidney stone formation, UTIs, or cyst hemorrhage. The pain can be constant and severe in those with enlarged kidneys. Bilateral, enlarged kidneys are often palpable. Those with ADPKD can have no symptoms, which can delay diagnosis.

ADPKD can affect the liver (liver cysts [Fig. 50.7]), pancreas, heart (abnormal heart valves), blood vessels (aneurysms), and intestines (diverticulosis). The most serious complication is a cerebral aneurysm, which can rupture.

Diagnosis is based on manifestations, family history, ultrasound (best screening measure), or CT scan (provides more precise images).

❖ Interprofessional and Nursing Care

There is no cure for PKD. Tolvaptan is an approved treatment for treating rapidly progressive ADPKD. It works to slow growth of renal cysts, helping to preserve kidney function. Other treatment aims include preventing or treating UTIs. Nephrectomy may be done if pain, bleeding, or infection becomes a chronic, serious problem. Dialysis and kidney transplant may be needed to treat ESRD (see Chapter 51).

When the patient begins to have progressive renal failure, the interventions depend on the remaining renal function. Measures we use are the same as those for managing ESRD. They include diet changes, fluid restriction, drugs (e.g., antihypertensives), and help for the patient and family in coping with having a chronic disease.

The patient with ADPKD often has children by the time the disease is diagnosed. Those children should receive genetic counseling. The patient needs counseling about plans for having more children. You can find more resources at the PKD Foundation website (www.pkdcure.org).

CHECK YOUR PRACTICE

You are doing a rotation in the dialysis unit. You have been doing vital sign checks on a 45-year-old man who receives dialysis 3 times/week. When you ask him why he is on dialysis, he tells you that he has ADPKD. After further discussion, he tells you that he has 1 son who is now 23 years old, but they do not speak. He does not want to tell him about his medical problems or why he is on dialysis.

- How would you respond to this patient?

MEDULLARY CYSTIC KIDNEY DISEASE

In *medullary cystic kidney disease,* cysts form in the medulla, or center, of the kidneys. It is a rare, autosomal dominant disorder. The patient has loss of renal function often starting in

their teens. Most progress to ESRD by the time they are age 65. The kidneys are typically normal or small in size with significant tubular-interstitial fibrosis. Defects in the kidneys' concentrating ability result in polyuria, which is a hallmark of the disease. Hyperuricemia is common. Genetic counseling may be helpful in family planning. Treatment measures are those related to ESRD (see Chapter 51). A similar disease, familial juvenile nephronophthisis, is found in young children. It is autosomal recessive and leads to 15% of pediatric ESRD cases.

ALPORT SYNDROME

Alport syndrome, or *chronic hereditary nephritis,* is an inherited disease that affects the glomeruli. The basic defect is a mutation in a gene for collagen that results in altered synthesis of the glomerular basement membrane.[18]

There are 3 genetic types of Alport syndrome: X-linked, autosomal recessive type, and autosomal dominant type. In X-linked, the most common type, the earliest manifestation is chronic asymptomatic microscopic hematuria. These patients can have progressive hearing loss and deformities of the lens of the eye. Ocular changes and sensorineural hearing loss occur with the autosomal recessive type but are rare in the autosomal dominant type.

Alport syndrome can cause progressive kidney damage, leading to ESRD. Those with X-linked and autosomal recessive type generally progress to ESRD between ages 16 and 35. People with autosomal dominant Alport syndrome usually develop ESRD around ages 45 to 60.

There is no specific treatment. Care is supportive. Corticosteroids and cytotoxic drugs are not effective. A kidney transplant is usually successful. The disease itself does not recur after a kidney transplant, but there is small risk of developing anti-GBM antibody disease.

URINARY TRACT TUMORS

KIDNEY CANCER

Tumors that arise from the cortex, pelvis, or calyces may be benign or cancerous. Eighty percent of *kidney cancers* develop in the renal cortex with 8% in the renal pelvis. Nephroblastoma is a common type of pediatric kidney cancer. The lifetime risk of developing kidney cancer is 1 in 80 for females and 1 in 46 for males.[19]

Most cases of kidney cancer are renal cell carcinomas (renal adenocarcinoma) (Fig. 50.8). It occurs twice as often in men as in women. The average age at diagnosis is 64 years. It is rare in those under 45 years old. Smoking and obesity are significant risk factors. An increased incidence occurs in first-degree relatives of people who have or had renal cell cancer. Other risk factors include hypertension and exposure to certain chemicals such as trichloroethylene and cadmium. Blacks have slightly higher rates of renal cell cancer.

Clinical Manifestations and Diagnostic Studies

Early-stage kidney cancer usually has no symptoms, so many patients go undiagnosed until the disease has significantly progressed. Many are diagnosed as incidental findings on imaging studies used to evaluate symptoms for unrelated conditions.

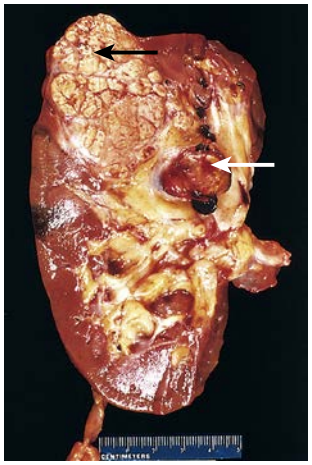

Fig. 50.8 Cross section of kidney with renal cell cancer. The cancer *(black arrow)* is on the pole of the kidney. Note that the renal vein is involved and thrombosed *(white arrow).* (From Kumar V, Abbas AK, Fausto N: *Robbins and Cotran pathologic basis of disease,* ed 7, Philadelphia, 2005, Saunders.)

Kidney tumors cause symptoms by compressing, stretching, or invading structures near or within the kidney. The most common presenting symptoms are hematuria and flank pain. Other manifestations include weight loss, fever, anemia, fatigue, hypercalcemia, and/or a palpable mass in the flank or abdomen.

About 33% of patients have metastasis at the time of diagnosis. Local extension of kidney cancer into the renal vein and vena cava is common (Fig. 50.8). The most common sites of metastases include lungs, lymph nodes, bone, and liver.

CT scan is often used in the diagnosis and can detect small kidney tumors. Ultrasound has improved the ability to determine between a solid mass tumor and a cyst. This is significant because most masses detected on imaging are cysts. Partial nephrectomy or nephrectomy are typically done at the time of biopsy.

Interprofessional and Nursing Care

Preventive measures, including quitting smoking, maintaining a healthy weight, controlling BP, and reducing exposure to toxins, help reduce the incidence of kidney cancer. Patients in high-risk groups should be aware of their increased risk. Teach them about early manifestations (e.g., hematuria, flank pain). A cure for kidney cancer may be possible if it is found and treated early.

Table 50.14 outlines the interprofessional care of the patient with kidney cancer. Staging provides a basis for determining treatment options. The following is a simple description of staging of kidney cancer based on the primary tumor:

Stage I: The tumor can be up to 7 cm in diameter and is confined to the kidney.

Stage II: The tumor is larger than a stage I tumor but still confined to the kidney.

Stage III: The tumor extends beyond the kidney to the surrounding tissue. Has not spread to the adrenal gland or to Gerota fascia.

Stage IV: Cancer spreads outside the kidney beyond Gerota fascia. Can involve multiple lymph nodes or spread to distant parts of the body, such as bones, brain, liver, or lung.

The treatment of choice for some kidney cancers is a partial nephrectomy (for smaller tumors), simple total nephrectomy,

TABLE 50.14 Interprofessional Care

Kidney Cancer

Diagnostic Assessment	Management

• History and physical assessment
• Urinalysis
• Ultrasound
• Abdominal CT scan
• MRI
• Renal biopsy
• Renal scan
	• Surgical therapy
	  • Partial nephrectomy
	  • Radical nephrectomy
	• Ablation
	  • Cryoablation
	  • Radiofrequency ablation
	• Radiation therapy
	• Chemotherapy
	• Immunotherapy
	• Targeted therapy

or a radical nephrectomy (for larger tumors). Radical nephrectomy involves removal of the kidney, adrenal gland, surrounding fascia, and draining lymph nodes. Nephrectomy can be done by a conventional (open) approach or laparoscopically. Other treatment options include cryoablation (freezing technique) and radiofrequency ablation (destroying tumor by using radiofrequency heat). These procedures can be used when surgery is not an option (e.g., patient has comorbid conditions) and for small renal tumors.

Kidney cancer is relatively resistant to most chemotherapy drugs. While kidney cancer can be resistant to radiation therapy, it may be useful in certain situations, such as metastasis to bone, brain, or lungs.

Immunotherapy, including α-interferon and interleukin-2 (IL-2), is a treatment option in metastatic disease (see Chapter 16.) Another drug used as immunotherapy is nivolumab (Opdivo) without or with ipilimumab (anti-CTLA-4 antibody). Nivolumab targets PD-1, a protein on T cells that normally helps keep these cells from attacking other cells in the body. By blocking PD-1, this drug boosts the immune response against cancer cells. This can shrink some tumors or slow their growth.

Targeted therapy is another treatment option for metastatic kidney cancer. Kinase inhibitors, a class of targeted therapies, block certain proteins (kinases) that play a role in tumor growth and cancer progression. Kinase inhibitors include sunitinib (Sutent), sorafenib (Nexavar), cabozantinib (Cabometyx), and axitinib (Inlyta). Bevacizumab (Avastin) inhibits the formation of new blood vessel growth to the tumor. Temsirolimus (Torisel) and everolimus (Afinitor) inhibit a specific protein known as the mechanistic target of rapamycin (mTOR).[20] These drugs are discussed in Table 16.13. The mechanisms of action are shown in Fig. 16.16.

The diagnosis of kidney cancer is devastating. Often the cancer has already metastasized by the time a person is diagnosed. See more about the care of the patient with cancer in Chapter 16.

BLADDER CANCER

Bladder cancer is the most common cancer of the urinary system.[21] About 83,730 new cases are diagnosed each year. About 17,240 deaths occur every year. Bladder cancer is most common in older adults. 90% of cases occur in those over the age of 55.

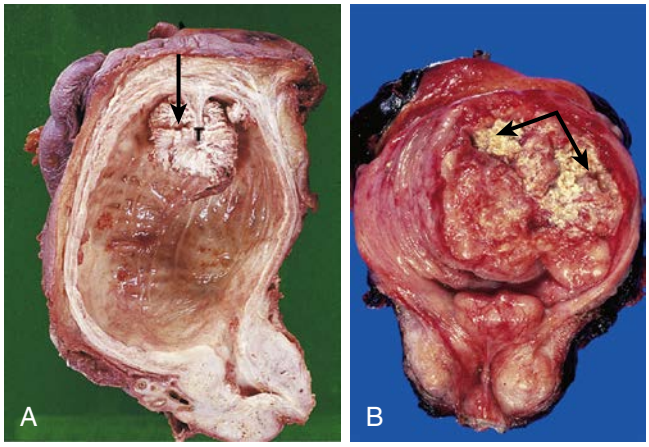

Fig. 50.9 (A) Papillary transitional cell cancer *(T)* seen arising from the dome of the bladder as a cauliflower-like lesion *(arrow).* (B) Opened bladder showing advanced stage bladder cancer. Yellow areas are ulcerations and necrosis *(arrows).* (A, From Stevens A, Lowe J: *Pathology: Illustrated review in colour,* ed 2, London, 2000, Mosby. B, From Kumar V, Abbas AK, Fausto N: *Robbins and Cotran pathologic basis of disease,* ed 7, Philadelphia, 2005, Saunders.)

It is far more common in men and in Whites.[22] Some bladder tumors are benign papillomatous growths (Fig. 50.9).

Urothelial cancer, or transitional cell cancer (TCC), is by far the most common type of bladder cancer. TCC can easily spread to other urinary tract areas given that the mucosal lining throughout the urinary tract is the same. Cancer recurrence within the bladder is common.

About half of bladder cancers are related to cigarette smoking.[21] Other risk factors include workplace exposure to certain chemicals. Others at risk include those treated with pelvic radiation for cancer; patients who received cyclophosphamide or aristolochic acid; and those who have indwelling catheters for long periods. People with chronic, recurrent urinary tract stones, often in the bladder, and chronic lower UTIs have an increased risk for non-urethral bladder cancer such as squamous cell carcinoma.

Clinical Manifestations and Diagnostic Studies

Microscopic or gross, painless hematuria (chronic or intermittent) is the most common manifestation of bladder cancer. Bladder irritability with dysuria, frequency, and urgency may also be the first signs and symptoms.

When cancer is suspected, the patient has a complete urologic work-up. This includes obtaining urine specimens to identify any cancer cells. Exfoliated cells from the bladder's epithelial surface are often found in voided specimens. Urine cytology and testing for bladder tumor antigens can be done. CT without and with contrast is the recommended study of choice. Alternatively, IV pyelogram or MRI are options. Cancer is confirmed by cystoscopy and biopsy.[23]

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: BLADDER CANCER

Most bladder cancers are diagnosed at an early stage when the cancer is treatable. Before starting treatment, bladder cancers

TABLE 50.15 Interprofessional Care

Bladder Cancer

Diagnostic Assessment
- History and physical assessment
- Urinalysis
- Urine cytology studies
- Cystoscopy with biopsy
- CT scan

Management
- Surgical therapy
  - Transurethral resection of bladder tumor
  - Partial cystectomy
  - Radical cystectomy
- Radiation therapy
- Immunotherapy
- Targeted drug therapy
- Intravesical immunotherapy
  - Bacille Calmette-Guérin (BCG)
  - α-interferon (Intron A)
- Intravesical chemotherapy
  - epirubicin
  - gemcitabine
  - mitomycin
  - valrubicin (Valstar)
- Systemic chemotherapy and immunotherapy

are graded based on the cell type and staged based on the extent and invasiveness of the cancer. We use a grading system to classify the cancerous potential of tumor cells, using a scale from well differentiated (closely resembling the normal tissue) to undifferentiated (poorly differentiated).

Clinical staging of bladder cancer is determined by the depth of invasion of the bladder wall and surrounding tissue. The following is a simple description of staging of bladder cancer:

Stage I: Cancer is in the inner lining of the bladder but has not invaded the bladder muscle wall.

Stage II: Cancer has invaded the bladder wall but is still confined to the bladder.

Stage III: Cancer has spread through the bladder wall to surrounding tissue.

Stage IV: Cancer has spread to the bowels, prostate, vagina, and/or uterus.

Interprofessional care of bladder cancer includes surgery, radiation, chemotherapy, targeted therapy, immunotherapy, and intravesical therapy (Table 50.15).

Surgical Therapy

Surgical therapy includes a variety of procedures. *Transurethral resection of the bladder tumor* (TURBT) is used for superficial lesions of the bladder's inner lining. The HCP uses a wire loop inserted through the cystoscope or a resectoscope with an attached loop to remove the tumor and tissue, which are sent for pathologic evaluation. After the tumor is removed, the tissue in the area where the tumor was may be burned. This is called fulguration. Cells can also be destroyed with a high-energy laser. Those with a low- or intermediate-risk tumor may get a one-time dose of intravesical chemotherapy in the immediate postoperative period. Repeat TURBT is often done 6 weeks later for those with higher-grade tumors. The primary disadvantages of TURBT include the chance of incomplete removal of the tumor, bleeding, and bladder perforation.[24]

A *segmental cystectomy (partial cystectomy)* is used to treat larger tumors or those that involve only 1 area of the bladder. The part of the bladder wall containing the tumor is removed along with a margin of normal tissue.

When the tumor is invasive and involves muscle, a radical cystectomy with urinary diversion is the treatment of choice. A *radical cystectomy* involves removal of the bladder, prostate, and seminal vesicles in men and the bladder, uterus, cervix, anterior vagina, and ovaries in women. After a radical cystectomy, a new way for urine to leave the body, or urinary diversion, must be created.[24]

Postoperative instructions for any of these procedures include drinking a large volume of fluid for the first week afterward. Teach the patient to monitor the color and consistency of the urine. Hematuria is common, but the blood in the urine should not contain clots and/or appear thick.

Give analgesics and stool softeners for a brief period after the procedure. Help the patient and family cope with fears about cancer, surgery, and sexuality. Emphasize the importance of regular follow-up care. Follow-up cystoscopies are done on a regular basis after surgery for bladder cancer.

Radiation Therapy, Chemotherapy, Targeted Therapy, and Immunotherapy

Radiation therapy can be used in combination with cystectomy or as the primary therapy when the cancer is inoperable or the patient refuses surgery. Chemotherapy is often used in combination with radiation. Targeted therapy includes FGFR inhibitors (e.g., erdafitinib) that affect proteins that help the cancer cells grow. Immunotherapy can be used to treat bladder cancer. Options include immune checkpoint inhibitors, PD-1 and PD-L1 inhibitors, and intravesical BCG.

Intravesical Therapy

In intravesical therapy, chemotherapy or immunotherapy is placed directly into the bladder by a urethral catheter.[23] The drug is then retained for 1 to 2 hours. During that time, the patient may have to change position every 15 minutes so the solution washes over the entire bladder. The patient's bladder must be empty before instillation. Intravesical therapy is usually given once per week for 6 to 12 weeks. Maintenance therapy after the initial induction regimen may be given.

Bacillus Calmette-Guérin (BCG), a weakened strain of *Mycobacterium bovis,* is the treatment of choice for high-risk bladder tumors. It can also treat intermediate risk tumors. BCG stimulates the immune system to attack the cancer cells. Interferon-alpha therapy may be given with BCG. Other intravesical chemotherapy options include mitomycin, epirubicin, gemcitabine, and valrubicin.[23]

Most patients have irritative voiding symptoms and hematuria after intravesical therapy. BCG may cause flu-like symptoms, increased urinary frequency, hematuria, and, rarely, systemic

infection. Other side effects of chemotherapy (e.g., nausea, vomiting, hair loss) do not occur with intravesical chemotherapy.

Encourage patients to increase their daily fluid intake and quit smoking. Assess the patient for secondary UTI. Stress the need for routine urologic follow-up. The patient may have fears or concerns about sexual activity or bladder function that we must address. Because of the high rate of disease recurrence and progression in bladder cancer, follow-up studies are important.

BLADDER DYSFUNCTION

URINARY INCONTINENCE

Urinary incontinence (UI) is an involuntary leakage of urine. Although UI is more prevalent among older adults, it is not a natural consequence of aging. UI has a major effect on quality of life and contributes to emotional, social, and potential serious health problems, especially in older adults.

Etiology and Pathophysiology

UI occurs when bladder pressure exceeds urethral closure pressure. Anything that interferes with internal and/or external urethral sphincter control can result in UI. There are many risk factors for UI. These include obesity, BPH, smoking, recurrent UTIs, GU surgeries, vaginal delivery, impaired functional status, certain drugs, certain neurologic problems, and a family history of UI (Box 50.4). Patients may have more than 1 type of UI (Table 50.16). The combination of stress and urge incontinence is called mixed incontinence.

Diagnostic Studies

The basic evaluation for UI includes a focused history, physical assessment, and a urinalysis. Obtain information about the onset of UI, factors that provoke urinary leakage, any associated systemic symptoms, use of caffeine and alcohol, medications taken, and associated conditions. Pay special attention to factors known to produce transient UI, especially when the onset of urine loss is sudden. It may be useful to have the patient keep a bladder log or voiding diary. Have them record the timing of urinations, episodes of urinary leakage, and frequency of nocturia for a period of 1 to 7 days (minimum of 3 days if possible). Nursing staff can keep this record if the person is in an inpatient or long-term care facility.

Begin the assessment with looking at general health and functional issues related to urination, including mobility, dexterity, and cognitive function. A pelvic examination may be done. Carefully inspect the perineal skin for signs of erosion or rashes related to UI. Is there any pelvic organ prolapse? Assess local innervation and pelvic floor muscle strength. Perform a digital examination of the pelvic floor muscle to assess for weakness or tension.

A urinalysis can identify factors contributing to transient UI (e.g., UTI, diabetes). A bladder stress test can be useful when we suspect stress incontinence. Measuring postvoid residual (PVR) urine may be of use. PVR volume is obtained by asking the patient to void, followed by catheterization or use of a bladder ultrasound (preferably within 10 to 20 minutes).

Some patients have urodynamic testing. Imaging studies of the upper and lower urinary tract (e.g., ultrasound) and cystoscopy may also be done.

BOX 50.4 BIOLOGIC SEX CONSIDERATIONS

Urinary Incontinence

Men
- A common manifestation of BPH and prostate cancer
- More likely to have overflow incontinence caused by urinary retention

Women
- Have a higher prevalence of UI
- More likely to have stress and urge incontinence

Interprofessional Care

Many cases of UI can be cured or significantly improved. Transient, reversible factors are first corrected, followed by management of the type of UI (Table 50.16). In general, we try less invasive treatments before more invasive ones (e.g., surgery). The choice of the initial treatment is patient specific, based on patient preference, the type and severity of UI, and associated anatomic defects.

Several behavioral therapies may improve UI (Table 50.17). Pelvic floor muscle training (Kegel exercises) is used to treat UI, especially stress UI (Table 50.18).[25] Biofeedback can help the patient identify, isolate, contract, and relax the pelvic muscles. Bladder training may help.

Drug Therapy

Drug therapy varies according to the UI type (Table 50.19). There are no drugs approved to treat stress UI. In urge and reflex UI, drugs play a key role.

Anticholinergic drugs (muscarinic receptor blockers) block the action of acetylcholine at muscarinic receptors. They relax the bladder muscle and inhibit overactive detrusor contractions (Table 50.19). Side effects include dry mouth and eyes, constipation, blurred vision, and sleepiness.

Botox (onabotulinumtoxin A) can be used to treat UI from detrusor overactivity. Botox is injected into the bladder. It results in bladder relaxation, an increase in its storage capacity, and a decrease in UI.

DRUG ALERT

Antimuscarinic Agents

- Overdosage can result in severe anticholinergic effects.
- These effects include constipation, decreased sweating, eye pain, blurred vision, and difficulty starting urination and/or completely emptying the bladder.

