Vitreous humor is a transparent gel-like substance that fills the posterior cavity (Fig. 22.4). Any nontransparent substance in the vitreous will block light passing through the vitreous. The effect on vision varies, depending on the amount, type, and location of the substance blocking the light.

Retina

The retina lines the back of the eye, extending from the area of the optic nerve to the ciliary body (Fig. 22.4). Neurons make up most of the retina. This means retinal cells are unable to regenerate if destroyed. The retina converts images into a form that the brain can understand and process as vision.

The retina has 2 main parts, the peripheral retina and central retina. The central retina contains the macula and fovea. The macula is around 6 mm in diameter. It is responsible for the central visual field. The fovea is at the center of the macula. This area provides the sharpest visual acuity, which we need for activities in which detail is important, like reading and driving.

The retina contains light-sensitive structures called photoreceptor cells. There are 2 types of photoreceptors, rods and cones. Rods and cones convert light to neural signals, which the nervous system translates into vision. Rods are mostly found in the peripheral retina. They are responsible for most of our peripheral vision and night vision. Rods perceive only light and dark. They do not contribute to color vision. Cones are in the central retina, condensed mostly in the fovea. They are responsible for central vision and color vision. There are 3 types of cone cells: red, green, and blue. They all work together to create the full color spectrum.

The retina receives oxygen and nutrients from the choroid and the retinal vascular systems. The central retinal artery carries blood and nutrients into the retina. The central retinal vein carries blood away from the retina.

Optic Nerve

The optic nerve, or CN II, transmits vision information from the retina to the brain. The optic nerve begins at the optic disc. That is the region of the retina where the optic nerve and vessels leave the retina. Because there are no photoreceptor cells over the optic disc, there is an anatomic blind spot in this area. In the center of the optic disc is a white, cup-shaped area called the optic cup.

VISUAL PATHWAY

For light to reach the retina, it must pass through many structures: the cornea, aqueous humor, lens, and vitreous humor. These structures must be clear for light to reach the retina and stimulate the photoreceptor cells. Once the image travels through the refractive media, it is focused on the retina (Fig. 22.5). From the retina, the impulses travel through the optic nerve to the optic chiasm, where the nasal fibers of each eye cross over to the other side. Fibers from the left field of both eyes form the left optic tract and travel to the left occipital cortex. The fibers from the right field of both eyes form the right optic tract and travel to the right occipital cortex.

Gerontologic Considerations: Effects of Aging on the Visual System

Every structure of the visual system is subject to changes as a person ages. Many of these changes are not serious. Others may result in severely compromised visual acuity in the older adult. Table 22.1 shows age-related changes in the visual system and differences in assessment findings.

ASSESSMENT OF VISUAL SYSTEM

Assessing the visual system may be as simple as determining a patient's visual acuity or as complex as collecting complete subjective and objective data about the visual system. The patient in a clinic or office setting is often seeking routine eye care or a

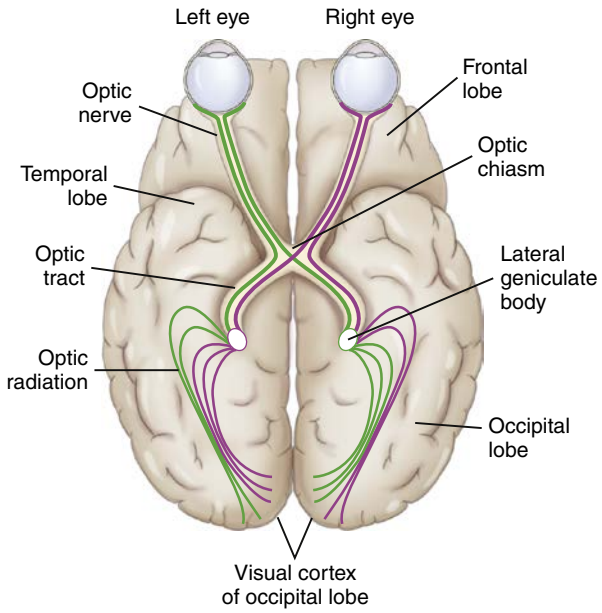

Fig. 22.5 The visual pathway. Fibers from the nasal portion of each retina cross over to the opposite side of the optic chiasma, ending in the lateral geniculate body of the opposite side. Location of a lesion in the visual pathway determines the resulting visual defect.

change in their eyewear prescription. However, the patient may have some underlying concerns that they do not mention or even recognize. To perform an appropriate visual assessment, determine what is necessary for the specific patient. While many of these assessments are within your scope of practice, some require special training.

Case Study

Patient Introduction

(© Jack Hollingsworth/Photodisc/Thinkstock.)

F.M. is an 81-year-old woman who comes to the emergency department with visual changes. F.M. states that her vision "looks like everything is covered with a spider web." She reports seeing periodic light flashes and small white spots "floating" in the air.

Discussion Questions

1. What are some possible causes of F.M.'s vision problems?
2. What type of assessment would be most appropriate for F.M.: comprehensive, focused, or emergency?
3. What assessment questions will you ask her?

You will learn more about F.M. and her condition as you read through this assessment chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Subjective Data

Important Health Information

Health history. Take a health history, including the ocular and nonocular history. The patient's nonocular history can be significant in assessing and treating an eye problem. Ask the patient about systemic diseases that may have eye manifestations. These include diabetes, hypertension, cancer, rheumatoid arthritis, syphilis and other sexually transmitted infections (STIs), acquired immunodeficiency syndrome (AIDS), muscular dystrophy, myasthenia gravis, multiple sclerosis, inflammatory bowel disease, and thyroid disease. Include any history of stroke or neurologic problems because these have the potential to result in visual field defects.