Surgical Therapy

Surgical techniques vary depending on the type of UI. Surgical correction of stress UI is aimed at making the urinary structures more receptive to intraabdominal pressure and augmenting the urethral resistance of the internal sphincter. It may involve

TABLE 50.16 Types of Urinary Incontinence

Description	Causes	Treatment
Functional Incontinence		
• Loss of urine resulting from cognitive, functional, environmental factors	• Neurologic and/or muscular limitations (e.g., severe arthritis) • Cognitive problems (e.g., dementia) • Psychologic issues • Environment barriers	• Modifying the environment or care plan to facilitate regular, easy access to toilet and promote patient safety • Includes better lighting, ambulatory assistance equipment, clothing alterations, timed voiding, different toileting equipment
Incontinence After Trauma or Surgery		
• In women, vesicovaginal or urethrovaginal fistula may occur • In men, inadequate urethral sphincter function, can lead to stress, urge, overflow, or mixed UI	• Fistulas may occur as a complication of pregnancy and delivery of baby, after hysterectomy or invasive cancer of cervix, or after radiation therapy • Incontinence is a postoperative complication of radical prostatectomy, and rarely transurethral resection of the prostate	• External condom catheter • Penile clamp • Sling surgery (male) • Surgery to correct fistula • Periurethral balloons
Overflow Incontinence		
• Occurs when pressure of urine in overfull bladder overcomes sphincter control and/or detrusor underactivity • Leakage of small amounts of urine is frequent or continual throughout day and night • Concurrent incomplete bladder emptying • Bladder can stay distended and is usually palpable	• Caused by bladder or urethral outlet obstruction (bladder neck obstruction, urethral stricture, pelvic organ prolapse) or by underactive detrusor muscle caused by myogenic or neurogenic factors (e.g., herniated disc, diabetic neuropathy) • May occur after pelvic floor surgery • Neurogenic bladder (flaccid type)	• Urinary catheterization to decompress bladder • α-Adrenergic blockers (Table 50.20) • 5α-Reductase inhibitors (Table 50.20) to decrease outlet resistance • Bethanechol to enhance bladder contractions • Intermittent catheterization • Intravaginal device, such as a pessary, to support prolapse • Surgery to correct underlying problem
Reflex Incontinence		
• Condition occurs with no warning, periodic involuntary urination • Urination can be frequent, large in volume, and occurs equally during day and night	• CNS problems, including, multiple sclerosis, brain tumors, CVA, Parkinson disease, spinal cord injuries	• Treat underlying cause • Intermittent self-catheterization • Behavioral therapy including bladder training, pelvic floor muscle exercises • Certain medications may be useful: anticholinergics, β3-adrenergic agonist, tricyclic antidepressants, topical estrogen (women)
Stress Incontinence		
• Sudden increase in intraabdominal pressure causes involuntary passage of urine • Can occur during coughing, laughing, sneezing, or physical activities, such as heavy lifting, exercising • Leakage usually is in small amounts and may not be daily	• Most common in women with relaxed pelvic floor musculature (from delivery, use of instrumentation during vaginal delivery, or multiple pregnancies) • Structures of female urethra atrophy when estrogen decreases • Prostate surgery for BPH or prostate cancer	• Pelvic floor muscle exercises (e.g., Kegel exercises), weight loss if obese, topical estrogen products, transurethral bulking agents, surgery • Continence pessary. Use of duloxetine may be of aid
Urge Incontinence		
• Often referred to as overactive bladder • Occurs randomly when urgency precedes involuntary urination • Leakage is periodic but can be frequent and varies in amount • Nocturnal frequency and incontinence are common	• Caused by uncontrolled contraction or overactive detrusor muscle • Bladder escapes central inhibition and contracts reflexively • Conditions include: • CNS problems (e.g., stroke, Alzheimer disease, brain tumor, Parkinson disease) • Bladder disorders (e.g., cancer, radiation effects, interstitial cystitis) • Interference with spinal inhibitory pathways (e.g., cancer in spinal cord, spondylosis) • Bladder outlet obstruction or conditions of unknown cause	• Treat underlying cause • Biobehavioral interventions (bladder retraining with urge suppression, decrease in diet irritants, bowel regularity, pelvic floor muscle exercises) • Anticholinergic drugs (Table 50.20) • mirabegron (Myrbetriq) • Vaginal estrogen creams • Containment devices (e.g., external condom catheters) • Absorbent products

TABLE 50.17 Interventions for Urinary Incontinence

Intervention	Description
Lifestyle changes	Self-management to reduce or eliminate risk factors, including: • Smoking cessation • Weight reduction • Bowel regimen • Reduction of bladder irritants (e.g., caffeine, aspartame artificial sweetener, citrus juices) • Fluid modifications for those with urge incontinence
Scheduled Voiding Regimens	
Bladder retraining and urge-suppression strategies	Scheduled toileting with progressive voiding intervals. Includes teaching of urge control using relaxation and distraction techniques, self-monitoring, reinforcement techniques, and other strategies, such as conscious contraction of pelvic floor muscles.
Habit retraining	Scheduled toileting with adjustments of voiding intervals (longer or shorter) based on the person's voiding pattern.
Prompted voiding	Scheduled toileting that requires prompts to void from a caregiver (typically every 3 hr). Used in conjunction with operant conditioning techniques to reward people for maintaining continence and appropriate toileting.
Timed voiding	Toileting on a fixed schedule (typically every 2–3 hr during waking hours).
Pelvic Floor Muscle Rehabilitation	
Biofeedback	Feedback from vaginal pressure sensor about pelvic floor contractions.
Electrical stimulation	Application of low-voltage electric current to sacral and pudendal afferent fibers through vaginal, anal, or surface electrodes. Used to inhibit bladder overactivity and improve awareness, contractility, and efficiency of pelvic muscle contraction.
Pelvic floor muscle (Kegel) exercises or training	Table 50.18.
Vaginal weight training	Active retention of vaginal weights (devices designed and shaped to exercise and strengthen pelvic floor muscles) at least twice a day. Typically used in combination with pelvic floor muscle exercises.
Anti-Incontinence Devices	
Incontinence clamps (penile compression devices)	Mechanical fixed compression applied to the penis to prevent any flow or leakage via the urethra. Must be released to void.
Intraurethral occlusive device (urethral plug)	Device worn in the urethra to provide mechanical obstruction to prevent urine leakage. Removed for voiding and after several hours of wearing.
Intraurethral valve pump	Replaceable urinary prosthesis for use in women who have impaired detrusor contractility (cannot contract muscles to push urine out of the bladder). Draws urine out to empty bladder and blocks urine flow when continence is desired.
Intravaginal support devices (pessaries)	Devices support bladder neck, relieve minor pelvic organ prolapse, and change pressure transmission to the urethra.
Containment Devices	
Absorbent products	Variety of reusable and disposable pads and undergarment systems.
External collection devices	External catheter (condom) systems (e.g., penile sheaths) direct urine into a drainage bag. Most often used by men.

repositioning the urethra and/or creating a backboard of support to stabilize the urethra and bladder neck and make them more receptive to changes in intraabdominal pressure. Another technique for stress UI augments the urethral resistance of the intrinsic sphincter with a sling or periurethral injectable.

Placement of a suburethral sling, typically midurethral, using the person's own fascia or a synthetic material, can correct stress UI in women. Complications include vascular and bowel injury, urinary retention, mesh or sling erosion, infection, urgency, and bladder perforation. Suburethral slings have better success rates compared to conservative therapy.

A bulking agent can be injected underneath the mucosa of the urethra to correct stress UI in women or men. Bulking agents include glutaraldehyde cross-linked bovine collagen (GAX collagen), autologous fat, carbon beads, carbon hydroxylapatite, and polydimethylsiloxane injections. Although treatment with bulking agents avoids the risk from open surgery, reinjection is typically needed after several years.

In artificial urethral sphincter surgery, the bladder sphincter that no longer works is replaced with an artificial one. An inflatable cuff is placed around the urethra internally. The patient inflates it to stop the flow and deflates it when the need to empty occurs. The patient must be able to work the internal pump. It is usually done in men. This procedure is done only as a last resort.[26]

❖ NURSING MANAGEMENT: URINARY INCONTINENCE

It is important to recognize both the physical and emotional problems from UI. Maintain and enhance the patient's dignity, privacy, and feelings of self-worth. This involves a 2-step

TABLE 50.18 PATIENT & CAREGIVER TEACHING

Pelvic Floor Muscle (Kegel) Exercises

Include the following instructions when teaching the patient to perform Kegel exercises:

What Are the Pelvic Floor Muscles?

- Your pelvic floor muscles provide support for your bladder and rectum and, in women, the vagina and uterus.
- If the muscles weaken or are damaged, they cannot support these organs and their position can change.
- This causes problems with the normal bladder and rectal function.
- If you have weak pelvic floor muscles, you may want to do special exercises to make the muscles stronger, prevent unwanted urine leakage, and lessen urinary urgency.

Finding the Pelvic Floor Muscles

- Without tensing the muscles of your leg, buttocks, or abdomen, imagine that you are trying to control the passing of gas or pinching off a stool.
- Imagine you are in an elevator full of people and feel the urge to pass gas. What do you do?
- You tighten or pull in the ring of muscle around your rectum.
- You should feel a lifting sensation in the area around the vagina or a pulling in of your rectum.

How to Do the Exercises

1. Squeeze the pelvic floor muscles.
2. Hold the muscle contraction for 3–5 seconds building up over time to longer and harder contractions.
3. Relax the pelvic floor muscles for 3–5 seconds.

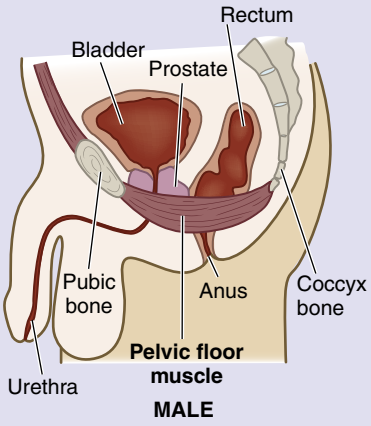
Do these exercises 10 times at 3 different times of the day each day.

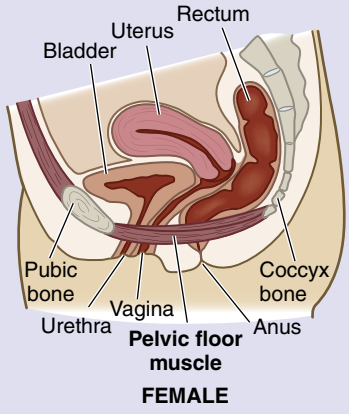
When to Do These Exercises

- You can do these exercises anytime and anywhere.
- You can do these exercises in any position but sitting or lying down may be the easiest.

How Long Does It Take Before I Notice a Change?

After a few weeks or months of doing these exercises, you should start to see less urine leakage and urinary urgency.





(Courtesy Diane Newman.)

approach with (1) containment devices to manage existing urinary leakage and (2) a plan to reduce or resolve the factors leading to UI.

CHECK YOUR PRACTICE

You are doing BP and glucose screening at the community senior center. While you are checking the BP on a 78-year-old woman, she starts to sob quietly. You tell her that her BP is 134/84 and gently place your hand on her arm. You ask her what is wrong. She tells you, "I have to pee all the time. I soak the bed, and my husband won't sleep with me anymore. I am washing sheets and my clothes all the time. Our whole house smells like urine."

- How would you respond to her?

Management options are shown in Tables 50.17 and 50.18. They include lifestyle interventions such as teaching the patient about consuming an adequate volume of fluids and reducing or eliminating bladder irritants, especially caffeine and alcohol, from the diet. Have the patient maintain a regular, flexible schedule of urination, usually every 3 to 4 hours while awake. Advise patients to quit smoking because it increases the risk for stress UI. Teach patients about the relationships among constipation, UI, and urinary retention. Aggressive management of constipation is recommended. Begin with ensuring adequate fluid intake, increasing fiber, lightly exercising, and judiciously using stool softeners. The management of constipation is discussed in Chapter 47.

Behavioral treatments include scheduled voiding regimens (timed voiding, habit training, prompted voiding), bladder retraining, and pelvic floor muscle training. Assess how the patient contains urine and offer alternatives if needed (Table 50.20). Many women use feminine hygiene pads. Many people use household products, such as rags, paper towels, or folded toilet tissue. Unfortunately, none of these products is designed to wick urine away from the skin, prevent soiling of clothing, and eliminate odor.

Provide information on products specifically designed to contain urine. For example, patients with mild to moderate UI often benefit from incontinent pads containing superabsorbent

TABLE 50.19 Drug Therapy

Voiding Dysfunction

Class and Mechanism of Action	Drug
α-Adrenergic Blockers	
Reduce urethral sphincter resistance to urinary outflow	alfuzosin (Uroxatral) doxazosin (Cardura) phenoxybenzamine (Dibenzyline) prazosin (Minipress) silodosin (Rapaflo) tamsulosin (Flomax) terazosin
5α-Reductase Inhibitors	
Suppress androgen resulting in epithelial atrophy and decrease in prostate size	dutasteride (Avodart) finasteride (Proscar)
β_3-Adrenergic Agonist	
Improves bladder's storage capacity by relaxing bladder muscle during filling	mirabegron (Myrbetriq)
Anticholinergics (Muscarinic Receptor Blockers)	
Reduce overactive bladder contractions in urge incontinence Relax bladder muscle during filling and improves the storage capacity of bladder	darifenacin (Enablex) fesoterodine (Toviaz) oxybutynin (Ditropan, Oxytrol Transdermal System) solifenacin (Vesicare) tolterodine (Detrol, Detrol LA) trospium
Hormone Therapy	
Local application reduces urethral irritation and increases host defenses against UTI	estrogen cream (Premarin) estrogen vaginal ring (Estring)
Serotonin-Norepinephrine Reuptake Inhibitor	
Unclear mechanism, decreases UI in some patients	Duloxetine
Tricyclic Antidepressants	
Reduce sensory urgency and burning pain of interstitial cystitis Reduce overactive bladder contractions	Amitriptyline imipramine (Tofranil)

TABLE 50.20 NURSING MANAGEMENT

Caring for the Patient With Incontinence

- Assess for risk factors for UI or urinary retention.
- Determine type of UI that patient has.
- Develop plan of care to decrease UI.
- Teach patient ways to decrease UI, such as pelvic floor muscle (Kegel) exercises.
- Assist patient in choosing appropriate products to contain urine.
- Delegate to the LPN/VN:
  - Use bladder scanner to estimate the postvoid residual volume (PVR).
  - Catheterize patient and measure PVR.
  - Give medications to decrease UI or urinary retention.
- Supervise AP:
  - Help patient to commode or bedpan at regular intervals.
  - Clean patient and provide skin care.
  - Notify RN about new-onset UI in a previously continent patient.

material, designed to absorb many times its weight in water. Patients with higher-volume urine loss or those with both urinary and fecal incontinence may need disposable or reusable incontinence protective underwear, briefs, or pad/pant systems.

In inpatient or long-term care facilities, nursing management of UI includes maximizing toilet access. This may take the form of offering the urinal or bedpan or helping the patient to the bathroom every 3 to 4 hours or at scheduled times. Ensure that toilets are accessible to patients and provide privacy to allow effective urine elimination. See Table 50.20.

URINARY RETENTION

Urinary retention is the inability to empty the bladder when a person voids or the accumulation of urine in the bladder because of an inability to void. In some cases, there is urinary leakage or postvoid dribbling, called *overflow UI*. *Acute urinary retention* is the total inability to pass urine via micturition. It is a medical emergency. *Chronic urinary retention* is an incomplete bladder emptying despite urination. The PVR volumes in patients with chronic urinary retention vary widely. Normal PVR is under 50 mL and for the elderly, 50 to 100 mL. A PVR over 200 mL is abnormal. A PVR between 100 to 200 mL can justify further evaluation when the patient has issues such as recurring UTIs or LUTS suggestive of UTI.

Etiology and Pathophysiology

Several different problems can cause urinary retention. The most common are neurologic impairment, bladder outlet obstruction, and deficient detrusor (bladder muscle) contraction strength. *Bladder outlet obstruction* leads to urinary retention when the blockage is so severe that the bladder can no longer evacuate its contents despite a detrusor contraction. A common cause of obstruction in men is an enlarged prostate.

Deficient detrusor contraction strength leads to urinary retention when the muscle is no longer able to contract with enough force or for enough time to completely empty the bladder. Common causes include neurologic impairment, diabetic neuropathy, overdistention, chronic alcohol use, and drugs (e.g., anticholinergic drugs).

Diagnostic Studies

The diagnostic studies for urinary retention are similar to the ones used for UI. Other studies include PVR measurement, ultrasound, urodynamic evaluation, video urodynamic evaluation, cystourethroscopy, and electromyography.

Interprofessional Care

Behavioral therapies for UI may be used in the management of urinary retention. Scheduled toileting and double voiding may be effective in chronic urinary retention with moderate PVR volumes. *Double voiding* is an attempt to maximize bladder evacuation. The patient is asked to void, sit on the toilet for 3 to 4 minutes, and void again before exiting the bathroom.

Catheterization may be needed. Intermittent catheterization allows the patient to remain free of an indwelling catheter with its associated risk of CAUTI and urethral irritation. In some

situations, an indwelling catheter is preferred (e.g., if the patient is unwilling or unable to perform intermittent catheterization). An indwelling catheter is also used when urethral obstruction makes intermittent catheterization uncomfortable or infeasible.

Drug Therapy

Several drugs may be given to promote bladder evacuation. For the patient with dysfunctional voiding, an α-adrenergic blocker may be prescribed. These drugs relax the smooth muscle of the bladder neck and prostatic urethra and may decrease urethral resistance. Examples of α-adrenergic blockers are listed in Table 50.20. They are given to patients with BPH and may help with bladder neck or detrusor sphincter dyssynergia (muscle incoordination).

Surgical Therapy

Surgical interventions are used to manage retention from an obstruction. Transurethral or open surgical techniques are used to treat benign or cancerous prostatic enlargement, bladder neck contracture, urethral strictures, or dyssynergia of the bladder neck. Pelvic reconstruction using an abdominal or transvaginal approach can correct bladder outlet obstruction in women with severe pelvic organ prolapse.

While surgery has had a minimal role in the management of urinary retention caused by deficient detrusor contraction strength, there are procedures that may be helpful. Sacral neuromodulation involves a stimulator device and placement of a lead wire into the S3 foramen. Placement of an intraurethral valve pump, which empties the patient's bladder on command, may be an option.

❖ NURSING MANAGEMENT: URINARY RETENTION

Acute urinary retention is a medical emergency that requires prompt recognition and bladder drainage. Insert a catheter as ordered. Use a catheter with a retention balloon in anticipation of the need for an indwelling catheter.

Teach the patient with acute urinary retention and the patient predisposed to these episodes ways to minimize risk. Have them pay attention to when they need to urinate and to void when they feel the need to do so. Take medications as prescribed. Pelvic floor muscle exercises may be helpful. Teach the patient to drink small amounts throughout the day and avoid the intake of large volumes of fluid over a brief period. Tell the patient (if chilled) to warm up before trying to void. They should avoid excess alcohol use because it leads to polyuria and a diminished awareness of the need to void until the bladder is distended. Tell patients that sitting in a tub of warm water or taking a warm shower may help them void. If these measures do not lead to successful urination, have the patient seek immediate care.

Patients with chronic urinary retention may be managed by behavioral methods, indwelling or intermittent catheterization, surgery, or drugs. Scheduled toileting and double voiding are the primary behavioral interventions used for chronic retention. Scheduled toileting can reduce, rather than expand, bladder capacity. In this case, have the patient void every 3 to 4 hours regardless of the desire to void. This is especially useful in the patient with chronic overdistention, diabetes, or chronic alcohol use with a large bladder capacity and diminished or delayed sensations of bladder filling and urgency.

CATHETERIZATION

INDICATIONS FOR AND COMPLICATIONS OF CATHETERIZATION

Urinary catheterization is often used in the management of the hospitalized patient. Indications for short-term urinary catheterization are listed in Table 50.21. Catheterization for sterile urine specimens may be needed if the patient has a history of complicated UTI. The risk for CAUTI is too high to perform catheterization for (1) routine acquisition of a urine specimen for laboratory analysis or (2) the convenience of the health care team or caregivers. A catheter should be the last resort to provide the patient with a dry environment to prevent skin breakdown and protect dressings or skin lesions.

Having a catheter is not without serious complications. Complications that are seen with long-term use (more than 28 days) of indwelling catheters include CAUTI, bladder spasms, periurethral abscess, chronic pyelonephritis, urosepsis, urethral trauma or erosion, fistula or stricture formation, and stones. CAUTIs are the most common HAI.

Aseptic technique is mandatory when inserting a urinary catheter (Table 50.22). After insertion, maintaining the closed drainage system and preventing infection are major nursing responsibilities. Do not routinely irrigate the catheter. Only irrigate if ordered. While the catheter is in place, manage fluid intake and provide for the patient's comfort. Address the psychologic

TABLE 50.21 Indications for Urinary Catheterization

Indwelling Catheter

- Relieve urinary retention caused by lower urinary tract obstruction, paralysis, or inability to void
- Bladder decompression preoperatively and operatively for lower abdominal or pelvic surgery
- Facilitate surgical repair of urethra and surrounding structures
- Splinting of ureters or urethra to promote healing after surgery or other trauma in area
- Accurate measurement of urine output
- Contamination of stage III or IV pressure injuries with urine that has impeded healing, despite appropriate personal care for the incontinence
- Terminal illness or severe impairment, which makes positioning or clothing changes uncomfortable, or which is associated with intractable pain

Intermittent (Straight, In-and-Out) Catheter

- Relieve urinary retention caused by lower urinary tract obstruction, paralysis, or inability to void
- Study of anatomic structures of urinary system
- Urodynamic testing
- Collect sterile urine sample in certain situations
- Instill medications into bladder
- Measure residual urine after voiding (postvoid residual [PVR]) if portable ultrasound not available

TABLE 50.22 NURSING MANAGEMENT

Care of the Patient With a Urethral Catheter

The following measures can be used to manage patients with a urethral catheter and prevent a CAUTI.

- Determine need for catheterization, but HCP must order.
- Choose appropriate type and size of catheter.
- Insert catheter using sterile technique.
- Develop plan of care to decrease risk for CAUTI.
- Teach catheter care to the patient, especially one who is ambulatory.
- Maintain a sterile, closed drainage system.
- Do not disconnect the distal urinary catheter and proximal drainage tube except for catheter irrigation (if ordered).
- Use sterile technique whenever the collecting system is open. If frequent irrigations are needed in short-term catheterization to maintain catheter patency, a triple-lumen catheter may be preferable, permitting continuous irrigations within a closed system.
- A routine catheter change is not needed if the patient is catheterized for less than 2 weeks. For long-term use of an indwelling catheter, replace the catheter based on patient assessment and not on a routine changing schedule.
- If ordered, aspirate small volumes of urine for culture from the catheter sampling port using a sterile syringe and needle. Prepare the puncture site with an antiseptic solution.
- With long-term use of a catheter, a leg bag may be used. If the collection bag is reused, wash it in soap and water and rinse thoroughly. When it is not reused immediately, fill it with 1/2 cup of vinegar and drain. Vinegar is effective against *Pseudomonas* and other organisms and eliminates odors.
- Remove the catheter as early as possible. Intermittent catheterization and external catheters are alternatives that have less risk of CAUTI.
- Ensure that AP:
  - Maintain unobstructed downhill flow of urine.
  - Empty the collecting bag regularly and accurately record the urine output.
  - Provide perineal care (once or twice a day and when needed), cleaning the meatus-catheter junction with soap and water.
  - Do not use lotion or powder near the catheter.
  - Anchor catheter using a securement device. Anchor catheter to upper thigh in women and lower abdomen in men to prevent catheter movement and urethral tension.

implications of urinary drainage. Patient concerns can include embarrassment, an altered body image, and fear that care of the catheter will result in increased dependency.

CATHETER CONSTRUCTION

Catheters vary in construction materials, size of the lumen, and tip shape (Fig. 50.10). Catheter materials include polyvinyl chloride, red rubber, silicone, and latex. Some are DEHP-free. Catheters coated with antimicrobial agents may prevent CAUTIs.

A coudé tip catheter is often used in men. We size catheters using the French scale. Each French unit (Fr) equals 0.33 mm of diameter. The diameter listed is the external diameter of the catheter. The size used varies with the patient's size and the purpose of catheterization. In women, urethral catheter sizes 10Fr to 12Fr are the most common. In men, the most common sizes are 14Fr to 16Fr. Balloon sizes are either 5 or 30 mL. The primary problem resulting from too large a catheter is tissue erosion from excessive pressure on the meatus or urethra.

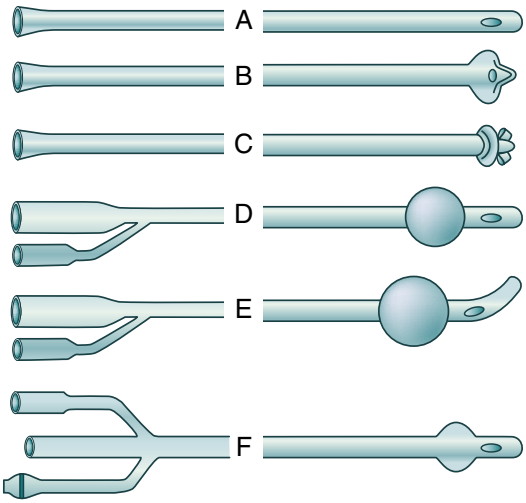


Fig. 50.10 Types of urinary catheters. (A) Simple urethral catheter. (B) Mushroom-tip de Pezzer catheter (can be for suprapubic catheterization). (C) Wing-tip Malecot catheter (wings hold catheter in place for temporary drainage). (D) Indwelling urethral catheter with inflated balloon. (E) Indwelling Tiemann catheter with coudé tip (slightly curved tip allows for passage past obstruction). (F) 3-Way indwelling catheter (third lumen can be used for irrigation).

TYPES OF CATHETERS

Four routes are used for urinary tract catheterization: urethral, ureteral, suprapubic, and via a nephrostomy tube.

Urethral Catheterization

Urethral catheterization is the most common route of catheterization. It involves the insertion of a catheter through the external meatus into the urethra, past the internal sphincter, and into the bladder.

Ureteral Catheters

A *ureteral catheter* is often called a ureteral stent. It is placed through the ureters into the renal pelvis. The catheter is inserted either (1) by being threaded up the urethra and bladder to the ureters under cystoscopic observation or (2) by surgical insertion through the abdominal wall into the ureters. The ureteral catheter is used either during surgery with removal immediately afterward or after surgery to splint the ureters and prevent them from being obstructed by edema.

A self-retaining ureteral catheter is often inserted after a lithotripsy procedure or when ureteral obstruction from adjacent tumors or fibrosis threatens renal function. They can be placed short or long term. When used long term, we replace the catheter every 3 to 6 months. A double-J ureteral catheter is often used. It allows the patient to ambulate. One end coils up in the kidney pelvis, while the other coils in the bladder.

Care of these catheters is similar to that of urethral catheters. Avoid situations that could cause dislodgement or displacement of the catheter. If the output is decreased, notify the HCP immediately.

Suprapubic Catheters

Suprapubic catheterization requires surgical placement. It is the oldest method of urinary diversion. The 2 ways to insert a suprapubic catheter are (1) through an open approach with a small incision made in the abdominal wall or (2) through a percutaneous approach. The catheter is placed while the patient is under general anesthesia for another procedure or at the bedside with a local anesthetic. The catheter may be sutured into place. Tape the catheter to prevent dislodgment. Teaching includes the need to stay well hydrated and how to monitor for infection, catheter obstruction or kinking, and urinary leakage around the catheter.

Suprapubic catheters can be used either short or long term. Common situations where a suprapubic catheter may be placed include acute urinary retention, urethra trauma, need for long-term urinary diversion, and to aid in treating a complicated UTI. The catheter should be changed at least each month.

A suprapubic catheter is prone to poor drainage because of mechanical obstruction of the catheter tip by the bladder wall, sediment, and clots. To ensure patency of the tube (1) prevent tube kinking by coiling the excess tubing and maintaining gravity drainage, (2) have the patient turn from side to side, and (3) milk the tube. If these measures are not effective, obtain an order from the HCP to irrigate the catheter using sterile technique.

If the patient has bladder spasms that are hard to control, urinary leakage may result. Oxybutynin or solifenacin can decrease bladder spasms.

Nephrostomy Tubes

The *nephrostomy tube* (catheter) is typically inserted on a temporary basis but can be placed long term to preserve renal function. Nephrostomy tubes are placed most often for urinary obstruction. The tube is inserted through a small flank incision directly into the pelvis of the kidney and attached to connecting tubing for closed drainage. The principle is the same as with other catheters—that is, the catheter should never be kinked, twisted, or tugged on. If the patient has excessive pain in the area or if there is excess drainage around the tube, check the catheter for patency. Use aseptic technique when performing irrigation. Gently instill no more than 5 mL of sterile saline solution at one time to prevent overdistention of the kidney pelvis and renal damage. Good wound care is critical. Infection, including pyelonephritis, is a common complication.

Intermittent Catheterization

An alternative approach to a long-term indwelling catheter is *intermittent catheterization,* often referred to as "straight" or "in-and-out" catheterization. The main goal of intermittent catheterization is to prevent urinary retention, stasis, and compromised blood supply to the bladder caused by prolonged pressure.[27]

It can be used short or long term and for conditions such as neurogenic bladder dysfunction (e.g., spinal cord injuries, chronic neurologic diseases). Barriers to intermittent catheterization include obesity, patient unwillingness, discomfort due to the catheterization, urinary obstruction, and limited upper extremity strength and/or movement.

The technique consists of inserting a urethral catheter into the bladder every 4 to 6 hours, including first thing upon awakening and before going to bed. Some patients perform intermittent catheterization only once or twice a day to measure residual urine and ensure an empty bladder.

The techniques for intermittent catheterization vary. Catheters can be sterile (single use) or clean (multiple use). Research shows no evidence that any technique (sterile or clean), catheter type (coated or uncoated), method (single-use or multiple-use), person (self or other), or strategy is better than any other.

We often use sterile technique in the hospital or long-term care facility. Depending on agency policy, you will see clean technique used.[27] Clean intermittent catheterization done correctly at home does not seem to increase the risk for UTIs and is more cost-effective. For home care, clean technique includes good hand washing with soap and water. Teach patients to wash and rinse the catheter before and after catheterization.

Using a lubricant makes catheterization more comfortable and minimizes trauma. Catheters come coated (pre-lubricated) or uncoated. Patients may prefer one type of catheter for use at home and another type while at work or during travel. The patient, caregiver, or HCP may insert the catheter.

Teach the patient to observe for signs of UTI so it can be treated early. Some patients receive prophylactic antibiotics. Complications include urethritis, urethral sphincter damage (especially if there is a forceful catheterization against a closed sphincter), urethral stricture, and creation of a false passage. Urethral damage from intermittent catheterization in men is similar to problems seen with indwelling catheterization.

URINARY TRACT SURGERY

RENAL AND URETERAL SURGERY

The most common indications for nephrectomy are a renal tumor, polycystic kidneys that are bleeding or severely infected, massive traumatic injury to the kidney, and the elective removal of a kidney for transplant into a person with ESRD. Surgery involving the ureters and kidneys can be done to remove stones that become obstructive, correct congenital anomalies, and divert urine when necessary. It is important that the patient having a nephrectomy has 1 working kidney to maintain normal renal function.

Surgical Procedure

Nephrectomy can be done by a conventional (open) approach or laparoscopically. In the open approach, an incision of about 8 to 12 inches is made through several layers of muscle. The incision can be made in the flank or abdominal area.

Laparoscopic Nephrectomy

With a laparoscopic nephrectomy, there are 3 to 5 puncture sites. When removing a kidney for donation, 1 incision is enlarged to 6 to 9 cm so the kidney can be removed in 1 piece. The kidney can also be removed through morcellation. Once dissected, the kidney is placed in a special sac then broken into smaller pieces before being removed from the patient. Compared with conventional nephrectomy, the laparoscopic approach is less painful, involves a shorter hospital stay, and has a much faster recovery.

Preoperative Management

The basic needs of the patient having renal and ureteral surgery are similar to those of any patient who has surgery (see Chapters 18 through 20). Before surgery ensure adequate fluid intake and a normal electrolyte balance. Tell the patient that if there is a flank incision, surgery will require a hyperextended, side-lying position. This position often causes the patient to have muscle aches after surgery.

Postoperative Management

Specific postoperative needs of a patient are related to urine output, respiratory status, and abdominal distention.

Urine Output

In the immediate postoperative period, measure and record the urine output at least every 1 or 2 hours. Measure drainage from the various catheters and record it separately. Do not clamp or irrigate the catheter or tube without a specific order. The total urine output should be at least 0.5 mL/kg/hr. It is important to assess for urine drainage on the dressing and to estimate this amount. Observe and monitor the color and consistency of urine. Urine with increased amounts of mucus, blood, or sediment may occlude the drainage tubing or catheter.

Weigh the patient daily using the same scale. Have the patient wear similar clothing and dressings each time. A significant change in daily weight can indicate retention of fluids, which places the patient at risk for heart failure. Fluid retention can increase the work required of the remaining kidney to perform its functions.

Respiratory Status

A nephrectomy can be done through a flank incision just below the diaphragm. It is important to ensure adequate ventilation. The patient is often reluctant to turn, cough, and breathe deeply because of the incisional pain. Give adequate pain medication to ensure the patient's comfort and ability to perform coughing and deep-breathing exercises. Have the patient use an incentive spirometer every 2 hours while awake. Early and frequent ambulation helps maintain respiratory function.

Abdominal Distention

Abdominal distention is present to some degree in most patients who have had surgery on their kidneys or ureters. It is often due to paralytic ileus caused by manipulation and compression of the bowel during surgery. We restrict oral intake until bowel sounds are present (usually 24 to 48 hours after surgery). Give IV fluids as ordered until oral intake resumes. Progression to a regular diet follows.

URINARY DIVERSION

Urinary diversion procedures are done when urine needs to be redirected from the bladder. Common reasons include bladder cancer, neurogenic bladder, congenital anomalies, strictures, trauma to the bladder, and chronic bladder inflammation. Numerous urinary diversion techniques and bladder substitutes are possible. These include an incontinent urinary diversion, a continent urinary diversion catheterized by the patient, or an orthotopic neobladder bladder so that the patient voids urethrally.[28] Surgical procedures for urinary diversion are described in Table 50.23 and Fig. 50.11. Urinary diversion may be done with or without cystectomy.

Incontinent Urinary Diversion

Incontinent urinary diversion is diversion to the skin, requiring a pouch. The simplest form is the cutaneous ureterostomy. However, complications (e.g., scarring, ureteral strictures) have led to the more frequent use of ileal or colonic conduits. The most common incontinent urinary diversion procedure is the **ileal conduit** (ileal loop). In this procedure a 4- to 6-in (10- to 15-cm) segment of the ileum is converted into a conduit for urinary drainage. The colon (colon conduit) can also be used. The ureters are anastomosed into one end of the conduit, and the other end of the bowel is brought out through the abdominal wall to form a stoma (Fig. 50.12). Although the mesentery still supports the bowel segment, it is completely isolated from the GI tract. The bowel is anastomosed and continues to function normally.

TABLE 50.23 Urinary Diversion Surgery

Description	Advantages	Disadvantages	Special Considerations
Cutaneous Ureterostomy			
Ureters excised from bladder and brought through abdominal wall, and stoma is created. Ureteral stomas may be created from both ureters, or ureters may be brought together, and 1 stoma created.	No need for major surgery.	External pouch needed because of continuous urine drainage. Possible stricture or stenosis of small stoma.	Periodic catheterizations may be needed to dilate stomas to maintain patency.
Ileal Conduit			
Ureters implanted into part of ileum or colon that has been resected from GI tract. Abdominal stoma is created.	Relatively good urine flow with few physiologic alterations.	External pouch needed to continually collect urine.	Surgery is complex. Increased risk for complications. Metabolic complications include electrolyte imbalances. Meticulous attention is necessary to care for stoma and collecting device.
Nephrostomy			
Catheter inserted into pelvis of kidney. Procedure may be done to 1 or both kidneys. May be temporary or permanent. Most often done in advanced disease as palliative procedure.	No need for major surgery.	High risk for renal infection.	May have to change nephrostomy tube every 10–12 weeks. Never clamp the catheter.

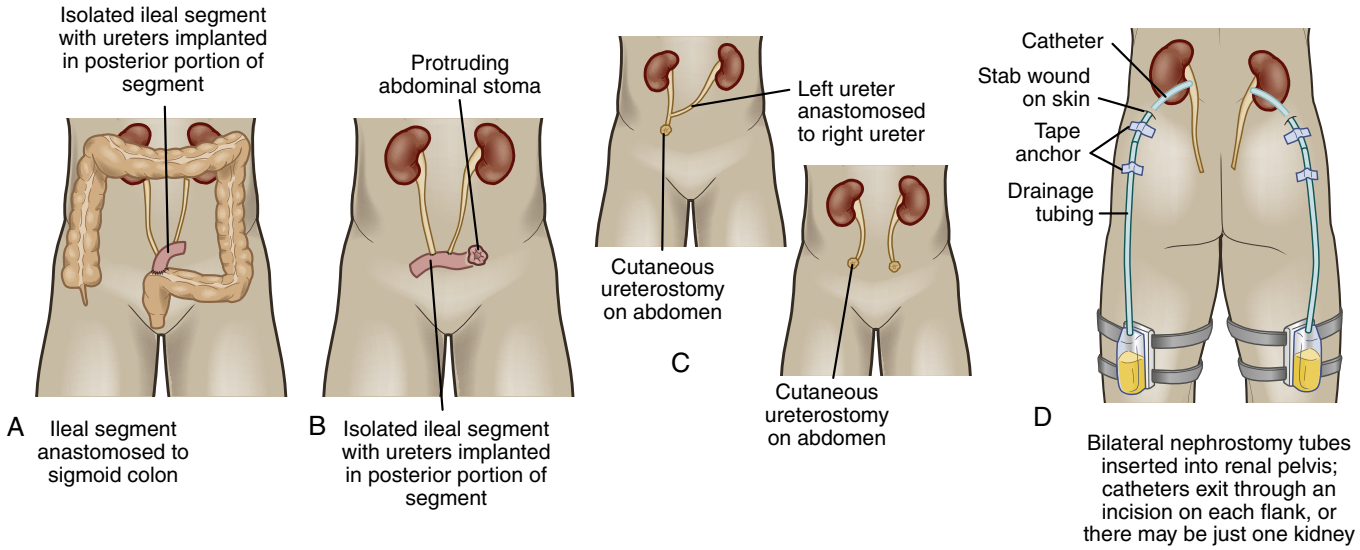

Fig. 50.11 Methods of urinary diversion. (A) Ureteroileosigmoidostomy. (B) Ileal loop (ileal conduit). (C) Ureterostomy (transcutaneous ureterostomy and bilateral cutaneous ureterostomies). (D) Nephrostomy.

Fig. 50.12 Urinary stoma. Symmetric, no skin breakdown, protrudes about 1.5 cm. Mucosa is healthy red. This configuration is flat when the patient is upright or supine. (Courtesy Lynda Brubacher, Virginia Mason Hospital, Seattle, WA.)

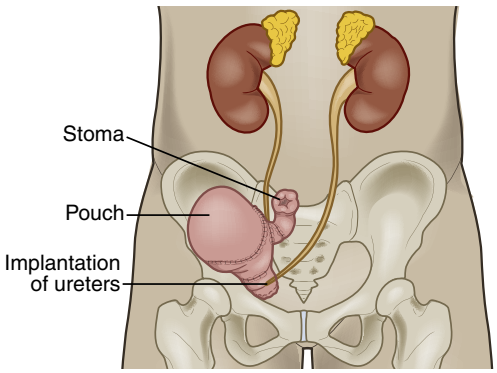

Fig. 50.13 Creation of a Kock pouch with implantation of ureters into one intussuscepted part of the pouch and creation of a stoma with the other intussuscepted part.

Because there is no valve and no voluntary control over the stoma, drops of urine flow from the stoma every few seconds, requiring a permanent external collecting device. The visible stoma and need for external collection devices are disadvantages. The lifelong need to care for and deal with the stoma and collection devices may be difficult. These problems have led to the increasing use of continent diversions and neobladder bladder substitutes.

Continent Urinary Diversions

A *continent urinary diversion* is an intraabdominal urinary reservoir that can be catheterized. Continent diversions are internal pouches created similarly to the ileal conduit. Reservoirs are constructed from the ileum, ileocecal segment, or ascending colon. Large segments of bowel are altered to prevent peristaltic action. A surgically created valve and the large, low-pressure reservoir helps prevent involuntarily leakage. The patient with a continent reservoir needs to self-catheterize every 4 to 6 hours but does not need to wear external attachments. Patients may wear a small bandage on the stoma to collect any mucous drainage or excess drainage. Examples of continent diversions are the Kock (Fig. 50.13), Indiana (most often used), and Miami pouches. The main difference among the diversions is the bowel segment used. For example, the Indiana pouch uses part of the ilium, cecum, and ascending colon as the reservoir.

Orthotopic Bladder Reconstruction

Orthotopic bladder reconstruction, or orthotopic neobladder, is the construction of a new bladder in the bladder's normal anatomic position, with discharge of urine through the urethra. The neobladder is surgically shaped from intestinal segments to make a low-pressure reservoir. An isolated segment of the terminal ileum is often used. The ureters and urethra are sutured into the neobladder. There are multiple procedure types based on the type of intestine and the construction technique used.

Orthotopic bladder reconstruction has become a more viable option if cancer does not involve the bladder neck or prostate apex. Ideal patients have normal renal and liver function, longer than 1- to 2-year life expectancy, adequate motor skills, and no history of inflammatory bowel disease or colon cancer. The advantage of an orthotopic bladder is that it allows for natural micturition. Incontinence is a possible problem. Intermittent catheterization may be needed.

❖ NURSING MANAGEMENT: URINARY DIVERSION

Preoperative Care

Teaching is important for the patient awaiting cystectomy and urinary diversion surgery. Assess the patient's ability and readiness to learn before starting a teaching program. The patient's anxiety and fear may be decreased by providing information. However, anxiety and fear may also interfere with learning. Involve caregivers in the teaching process.

Discuss the psychosocial aspects of living with a stoma. Include clothing options, changes in body image and sexuality, exercise, and odor control. This may allay some fears. The patient with an orthotopic neobladder may have problems with incontinence, especially nocturnal. Discuss patients' concerns about sexual activities and let them know that counseling is available. Involve a wound, ostomy, and continence nurse (WOCN). A visit from an ostomate can be helpful. Additional interventions are discussed in eNursing Care Plan 50.3 for the patient with an ileal conduit (on the website for this chapter).

Postoperative Care

Plan interventions during the postoperative period to prevent surgical complications, such as atelectasis (see Chapter 20). After pelvic surgery, there is an increased incidence of thrombophlebitis and UTI. Removing part of the bowel increases the risk of paralytic ileus and small bowel obstruction. The patient is NPO. They may need a nasogastric tube for a few days.

Prevent injury to the stoma and maintain urine output. Tell the patient that mucus in the urine is normal. The mucus is secreted by the mucosa of the intestine (used to create the ileal conduit) in response to the irritating effect of urine. Encourage a high fluid intake to "flush" the ileal conduit or continent diversion and prevent obstruction.

Provide meticulous care for the skin around the stoma. Alkaline encrustations with dermatitis may occur when alkaline urine comes in contact with exposed skin (Fig. 50.14). The urine is often kept slightly acidic to prevent alkaline encrustations. Other common peristomal skin problems include yeast infections, product allergies, and shearing-effect excoriations.

The patient is fitted for a pouching system to collect urine passed out of the stoma. It may need refitted later, depending on the degree of stoma healing and shrinkage. There are 2 types of pouching systems. There is a 1-piece pouch that has an attached skin barrier. The other type is a 2-piece system composed of a skin barrier with a detachable pouch. A properly fitting pouch helps prevent skin problems (Fig. 50.15). The pouch should be more than 1/8th inch (3 mm) larger than the stoma. It is normal for the stoma to shrink within the first few weeks after surgery. Table 50.24 describes how to change the pouch.

TABLE 50.24 PATIENT & CAREGIVER TEACHING

Ileal Conduit Appliances

Include the following instructions when teaching a patient or a caregiver how to change an ileal conduit appliance:

Temporary

1. Cut hole in pouch to fit over stoma (pouch 0.1 in [0.2 cm] larger than stoma).
2. Remove old pouch.
3. Clean area gently and remove old adhesive.
4. Wash area with warm water.
5. Place wick (rolled-up 4 × 4–in pad) over stoma to keep area dry during rest of procedure.
6. Dry skin around stoma.
7. Unless recommended by WOCN or HCP, avoid using creams or powders on the skin around the stoma.
8. Apply pouch by first smoothing its edges toward side and lower part of body.
9. Remove wick and complete application of pouch.
10. If patient is usually in bed, apply pouch so that it lies toward side of body.
11. If patient is ambulatory, apply pouch so that it lies vertically.
12. Connect drainage tubing to pouch.
13. Keep drainage pouch on same side of bed as stoma.

Permanent

1. Keep pouch in place for 3–4 days. May need changed more or less often as needed.
2. Change pouch when fluid intake has been restricted for several hours.
3. Sit or stand in front of mirror.
4. Can moisten edge of faceplate with warm water or adhesive solvent and gently remove.
5. Use warm water and a washcloth to clear the skin around the stoma. Use soap to remove any adhesive solvent.
6. Dry skin and inspect.
7. Place wick (rolled-up 4 × 4–inch pad) over stoma to keep skin free of urine.
8. Place pouch over stoma.