Obtain a history of tests for visual acuity. Include the date of the last examination and any change in glasses or contact lenses. Ask the patient about a history of strabismus, amblyopia, cataracts, retinal detachment, refractive surgery, or glaucoma. Note any trauma to the eye, its treatment, and sequelae.

Obtain information about allergies. Allergies often cause eye symptoms, such as itching, burning, watering, drainage, and blurred vision.

Medications. Obtain a complete medication history, including eyedrops. Many drugs effect the eye. For example, many cold preparations contain a form of epinephrine (e.g., pseudoephedrine) that can dilate the pupil. Note the use of any antihistamine or decongestant since these can cause dry eyes. Ask whether the patient uses corticosteroids, thyroid medications, or oral hypoglycemics and insulin. Long-term use of corticosteroid preparations can contribute to the development of glaucoma or cataracts.[1] Note whether the patient is taking any β-blockers, since β-blockers used to treat glaucoma can potentiate their effects. Hydroxychloroquine, which we use to treat rheumatoid arthritis and other autoimmune diseases, has the potential to result in retinal toxicity. It is important that these patients have annual eye examination.

Surgery or other treatments. Obtain a history of both ocular and nonocular surgeries. Include laser-based surgery and invasive treatments, such as retinal injections.

Functional Health Patterns

The focus of the functional health pattern assessment depends on the presence or absence of vision loss and whether the loss is permanent or temporary. Table 22.2 lists suggested health history questions related to the functional health patterns.

Health perception–health management pattern. Patient characteristics, such as gender, ethnicity, and age, are important in assessing eye problems (Box 22.1). Men are more likely to have color blindness. Age-related macular degeneration (AMD) occurs more often in women.

The patient's visual health can affect activities at home or at work. It is important to know how the patient perceives the current health problem. As outlined in Table 22.2, guide the patient in describing the current problem. Assess the patient's ability to perform self-care, especially any eye care related to the patient's eye problem.

The patient may not recognize the importance of eye-safety practices, such as wearing protective eyewear during potentially hazardous activities or avoiding noxious fumes and other eye irritants. Ask about the use of sunglasses in bright light. Prolonged exposure to ultraviolet (UV) light can affect the retina. Ask about night driving habits and any problems encountered. Today, millions of people wear contact lenses, but many do not care for them properly. The type of contact lenses and the patient's wearing and care habits may provide an opportunity for teaching.

Hereditary systemic diseases (e.g., sickle cell anemia) can significantly affect eye health. In addition, many refractive errors and other eye problems are hereditary. Determine whether the patient

TABLE 22.1 GERONTOLOGIC ASSESSMENT DIFFERENCES

Visual System

Changes	Differences in Assessment Findings
Eyebrows and Eyelashes	
Loss of pigment in hair	Graying of eyebrows, eyelashes
Eyelids	
Loss of orbital fat, decreased muscle tone	Entropion, ectropion
Tissue atrophy and stretching, prolapse of fat into eyelid tissue, loosening of the levator palpebrae superioris muscle	Dermatochalasis (excess upper lid skin), ptosis
Conjunctiva	
Tissue damage related to chronic exposure to ultraviolet light or to other chronic environmental exposure	Pinguecula (small yellowish spot usually on medial aspect of conjunctiva)
Sclera	
Lipid deposition	Scleral color yellowish as opposed to bluish
Cornea	
Cholesterol deposits in peripheral cornea	Arcus senilis (milky white-gray ring encircling periphery of cornea) (Fig. 22.6)
Tissue damage related to chronic exposure	Pterygium (thick, triangular bit of pale tissue that extends from inner canthus of eye to nasal border of cornea)
Decrease in water content, atrophy of nerve fibers	Decreased corneal sensitivity and corneal reflex
Epithelial changes	Loss of corneal luster
Accumulation of lipid deposits	Blurred vision
Lacrimal Apparatus	
Decreased tear secretion	Dryness
Malposition of eyelid and punctal eversion resulting in tears overflowing lid margins instead of draining through puncta	Tearing, irritated eyes
Iris	
Increased rigidity of iris	Decreased pupil size
Dilator muscle atrophy or weakness	Slow recovery of pupil size after light stimulation
Loss of pigment	Change of iris color
Ciliary muscle becoming smaller, stiffer	Decrease in near vision and accommodation
Lens	
Biochemical changes in lens proteins, oxidative damage, chronic exposure to ultraviolet light	Cataracts
Increased rigidity of lens	Presbyopia
Opacities in lens (also may be related to opacities in cornea and vitreous)	Reports of glare, night vision impaired
Accumulation of yellow substances	Yellow color of lens
Retina	
Retinal vascular changes related to atherosclerosis and hypertension	Narrowed, pale, straighter arterioles. Acute branching
Decrease in number of cones	Changes in color perception, especially blue and violet
Loss of photoreceptor cells, retinal pigment, epithelial cells, and melanin	Decreased visual acuity
AMD due to vascular changes	Loss of central vision, presence of yellow deposits, atrophy of macular retinal pigment
Vitreous	
Liquefaction and detachment of vitreous	Increased "floaters"

has a family history of eye problems, including cataracts, tumors, glaucoma, refractive errors (especially myopia, hyperopia), and retinal degenerative conditions (e.g., AMD, retinal detachment).

Nutritional-metabolic pattern. High doses of vitamins containing antioxidant, carotenoids, and omega-3 fatty acids (vitamins C and E, beta-carotene, zinc) may be important to eye health. Some patients with AMD may benefit from vitamin supplements.

Elimination pattern. Straining to defecate (Valsalva maneuver) can raise IOP. After eye surgery, many HCPs do not want patients to strain. Assess the patient's usual elimination pattern. Determine whether there is the potential for constipation in the patient who has had eye surgery.

Activity-exercise pattern. Reduced vision, symptoms accompanying an eye problem, or activity restrictions after surgery can affect the patient's usual level of activity or exercise.

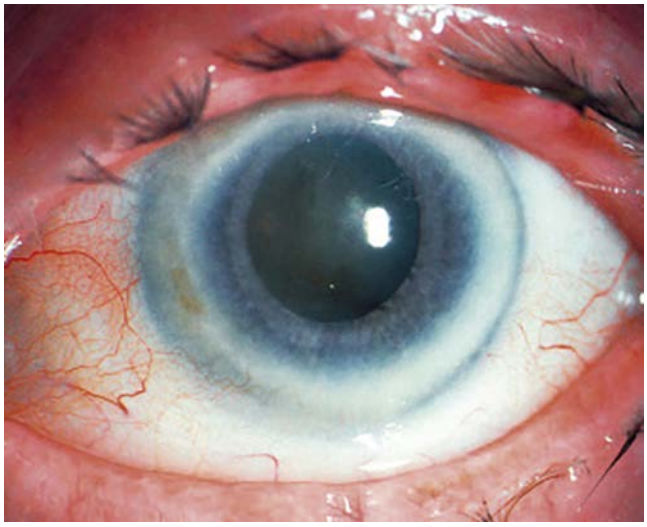

Fig. 22.6 Arcus senilis, or age-related degeneration of the cornea. (From Stein HA: Preliminary evaluation. *Ophthalmic Assistant*, 1:107, 2018.)

Ask about leisure activities during which the patient may incur an eye injury. For example, gardening, woodworking, and other craft activities can result in corneal or conjunctival foreign bodies or even penetrating injuries of the globe. Sports activities, such as racquetball, baseball, and tennis, carry risks for blunt trauma to the eyes. People should wear protection goggles for these sports.

Sleep-rest pattern. In the otherwise healthy person, lack of sleep may cause eye irritation, especially if the patient wears contact lenses. Painful eye problems, such as corneal abrasions, may disrupt normal sleep.

Cognitive-perceptual pattern. Assess for other cognitive or perceptual problems. For example, the functional ability of a patient with a visual deficit will be further compromised if the patient also has hearing problems. The patient who cannot see to read may find it harder to follow discharge instructions if they also have trouble hearing or remembering verbal instructions. Eye pain is always an important symptom to assess. If eye pain is present, ask the patient about treatment and response.

Self-perception–self-concept pattern. The loss of independence that can follow a partial or complete loss of vision, even if the condition is temporary, can have devastating effects on the patient's self-concept. Evaluate the potential effect of vision loss on the patient's self-image. For instance, disabling glare from a cataract may prevent nighttime driving. In today's highly mobile society, losing the ability to drive can represent a significant loss of independence and self-esteem.

Role-relationship pattern. Eye problems can negatively affect the patient's ability to take part in roles and responsibilities in the home, work, and social environments. For example, with decreased visual acuity, the patient may no longer adequately function at work. Many occupations place workers in conditions in which eye injury may occur. For example, factory workers may be at risk from flying metal debris. Eye-safety practices, such as the use of goggles or safety glasses, are now a legal requirement in some workplaces. The patient with diabetes may not be able to see well enough to self-administer insulin. This patient may resent dependence on a caregiver who takes over this function. Sensitively ask if the problem has affected the patient's preferred roles and responsibilities.

TABLE 22.2 HEALTH HISTORY

Visual System

Health Perception–Health Management
- Describe the change in your vision. Describe how this affects your daily life.
- Do you wear protective eyewear (sunglasses, safety goggles, hats)?[a]
- Do you wear contact lenses? If so, how do you take care of them?
- If you use eyedrops, how do you instill them?
- Do you have any allergies that cause eye symptoms?[a]
- Do you have a family history of cataracts, glaucoma, or macular degeneration?[a]

Nutritional-Metabolic
- Do you take any nutrition supplements?[a]
- Describe your diet.
- Does your visual problem affect your ability to obtain and prepare food?[a]

Elimination
- Do you have to strain to void or defecate?[a]

Activity-Exercise
- Are your activities limited in any way by your eye problem?[a]
- Do you take part in any leisure activities that have the potential for eye injury?[a]

Sleep-Rest
- Is your vision affected by the amount of sleep you get?[a]
- Does your eye problem affect your sleep?[a]

Cognitive-Perceptual
- Does your eye problem affect your ability to read?[a]
- Do you have any eye pain?[a]
- Do you have any eye itching, burning, or foreign body sensation?[a]

Self-Perception–Self-Concept
- How does your eye problem make you feel about yourself?