Teach the patient with a continent diversion (e.g., Indiana pouch) to catheterize at first every few hours. Over time this can be extended to every 4 to 6 hours. Irrigation of the pouch with normal saline or sterile water is often needed.

Patients with a neobladder may have postoperative urinary retention and need catheterization. It may take up to 6 months for them to regain bladder control. Patients empty their neobladders by relaxing their outlet sphincter muscles and bearing down with their abdominal muscles. Since there is no longer neurologic feedback between the reservoir and the brain, the patient should not expect a normal desire to void. To avoid bladder overdistention, patients should void at least every 2 to 3 hours, sit during voiding, and practice pelvic floor muscle relaxation to aid voiding.

Discharge teaching includes teaching the patient about symptoms of obstruction and infection and care of the ostomy. Acceptance of the surgery and changes in body image ensures the patient's best adjustment to a urinary diversion. Concerns include fear that the stoma will be offensive to others and will interfere with sexual, personal, professional, and recreational activities. Teach the patient that few activities will be restricted because of the urinary diversion. Meeting and sharing feelings with similar patients can help.

Tell the patient and caregiver about where to buy supplies, emergency telephone numbers, location of ostomy clubs, and follow-up visits with a WOCN. Follow-up with an HCP is important to monitor the patient's recovery, detect complications, and assess renal function.

Case Study

Painful Bladder and Frequent Urination

(© marilook/iStock/Thinkstock.)

Patient Profile

L.T., a 38-year-old woman, comes to the HCP's office today for the 8th time in the past year for a history of pelvic pain with urinary frequency during the day, nocturia, and urgency to void. All previous urine cultures have been negative for bacteria. A recent evaluation by her gynecologist was negative for endometriosis.

Subjective Data

- Has a history of suprapubic and vaginal pain, urinary frequency, and urgency
- Reports bladder pain that increases with bladder filling
- States this is her 3rd attack of suprapubic pain and painful urination in 2 months
- Constant pain and discomfort that is physically and emotionally exhausting
- Worried that she has cancer, and no one cares
- Had 4 pregnancies with uneventful vaginal deliveries
- Normal menstrual cycles
- Her husband and she rarely have sexual intercourse because she has pain with intercourse
- Has a bowel movement every day. Denies constipation and/or diarrhea
- Recalls having many UTIs as a child

Objective Data

Physical Assessment

- Lungs clear. BP 132/86. Heart rate 86/min. Respiratory rate 18/min. Abdomen soft, tender in suprapubic region.

Diagnostic Studies

- Urinalysis today: normal
- Previous urine cytology ordered to rule out cancer: normal
- Recent referral to urologist for cystoscopy, which was done 2 weeks ago

Interprofessional Care

- Cystoscopy results show glomerulations and Hunner lesions
- Urologist diagnosed interstitial cystitis
- Urologist prescribed pentosan (Elmiron), which she has not started yet
- Follow-up in 4 weeks with the urologist

Discussion Questions

1. ***Recognize***: After taking L.T.'s history, would you consider a UTI as a cause of her symptoms? Why or why not?
2. ***Analyze***: What additional testing and assessment would be helpful?
3. ***Analyze***: What is the significance of the cystoscopy findings?
4. ***Analyze***: What is the reason for the use of pentosan?
5. ***Prioritize:*** What are the priority clinical problems?
6. ***Act:*** How can you help L.T. deal with her diagnosis and treatment plan?
7. ***Act***: Why is it important to involve the dietitian in L.T.'s care?
8. ***Act:*** L.T. asks you how she can control her interstitial cystitis. How would you respond?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The nurse teaches the female patient who has frequent UTIs to
   - **a.** take tub baths with bubble bath.
   - **b.** void before and after sexual intercourse.
   - **c.** take prophylactic sulfonamides for the rest of her life.
   - **d.** restrict fluid intake to prevent the need for frequent voiding.
2. One of the *most* important nursing roles in relation to acute poststreptococcal glomerulonephritis (APSGN) is to
   - **a.** promote early diagnosis and treatment of sore throats and skin lesions.
   - **b.** encourage patients to obtain antibiotic therapy for upper respiratory tract infections.
   - **c.** teach patients that long-term prophylactic antibiotic therapy is needed to prevent recurrence.

d. monitor for respiratory symptoms that indicate the disease is affecting the alveolar basement membrane.

3. The edema that occurs in nephrotic syndrome is due to
   a. increased hydrostatic pressure caused by sodium retention.
   b. decreased aldosterone secretion from adrenal insufficiency.
   c. increased fluid retention caused by decreased glomerular filtration.
   d. decreased colloidal osmotic pressure caused by loss of serum albumin.
4. The nurse's *first priority* in managing the care of the patient with severe renal colic is to
   a. administer opioids as prescribed.
   b. obtain supplies for straining all urine.
   c. encourage fluid intake of 3 to 4 L/day.
   d. keep the patient NPO in preparation for surgery.
5. The nurse recommends genetic counseling for the children of a patient with
   a. nephrotic syndrome.
   b. chronic pyelonephritis.
   c. malignant nephrosclerosis.
   d. adult-onset polycystic kidney disease.
6. Which factor from the patient's history does the nurse identify as a risk factor for kidney and bladder cancer?
   a. Aspirin use
   b. Tobacco use
   c. Chronic alcohol use
   d. Use of artificial sweeteners
7. In planning nursing interventions to increase bladder control in the patient with urinary incontinence, the nurse includes *(select all that apply)*
   a. teaching the patient to use Kegel exercises.
   b. clamping and releasing a catheter to increase bladder tone.
   c. teaching the patient biofeedback mechanisms to train pelvic floor muscles.
   d. counseling the patient concerning choice of incontinence containment device.
   e. developing a fluid modification plan, focusing on decreasing intake before bedtime.
8. A patient with a ureterolithotomy returns from surgery with a nephrostomy tube in place. Postoperative nursing care includes
   a. clamping the tube for 10 minutes every hour to decrease spasms.
   b. encouraging fluids of at least 2 to 3 L/day after nausea has subsided.
   c. notifying the provider if nephrostomy tube drainage is more than 30 mL/hr.
   d. irrigating the nephrostomy tube with 10 mL of normal saline solution as needed.
9. A patient has had a cystectomy and ileal conduit diversion. Four days after surgery, the nurse notes mucous shreds in the pouch. The nurse would
   a. notify the provider.
   b. notify the charge nurse.
   c. irrigate the drainage tube.
   d. document it as a normal observation.

1. b; 2. a; 3. d; 4. a; 5. d; 6. b; 7. a, c; 8. b; 9. d.

Acute Kidney Injury and Chronic Kidney Disease

Hazel A. Dennison

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Acid-Base Balance
Adherence
Coping
Elimination
Fluids and Electrolytes
Nutrition

LEARNING OUTCOMES

1. Outline criteria used to classify acute kidney injury using the acronym RIFLE (*R*isk, *I*njury, *F*ailure, *L*oss, *E*nd-stage renal disease).
2. Relate the clinical course of acute kidney injury.
3. Explain the interprofessional and nursing management of a patient with acute kidney injury.
4. Define chronic kidney disease and delineate its 5 stages based on the glomerular filtration rate.
5. Identify risk factors for chronic kidney disease.
6. Explain the conservative interprofessional care and related nursing management of the patient with chronic kidney disease.
7. Distinguish among renal replacement therapy options for persons with end-stage renal disease.
8. Compare and contrast nursing interventions for patients on peritoneal dialysis and hemodialysis.
9. Discuss the role of nurses in managing patients who receive a kidney transplant.

KEY TERMS

acute kidney injury (AKI)
acute tubular necrosis (ATN)
anuria
arteriovenous fistula (AVF)
arteriovenous grafts (AVGs)
automated peritoneal dialysis (APD)
azotemia
chronic kidney disease (CKD)
CKD mineral and bone disorder (CKD-MBD)
continuous ambulatory peritoneal dialysis (CAPD)
continuous renal replacement therapy (CRRT)
dialysis
end-stage renal disease (ESRD)
hemodialysis (HD)
peritoneal dialysis (PD)
uremia

Kidney failure, also called *renal failure,* is the partial or complete impairment of kidney function. It results in the inability to excrete metabolic waste products and water. Kidney failure contributes to problems with all body systems. Patients have problems with fluid, electrolyte, and acid-base imbalance. Adhering to diet therapy and the treatment plan can be challenging. The patient must deal with changes in lifestyle, occupation, family relationships, and self-image that can lead to withdrawal and depression. The patient grieves the loss of kidney function and independence.

We classify kidney failure as acute or chronic (Table 51.1). Acute kidney injury (AKI) has a rapid onset. Chronic kidney disease (CKD) is gradual with a progressive decline in kidney function.

ACUTE KIDNEY INJURY

Acute kidney injury (AKI) is the term used to encompass the entire scope of the syndrome, ranging from a slight deterioration in kidney function to severe impairment. AKI is characterized by a rapid loss of kidney function with or without decreased urine output. This loss is accompanied by progressive increases in blood urea nitrogen (BUN), creatinine, and potassium. The severity of dysfunction can range from a small increase in serum creatinine or reduction in urine output to the development of **azotemia,** an accumulation of nitrogenous waste products (urea nitrogen, creatinine) in the blood.

AKI can develop over hours or days. Although AKI is potentially reversible, it has a high mortality rate.[1] AKI usually affects

people with other life-threatening problems (Table 51.2).[2] It often follows severe, prolonged hypotension, hypovolemia, or exposure to a nephrotoxic agent. Hospitalized patients develop AKI at a high rate (1 in 5) and have a high mortality rate. When AKI develops in an intensive care unit (ICU) patient, the mortality rate can be as high as 80%.[2]

Etiology and Pathophysiology

The causes of AKI are multiple and complex. We categorize them as prerenal, intrarenal (or intrinsic), and postrenal causes (Table 51.2 and Fig. 51.1).

Prerenal

Prerenal causes are factors that reduce systemic circulation, causing decreased renal blood flow. The decrease in blood flow leads to decreased glomerular perfusion and filtration of the kidneys.

It is important to distinguish prerenal oliguria from the oliguria of intrarenal AKI. In prerenal oliguria there is no damage to the kidney tissue (parenchyma). The oliguria is caused by a decrease in circulating blood volume (e.g., severe dehydration, heart failure [HF], decreased cardiac output). Prerenal oliguria

TABLE 51.1 Comparison of AKI and CKD

	AKI	CKD
Onset	Sudden	Gradual, often over many years
Most common cause	Acute tubular necrosis	Diabetic nephropathy
Diagnostic criteria	Acute reduction in urine output *AND/OR* ↑ Serum creatinine	GFR <60 mL/min/1.73 m^2 for >3 months *AND/OR* Kidney damage >3 months
Reversibility	Potentially	Progressive and irreversible
Main cause of death	Infection	CVD

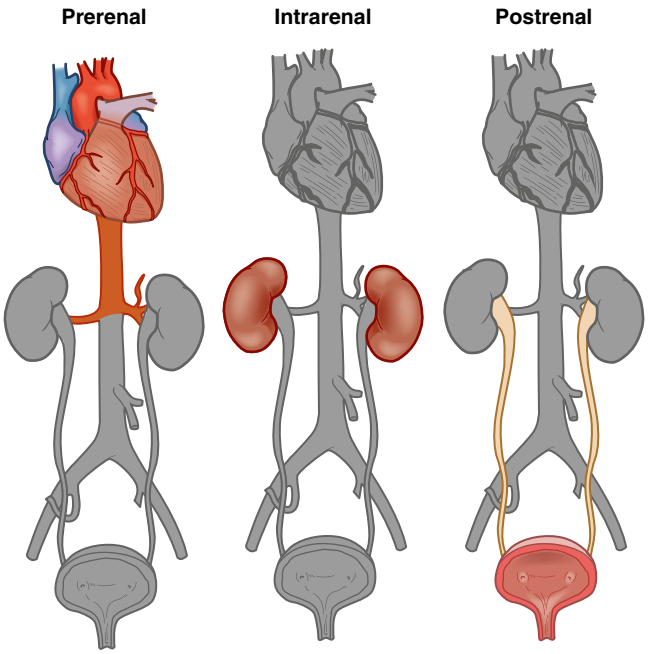

Fig. 51.1 Prerenal, intrarenal, and postrenal causes of AKI.

TABLE 51.2 Common Causes of AKI

Prerenal

Decreased Cardiac Output
- Cardiogenic shock
- Dysrhythmias
- HF
- MI

Decreased Peripheral Vascular Resistance
- Anaphylaxis
- Neurologic injury
- Septic shock

Decreased Renovascular Blood Flow
- Bilateral renal vein thrombosis
- Embolism
- Hepatorenal syndrome
- Renal artery thrombosis

Hypovolemia
- Burns
- Dehydration
- Excessive diuresis
- GI losses (diarrhea, vomiting)
- Hemorrhage
- Hypoalbuminemia

Intrarenal

Interstitial Nephritis
- Allergies: antibiotics (sulfonamides, rifampin), NSAIDs, ACE inhibitors
- Infections: bacterial (acute pyelonephritis), viral (Epstein-Barr), fungal (candidiasis)

Nephrotoxic Injury
- Chemical exposure: ethylene glycol, lead, arsenic, carbon tetrachloride
- Contrast media
- Drugs: aminoglycosides (gentamicin, amikacin), amphotericin B
- Hemolytic blood transfusion reaction
- Severe crush injury

Other
- Acute glomerulonephritis
- Malignant hypertension
- Prolonged prerenal ischemia
- Systemic lupus erythematosus
- Thrombotic disorders
- Toxemia of pregnancy

Postrenal
- BPH
- Bladder cancer
- Calculi formation
- Neuromuscular disorders
- Prostate cancer
- Spinal cord disease
- Strictures
- Trauma (back, pelvis, perineum)

is readily reversible with proper treatment.[3] With a decrease in circulating blood volume, autoregulatory mechanisms that increase angiotensin II, aldosterone, norepinephrine, and antidiuretic hormone try to preserve blood flow to essential organs. Prerenal azotemia results in decreased sodium excretion (less than 20 mEq/L), increased sodium and water retention, and decreased urine output. Prerenal problems can contribute to intrarenal AKI. If decreased perfusion persists for an extended time, the kidneys lose their ability to compensate and damage to kidney tissue occurs (intrarenal damage).

Intrarenal

Intrarenal causes of AKI (Table 51.2) include problems that cause direct damage to the kidney tissue, resulting in impaired nephron function. The damage from intrarenal causes usually results from prolonged ischemia, nephrotoxins (e.g., aminoglycosides, contrast media), hemoglobin released from hemolyzed red blood cells (RBCs), or myoglobin released from necrotic muscle cells.

Nephrotoxins can cause obstruction of intrarenal structures by crystallizing or causing damage to the epithelial cells of the tubules. Hemoglobin and myoglobin can block the tubules and cause renal vasoconstriction. Kidney diseases, such as acute glomerulonephritis and systemic lupus erythematosus (SLE), may cause AKI.

Acute tubular necrosis (ATN) is the most common intrarenal cause of AKI in hospitalized patients. It can result from ischemia, nephrotoxins, or sepsis. Ischemic and nephrotoxic ATN causes 90% of intrarenal AKI cases.[3] Severe kidney ischemia causes a disruption in the basement membrane and patchy destruction of the tubular epithelium. Nephrotoxic agents cause necrosis of tubular epithelial cells, which slough off and plug the tubules. Other risk factors for ATN while in the hospital include major surgery, shock, blood transfusion reaction, muscle injury from trauma, and prolonged hypotension. ATN is potentially reversible if the basement membrane is not destroyed and the tubular epithelium regenerates.

Postrenal

Postrenal causes of AKI involve mechanical obstruction in the outflow of urine. With the flow of urine obstructed, urine refluxes into the renal pelvis, impairing kidney function. The most common postrenal causes are benign prostatic hyperplasia (BPH), prostate cancer, stones, trauma, and extrarenal tumors. Bilateral ureteral obstruction leads to *hydronephrosis* (kidney dilation), increase in hydrostatic pressure, and tubular blockage, resulting in a progressive decline in kidney function. If bilateral obstruction is relieved within 48 hours of onset, complete recovery is likely. Prolonged obstruction can lead to tubular atrophy and irreversible kidney fibrosis. Postrenal causes of AKI account for less than 10% of AKI cases.[3]

Clinical Manifestations

Prerenal and postrenal AKI that has not caused intrarenal damage usually resolves quickly with treatment. When tissue damage occurs from either prerenal or postrenal causes, or when damage occurs directly as with intrarenal causes, AKI has a prolonged course. Clinically, AKI may progress through phases: oliguric, diuretic, and recovery. When a patient does not recover from AKI, CKD may develop.

The RIFLE classification describes the stages of AKI (Table 51.3). *R*isk, the first stage of AKI, is followed by *I*njury, which is the second stage. Then AKI increases in severity to the last, or third, stage, *F*ailure. The 2 outcome variables are *L*oss and *E*nd-stage renal disease.[3]

TABLE 51.3 Diagnostic Criteria

RIFLE Classification for Acute Kidney Injury

Stage	GFR Criteria	Urine Output Criteria	Clinical Example
Risk	Serum creatinine increased × 1.5 *OR* GFR decreased by 25%	Urine output <0.5 mL/kg/hr for 6 hr	• 68-year-old patient with type 2 diabetes, hypertension, CAD, CKD • Scheduled for emergency coronary artery bypass graft • Serum creatinine is 1.8 mg/dL (increased), weight 60 kg • Calculated GFR is 35 mL/min/1.73 m^2 • Has stage 3b CKD
Injury	Serum creatinine increased × 2 *OR* GFR decreased by 50%	Urine output <0.5 mL/kg/hr for 12 hr	• During surgery, hypotensive for a sustained period • Diagnosed with acute tubular necrosis • After surgery: serum creatinine is 3.6 mg/dL, urine output reduced to 28 mL/hr
Failure	Serum creatinine increased × 3 *OR* GFR decreased by 75% *OR* Serum creatinine >4 mg/dL with acute rise ≥0.5 mg/dL	Urine output <0.3 mL/kg/hr for 24 hr (oliguria) *OR* Anuria for 12 hr	• 72 hr after surgery, develops ventilator-associated pneumonia and sepsis while in ICU • Serum creatinine rises to 5.2 mg/dL, urine output drops to 10 mL/hr • BP remains low despite dopamine therapy
Loss	Persistent acute kidney failure. Complete loss of kidney function >4 weeks	—	• Starts on continuous venovenous hemodialysis • After 3 weeks of therapy has a cardiopulmonary arrest and does not survive
End-stage renal disease	Complete loss of kidney function >3 months	—	—

Oliguric Phase

Next, we will discuss the most common manifestations of AKI.

Urinary changes. The most common initial manifestation of AKI is *oliguria*, a reduction in urine output to less than 400 mL/day. It usually occurs within 1 to 7 days of the injury to the kidneys. If the cause is ischemia, oliguria often occurs within 24 hours. When nephrotoxic drugs are involved, the onset may be delayed for as long as 1 week. This phase lasts on average 10 to 14 days. It can last months in some cases. The longer the oliguric phase lasts, the poorer the prognosis for complete recovery of kidney function.[1]

Nonoliguric AKI has a urine output greater than 400 mL/day. About 50% of patients will be nonoliguric. This makes their initial diagnosis more difficult.[2]

While changes in urine output often do not correspond to changes in glomerular filtration rate (GFR), they can help us determine the cause of AKI. For example, **anuria** (no urine output) is usually seen with urinary tract obstruction. Oliguria often occurs with prerenal causes. Nonoliguric AKI occurs with acute interstitial nephritis and ATN.[2]

A urinalysis may show casts, RBCs, and white blood cells (WBCs). Casts form from mucoprotein impressions of the necrotic renal tubular epithelial cells, which slough into the tubules. The specific gravity may be fixed at around 1.010, with urine osmolality at about 300 mOsm/kg (300 mmol/kg). This is the same specific gravity and osmolality of plasma, thus reflecting tubular damage and the loss of concentrating ability by the kidney. Proteinuria may be present if AKI is related to glomerular membrane dysfunction.

Fluid volume. Hypovolemia (volume depletion) has the potential to worsen all forms of AKI. Fluid replacement is often enough to treat many forms of AKI, especially prerenal causes. When urine output decreases, fluid retention occurs. The severity of the manifestations depends on the extent of the fluid overload. In the case of reduced urine output (anuria, oliguria), the neck veins may become distended with a bounding pulse. Edema and hypertension may develop. Fluid overload can eventually lead to HF, pulmonary edema, and pericardial and pleural effusions.

Metabolic acidosis. In the normal kidney, excess hydrogen ions are excreted to keep a physiologic balance of the blood pH. Impaired kidneys cannot excrete hydrogen ions or the acid products of metabolism. Serum bicarbonate (HCO_3^-) production decreases from defective reabsorption and regeneration of HCO_3^- ions. Serum HCO_3^- is depleted through buffering of acidic hydrogen ions and metabolic end products. The patient with severe acidosis may develop rapid, deep respirations to try to compensate by increasing CO_2 exhalation.

Sodium balance. Damaged tubules cannot conserve sodium. Urinary sodium excretion may increase, resulting in normal or below-normal levels of serum sodium. Excess sodium intake is avoided because it can lead to volume expansion, hypertension, and HF. Uncontrolled hyponatremia or water excess can lead to cerebral edema.

Potassium excess. The kidneys normally excrete 80% to 90% of the body's potassium. In AKI the serum potassium level increases because the kidney's normal ability to excrete potassium is impaired. The risk for hyperkalemia increases if AKI is caused by massive tissue trauma because the damaged cells release potassium into the extracellular fluid (ECF). Bleeding and blood transfusions may cause cellular destruction, releasing more potassium into the ECF. Metabolic acidosis worsens hyperkalemia as hydrogen ions enter the cells, and potassium is driven out of the cells into the ECF.

While patients with hyperkalemia are often asymptomatic, some may have weakness with severe hyperkalemia. Acute or rapid development of hyperkalemia may result in electrocardiogram (ECG) changes (see Fig. 17.14). These changes include peaked T waves, widening of the QRS complex, and ST segment depression.[4] Because cardiac muscle is intolerant of acute increases in potassium, emergency treatment of hyperkalemia is needed.

Hematologic problems. Several hematologic problems occur in patients with AKI. Hospital-acquired AKI often occurs in patients who have multiorgan failure. Leukocytosis is often present. The most common cause of death in AKI is infection. The most common sites of infection are the urinary and respiratory systems.

Waste product accumulation. The kidneys are the main excretory organs for urea (an end product of protein metabolism) and creatinine (an end product of endogenous muscle metabolism). BUN and serum creatinine levels are increased in kidney disease. An increased BUN level also can be caused by dehydration, corticosteroids, or catabolism resulting from infections, fever, severe injury, or GI bleeding. The best serum indicator of AKI is creatinine because it is not affected by other factors.

Neurologic problems. Neurologic changes can occur as the nitrogenous waste products accumulate in the brain and other nervous tissue. The manifestations can be as mild as fatigue and difficulty concentrating and escalate to seizures, stupor, and coma.

Diuretic Phase

During the diuretic phase of AKI, daily urine output is usually around 1 to 3 L. It may reach 5 L or more. The nephrons are still not fully functional even as urine output increases. The high urine volume is caused by osmotic diuresis from the high urea concentration in the glomerular filtrate and the inability of the tubules to concentrate the urine. In this phase, the kidneys have recovered their ability to excrete wastes but not to concentrate the urine. Hypovolemia and hypotension can occur from massive fluid losses.

Patients who had an oliguric phase will have greater diuresis as kidney function returns. Large losses of fluid and electrolytes require us to monitor for hyponatremia, hypokalemia, and dehydration. The diuretic phase may last 1 to 3 weeks. Near the end of this phase, the patient's acid-base, electrolyte, and waste product (BUN, creatinine) values stabilize.

Recovery Phase

The recovery phase begins when the GFR increases, allowing the BUN and serum creatinine levels to decrease. Major improvements occur in the first 1 to 2 weeks of this phase. It may take

12 months for kidney function to stabilize. The patient's overall health, severity of kidney injury, and number and type of complications influence their outcome. Some patients do not recover and progress to end-stage renal disease (ESRD). The older adult is less likely to have a complete recovery of kidney function. Patients who recover may achieve clinically normal kidney function but remain in an early stage of CKD.

Diagnostic Studies

The history is essential for diagnosing the cause of AKI. Consider prerenal causes when there is a history of dehydration, hypotension, or blood loss. Suspect intrarenal causes if the patient was exposed to nephrotoxic drugs or contrast media. A history of changes in the urinary stream, stones, BPH, or bladder or prostate cancer suggests postrenal causes.

Although changes in urine output and serum creatinine occur late in the course of AKI, they are known diagnostic indicators. An increase in serum creatinine may not be present until there is a loss of more than 50% of kidney function. The rate of increase in serum creatinine is important as a diagnostic indicator in determining the severity of injury.

Urinalysis is an important diagnostic test. Urine sediment containing abundant cells, casts, or proteins suggests intrarenal disorders. The urine osmolality, sodium content, and specific gravity help in distinguishing the causes of AKI. Urine sediment may be normal in both prerenal and postrenal AKI. In intrarenal problems, hematuria, pyuria, and crystals may be seen. Other testing may be done (Table 51.4). A kidney ultrasound is often the first test done. It provides imaging without exposure to nephrotoxic contrast agents. It can evaluate kidney disease and urinary tract obstruction. A renal scan can assess abnormalities in kidney blood flow, tubular function, and the collecting system. A CT scan can show lesions, masses, obstructions, and vascular anomalies. A renal biopsy is the best way to confirm intrarenal causes of AKI.

Having an MRI or magnetic resonance angiography (MRA) study with the contrast media gadolinium is not advised in patients with kidney failure. Giving gadolinium can be potentially fatal.

TABLE 51.4 Interprofessional Care

Acute Kidney Injury

Diagnostic Assessment

- History and physical assessment
- Identify cause
- Serum creatinine and BUN levels
- Serum electrolytes
- Urinalysis
- Renal ultrasound
- Renal scan
- CT scan

Management

- Treat cause
- Fluid restriction (600 mL plus previous 24-hr fluid loss)
- Nutrition therapy
  - Adequate protein intake (0.8–1.0 g/kg/day) depending on degree of catabolism
  - Enteral nutrition
  - PN
  - Diet restrictions (potassium, phosphate, sodium)
- Measures to lower potassium (if high) (Table 51.5)
- Calcium supplements or phosphate-binding agents
- Dialysis (if necessary)
- Continuous RRT (if necessary)

Interprofessional Care

Because AKI is potentially reversible, the main goals of treatment are to eliminate the cause, manage the signs and symptoms, and prevent complications while the kidneys recover (Table 51.4). The first step is to determine if there is adequate intravascular volume and cardiac output to ensure adequate kidney perfusion.[4] Diuretic therapy may be given. It usually includes loop diuretics (e.g., furosemide [Lasix], bumetanide) or an osmotic diuretic (e.g., mannitol). If AKI is established, forcing fluids and diuretics will not be effective and may be harmful. Closely monitor fluid intake during the oliguric phase of AKI.

The general rule for calculating the fluid restriction is to add all losses for the previous 24 hours (e.g., urine, diarrhea, emesis, blood) plus 600 mL for insensible losses (e.g., respiration, diaphoresis). For example, if a patient excreted 300 mL of urine on Tuesday with no other losses, the fluid allocation on Wednesday would be 900 mL.

Hyperkalemia is one of the most serious complications in AKI because it can cause life-threatening dysrhythmias. Therapies used to treat high potassium levels are listed in Table 51.5. Both insulin and sodium bicarbonate are temporary measures for treating hyperkalemia by promoting a transient shift of potassium into the cells. Potassium will eventually diffuse back into the bloodstream. Calcium gluconate raises the threshold at which dysrhythmias occur, temporarily stabilizing the myocardium. Sodium polystyrene sulfonate (Kayexalate) and dialysis remove potassium rapidly from the body.

Conservative therapy may be all that is necessary until kidney function improves. If conservative therapy is not effective in treating AKI, then *renal replacement therapy* (RRT) is used. Controversy exists about the timing of RRT in AKI.[5] The most common indications for RRT in AKI are (1) volume overload, resulting in compromised cardiac and/or pulmonary status; (2) high serum potassium level; (3) metabolic acidosis (serum HCO_3^- level less than 15 mEq/L [15 mmol/L]); (4) BUN level greater than 120 mg/dL (43 mmol/L); (5) significant change in mental status; and (6) pericarditis, pericardial effusion, or cardiac tamponade.[6] Although laboratory values provide rough parameters, the best guideline is the clinical status of the patient.

Of the several RRT therapy options available, there is no consensus about the best approach.[6] Even though peritoneal dialysis (PD) is a viable option for RRT, it is not often used. Intermittent hemodialysis (HD) and continuous renal replacement therapy (CRRT) have both been used effectively.

CRRT is provided continuously over 24 hours through cannulation of a vein or catheter placement. CRRT has much slower blood flow rates compared with intermittent HD. HD is the method of choice when changes are needed emergently. It

TABLE 51.5 Therapies for High Potassium Levels

Regular Insulin IV
- Potassium moves into cells when insulin is given
- IV glucose given concurrently to prevent hypoglycemia
- IV Calcium Gluconate often given concurrently to improve cardiac contractility
- When effects of insulin decrease, potassium shifts back out of cells

Sodium Bicarbonate
- May be considered to correct acidosis and cause a shift of potassium into cells

Calcium Gluconate IV
- Generally used in advanced cardiac toxicity (evidence of hyperkalemic ECG changes)
- Raises the threshold for excitation, resulting in dysrhythmias

Sodium Polystyrene Sulfonate (Kayexalate)
- Given by mouth or retention enema
- When resin is in the bowel, potassium is exchanged for sodium
- Produces osmotic diarrhea, allowing for evacuation of potassium-rich stool
- Removes 1 mEq of potassium per 1 g of drug
- Do not give to a patient with a paralytic ileus as bowel necrosis can occur

Patiromer (Veltassa) and Sodium Zirconium Cyclosilicate (SZC)
- Oral suspension that binds potassium in GI tract
- Used to treat patients with CKD
- Do not use as an emergency drug for life-threatening hyperkalemia
- Has a delayed onset of action
- Do not give to a patient with a paralytic ileus as bowel necrosis can occur

Hemodialysis
- Most effective therapy to remove potassium
- Works within a short time

Diet Restriction
- Potassium intake is limited to 40 mEq/day
- Used to prevent recurrent elevation, not for acute elevation

is technically more complicated because it requires special staff and equipment and vascular access. The patient needs anticoagulation therapy to prevent blood clotting when the blood makes contact with the dialysis circuit. Rapid fluid shifts during HD may cause hypotension.

Nutrition Therapy

The goal of nutrition therapy in AKI is to provide adequate calories to prevent catabolism despite restrictions that prevent electrolyte and fluid problems and azotemia. Intake must provide adequate calories (30 to 35 kcal/kg and 0.8 to 1.0 g of protein/kg of desired body weight) to prevent the breakdown of body protein.

Adequate energy should mainly come from carbohydrate and fat sources to prevent ketosis from endogenous fat breakdown and gluconeogenesis from muscle protein breakdown. Essential amino acids may be supplemented. Potassium and sodium are regulated per plasma levels. Sodium is restricted as needed to prevent edema, hypertension, and HF.[7] Fat intake is increased so that the patient receives at least 30% to 40% of total calories from fat. IV fat emulsion infusions provide a good source of nonprotein calories. If a patient cannot maintain adequate oral intake, enteral nutrition is the preferred route for nutrition support (see Chapter 44). When the GI tract is not functional, parenteral nutrition (PN) can provide adequate nutrition. The patient treated with PN may need daily HD or CRRT to remove the excess fluid. Concentrated PN formulas are available to minimize fluid volume.

NURSING MANAGEMENT: ACUTE KIDNEY INJURY

Assessment

Several assessments are essential for developing the plan of care. Daily weights, strict intake and output, and vital signs are key. Daily monitoring of urine output has prognostic value. It is crucial for determining therapy and daily fluid volume replacement. Assess the urine for color, specific gravity, glucose, protein, blood, and sediment. Note the patient's general appearance, including skin color. Is there any edema, neck vein distention, or bruises? If a patient is receiving dialysis, check the access site for inflammation and exudate. Assess mental status and level of consciousness. Check the oral mucosa for dryness and inflammation. Auscultate the lungs for crackles, wheezes, or decreased breath sounds. Monitor the heart for an S_3 gallop, murmurs, or a pericardial friction rub. Assess ECG readings for dysrhythmias. Review all laboratory values and diagnostic test results.

Clinical Problems

Clinical problems for the patient with AKI include:
- Electrolyte imbalance
- Fluid imbalance
- Risk for infection
- Anxiety

Planning

The overall goals are that the patient with AKI will (1) completely recover without any loss of kidney function, (2) maintain normal fluid and electrolyte balance, (3) have decreased anxiety, and (4) adhere to and understand the need for careful follow-up care.

Implementation

Health Promotion

Prevention and early recognition of AKI are the most important aspects of care. Prevention is directed toward identifying and monitoring high-risk populations, controlling exposure to nephrotoxic drugs and industrial chemicals, and preventing prolonged episodes of hypotension and hypovolemia. In the hospital, factors that increase the risk for developing AKI are preexisting CKD, older age, massive trauma, major surgery, extensive burns, HF, sepsis, and obstetric complications.[8]

Contrast-induced nephropathy (CIN) can occur when contrast media for diagnostic studies causes nephrotoxic injury. In patients with diabetes receiving metformin, the drug should be held for 48 hours prior to and after the use of contrast media to decrease the risk for lactic acidosis. The best way to avoid CIN is to avoid exposure to contrast media by using other diagnostic tests, such as ultrasound. If contrast media is given to a high-risk patient, ensure adequate fluid intake. They should receive the lowest possible dose or a lower osmolality contrast agent.[9]

Monitor the patient's weight, intake and output, and fluid and electrolyte balance. Assess and record extrarenal losses of fluid from vomiting, diarrhea, hemorrhage, and increased insensible losses. Prompt replacement of significant fluid losses helps prevent ischemic tubular damage from trauma, burns, and extensive surgery. Intake and output and weight are valuable indicators of fluid volume status. Aggressive diuretic therapy for the patient with fluid overload from any cause can lead to decreased renal blood flow.

Monitor kidney function in persons who are taking drugs that are potentially nephrotoxic (see Table 49.3). These drugs should be used sparingly in the high-risk patient. When they must be used, they should be given in the smallest effective doses for the shortest possible periods. Caution the patient about over-the-counter (OTC) analgesics (especially nonsteroidal antiinflammatory drugs [NSAIDs]). They may worsen kidney function in the patient with mild CKD.

Angiotensin-converting enzyme (ACE) inhibitors can decrease perfusion pressure and cause hyperkalemia. If other measures, such as diet changes and diuretics, cannot control hyperkalemia, ACE inhibitors may have to be reduced or stopped. However, ACE inhibitors are often used to prevent proteinuria and progression of kidney disease, especially in patients with diabetes.

Acute Care

The patient with AKI is critically ill and may have comorbid problems (e.g., diabetes, cardiovascular disease [CVD]) in addition to kidney injury. Focus on the patient holistically since they will have many physical and emotional needs. Usually, the changes caused by AKI arise suddenly. The patient needs help in understanding that kidney disease may affect the entire body's functions.

You have a key role in managing fluid and electrolyte balance during the oliguric and diuretic phases. Observe and record intake and output. Take daily weights with the same scale at the same time each day to detect excessive gains or losses of body fluid (1 kg is equivalent to 1000 mL of fluid). Assess for signs and symptoms of hypervolemia (in the oliguric phase) or hypovolemia (in the diuretic phase), potassium and sodium problems, and other electrolyte imbalances that may occur in AKI (see Chapter 17).

Because infection is the leading cause of death in AKI, meticulous aseptic technique is critical. Protect the patient from those with infectious diseases. Be alert for local manifestations of infection (e.g., swelling, redness, pain) as well as systemic manifestations (e.g., fever, malaise, leukocytosis).

If a patient with renal failure has an infection, be aware that they may not have a fever. Patients with AKI have a blunted febrile response to infection (e.g., pneumonia). If antibiotics are given to treat infection, we carefully consider the type, frequency, and dosage because the kidneys are the main route of excretion for many antibiotics. Dosages may be decreased depending on the patient's level of kidney function if the drug is eliminated by the kidneys. Nephrotoxic drugs (see Table 49.3) should be used with caution.

Perform good skin care. Take measures to prevent pressure injuries as mobility may be impaired. Mouth care is important to prevent stomatitis, which develops when ammonia (made by bacterial breakdown of urea) in saliva irritates the mucous membranes.

Ambulatory Care

Recovery from AKI is highly variable. It depends on whether other body systems fail, the patient's general health and age, the length of the oliguric phase, and the severity of nephron damage. Protein and potassium intake are dictated by kidney function. Regular evaluation of kidney function is necessary. Teach the patient the signs and symptoms of recurrent kidney disease. Emphasize measures to prevent the recurrence of AKI.

The long-term convalescence of 3 to 12 months may cause psychosocial and financial hardships for the patient, caregiver, and family. Make appropriate referrals for counseling. If the kidneys do not recover, the patient will need to transition to life on chronic dialysis or a possible transplant.

Evaluation

The expected outcomes are that the patient with AKI will

- Regain and maintain normal fluid and electrolyte balance
- Adhere to the treatment regimen
- Have no complications
- Have a complete recovery

Gerontologic Considerations: Acute Kidney Injury

Older adults are at an increased risk for AKI. The GFR declines with age. In older adults, impaired function of other organ systems from CVD or diabetes can increase the risk for AKI. The aging kidney is less able to compensate for changes in fluid volume, solute load, and cardiac output. Dehydration is a predisposing factor. It can occur from polypharmacy (diuretics, laxatives, drugs that suppress appetite or consciousness), acute febrile illness, and immobility.

Other common causes of AKI in the older adult include hypotension, diuretic therapy, aminoglycoside therapy, obstructive disorders (e.g., BPH), surgery, infection, and contrast media. Mortality rates are similar for older and younger patients. Patients over 65 years of age are less likely to recover from AKI. Despite this, age is not a barrier to offering RRT.

CHRONIC KIDNEY DISEASE

Chronic kidney disease (CKD) involves progressive, irreversible loss of kidney function. More than 26 million American adults, or 1 out of every 9, have CKD. CKD is much more

TABLE 51.6 Risk Factors for CKD

Risk Factors	Prevention and Management
Age >60 years	Prevent insult or injury to kidneys
Cardiovascular disease	Institute risk factor reduction measures
Diabetes	Achieve optimal glycemic control
Ethnic minority (e.g., Black, Native American)	Teach about ↑ risk and assist with appropriate screening (BP measurement, urinalysis)
Exposure to nephrotoxic drugs	Limit exposure and give sodium bicarbonate as treatment
Family history of CKD	Teach about ↑ risk and assist with appropriate screening
Hypertension	Maintain BP in normal range with ACE inhibitors or ARBs

common than AKI (Table 51.1). We partially attribute the increasing prevalence of CKD to increased risk factors, including an aging population, and increased rates of obesity, diabetes, and hypertension.

Because the kidneys are highly adaptive, CKD is often not recognized until there has been considerable loss of nephrons. Patients with CKD are often asymptomatic. This often results in CKD being underdiagnosed and untreated. We think about 70% of people with CKD are unaware that they have the disease.[10]

CKD has many different causes. The leading ones are diabetes (about 50%) and hypertension (about 25%) (Table 51.6).[11,12] Less common causes include glomerulonephritis, cystic diseases, and urologic diseases. Kidney diseases are discussed in Chapter 50.

Kidney Disease Improving Global Outcomes (KDIGO) Clinical Practice Guidelines defines CKD as either the presence of kidney damage or a decreased GFR less than 60 mL/min/1.73 m^2 for longer than 3 months.[11] Table 51.7 shows the stages of CKD. The last stage of kidney disease, **end-stage renal disease (ESRD)**, occurs when the GFR is less than 15 mL/min. At this point, RRT (dialysis, transplant) is needed to maintain life.[11]

Over half a million Americans are receiving treatment for ESRD. Despite all the technologic advances in life-sustaining treatment with dialysis, patients with ESRD have a high mortality rate. As the stage of kidney disease progresses, the mortality rate increases. Mortality rates are as high as 19% to 24% for patients with ESRD on dialysis.[12,13]

The prognosis and course of CKD are highly variable. They depend on the cause, patient's health and age, and adequacy of health care follow-up (Box 51.1). Some people live normal, active lives with kidney disease, while others may rapidly progress to ESRD (stage 5).

Since 1972, the United States has covered most of the costs of dialysis through Medicare benefits. Under Title XVIII of the Social Security Act, ESRD was recognized as a disability. Medicare pays for 80% of eligible charges. The state, private insurance, or patient covers the rest.[14]

Clinical Manifestations

As kidney function deteriorates, all body systems become affected. The manifestations result from retained urea, creatinine, phenols, hormones, electrolytes, and water. **Uremia** is a syndrome in which kidney function declines to the point that symptoms may develop in multiple body systems (Fig. 51.2). It often occurs when the GFR is 15 mL/min or less. The manifestations of uremia vary depending on the cause, comorbid problems, age, and degree of adherence to the treatment plan. Many patients are tolerant of the changes caused by declining kidney function because they occur gradually.[10]

TABLE 51.7 Diagnostic Criteria

Stages of CKD

Description	GFR (mL/min/1.73 m^2)	Clinical Action Plan
Stage 1		
Kidney damage with normal or ↑ GFR	≥90	Diagnosis and treatment CVD risk reduction Slow progression
Stage 2		
Kidney damage with mild ↓ GFR	60–89	Estimation of progression
Stage 3a		
Moderate ↓ GFR	45–59	Evaluation and treatment of complications
Stage 3b		
Moderate ↓ GFR	30–44	More aggressive treatment of complications
Stage 4		
Severe ↓ GFR	15–29	Preparation for RRT (dialysis, kidney transplant)
Stage 5		
Kidney failure	<15 (or dialysis)	RRT (if uremia present and patient desires treatment)

BOX 51.1 PROMOTING HEALTH EQUITY

Chronic Kidney Disease

Blacks
- Have a high risk for CKD as a complication of hypertension
- Have the highest rate of CKD, nearly 4 times that of Whites

Native Americans
- Have a rate of CKD twice that of Whites
- Rate of CKD is 6 times higher among Native Americans with diabetes than among other ethnic groups with diabetes

Hispanics
- Rate of CKD in Hispanics is 1.5 times higher than in non-Hispanic Whites

Urinary System

In the early stages of CKD, patients usually do not report any change in urine output. Since diabetes is the main cause of CKD, polyuria may be present, but not necessarily from kidney disease. As CKD progresses, patients have increasing difficulty

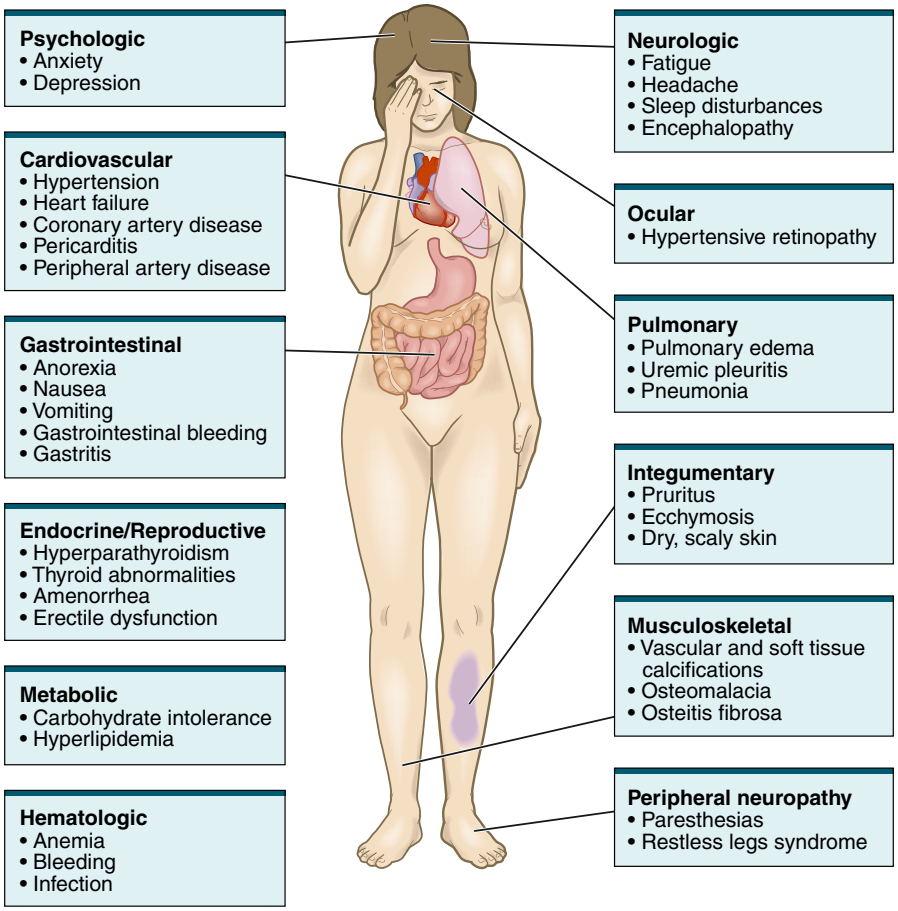

Fig. 51.2 Possible manifestations of CKD.

with fluid retention and need diuretic therapy. After a period on dialysis, patients may develop anuria.