Role-Relationship
- Do you have any problems at work or home because of your eyes?[a]
- Have you made any changes in your social activities because of your eyes?[a]

Sexuality-Reproductive
- Has your eye problem caused a change in your sex life?[a]
- For women: Are you pregnant? Do you use birth control pills?[a]
- For men: Do you use any erectile dysfunction drugs? Any vision problems with their use?[a]

Coping-Stress Tolerance
- Do you feel able to cope with your eye problem?[a]
- How do you feel that your eye problem has affected your life? How do you cope with these changes?[a]

Value-Belief
- Do you have any conflicts about the treatment of your eye problem?[a]

[a] If yes, describe.

Sexuality-reproductive pattern. The patient with severe vision loss may develop such a poor self-image that they lose the ability to be sexually intimate. Assure the patient that low vision or blindness does not affect a person's ability to be sexually expressive. Often touch is more important than vision.

BOX 22.1 PROMOTING HEALTH EQUITY

Visual Problems

- Glaucoma is the leading cause of blindness among Blacks and Hispanics.[2]
- Hispanics, Blacks, and Native Americans have the highest incidence of diabetic retinopathy.
- Whites have the highest incidence of AMD.

Coping–stress tolerance pattern. The patient with temporary or permanent vision problems may have emotional stress. Assess the patient's coping methods and availability of support systems.

Value-belief pattern. Be sensitive to each patient's values and spiritual beliefs as these may guide decisions about eye care. It can be hard to understand why a patient refuses treatment that has potential benefit or wants treatment that may have limited potential benefit.

Case Study

Subjective Data

(© Jack Hollingsworth/Photodisc/Thinkstock.)

A focused subjective assessment of F.M. revealed the following information:

- ***History:*** Extraocular extraction of cataract on right eye with implantation of intraocular lens 2 months ago. Type 2 diabetes, hypothyroidism, and hypertension.
- ***Medications:*** Glucophage 500 mg twice daily, levothyroxine 100 mcg daily, metoprolol 50 mg daily.
- ***Health Perception–Health Management:*** States she used antibiotic and corticosteroid eyedrops after surgery as directed and followed up with surgeon. Recovery was uneventful. Stopping using eyedrops 2 weeks ago. Does not have allergies. Had excellent eyesight until today.
- ***Elimination:*** Has had problems moving bowels with increased straining. Trying prune juice to help.
- ***Activity-Exercise:*** Walks in the mall at least 1/2 mile 3 times a week. No resistance or isotonic exercises.
- ***Cognitive-Perceptual:*** Denies eye pain, itching, or tearing. Having difficulty reading.
- ***Coping–Stress Tolerance:*** Afraid she is having a stroke.

Discussion Questions

1. Which subjective assessment findings most concern you?
2. What should you include in the physical assessment? For what would you be looking?
3. How will you individualize the assessment based on her age and condition?

You will learn more about the physical assessment of the visual system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Objective Data

Physical Assessment

Physical assessment of the visual system includes inspecting the eye structures and determining the status of their respective functions. Physiologic functional assessment includes (1) assessing the patient's visual acuity, ability to judge closeness and distance, and extraocular muscle function; (2) evaluating visual fields; (3) checking pupil function; and (4) measuring IOP. Assessment should include examining the ocular adnexa, external eye, and internal structures. We assess some structures, such as the retina, blood vessels, and optic disc, with an ophthalmoscope.

TABLE 22.3 Normal Physical Assessment of Visual System

- Visual acuity 20/20 both eyes. No diplopia
- External eye structures symmetric and without lesions or deformities
- Lacrimal apparatus nontender and without drainage
- Conjunctiva clear. Sclera white
- PERRLA (pupils equal, round, reactive to light and accommodation)
- Lens clear
- EOMs intact (extraocular movements intact)

Normal physical assessment of the visual system is outlined in Table 22.3. Assessment techniques related to vision are described in Table 22.4. Table 22.5 shows select assessment abnormalities. We use a *focused assessment* (Box 22.2) to evaluate the status of previously identified vision problems and to monitor for signs of new problems.

Initial observation. Your initial observation of the patient can provide information that will help focus the assessment. A patient dressed in clothing with unusual color combinations may have a color-vision deficit. Note an unusual head position. The patient with diplopia may hold the head in a skewed position to try to see a single image. The patient with a corneal abrasion or photophobia will cover the eyes with the hands to try to block out room light. Make a crude estimate of depth perception by extending a hand for the patient to shake.

During the initial observation, observe the patient's overall facial and eye appearance. The eyes should be symmetric and normally placed on the face. The globes should not have a bulging or sunken appearance.

Assessing functional status

Visual acuity. Always record the patient's visual acuity. When doing your eye assessment, assess the right eye first and then the left eye. Note the patient's visual acuity before the patient receives any eye care.

To assess visual acuity, position the person on a mark exactly 20 feet (6 m) from the Snellen eye chart. If the person wears glasses or contacts, leave them on. Cover 1 eye at a time during the test. Ask the person to read down the lines of the chart to the smallest line of letters and numbers possible. Record the result using the numeric fraction at the end of the last successful line read. Indicate whether any letters were missed and if corrective lenses were worn (e.g., "Right eye, 20/30-2, with contacts"). Next ask the patient to cover the other eye and repeat the process. Normal visual acuity is 20/20. The first number indicates the distance the person is standing or sitting from the chart. The second number gives the distance at which a normal eye can read that line.

If the patient reports near vision problems or is 40 years of age or older, use a hand-held vision screener with varying print sizes (e.g., a Jaeger chart). Hold the card at 14 in (35 cm) from the eye in good light to assess near vision. Examine each eye separately, with glasses on if worn. A normal result is "14/14" in each eye, read without hesitancy and without the patient moving the card. If you must assess near visual acuity without access to a Jaeger eye chart, you can still make an accurate assessment using newsprint

TABLE 22.4 NURSING ASSESSMENT

Assessment Techniques: Visual System

Description	Purpose
Color Vision Testing	
In the Ishihara test, a patient identifies numbers or paths formed by pattern of dots in series of color plates.	Determines ability to distinguish colors
Confrontation Visual Field Test	
Patient faces examiner, covers 1 eye, fixates on examiner's face, and counts number of fingers that examiner brings into patient's field of vision.	Determines if patient has a full field of vision, without obvious blind spots or vision loss
Intraocular Pressure Testing: Tonometry	
Anesthetized corneal surface is gently touched several times with covered end of probe. Examiner records several readings to obtain a mean IOP.	Measures IOP. Normal pressure is 10–21 mm Hg
Keratometry	
Examiner aligns projection and notes readings of corneal curvature. Often done before fitting contact lenses, before refractive surgery, or after corneal transplantation.	Measures corneal curvature
Ophthalmoscopy	
Examiner holds ophthalmoscope close to patient's eye, shining light into back of eye and looking through aperture on ophthalmoscope. Examiner adjusts dial to choose the ophthalmoscope lens that produces desired amount of magnification to inspect retina.	Provides magnified view of retina and optic nerve (Fig. 22.7)
Pupil Function Testing	
Examiner shines light into patient's pupil and checks pupillary response. Each pupil is examined independently. Examiner checks for consensual and accommodative response.	Determines if patient has normal pupillary response
Visual Acuity Testing	
Patient reads from Snellen chart at 20 ft (distance vision test) or Jaeger chart at 14 in (near vision test). Examiner notes smallest print patient can read on each chart.	Determines distance and near visual acuity

or a container label. Record the acuity as "reads newspaper headline at X inches." If the patient is unable to read any of the lines on both the near and distant visual acuity charts, the next step is to assess whether they can see hand motion and light perception.

Extraocular muscle functions. Assess the corneal light reflex to evaluate for weakness or imbalance of the extraocular muscles. In a darkened room, ask the patient to look straight ahead while shining a penlight directly on the cornea. The light reflection should be in the center of both corneas as the patient faces the light source.

To assess eye movement, hold a finger or an object within 10 to 12 inches of the patient's nose. Ask the patient to follow with eyes only the movement of the object or finger in the 6 cardinal positions of gaze. This test can indicate weakness or paralysis in the extraocular muscles and cranial nerves (CN III, CN IV, and CN VI).

Pupil function and intraocular pressure. Pupil function is determined by inspecting the pupils and their reactions to light. We often abbreviate the normal finding as PERRL (pupils are equal [in size], round, and reactive to light). The pupils should react to light directly (pupil constricts when a light shines into the eye) and consensually (pupil constricts when a light shines into the opposite eye). In a small number of people, the pupils are normally unequal in size *(anisocoria)*.

To test for accommodation, ask the person to focus on a distant object. This process dilates the eyes. Then have the person shift the focus to a near object, such as your finger held about 3 inches from the person's nose. A normal response is constriction of the eyes and convergence (inward movement of both eyes toward each other). When you assess accommodation with the pupillary light reflex, a normal response is *PERRLA* (pupils are equal, round, and reactive to light and accommodation).

We measure IOP (Table 22.4) by a variety of methods, including tonometry. Normal IOP ranges from 10 to 21 mm Hg.

Assessing structures. We assess the visual system structures primarily by inspection. The visual system is unique because we can inspect not only the external structures but also many of the internal structures. The iris, lens, vitreous, retina, and optic nerve can be seen directly through the clear cornea and pupil opening. This direct inspection requires special observation equipment, such as the slit lamp microscope or ophthalmoscope. These allow us to examine the conjunctiva, sclera, cornea, anterior chamber, iris, lens, vitreous, and retina under magnification.

The *ophthalmoscope* is a hand-held instrument with a light source and magnifying lenses. It allows us to be able to see the posterior part of the eye. It is used to magnify the retina and optic nerves and bring them into crisp focus (Fig. 22.7). We can get vital information about the vascular system and CNS. Skilled use of this instrument takes practice.

Eyebrows, eyelashes, and eyelids. All structures should be present and symmetric, without deformities, redness, or swelling. Eyelashes extend outward from the lid margins. In normal closing, the upper and lower eyelid margins just touch. The lacrimal puncta should be open and positioned properly against the globe.

Conjunctiva and sclera. We can easily assess the conjunctiva and sclera at the same time. Assess the color and smoothness. Look for lesions or foreign bodies. The conjunctiva covering the sclera is normally clear, with fine blood vessels visible. These blood vessels are more common in the periphery.

The sclera is normally white. A slight yellow cast may be found in some dark-skinned people, such as Blacks and Native Americans, or in the older adult from lipid deposition. A pale blue cast caused by scleral thinning can be normal in older adults.

Cornea. The cornea should be clear, transparent, and shiny. The iris should appear flat and not bulge toward the cornea. The area between the cornea and iris should be clear, with no blood or purulent material visible in the anterior chamber.

Iris. Both irises should be of similar color and shape. However, a color difference between the irises occurs normally in a small number of people.