Metabolic Disturbances

Waste product accumulation. As the GFR decreases, the BUN and serum creatinine levels increase. The BUN increase is not only from kidney disease but also protein intake, fever, corticosteroids, and catabolism. For this reason, serum creatinine clearance determinations (calculated GFR) are more accurate indicators of kidney function than BUN or creatinine (Table 51.8). Significant increases in BUN contribute to nausea, vomiting, lethargy, fatigue, impaired cognition, and headaches.

Altered carbohydrate metabolism. Impaired glucose metabolism, from cellular insensitivity to the normal action of insulin, causes defective carbohydrate metabolism. Mild to moderate hyperglycemia and hyperinsulinemia may occur.

Insulin and glucose metabolism may improve (but not to normal values) after starting dialysis. Patients with diabetes who use insulin before starting dialysis may need less insulin therapy when they start dialysis, and their kidney disease progresses. Patients with diabetes who develop uremia may need less insulin than before the onset of CKD. Insulin, which depends on the kidneys for excretion, stays in the circulation longer. Insulin dosing is patient specific. We monitor glucose levels carefully.

CHECK YOUR PRACTICE

You are working in a community-based HD unit. One of your patients is a 56-year-old woman who has been on HD for 3 weeks. You are reviewing her medications with her. She is surprised that her dose of glargine insulin has been decreased. She tells you, "I have been a diabetic for 10 years. This is the first time ever that my dose of insulin has been decreased."

- How would you respond?

Elevated triglycerides. Hyperinsulinemia stimulates hepatic triglyceride production. Many patients develop dyslipidemia, with increased very-low-density lipoproteins (VLDLs), increased low-density lipoproteins (LDLs), and decreased high-density lipoproteins (HDLs). The altered lipid metabolism is related to decreased levels of the enzyme lipoprotein lipase, which is important in the breakdown of lipoproteins. Most patients with CKD die from CVD.[12]

Electrolyte and Acid-Base Imbalances

Potassium. Hyperkalemia is a serious electrolyte disorder associated with CKD. Fatal dysrhythmias can occur when the serum potassium level reaches 7 to 8 mEq/L (7 to 8 mmol/L). Hyperkalemia results from the kidneys excreting less potassium, the breakdown of cellular protein, bleeding, and metabolic acidosis. Potassium may come from foods, diet supplements, drugs, and IV infusions.

TABLE 51.8 Indicators of Kidney Function

This example shows why serum creatinine alone is a poor indicator of kidney function. Calculation of GFR is considered the best index to estimate kidney function as shown by the following example.

	PATIENT EXAMPLE	
Estimation of GFR	76-Year-Old Woman (Weight 56 kg)	28-Year-Old Man (Weight 74 kg)
Serum creatinine	1.4 mg/dL	1.4 mg/dL
GFR, estimated by the Cockcroft-Gault formula: (140–Age) × (Weight in kg) × (0.85 if female)/(72 × Cr)	30.2 mL/min	82.2 mL/min
GFR, estimated by MDRD equation: $186 \times (\text{Creatinine}/88.4)^{-1.154} \times (\text{Age})^{-0.203} \times (0.742 \text{ if female}) \times (1.21 \text{ if Black})$	47 mL/min/1.73 m^2	64 mL/min/1.73 m^2

Sodium. Sodium may be high, normal, or low in kidney disease. Because of impaired sodium excretion, sodium is retained with water. If large quantities of water are retained, dilutional hyponatremia occurs. Sodium retention can contribute to edema, hypertension, and HF. Sodium intake is patient specific but is often restricted to 2 g/day.

Calcium and phosphate. Calcium and phosphate changes are discussed in the section on the musculoskeletal system.

Magnesium. Magnesium is mainly excreted by the kidneys. Hypermagnesemia is often not a problem unless the patient is ingesting magnesium (e.g., magnesium citrate, antacids containing magnesium). Manifestations can include absent reflexes, decreased mental status, dysrhythmias, and hypotension.

Metabolic acidosis. Metabolic acidosis results from the kidneys' impaired ability to excrete excess acid and from defective reabsorption and regeneration of HCO_3^-. The average adult makes 80 to 90 mEq of acid per day. This acid is normally buffered by HCO_3^-. In kidney disease, plasma HCO_3^-, which is an indirect measure of acidosis, usually falls to a new steady state at around 16 to 20 mEq/L (16 to 20 mmol/L). The decreased plasma HCO_3^- reflects its use in buffering metabolic acids. The HCO_3^- level often does not progress below this level because H^+ production is balanced by buffering from bone demineralization.

Hematologic System

Anemia. Normocytic, normochromic anemia is associated with CKD. Anemia in CKD is due to decreased erythropoietin production. Erythropoietin normally stimulates precursor cells in the bone marrow to make RBCs (erythropoiesis). Other factors contributing to anemia are nutrition deficiencies, decreased RBC life span, increased RBC hemolysis, frequent blood samplings, and GI bleeding. For patients receiving maintenance HD, blood loss in the dialyzer can contribute to the anemic state. Increased parathyroid hormone (PTH) (made to compensate for low serum calcium levels) can inhibit erythropoiesis, shorten RBC survival, and cause bone marrow fibrosis, which can result in decreased numbers of hematopoietic cells.

Sufficient iron stores are needed for erythropoiesis. Many patients with kidney disease are iron deficient and need iron supplementation. Oral iron supplements may not be effective for the person with CKD. GI side effects can cause adherence problems. Medications, such as proton pump inhibitors or phosphate binders, decrease absorption. Patients on dialysis may need IV iron to restore iron levels. Folic acid, needed for RBC maturation, is dialyzable because it is water soluble. Many patients receive folic acid supplements (1 mg/day).[15]

Bleeding tendencies. The most common cause of bleeding in uremia is a defect in platelet function. This problem is caused by impaired platelet aggregation and impaired release of platelet factor III. Changes in the coagulation system occur due to increased concentrations of both factor VIII and fibrinogen. The altered platelet function, hemorrhagic tendencies, and GI bleeding susceptibility can usually be corrected with regular HD or PD.

Infection. Patients with advanced CKD have an increased risk of infection. This is due to changes in WBC function and altered immune response and function. Both cellular and humoral immune responses are suppressed. Other factors contributing to the increased risk for infection include hyperglycemia and external trauma (e.g., catheters, needle insertions into vascular access sites).

Cardiovascular System

The most common cause of death in patients with CKD is CVD. Leading causes of death are myocardial infarction (MI), ischemic heart disease, peripheral arterial disease, HF, cardiomyopathy, and stroke.[16] CVD and CKD are so closely linked that if patients develop cardiac events (e.g., MI, HF), kidney function is evaluated. Traditional CVD risk factors, such as hypertension and increased lipids, are common in CKD patients.

CVD may be related to vascular calcification and arterial stiffness. Calcium deposits in the vascular medial layer can cause stiffening of the blood vessels. The mechanisms involved are multifactorial. They include (1) vascular smooth muscle cells changing into chondrocytes or osteoblast-like cells, (2) high total body amount of calcium and phosphate resulting from abnormal bone metabolism, (3) impaired renal excretion, and (4) drug therapies to treat the bone disease (e.g., calcium-phosphate binders).[17]

Hypertension, which is prevalent in patients with CKD, is both a cause and a consequence of CKD. Hypertension is worsened by sodium retention and increased ECF volume.[16] In some people, increased renin production contributes to hypertension. Hypertension and diabetes are contributing risk factors for vascular complications.[11,12] Long-standing hypertension, ECF volume overload, and anemia contribute to development of left ventricular hypertrophy that may eventually lead to cardiomyopathy and HF. Hypertension can cause retinopathy, encephalopathy, and nephropathy. Because of the many effects of hypertension, BP control is one of the most important therapeutic goals in CKD management.[12,16]

Patients with CKD are susceptible to dysrhythmias from hyperkalemia and decreased coronary artery perfusion. Uremic

pericarditis can develop and sometimes progresses to pericardial effusion and cardiac tamponade. Pericarditis typically presents with a friction rub, chest pain, and low-grade fever.

Respiratory System

With severe acidosis, the respiratory system may try to compensate with Kussmaul breathing, which increases CO_2 removal by exhalation (see Chapter 17). Dyspnea may occur because of fluid overload, pulmonary edema, uremic pleuritis (pleurisy), pleural effusions, and respiratory infections (e.g., pneumonia).

GI System

Stomatitis with exudates and ulcerations, a metallic taste in the mouth, periodontal disease, and *uremic fetor* (a urinous odor of the breath) often occur in CKD. Anorexia, nausea, and vomiting may develop if CKD progresses to ESRD and is not treated with dialysis. Weight loss and malnutrition may occur. Diabetic *gastroparesis* (delayed gastric emptying) can compound the effects of malnutrition for patients with diabetes. GI bleeding is a risk because of mucosal irritation and the platelet defect.

Constipation may be due to ingesting iron salts or calcium-containing phosphate binders. Limits on fluid intake and physical inactivity increase the risk for constipation.

Neurologic System

Neurologic changes are expected as kidney disease progresses. They are the result of increased nitrogenous waste products, electrolyte imbalances, metabolic acidosis, and atrophy and demyelination of nerve fibers.

The central nervous system (CNS) becomes depressed, resulting in lethargy, apathy, decreased ability to concentrate, fatigue, irritability, and altered mental ability. Seizures and coma may result from a rapidly increasing BUN and hypertensive encephalopathy.

Peripheral neuropathy initially manifests as a slowing of nerve conduction to the extremities. The patient may have paresthesias in the feet and legs as a burning sensation. Eventually, motor involvement may lead to bilateral foot drop, muscular weakness and atrophy, and loss of deep tendon reflexes. Muscle twitching, jerking, *asterixis* (hand-flapping tremor), and nighttime leg cramps may occur. In patients with diabetic neuropathy, uremic neuropathy can compound symptoms. Those with advanced stage 5 CKD may develop restless legs syndrome.

Dialysis should improve general CNS problems and may slow or halt the progression of neuropathies. Motor neuropathy may not be reversible. The treatment for neurologic problems is dialysis or a transplant. Altered mental status, a late manifestation of CKD stage 5, rarely occurs unless the patient has chosen not to have RRT.

Musculoskeletal System

CKD mineral and bone disorder (CKD-MBD) develops as a systemic disorder of mineral and bone metabolism caused by progressive deterioration in kidney function (Fig. 51.3). Activated vitamin D is necessary to optimize absorption of calcium from the GI tract. As kidney function declines, less vitamin D is converted to its active form, resulting in decreased serum levels. Low levels of active vitamin D result in decreased serum calcium levels.[17]

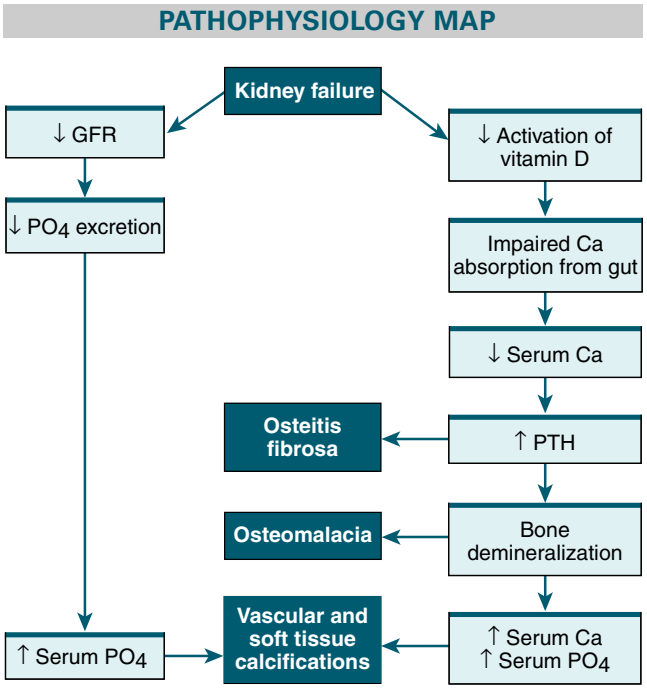

Fig. 51.3 Mechanisms of CKD-MBD. *GFR*, Glomerular filtration rate; *PTH*, parathyroid hormone.

Serum calcium levels are regulated primarily by PTH. When hypocalcemia occurs, the parathyroid gland secretes PTH, which stimulates bone demineralization, releasing calcium from the bones. Phosphate is also released, leading to high serum phosphate levels. Hyperphosphatemia also results from decreased phosphate excretion by the kidneys. It decreases serum calcium levels and further reduces the kidneys' ability to activate vitamin D.

Low serum calcium, increased phosphate, and decreased vitamin D contribute to stimulation of the parathyroid gland and excretion of PTH. PTH acts on the bone to increase remodeling. The accelerated rate of bone remodeling causes a weakened bone matrix and places the patient at a higher risk for fractures. Low ionized calcium levels can lead to tetany (see Chapter 17). However, in CKD, it is unusual for hypocalcemia to be symptomatic. In the acidotic state associated with CKD, more calcium is in the ionized form than is bound to protein.

CKD-MBD is a common complication of CKD. It results in skeletal, vascular, and soft tissue (extraskeletal) complications. Skeletal complications include (1) *osteomalacia* (results from demineralization from slow bone turnover and defective mineralization of newly formed bone) and (2) *osteitis fibrosa* (decalcification of the bone and replacement of bone tissue with fibrous tissue).

Soft tissue complications result from vascular calcifications. Vascular calcifications are a significant contributing factor to CVD. Irritation from calcium deposits in the eye can cause "uremic red eye." Cardiac calcifications can disrupt the conduction system and cause cardiac arrest. The gold standard for diagnosing CKD-MBD is a bone biopsy.

Skin

A small number of patients develop refractory itching that can have a devastating impact on their well-being and quality of life. Itching has multiple causes, including dry skin, calcium-phosphate deposition in the skin, and sensory neuropathy. It is more common in patients receiving dialysis than in the earlier stages of CKD. The itching may be so intense that it can lead to bleeding or infection from scratching. Uremic frost is a rare condition in which urea crystallizes on the skin. It is usually seen only when BUN levels are very high (e.g., over 200 mg/dL).

Reproductive System

Both men and women can have infertility and a decreased libido. Women usually have low levels of estrogen, progesterone, and luteinizing hormone, causing anovulation and menstrual changes (usually amenorrhea). Menses and ovulation may return after starting dialysis. Men have loss of testicular consistency, decreased testosterone levels, and low sperm counts.

Sexual problems may be caused by anemia, which causes fatigue and decreased libido. Peripheral neuropathy can cause impotence in men and anorgasmia in women. Other factors that may cause changes in sexual function are psychologic problems (e.g., anxiety, depression), physical stress, and drug side effects. Sexual function may improve with maintenance dialysis and become normal after a successful transplant.

Patients who become pregnant while receiving dialysis have been able to carry a fetus to term, but there is significant risk to the mother and infant. Pregnancy in patients with a kidney transplant is more common, but there is still considerable risk to the mother and fetus.

Psychologic Changes

Personality and behavioral changes, emotional lability, withdrawal, and depression often occur in patients with CKD. Fatigue and lethargy contribute to the feeling of illness. The changes in body image caused by edema, skin changes, and access devices (e.g., fistulas, catheters) may lead to anxiety and depression. Decreased ability to concentrate and slowed mental activity can give the appearance of dullness and disinterest in the environment. The patient must deal with significant changes in lifestyle, occupation, family responsibilities, and financial status. Long-term survival depends on medications, diet restrictions, dialysis, and possibly a transplant. The patient grieves the loss of kidney function and independence.

Diagnostic Studies

Persistent proteinuria is usually the first sign of kidney damage.[18] Screening for CKD involves a dipstick evaluation of protein in the urine or evaluation for albuminuria, which is not detected with routine urinalysis. The urine of patients with diabetes must be checked for albuminuria if no protein is present on routine urinalysis. A person with persistent proteinuria (1+ protein on standard dipstick testing 2 or more times over a 3-month period) should have further assessment of risk factors and a diagnostic workup with blood and urine tests to evaluate for CKD.

A urinalysis can detect RBCs, WBCs, protein, casts, and glucose. A renal ultrasound can detect any obstructions and determine the size of the kidneys. Other diagnostic studies (Table 51.9) help establish the diagnosis and cause of CKD. A kidney biopsy may be needed to provide a definitive diagnosis.

Serum creatinine alone poorly reflects kidney function. GFR is the preferred way to determine kidney function. There are several GFR calculators. The equations used most often are the Cockcroft-Gault formula and Modification of Diet in Renal Disease (MDRD) Study equation (Table 51.8). MDRD is the preferred method of calculation.[19]

TABLE 51.9 Interprofessional Care

CKD

Diagnostic Assessment

- History and physical assessment
- Identify reversible kidney disease
- Renal ultrasound, renal scan, CT scan
- Renal biopsy
- BUN, serum creatinine, and creatinine clearance levels
- Serum electrolytes
- Lipid profile
- Urinalysis
- Protein-to-creatinine ratio in 1st morning voided specimen
- Hematocrit and hemoglobin levels

Management

- Correct fluid volume overload or deficit
- RRT (dialysis, kidney transplant)
- Nutrition therapy (Tables 51.10 and 17.7)
- Measures to lower potassium (Table 51.5)

Drug Therapy

- Calcium supplementation, phosphate binders, or both
- Antihypertensive therapy
- ACE inhibitors or ARBs
- Erythropoietin therapy
- Lipid-lowering drugs
- Adjust drug dosages to degree of renal function

Interprofessional Care

The overall goals of CKD therapy are to preserve existing kidney function, reduce the risks for CVD, prevent complications, and provide for the patient's comfort. Early recognition, diagnosis, and treatment can prevent the progression of kidney disease. Patients with CKD need a referral to a nephrologist early in the course of the disease. Every effort is made to detect and treat potentially reversible causes of kidney failure (e.g., HF, dehydration, infections, nephrotoxins, urinary tract obstruction, glomerulonephritis, renal artery stenosis).

Patients with CKD have a high incidence of CVD. More patients die from CVD than live to need dialysis. When a patient has CKD, therapy is aimed at treating CVD plus slowing the progression of kidney disease (Table 51.9).

A focus during stages 1 through 4 (Table 51.7) before the need for dialysis (stage 5) includes controlling blood pressure, hyperparathyroidism, CKD-MBD, anemia, and dyslipidemia. The next section focuses on the drug and nutrition aspects of care.

Drug Therapy

Hyperkalemia. We use several strategies to manage hyperkalemia (Table 51.5). These include restricting high-potassium foods and drugs. Acute hyperkalemia may need treatment with IV glucose and insulin or IV 10% calcium gluconate.

Sodium polystyrene sulfonate, a cation-exchange resin, is often given to lower potassium levels in stage 4 CKD. Sodium polystyrene sulfonate has an osmotic laxative action and ensures potassium evacuation from the bowel. Tell the patient to expect some diarrhea. Since sodium polystyrene sulfonate exchanges sodium ions for potassium ions, observe the patient for sodium and water retention. If changes appear in the ECG, such as peaked T waves and widened QRS complexes, HD may be done to remove excess potassium.

Patiromer (Veltassa) is an oral suspension that binds potassium in the GI tract. It can treat hyperkalemia in persons with CKD. It should not be used in emergency situations to treat hyperkalemia because of its delayed onset of action. Because patiromer binds other oral medications, it must be taken at least 6 hours before or after other oral medications. Sodium zirconium cyclosilicate (SZC) is another long-term drug for hyperkalemia. It is an oral solution that should be given at least 2 hours apart from other medications.[20]

Hypertension. For some, the progression of CKD can be delayed by controlling hypertension.[16] Treatment of hypertension includes (1) weight loss (if needed), (2) lifestyle changes (e.g., exercise, avoid alcohol use, smoking cessation), (3) diet recommendations (DASH Diet), and (4) antihypertensive drugs. Most patients need 2 or more drugs to reach target BP. The treatment of hypertension is discussed in Chapter 36.

Drug therapy depends on whether the patient has diabetes. ACE inhibitors and ARBs are given to patients with diabetes and those with nondiabetic proteinuria.[11] They decrease proteinuria and may delay the progression of CKD. They must be used with caution as they can further decrease the GFR and increase serum potassium levels.

Measure the BP with the patient in the supine, sitting, and standing positions to assess the effect of antihypertensive drugs. Teach the patient and caregiver how to monitor the BP at home and what readings require immediate intervention.

CKD-MBD. Interventions for CKD-MBD include limiting phosphorus intake, giving phosphate binders, supplementing vitamin D, and controlling hyperparathyroidism.[17] Phosphate intake is not usually restricted until the patient needs RRT. At that time, phosphate is usually limited to about 1 g/day, but diet control alone is usually not enough.

Phosphate binders include calcium-based binders, such as calcium acetate, and calcium carbonate. They bind phosphate in the bowel and then excrete it in the stool. Giving calcium increases the calcium load which increased the risk for vascular calcifications. When calcium levels are increased or there is evidence of existing vascular or soft tissue calcifications, non–calcium-based phosphate binders are used. These include lanthanum carbonate (Fosrenol), sevelamer carbonate (Renvela), and iron-based, calcium-free phosphate binders, such as sucroferric oxyhydroxide (Velphoro) and ferric citrate (Auryxia).

To be most effective, give phosphate binders with each meal. Constipation is a frequent side effect. Stool softeners may be needed.

Because bone disease (osteomalacia) is associated with excess aluminum, aluminum preparations should be used with caution in patients with kidney disease. Do not use magnesium-containing antacids (e.g., Maalox, Mylanta) because magnesium depends on the kidneys for excretion.

Hypocalcemia is a problem in the later stages of CKD due to the inability of the GI tract to absorb calcium in the absence of active vitamin D. If hypocalcemia persists even if the serum phosphate levels are normal, supplemental calcium and vitamin D may be given. Assess vitamin D levels to determine the need for a supplement. If the levels are low, vitamin D is given in the form of cholecalciferol.