Retina and optic nerve. Examine the optic nerve or disc for size, color, and abnormalities. The optic disc is creamy yellow

TABLE 22.5 ASSESSMENT ABNORMALITIES

Visual System

Finding	Description	Possible Etiology and Significance
Subjective Data		
Blurred vision	Gradual or sudden inability to see clearly	Refractive errors, corneal opacities, cataracts, migraine aura, retinal changes (detachment, AMD)
Diplopia	Double vision	Abnormal extraocular muscle action related to muscle or cranial nerve pathologic condition
Dryness	Discomfort, sandy, gritty, irritation, burning	Decreased tear formation or changes in tear composition from aging or various systemic diseases
Pain	Foreign body sensation	Superficial corneal erosion or abrasion. Can result from contact lens wear or trauma. Conjunctival or corneal foreign body
	Severe, deep, throbbing	Anterior uveitis, acute glaucoma, infection. Acute glaucoma may cause nausea, vomiting
Photophobia	Persistent abnormal intolerance to light	Inflammation or infection of cornea or anterior uveal tract (iris and ciliary body)
Spots, floaters	Patient describes seeing spots, "spider webs," "curtain," or floaters within the field of vision	Most common cause is vitreous liquefaction (benign phenomenon). Other causes include hemorrhage into the vitreous humor, retinal holes or tears
Objective Data		
Eyelids		
Allergic reactions	Redness, excessive tearing, and itching of lid margins	Many possible allergens. Associated eye trauma can occur from rubbing itchy eyelids
Blepharitis	Redness, swelling, and crusting along lid margins	Bacterial invasion of lid margins. Often chronic
Dermatochalasis	Excess eyelid skin	May eventually obstruct superior and peripheral vision
Ectropion	Outward turning of lower lid margin	Age-related tissue changes, posttraumatic changes, facial paralysis
Entropion	Inward turning of upper or lower lid margin, unilateral or bilateral	Age-related tissue changes, posttraumatic changes, facial paralysis
Hordeolum (sty) (Fig. 22.8)	Small, superficial white nodule along lid margin	Infection of meibomian gland of eyelid. Causative organism is usually bacterial (most often *Staphylococcus aureus*)
Ptosis	Drooping of upper eyelid, unilateral or bilateral	Myasthenia gravis, congenital, or mechanical causes from eyelid tumors or excess skin
Conjunctiva		
Conjunctivitis	Redness, swelling of conjunctiva. May be itchy	Bacterial or viral infection. May be allergic response or inflammatory response to chemical exposure
Subconjunctival hemorrhage	Appearance of blood spot on sclera. May be small or can affect entire sclera	Conjunctival blood vessels rupture, leaking blood into the subconjunctival space.
Cornea		
Corneal abrasion	Localized painful disruption of the epithelial layer of cornea. Can be seen with fluorescein dye	Trauma. Overwear or improper fit of contact lenses
Globe		
Exophthalmos (Fig. 22.9)	Protrusion of globe beyond its normal position within bony orbit. Sclera often visible above iris when eyelids are open	Intraocular or periorbital tumors Hyperthyroidism
Pupil		
Abnormal response to light or accommodation	Pupils respond asymmetrically or abnormally to light stimulus or accommodation	CNS disorders, general anesthesia
Anisocoria	Pupils unequal, constricted	CNS disorders. Slight difference in pupil size is normal in some people
Extraocular Muscles		
Strabismus	Deviation of eye position in 1 or more directions	Overaction or underaction of 1 or more extraocular muscles
Lens		
Cataract	Opacification of lens. Pupil can appear cloudy or white when opacity is visible behind pupil opening	Aging, trauma, diabetes, long-term systemic corticosteroid therapy
Visual Field Defect		
Central	Loss of central vision	Macular disease
Peripheral	Partial or complete loss of peripheral vision	Glaucoma. Interruption of visual pathway (e.g., tumor, stroke). Migraine headache

BOX 22.2 FOCUSED ASSESSMENT

Visual System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Changes in vision (e.g., acuity, blurred)	Y	N
Eye redness, itching, discomfort	Y	N
Drainage from eyes	Y	N

Objective: Physical Assessment

Inspect

Eyes for any discoloration or drainage	✓
Conjunctiva and sclera for color and vascularity	✓
Lens for clarity	✓
Eyelid for ptosis	✓

Assess

Vision based on patient looking at nurse or Snellen chart	✓
Extraocular movements (EOMs)	✓
Peripheral vision	✓
PERRLA	✓

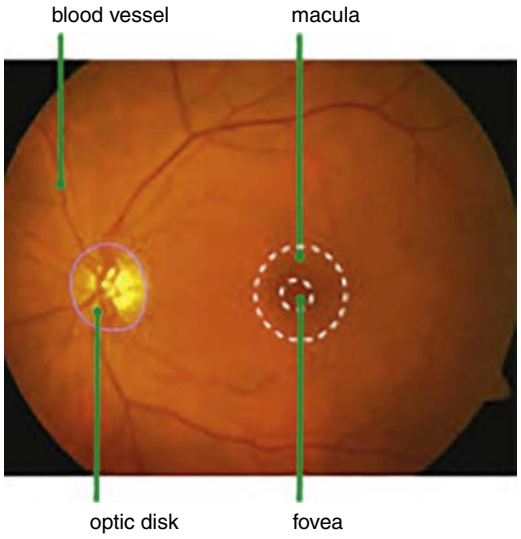

Fig. 22.7 Magnified view of retina. (From Acharya UR, Mookiah MR: Automated screening system for retinal health, *Computers in Biology and Medicine*, 75:54, 2016.)

with distinct margins. A central depression in the disc, called the *physiologic cup,* may be seen. This area is the exit site for the optic nerve. The cup should be less than half the diameter of the disc. Normally, no hemorrhages or exudates are present in the fundus (retinal background). Careful inspection of the fundus can reveal retinal holes, tears, detachments, or lesions. Small hemorrhages can occur with diabetes or hypertension. They can appear in various shapes, such as dots or flames. Finally, examine the macula for shape and appearance. This area normally has no blood vessels.