Treatment of secondary hyperparathyroidism in ESRD patients requires the activated form of vitamin D because the kidneys cannot activate vitamin D. Active vitamin D is available as oral or IV calcitriol (Rocaltrol), IV paricalcitol (Zemplar), or oral or IV doxercalciferol (Hectorol). Their use can reduce high PTH levels. Cinacalcet (Sensipar), a calcimimetic agent, can control secondary hyperparathyroidism. Calcimimetics mimic calcium and increase the sensitivity of the calcium receptors in the parathyroid glands. As a result, the parathyroid glands detect calcium at lower serum levels and decrease PTH secretion.

If parathyroid disease becomes severe, a subtotal or total parathyroidectomy may be done to decrease the synthesis and secretion of PTH. In most cases, a total parathyroidectomy is done and parathyroid tissue transplanted into the forearm. The transplanted cells make PTH as needed. If PTH production becomes excessive, some cells can be removed from the forearm.

Hypercalcemia may occur with calcium and vitamin D supplementation. If hypercalcemia occurs, vitamin D may be withheld, and calcium-based phosphate binders replaced with non–calcium-based phosphate binders.

Anemia. Anemia is caused by the kidneys making less erythropoietin. We give exogenous erythropoietin (EPO) to treat anemia. One option is epoetin alfa (Epogen, Procrit). It can be given IV or subcutaneously, usually 2 or 3 times per week. Darbepoetin alfa (Aranesp) is longer acting and can be given weekly or biweekly.

Hemoglobin and hematocrit levels may take 2 to 3 weeks to increase. Higher doses of EPO increase the risk of thromboembolic events and death from serious CV events (MI, HF, stroke). The recommendation is to use the lowest possible dose of EPO. EPO can increase BP. It is contraindicated in uncontrolled hypertension. The increased BP is due to hemodynamic changes (e.g., increased whole blood viscosity) that occur as the anemia is corrected.

Treatment of CKD-related anemia is patient specific with the goal being to reduce the need for blood transfusions. There is no target hemoglobin or widely accepted EPO dosing strategy. Teach people who are prescribed EPO about the risks and benefits and allow them to decide about their treatment plan.

EPO therapy may lead to iron deficiency from the increased demand for iron to support erythropoiesis. Iron supplements are

TABLE 51.10 NUTRITION THERAPY

CKD

	Pre-ESRD	Hemodialysis	Peritoneal Dialysis
Calcium	About 1000–1500 mg/day	Patient specific	Patient specific
Calories	30–35 kcal/kg/day	30–35 kcal/kg/day	25–35 kcal/kg/day (includes calories from dialysate glucose absorption)
Fluid allowance	As desired or depends on urine output	Urine output plus 600–1000 mL	Unrestricted if weight and BP controlled and residual renal function
Iron	Supplement recommended if receiving erythropoietin	Supplement recommended if receiving erythropoietin	Supplement recommended if receiving erythropoietin
Phosphate	Patient specific or 1.0–1.8 g/day	Patient specific or about 0.6–1.2 g/day	Patient specific or about 0.6–1.2 g/day
Potassium	Based on laboratory values	Patient specific or about 2–4 g/day	Usually not restricted
Protein	Patient specific or 0.6–1.0 g/kg/day (low protein)	1.2 g/kg/day	1.2–1.3 g/kg/day
Sodium	Patient specific or 1–3 g/day	Patient specific or 2–3 g/day	Patient specific or 2–4 g/day

recommended if the plasma ferritin concentrations fall below 100 ng/mL. Most CKD patients receive an iron supplement.

Iron can be given by mouth or IV. Oral use is limited due to GI side effects, which decrease adherence. Oral iron should not be taken at the same time as phosphate binders because calcium binds the iron, preventing its absorption. Tell the patient that iron may make the stool dark in color. Most patients receiving HD are prescribed IV iron sucrose (Venofer) or sodium ferric gluconate complex (Ferrlecit). Supplemental folic acid (1 mg/day) is usually given because it is needed for RBC formation and removed by dialysis.

Blood transfusions are avoided unless the patient has an acute blood loss or symptomatic anemia (i.e., dyspnea, excess fatigue, tachycardia, palpitations, chest pain). Transfusions increase the development of antibodies. This makes it harder to find a compatible donor for a kidney transplant. Multiple blood transfusions may lead to iron overload since each unit of blood has about 250 mg of iron.

Dyslipidemia. Dyslipidemia, a risk factor for CVD, is a common problem in CKD. Statins (HMG-CoA reductase inhibitors), such as atorvastatin (Lipitor), can lower LDL cholesterol levels (see Table 37.6). Statins should be used in patients with CKD, especially those with diabetes, not yet on dialysis.[13,16]

Fibrates (fibric acid derivatives), such as gemfibrozil (Lopid), are used to lower triglyceride levels (see Table 37.6) and can increase HDLs. Specific drugs used in these classes depend on the patient response and HCP recommendation.

Complications of drug therapy. The kidneys partially or totally excrete many drugs. CKD causes decreased elimination that leads to an accumulation of drugs and the potential for drug toxicity. Drug doses and frequency are adjusted based on the severity of the kidney disease. Increased sensitivity may result as drug levels increase in the blood and tissues. Drugs of particular concern include digoxin, diabetic agents (metformin, glyburide), antibiotics (e.g., vancomycin, gentamicin), and opioid drugs.

Nutrition Therapy

Protein restriction. The current diet for the person with CKD is designed to maintain good nutrition (Table 51.10). Calorie-protein malnutrition is a potential, serious problem that results from altered metabolism, anemia, dental problems, anorexia, and nausea (Box 51.2). Other factors leading to malnutrition include depression and complex diets that restrict protein, phosphorus, potassium, and sodium.

BOX 51.2 EVIDENCE-BASED PRACTICE

Oral Health and CKD

You work in an outpatient HD clinic. A new patient, K.D., is a 56-year-old woman with CKD who is scheduled for HD 3 times a week. During her first visit, you note several discolored teeth and swollen gums and suspect periodontal disease. When you ask K.D. about her oral care, she tells you she has not seen a dentist "in years." "Now that you mention it," she says, "my mouth always feels dry. Even when I try to drink a lot of water, it doesn't seem to help. Nothing tastes right." K.D. agrees when you tell her you would like to discuss her oral care options with her nephrology provider. K.D. comments, "My mother paid an arm and a leg for dental work. I don't even have enough money for a co-pay."

Making Clinical Decisions

Synthesis of Best Available Evidence

Research has identified a strong relationship between CKD and periodontitis. For patients who are undergoing dialysis, periodontal disease can increase the risk of CVD and mortality. Poor oral health can affect the ability to eat, taste, and swallow, and lead to dry mouth, gingivitis, dental caries, and pain.

Clinician Expertise

You contact the nurse practitioner (NP) at the nephrologist's office to discuss K.D.'s oral health. The NP tells you the patient has seemed defensive in past discussions about oral care. The NP says he is encouraged by her conversation with you. He confirms K.D. is insured and tells you he will make a referral to a local free clinic for dental care to minimize the cost.

Patient Preferences and Values

When you report to K.D. about the plan, she agrees to explore the options the NP and you are exploring.

Implications for Nursing Practice

1. What would you suggest as part of the oral care plan for K.D.?
2. How would you prepare K.D. for the dental work she is likely to need?

Reference for Evidence

Wallace K, Shafique S, Piamjariyakul U: The relationship between oral health and hemodialysis treatment among adults with CKD: a systematic review, *Nephrol Nurs J* 46(375), 2019.

Frequent monitoring of laboratory tests and anthropometric measurements are needed to evaluate nutrition status. All patients with CKD should be referred to a dietitian for nutrition teaching.

For CKD stages 1 through 4, many HCPs encourage a diet with normal protein intake. For the patient on HD, protein is not routinely restricted. The patient should avoid high-protein diets and supplements because they may overburden the diseased kidneys.[21]

Protein guidelines for PD differ from those for HD because of protein loss through the peritoneal membrane. During PD, protein intake must be high enough to compensate for the losses so that the nitrogen balance is maintained. The recommended protein intake is at least 1.2 g/kg of ideal body weight (IBW) per day. This can be increased depending on the patient's needs.

For patients with malnutrition or inadequate caloric or protein intake, commercially prepared products that are high in protein but low in sodium and potassium are available (e.g., Nepro, Amin-Aid). As an alternative, the patient may use liquid or powder breakfast drinks.

Fluid restriction. Water and any other fluids are not routinely restricted in patients with CKD stages 1 to 5 who are not receiving HD. To reduce fluid retention, diuretics are often used. Patients on HD have a more restricted fluid intake than patients on PD. For those on HD, as their urine output decreases, fluids are restricted. Recommended fluid intake depends on the daily urine output. Generally, 600 mL (from insensible loss) plus an amount equal to the previous day's urine output is allowed for a patient on HD.

Foods that are liquid at room temperature (e.g., gelatin, ice) are counted as fluid intake. Space fluid allotment throughout the day so that the patient does not become thirsty. Teach patients to limit fluid intake so that weight gains are no more than 1 to 3 kg between dialyses (interdialytic weight gain).

Sodium and potassium restriction. Teach patients with CKD to restrict sodium. Sodium-restricted diets may vary from 2 to 4 g/day. Teach the patient to avoid high-sodium foods, such as processed meats, canned soups and stews, cold cuts, and many dressings (see Table 38.8). Salt substitutes should be avoided in potassium-restricted diets because they contain potassium chloride.

Potassium restriction depends on the kidneys' ability to excrete potassium. Restrictions range from 2000 to 3000 mg (39 mg = 1 mEq). Teach patients receiving HD to avoid foods that are high in potassium (see Table 17.7). Patients using PD do not usually need potassium restrictions. They may need oral potassium supplementation because of the loss of potassium with dialysis exchanges.

Phosphate restriction. As kidney function declines, phosphate elimination by the kidneys is decreased. The patient develops high phosphorus levels. By the time a patient reaches ESRD, they need to limit phosphate to around 1 g/day. Foods that are high in phosphate include meat and dairy products (e.g., milk, ice cream, cheese, yogurt, pudding). Many foods that are high in phosphate are also high in protein. When patients eat a diet containing protein, phosphate binders are given to control the phosphate level.

❖ NURSING MANAGEMENT: CHRONIC KIDNEY DISEASE

◆ Assessment

Obtain a complete history of any existing kidney disease or family history of kidney disease. Some kidney disorders, including Alport syndrome and polycystic kidney disease, have a genetic component. Other problems that can lead to CKD are diabetes, hypertension, and SLE.

Because many drugs are potentially nephrotoxic, obtain a medication history. Decongestants and antihistamines that contain pseudoephedrine and phenylephrine cause vasoconstriction and lead to an increase in BP. Magnesium and aluminum from antacids can accumulate in the body because they cannot be excreted. Some antacids have high levels of salt. This contributes to hypertension.

NSAIDs (aspirin, ibuprofen, naproxen) can contribute to the development of AKI and progression of CKD, especially when taken in higher doses than recommended. If taken as prescribed, these analgesics are usually considered safe.[22]

Assess the patient's diet habits and discuss any problems with intake. Measure height and weight. Evaluate any recent weight changes.

CKD and its long-term treatment affect virtually every area of a person's life, including family relationships, social and work activities, self-image, and emotional state. Assess the patient's support systems. The choice of treatment may be related to support systems available.

◆ Clinical Problems

Clinical problems for patients with CKD include:

- Fluid imbalance
- Electrolyte imbalance
- Impaired cardiac function
- Difficulty coping

More information on clinical problems and interventions for the patient with CKD is presented in eNursing Care Plan 51.1, available on the website for this chapter.

◆ Planning

The overall goals are that a patient with CKD will (1) adhere to the treatment plan, (2) have effective coping strategies, and (3) continue with activities of daily living within their limitations.

◆ Implementation

◆ Health Promotion

Identify those at risk for CKD. At-risk persons include those diagnosed with diabetes or hypertension and people with a personal or family history of kidney disease or repeated urinary tract infections (UTIs). They should have regular checkups that include a routine urinalysis and calculation of the estimated GFR.

People with diabetes need to have their urine checked for albuminuria if routine urinalysis is negative for protein. Teach patients with diabetes to report any changes in urine appearance (color, odor), frequency, or volume to the HCP. If a patient needs a potentially nephrotoxic drug, it is important

BOX 51.3 PROMOTING POPULATION HEALTH

Prevention and Detection of CKD

- Early detection and treatment are the ways to reduce CKD.
- Ensure diagnosis and treatment of diabetes as it is the leading cause of CKD.
- Monitor BP to detect elevations so that treatment can be started early.
- Treat hypertension appropriately as it is the 2nd leading cause of CKD.

TABLE 51.11 PATIENT & CAREGIVER TEACHING

CKD

Include the following information in the teaching plan for the patient and caregiver:

1. Diet (sodium, potassium, phosphate) and fluid restrictions.
2. Common problems patient will encounter in modifying diet and fluid intake.
3. Signs and symptoms of electrolyte imbalance, especially high potassium.
4. Alternative ways of reducing thirst, such as sucking on ice cubes, lemon, or hard candy.
5. Reasons for prescribed drugs and common side effects. *Examples:*
   - Phosphate binders (including calcium supplements used as phosphate barriers) should be taken with meals.
   - Take calcium supplements prescribed to treat hypocalcemia on an empty stomach, but not at the same time as iron supplements.
   - Iron supplements should be taken between meals.
6. The importance of reporting any weight gain >4 lb (2 kg), increasing BP, shortness of breath, edema, increasing fatigue or weakness, or confusion or lethargy
7. Need for support and encouragement. Share concerns about lifestyle changes, living with a chronic illness, and decisions about type of dialysis or transplantation.

to monitor kidney function with serum creatinine, BUN, and GFR. Those at risk must take measures to prevent or delay the progression of CKD. Most important are measures to reduce the risk or progression of CVD (Box 51.3). These include glycemic control for patients with diabetes (see Chapter 53), BP control (see Chapter 36), and lifestyle modifications, including smoking cessation.

Acute Care

Most of the care of the patient with CKD occurs on an outpatient basis. In-hospital care is needed for management of complications and kidney transplant.

Ambulatory Care

Encourage patients to take part in their care. Teach the patient and caregiver about the diet, drugs, and follow-up care (Table 51.11). The patient needs to understand the drugs and common side effects. Because patients with CKD take many medications, a pillbox organizer or a list of the drugs and the times of administration may be helpful. Tell the patient to avoid OTC drugs such as NSAIDs and aluminum- and magnesium-based laxatives and antacids. Teach the patient to take daily BP readings. They need to watch for signs and symptoms of fluid overload, hyperkalemia, and other electrolyte imbalances.

The dietitian should meet with the patient and caregiver on a regular basis for diet planning. A diet history and consideration of cultural variations help with diet planning and adherence. The rate of progression of CKD is dependent on the type of kidney disease and presence of other comorbid problems.

The patient can complete an evaluation for a kidney transplant prior to the need to start dialysis. Patients may receive a transplant before ever having to start dialysis. Even though a transplant offers the best outcome for many ESRD patients, the critical shortage of donor organs limits this option for many patients.

Most patients need either PD or HD. Most patients use HD. Explain to the patient and caregiver what is involved in PD or HD. Offer information about all treatment options so that the patient can be involved in the decision-making process, giving a sense of control over life-altering decisions. Tell the patient that even while on dialysis, transplant is still an option. Let the patient know that if a transplanted organ fails, the patient can return to dialysis.

Discuss palliative care as needed. Patients themselves often start the conversation about palliative care. Focus the discussion on moving from the curative approach to promotion of comfort care and consideration of hospice care. Listen to the patient and caregiver, allowing them to do most of the talking and pay special attention to their hopes and fears. Palliative and end-of-life care is discussed in Chapter 10.

Evaluation

The expected outcomes are that the patient with CKD will maintain

- Fluid and electrolyte levels within normal ranges
- An acceptable weight with no more than a 10% weight loss

DIALYSIS

Dialysis is the movement of fluid and molecules across a semipermeable membrane from one compartment to another. Clinically, dialysis is a technique in which substances move from the blood through a semipermeable membrane and into a dialysis solution *(dialysate)*. It corrects fluid and electrolyte imbalances and removes waste products in kidney failure. It also can be used to treat drug overdoses.

The 2 methods of dialysis available are **peritoneal dialysis (PD)** and **hemodialysis (HD)** (Table 51.12).[23,24] In PD the peritoneal membrane acts as the semipermeable membrane.[23] In HD an artificial membrane (usually made of cellulose-based or synthetic materials) is used as the semipermeable membrane and is in contact with the patient's blood.[24]

Dialysis is started when the patient's uremia can no longer be adequately treated with conservative medical management. Generally, this is when the GFR is less than 15 mL/min/1.73 m^2.[24] This criterion can vary widely in different clinical situations. The nephrologist decides when to start dialysis based on the patient's clinical status. Certain uremic complications, such as encephalopathy, neuropathies, hyperkalemia, pericarditis,

TABLE 51.12 Comparison of Peritoneal Dialysis and Hemodialysis

Advantages	Disadvantages
Peritoneal Dialysis (PD)	
• Immediate initiation in almost any hospital • Less complicated than hemodialysis • Portable system with CAPD • Fewer diet restrictions • Short training time • Usable in patient with vascular access problems • Less cardiovascular stress • Home dialysis possible • Preferable for patient with diabetes	• Bacterial or chemical peritonitis • Protein loss into dialysate • Exit site and tunnel infections • Self-image problems with catheter placement • Hyperglycemia • Surgery for catheter placement • Contraindicated in patient with multiple abdominal surgeries, trauma, unrepaired hernia • Requires completion of education program • Catheter can migrate • Best instituted with willing partner
Hemodialysis (HD)	
• Rapid fluid removal • Rapid removal of urea and creatinine • Effective potassium removal • Less protein loss • Lowering of serum triglycerides • Home dialysis possible • Can place temporary access at bedside	• Vascular access problems • Diet and fluid restrictions • Heparinization may be necessary • Extensive equipment necessary • Hypotension during dialysis • Added blood loss that contributes to anemia • Specially trained personnel necessary • Surgery for permanent access placement • Self-image problems with permanent access

and accelerated hypertension, indicate a need for immediate dialysis.

Most patients with ESRD are treated with dialysis because (1) there is a lack of donated organs, (2) some patients are physically or mentally unsuitable for a transplant, or (3) some patients do not want transplants. An increasing number of people, including older adults and those with complex medical problems, are receiving maintenance dialysis. A patient's age is not a factor in determining candidacy for dialysis.[22]

General Principles of Dialysis

Solutes and water move across the semipermeable membrane from the blood to the dialysate or from the dialysate to the blood per concentration gradients. Diffusion, osmosis, and ultrafiltration are involved in dialysis (Fig. 51.4). *Diffusion* is the movement of solutes from an area of greater concentration to an area of lesser concentration. In kidney failure, urea, creatinine, uric acid, and electrolytes (potassium, phosphate) move from the blood to the dialysate with the net effect of lowering their concentration in the blood. RBCs, WBCs, and plasma proteins are too large to diffuse through the pores of the membrane. Small-molecular-weight substances can pass from the dialysate into a patient's blood, so we must monitor and control the water purity used for dialysis.

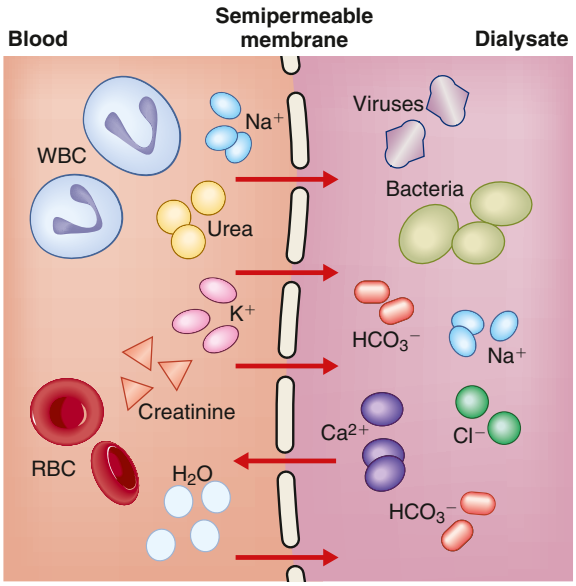

Fig. 51.4 Osmosis and diffusion across a semipermeable membrane.

Osmosis is the movement of fluid from an area of lesser concentration to an area of greater concentration of solutes. Glucose in the dialysate creates an osmotic gradient across the membrane, pulling excess fluid from the blood.

Ultrafiltration (water and fluid removal) results when there is an osmotic gradient or pressure gradient across the membrane. In PD, excess fluid is removed by increasing the osmolality of the dialysate (osmotic gradient) by adding glucose. In HD, the gradient is created by increasing pressure in the blood compartment (positive pressure) or decreasing pressure in the dialysate compartment (negative pressure). ECF moves into the dialysate because of the pressure gradient. The excess fluid is removed by creating a pressure differential between the blood and the dialysate solution with a combination of positive pressure in the blood compartment and negative pressure in the dialysate compartment.

PERITONEAL DIALYSIS

PD started to come into widespread use in the 1970s. That was when we developed soft, pliable peritoneal solution bags and continuous PD. The passage of the Executive Order on Advancing American Kidney Health in 2019 supported transplants and home dialysis. This led to more patients in the United States receiving PD.[23]

Catheter Placement

Peritoneal access is obtained by inserting a catheter through the anterior abdominal wall (Fig. 51.5). The catheter is about 24 in (60 cm) long and has 1 or 2 Dacron cuffs. The cuffs act as anchors and prevent the migration of microorganisms into the peritoneum. Within a few weeks, fibrous tissue grows into the Dacron cuff, holding the catheter in place and preventing bacterial penetration into the peritoneal cavity. The tip of the catheter rests in the peritoneal cavity. It has many perforations spaced along the distal end of the tubing, allowing fluid movement through the catheter.

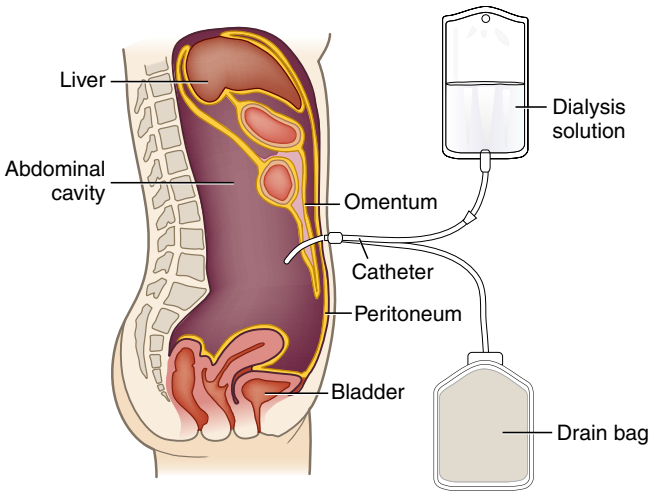

Fig. 51.5 PD showing peritoneal catheter inserted into peritoneal cavity.