Special Assessment Techniques

Color vision. Testing the patient's ability to distinguish colors is an important part of the assessment. Some occupations require accurate color discrimination. The Ishihara color test assesses the patient's ability to recognize a pattern of color in a series of color plates.

Stereopsis. Stereoscopic vision allows a patient to see objects in 3 dimensions. An event that causes a patient to have monocular vision (e.g., enucleation, patching) results in the loss of stereoscopic vision. Without stereopsis, the person's ability to judge distances or the height of a step is impaired. This can have profound consequences if the person trips over a step when walking or follows too closely behind another vehicle when driving.

Case Study

Objective Data: Physical Assessment and Diagnostic Studies

(© Jack Hollingsworth/Photodisc/Thinkstock.)

F.M.'s physical assessment findings were as follows:

- PERRL. No abnormalities noted of external eye structures.
- EOMs intact and symmetric.

The HCP performs an ophthalmoscopic examination and finds a partial retinal detachment. Ultrasonography confirms the diagnosis.

Discussion Questions

1. Are these the diagnostic studies that you expected to be ordered?
2. Which diagnostic study results most concern you?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

DIAGNOSTIC STUDIES OF VISUAL SYSTEM

Diagnostic studies of the visual system provide vital information in monitoring the patient's condition and planning appropriate interventions. Table 22.6 presents common diagnostic studies of the visual system.

VISION PROBLEMS

Refractive Errors

Refraction is the eye's ability to bend light rays so that they fall on the retina. In the normal eye, parallel light rays are focused through the lens into a sharp image on the retina. When the light does not focus properly, we call it a refractive error. This defect prevents light rays from converging into a single focus on the retina. Defects are a result of irregularities of the corneal curvature, focusing power of the lens, or length of the eye.

Refractive errors are the most common vision problem. Blurred vision is the major symptom. In some cases, the patient may have eye discomfort, eyestrain, or headaches. Most refractive errors can be corrected using eyeglasses or contact lenses, refractive eye laser surgery, or surgical implantation of an artificial lens.

Myopia (nearsightedness) is an inability to accommodate for objects at a distance. It causes light rays to be focused in front of the retina. This means the person can see near objects but objects in the distance are blurry. Myopia may occur from excessive light refraction by the cornea or lens or an abnormally long eye. Myopia is the most common refractive error. Around 30% of Americans have myopia.[3] There is strong evidence that many people inherit myopia or the tendency to develop myopia.[3]

Hyperopia (farsightedness) is an inability to accommodate for near objects. It causes the light rays to focus behind the

TABLE 22.6 Diagnostic Studies

Visual System

Study	Purpose	Description and Nursing Responsibility
Amsler grid test	Monitors macular problems	Self-administered test using a hand-held card printed with a grid of lines (like graph paper) (Fig. 22.15). Using 1 eye at a time, patient fixates on center dot and notes any abnormalities of grid lines, such as wavy, missing, or distorted areas.
Fluorescein angiography	Provides information about flow of blood through retinal vessels	Fluorescein injected IV into peripheral vein followed by serial photographs (over 10-min period) of retina through dilated pupils If extravasation occurs, fluorescein is toxic to tissue. Tell patient that dye can sometimes cause transient nausea or vomiting. Yellow-orange discoloration of urine and skin may occur.
Perimetry (visual field) testing	Detects changes in central and peripheral vision	Person sits and looks inside a bowl-shaped instrument called a *perimeter.* While staring at the center of bowl, a light flashes. The person presses a button each time flash is seen. A computer records the results. A printout shows if there are areas where flashes of light were not seen.
Refractometry	Measures refractive error	Patient sits looking through apertures at Snellen acuity chart and lenses are changed. Patient chooses lenses that make acuity sharpest. Eye dilation may help visualize retina and optic nerves. Pupil dilation may last 3–4 hr, making it difficult to focus on near objects.
Ultrasonography	Assesses size and structure of eye	*A-scan* determines the right power of a lens implant before cataract surgery. *B-scan* used to diagnose pathologic conditions, including intraocular foreign bodies or tumors, vitreous opacities, retinal detachments.

retina, and the person must use accommodation to focus the light rays on the retina for near objects. The person with hyperopia can see distant objects clearly. This type of error occurs when the cornea or lens does not have adequate focusing power or the eyeball is too short.

Presbyopia is the loss of accommodation associated with age. One usually starts to notice this condition in the early to mid-40s. As the eye ages, the lens becomes larger, firmer, and less elastic. These changes, which progress with aging, result in an inability to focus on near objects.

Astigmatism is an uneven or irregular curvature of the cornea. The irregularity causes the incoming light rays to be bent unequally. Thus the light rays do not come to a single point of focus on the retina. This results in vision distortion. Astigmatism can occur in conjunction with any of the other refractive errors.

Aphakia is the absence of the lens. Rarely, the lens may be absent congenitally. It may be removed during cataract surgery. A lens that is traumatically injured is removed and replaced with an intraocular lens (IOL) implant. The absence of the lens results in a significant refractive error. Without the focusing ability of the lens, images are projected behind the retina.