Fig. 51.6 Peritoneal catheter exit site. (Courtesy Mary Jo Holechek, Baltimore, MD.)

The technique for catheter placement varies. It is usually placed surgically so that the catheter can be seen directly, minimizing potential complications. Patient preparation for catheter insertion includes emptying the bladder and bowel, weighing the patient, and obtaining a signed consent form. After placement, PD may be started at once with low-volume exchanges or delayed for 2 weeks pending healing and sealing of the exit site. Once the catheter incision site is healed, the patient may shower and then pat the catheter and exit site dry.[23] Daily catheter care varies. Some patients just wash with soap and water and go without a dressing (Fig. 51.6). Others need daily dressing changes. Showering is preferred to bathing.

In PD it is critical to maintain aseptic technique to avoid peritonitis. Several tubing connections and devices are available to help maintain an aseptic system. Teach all patients to check their catheter site for signs of infection.

Dialysis Solutions and Cycles

PD is done by putting dialysis solution into the peritoneal space. The 3 phases of the PD cycle are inflow (fill), dwell (equilibration), and drain. Together, the 3 phases are an *exchange.* For manual PD, it takes about 30 to 50 minutes to complete an exchange. During *inflow,* a prescribed amount of solution, usually 2 L, is infused through an established catheter over about 10 minutes. The flow rate may be decreased if the patient has pain. After infusing the solution, the inflow clamp is closed.

Fig. 51.7 Automated PD can be used while the patient is sleeping.

The next part of the cycle is the *dwell* phase, or equilibration. This is when diffusion and osmosis occur between the patient's blood and peritoneal cavity. The duration of the dwell time is usually between 4 and 6 hours. *Drain* time takes 15 to 30 minutes. It may be facilitated by gently massaging the abdomen or changing position. The cycle starts again with the infusion of another 2 L of solution.

PD solutions vary. The exchange volume is mainly determined by the size of the peritoneal cavity. An average-size person typically uses a 2-L exchange. A larger person may need a 3-L exchange volume. Smaller exchange volumes are used for patients with a smaller body, pulmonary compromise (the added pressure of the large volume may cause respiratory problems), or inguinal hernias.

Ultrafiltration (fluid removal) during PD depends on osmotic forces. Dextrose is the most often used osmotic agent in PD solutions. It is safe and inexpensive. It is associated with high rates of peritoneal glucose absorption. This can lead to problems with hypertriglyceridemia, hyperglycemia, and long-term peritoneal membrane dysfunction.

Alternatives to dextrose PD solution include icodextrin and amino acid solutions. Icodextrin is a commercially available iso-osmolar preparation. It induces ultrafiltration by its oncotic effect. Amino acid PD solutions are an option for patients who need nutrition supplementation.

Peritoneal Dialysis Systems

Automated Peritoneal Dialysis

Automated peritoneal dialysis (APD) is the most popular form of PD because it allows patients to do dialysis while they sleep. An automated device called a *cycler* delivers the dialysate for APD (Fig. 51.7). The automated cycler times and controls the fill, dwell, and drain phases. The machine cycles 4 or more exchanges per night with 1 to 2 hours per exchange. Alarms and monitors built into the system make it safe for the patient to sleep while dialyzing. The patient disconnects from the machine in the morning. They usually leave fluid in the abdomen during the day.

It is hard to achieve the required solute and fluid clearance solely with nighttime APD. One or 2 daytime manual exchanges may be needed to ensure adequate dialysis.

Continuous Ambulatory Peritoneal Dialysis

Continuous ambulatory peritoneal dialysis (CAPD) is done every few hours during the day. The patient may perform an exchange of 2 L of peritoneal dialysate 4 times daily, with dwell times averaging 4 hours. A common schedule includes exchanges at 7 AM, 12 noon, 5 PM, and 10 PM.

In CAPD, the person instills 2 to 3 L of dialysate from a plastic bag into the peritoneal cavity through a disposable administration line. The bag and line are then disconnected. After the equilibration period, the line is reconnected to the catheter, the dialysate (effluent) is drained from the peritoneal cavity, and a new 2- to 3-L bag of dialysate solution is infused.

Complications of Peritoneal Dialysis

Exit Site Infection

Infection of the peritoneal catheter exit site is most often caused by *Staphylococcus aureus* or *Staphylococcus epidermidis* (from skin flora). Manifestations include redness at the site, tenderness, and drainage. Superficial exit site infections caused by these organisms generally resolve with antibiotic therapy. If not treated quickly, subcutaneous tunnel infections may progress and cause peritonitis, requiring catheter removal.

Peritonitis

Peritonitis results from contact contamination or an exit site or tunnel infection. Most often it occurs because of improper technique when connections for exchanges are contaminated. Peritonitis is usually caused by *S. aureus* or *S. epidermidis.* It rarely results from bacteria in the intestine crossing into the peritoneal cavity.

The main manifestations are abdominal pain, rebound tenderness, and cloudy peritoneal effluent with a WBC count greater than 100 cells/μL (more than 50% neutrophils) or bacteria in the peritoneal effluent shown by Gram stain or culture. GI manifestations may include diarrhea, vomiting, abdominal distention, and hyperactive bowel sounds. Fever may be present. To determine if the peritoneal effluent is cloudy, drain the effluent and place the drained bag on reading material, such as a newspaper. If you cannot read the print through the effluent, it is cloudy.

Cultures, Gram stain, and a WBC differential of the peritoneal effluent are used to confirm the diagnosis of peritonitis. Antibiotics can be given orally, IV, or intraperitoneally. In most cases, the patient is treated on an outpatient basis.

The formation of adhesions in the peritoneum can result from repeated infections and interferes with the peritoneal membrane's ability to act as a dialyzing surface. Repeated infections may require the removal of the peritoneal catheter and a temporary or permanent change of modality to HD.

Hernias

Increased intraabdominal pressure from the dialysate volume can cause hernias to develop in predisposed persons, such as multiparous women and older men. After hernia repair, PD often can be resumed after several days using small dialysate volumes and keeping the patient supine.

Lower Back Problems

Increased intraabdominal pressure can cause or worsen lower back pain. The lumbosacral curvature is increased by intraperitoneal infusion of dialysate. Orthopedic binders and a regular exercise program for strengthening the back muscles are helpful for some patients.

Bleeding

After peritoneal catheter placement, it is common for the PD effluent drained after the first few exchanges to be pink or slightly bloody from trauma after catheter insertion. Bloody effluent over several days or the new appearance of blood in the effluent can indicate active intraperitoneal bleeding. If this occurs, check the BP and hematocrit. Blood may be present in the effluent of women who are menstruating or ovulating. This requires no intervention.

Pulmonary Complications

Atelectasis, pneumonia, and bronchitis may occur from repeated upward displacement of the diaphragm, resulting in decreased lung expansion. Longer dwell times increase the risk for pulmonary problems. Frequent repositioning and deep-breathing exercises can help. When the patient is lying in bed, elevate the head of the bed to prevent these problems.

Protein Loss

The peritoneal membrane is permeable to plasma proteins, amino acids, and polypeptides. These substances are lost in the dialysate fluid. The amount of loss is usually about 0.5 g/L of dialysate drainage, but it can be as high as 10 to 20 g/day. This loss may increase to as much as 40 g/day during episodes of peritonitis as the peritoneal membrane becomes more permeable. Unresolved peritonitis can cause excessive protein loss that can result in malnutrition. PD may need to stop temporarily or sometimes permanently.

Effectiveness of Chronic Peritoneal Dialysis

Mortality rates are similar between in-center HD patients and PD patients for the first few years. After about 2 years, mortality rates for patients receiving PD increase, especially for the older person with diabetes and patients with a prior history of CVD.[23]

The main advantage of PD is its simplicity. It is a home-based program, increasing patient participation in their care. Learning the skills needed to do PD usually involves a 3- to 7-day training program. There is no need for special water systems. Equipment setup is fairly simple.

HEMODIALYSIS

Vascular Access Sites

HD requires a very rapid blood flow and access to a large blood vessel. Obtaining vascular access is one of the biggest problems associated with HD. Enough time is needed to determine the best arteriovenous (AV) access for HD. The types of vascular access include AV fistulas (AVFs), AV grafts (AVGs), and temporary vascular access.[25]

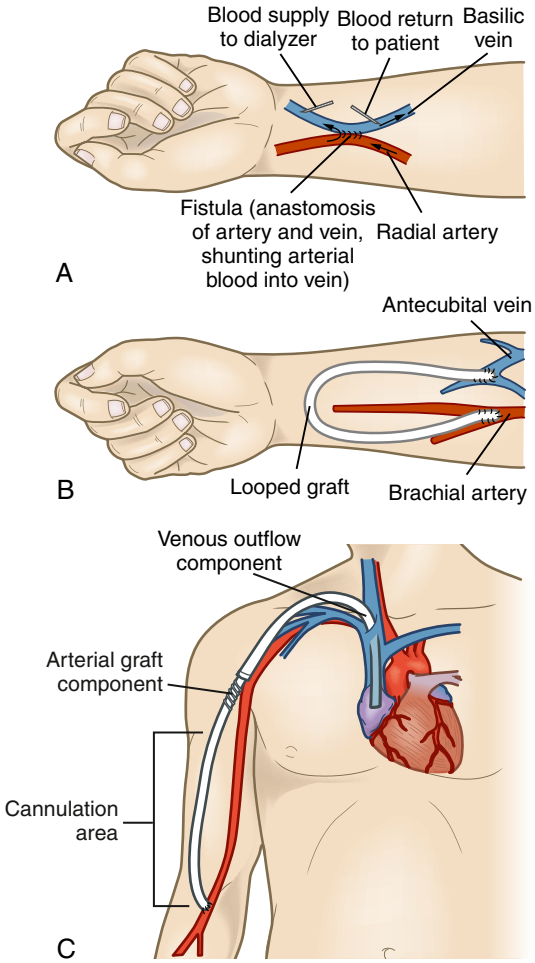

Fig. 51.8 Vascular access for hemodialysis. (A) AVF. (B) AVG. (C) HeRO Graft.

Arteriovenous Fistulas and Grafts

A subcutaneous **arteriovenous fistula (AVF)** is usually created in the forearm or upper arm with an anastomosis between an artery and a vein (usually cephalic or basilic) (Figs. 51.8A and 51.9). The fistula allows arterial blood to flow through the vein.

The vein becomes "arterialized," increasing in size and developing thicker walls. The arterial blood flow is essential to supply the rapid blood flow needed for HD. As the fistula matures, it is more amenable to repeated venipunctures. Maturation may take 6 weeks to months. AVF should be placed at least 3 months before starting HD. A fistula is the preferred access for HD.

Normally, a *thrill* (buzzing sensation) can be felt by palpating the fistula, and a *bruit* (rushing sound) can be heard with a stethoscope. The thrill and bruit are created by arterial blood moving at a high velocity through the vein.

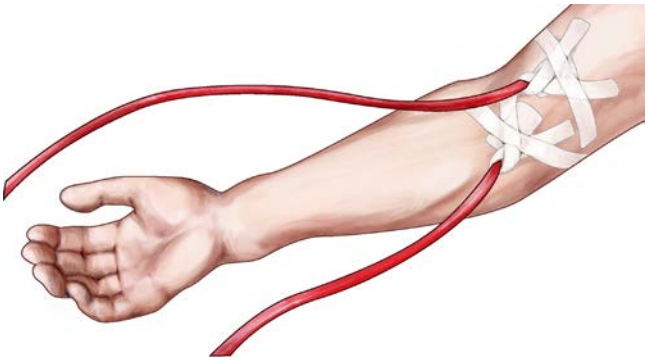

Fig. 51.9 AVF with cannulation needles for HD access.

AVFs are harder to create in patients with a history of severe peripheral vascular disease (e.g., people with diabetes), those with prolonged IV drug use, and obese women. These persons may need a synthetic graft.

Arteriovenous grafts (AVGs) are made of synthetic materials (polytetrafluoroethylene [PTFE, Teflon]). They form a "bridge" between the arterial and venous blood supplies. Grafts are placed under the skin and surgically anastomosed between an artery (usually brachial) and a vein (usually antecubital) (Fig. 51.8B). An interval of 2 to 4 weeks is usually needed to allow the graft to heal, but it may be used earlier. Because grafts are made of artificial materials, they are more likely than AVFs to become infected and tend to form clots. When AVG infections occur, they may need surgically removed, since it is hard to resolve infection from the synthetic material.

A common problem is central venous stenosis (CVS) or occlusion. CVS is serious because the central veins are the final pathway for blood flow to the heart. As CVS progresses, vascular access for HD is often lost.

A special bridge graft can be used in patients when other access options are exhausted. The Hemodialysis Reliable Outflow (HeRO) consists of 2 pieces: a reinforced tube to bypass blockages in veins and a graft anastomosed to an artery for HD access (Fig. 51.8C). It is placed under the skin, like both a fistula and standard graft. It bypasses the venous system and provides blood flow directly from a target artery to the heart. You may find it harder to auscultate the bruit or feel the thrill because of the absence of a venous anastomosis.

Surgical creation of AV access for HD has several risks. These include distal ischemia *(steal syndrome)* and pain because too much arterial blood is being shunted or "stolen" from the distal

CHECK YOUR PRACTICE

It is your first time working with a HD patient on your unit. You are helping a HD tech "hook up" a 56-year-old man to HD. He has been on HD for 5 years due to polycystic kidney disease. You take his vital signs, palpate his AV fistula, and then use your stethoscope to auscultate the AV fistula. You are concerned because you feel a super-strong pulse and hear a very loud "whoosh" sound. The patient turns to you and just smirks, "I bet you have never had a thrill like that."

- You are very flustered and not sure how to respond. What should you say to him?

SAFETY ALERT

AV Fistulas and Grafts

- Never perform BP measurements, IV line insertion, or venipuncture in an extremity with AV access.
- These precautions are taken to prevent infection and clotting of the vascular access.
- Place signs in patient's room and label the arm with a band that says, "No BP, blood draws, or IV in this arm."

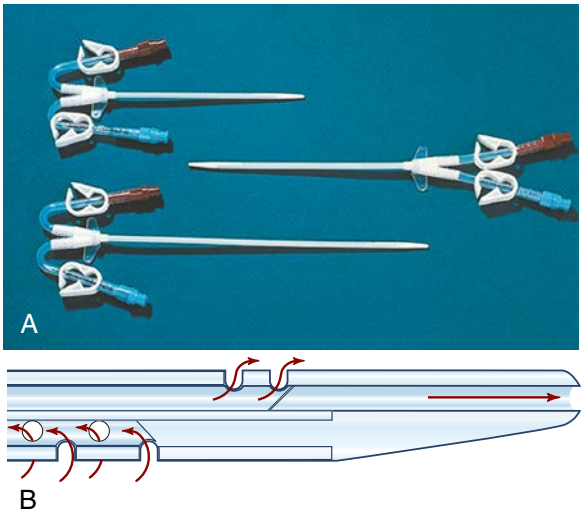

Fig. 51.10 Temporary double-lumen vascular access catheter for acute hemodialysis. (A) Soft, flexible double-lumen tube is attached to a Y hub. (B) The distance between the arterial intake lumen and the venous return lumen typically provides recirculation rates of 5% or less. (A, Courtesy Quinton Instrument Co., Seattle, WA.)

extremity. Manifestations of steal syndrome are pain distal to the access site, numbness or tingling of fingers that may worsen during HD, and poor capillary refill. Aneurysms can develop in the AV access and can rupture if left untreated.

Temporary Vascular Access

When immediate vascular access is needed, catheterization of the internal jugular or femoral vein is done. A flexible catheter inserted at the bedside into 1 of these large veins gives access to the circulation without surgery (Fig. 51.10). The catheters usually have a double external lumen with an internal septum separating the 2 internal segments. One lumen is used for blood removal and the other for blood return (Fig. 51.11A and B). Temporary catheters have high rates of infection, dislodgment, and malfunction. A patient should not be discharged from the hospital with a temporary catheter in place.

Long-term cuffed HD catheters are often used for temporary vascular access. These catheters give temporary access while the patient is waiting for fistula placement or as long-term access when other forms of access have failed. They exit on the upper chest wall and are tunneled subcutaneously to the internal or external jugular vein (Fig. 51.11C). The catheter tip rests in the right atrium. It has 1 or 2 subcutaneous Dacron cuffs that prevent infection from tracking along the catheter and anchor the catheter, eliminating the need for sutures.

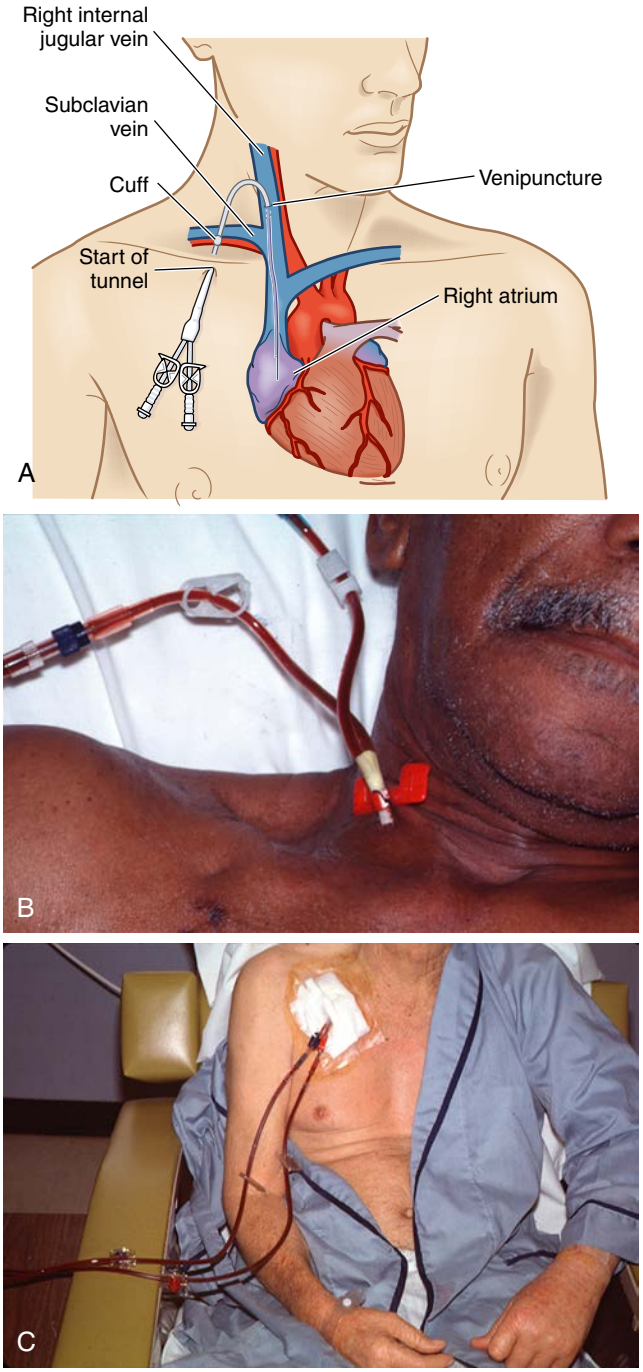

Fig. 51.11 (A) Right internal jugular placement for a tunneled, cuffed semipermanent catheter. (B) Temporary hemodialysis catheter in place. (C) Long-term cuffed hemodialysis catheter. (B and C, Courtesy Dr. Stephen Van Voorst, MD.)

Dialyzers

The HD dialyzer is a plastic cartridge that has thousands of parallel hollow tubes or fibers. The fibers are semipermeable membranes made of cellulose-based or other synthetic materials. The blood is pumped into the top of the cartridge and dispersed into all the fibers. Dialysis fluid *(dialysate)* is pumped into the bottom of the cartridge and bathes the outside of the fibers. Ultrafiltration, diffusion, and osmosis occur across the pores of this semipermeable membrane. When the dialyzed blood reaches the end of the thousands of semipermeable fibers, it converges into a single tube that returns it to the patient. Dialyzers differ in surface area, membrane composition and thickness, clearance of waste products, and removal of fluid.

Procedure for Hemodialysis

The needles used for HD are large bore, usually 14 to 16 gauge. They are inserted into the fistula or graft to obtain vascular access. One needle pulls blood from the circulation to the HD

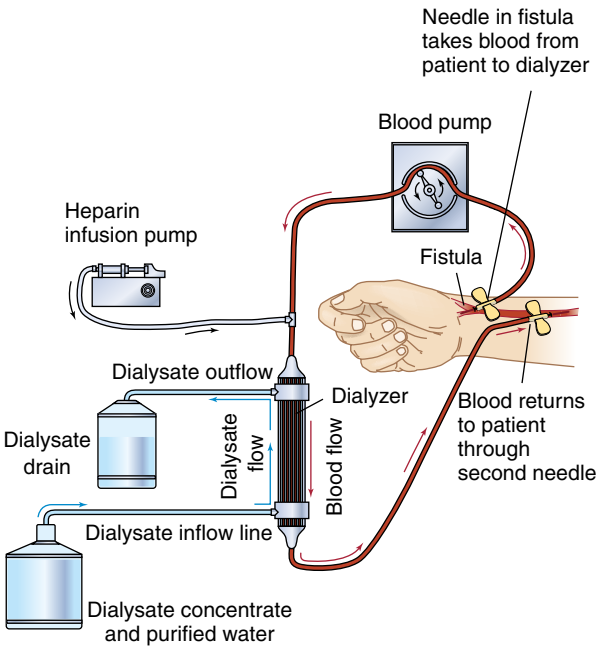

Fig. 51.12 Parts of a hemodialysis system. Blood is removed via a needle inserted in a fistula or via catheter lumen. A pump moves the blood to the dialyzer. Heparin is infused either as a predialysis bolus or through a heparin pump to prevent clotting. Dialysate flows in the opposite direction of the blood. The dialyzed blood is returned to the patient through a second needle or catheter lumen. Dialysate with waste products and ultrafiltrate are drained and discarded.

machine. The other needle returns the dialyzed blood to the patient. The needles are attached via tubing to dialysis lines. If a patient has a catheter, the 2 blood lines are attached to the 2 catheter lumens. The needle closer to the fistula (red catheter lumen) pulls blood from the patient to the dialyzer using a blood pump. Blood is returned from the dialyzer to the patient through the second needle (blue catheter lumen).[24]