Nonsurgical Corrections

Corrective glasses. The right corrective lenses can enhance vision in those with myopia, hyperopia, presbyopia, and astigmatism. Many people call glasses for presbyopia "reading glasses" because they are usually worn only for close work. Presbyopic correction may be combined with a correction for another refractive error, such as myopia or astigmatism. In these combined glasses, the presbyopic correction is in the lower part of the glass lens. A traditional bifocal or trifocal has visible lines. Many lenses that correct vision at various distances do not have visible lines. The prescription varies throughout the lens, allowing distance focusing in the top two-thirds and near focus in the bottom one-third of the lens.

Contact lenses. Contact lenses are another way to correct refractive errors. Contact lenses are made from various plastic and silicone substances. They are highly permeable to oxygen and have a high water content. These features allow for increased wearing time with greater comfort. If the oxygen supply to the cornea is decreased, it becomes swollen, visual acuity decreases, and the patient has severe discomfort.

In general, you need to know whether the patient wears contact lenses, the pattern of wear (daily or extended), and care practices. Shining a light obliquely on the eyeball can help you to see a contact lens. Contact lenses are associated with microbial keratitis, a severe sight-threatening complication. Risk factors for keratitis include poor hand cleaning, poor lens case hygiene, and inadequate lens cleaning. Teach the patient the importance of following recommended cleaning practices and reporting redness, sensitivity, vision problems, and pain to the eye care provider. Tell the patient to remove contact lenses at once if any of these problems occur.

Surgical Therapy

Surgery can eliminate or reduce the need for eyeglasses or contact lenses and correct refractive errors by changing the focus of the eye. Surgical management for refractive errors includes laser surgery and IOL implantation.

Laser. *Laser-assisted in situ keratomileusis* (LASIK) may be considered for patients with low to moderately high myopia or hyperopia, with or without astigmatism. The procedure first involves using a laser or surgical blade to create a flap in the cornea. The flap is folded back, exposing the middle section (stroma) of the cornea. Pulses from a computer-controlled laser vaporize a part of the stroma. The flap is then repositioned, adhering on its own without sutures in a few minutes.[4]

Photorefractive keratectomy (PRK) is indicated for low to moderate myopia or hyperopia, with or without astigmatism. It is a good option for a patient with insufficient corneal thickness for a LASIK flap. In PRK, the epithelium is removed, and the laser sculpts the cornea to correct the refractive error.

TABLE 22.7 Diagnostic Criteria

Classifications of Visual Impairment

Classification is based on the vision in the better eye with the best possible correction.

20/30 to 20/60	Mild vision loss or near-normal vision
20/70 to 20/160	Moderate visual impairment
20/200 or worse	Severe visual impairment
20/500 to 20/1000	Profound visual impairment
Less than 20/1000	Near-total visual impairment
No light perception	Total visual impairment or total blindness

Source: American Optometry Association. Retrieved from https://www.aoa.org/healthy-eyes/caring-for-your-eyes/low-vision-and-vision-rehab?sso=y.

Laser-assisted subepithelial keratomileusis (LASEK) is similar to PRK, except that the epithelium is replaced after surgery.

Implant. *Refractive intraocular lens* (refractive IOL) implantation is an option for patients with a high degree of myopia or hyperopia. Like cataract surgery, it involves removing the patient's natural lens and implanting an IOL. The IOL implant used is a special lens designed to correct the patient's refractive error. Refractive IOLs can correct both myopia and presbyopia.

Phakic intraocular lenses (phakic IOLs) are sometimes called *implantable contact lenses.* They are implanted into the eye without removing the eye's natural lens. They are used for patients with high degrees of myopia or hyperopia. Unlike refractive IOLs, the phakic IOL is placed in front of the eye's natural lens. Leaving the natural lens preserves the eye's ability to focus for reading vision.

VISUAL IMPAIRMENT

Visual impairment describes vision that cannot be fully corrected by corrective lenses, medical treatment, or surgery. Visual impairment includes conditions ranging from low vision to the absence of all vision (total blindness) (Table 22.7).

People with severe *v*isual impairment are unable to read ordinary print even with correction. They may or may not be legally blind. *Legal blindness* is defined as the best-corrected vision in the better eye of 20/200 or less or 20 degrees or less of remaining visual field. Most blindness in the United States is the result of common eye diseases, including cataracts, glaucoma, AMD, and diabetic retinopathy.

❖ NURSING MANAGEMENT: VISUAL IMPAIRMENT

◆ Assessment

It is important to assess how long the patient has had a visual impairment. Recent loss of vision has different implications for nursing care. Determine how the patient's visual impairment affects their functioning. Ask the patient about any problems with doing daily tasks. For example, how hard is it for the patient to read, use their phone, move around in their home, or watch television? Other questions can help to determine the personal meaning that the patient attaches to the visual impairment. Ask how the vision loss has affected specific aspects of the patient's life. Has the patient lost a job? What activities does the patient not engage in because of their vision?

Assess the patient's emotional reactions, coping methods, and support systems. The patient may attach many negative meanings to the impairment because of societal views of blindness. For example, the patient may view the impairment as punishment or view themselves as useless and burdensome.

BOX 22.3 PROMOTING POPULATION HEALTH

Responsible Eye Care

- Regular hand washing prevents the spread of disease from 1 eye to the other.
- Seeking appropriate health care can lead to early detection of disease and prevent further loss of vision in patients with certain types of partial vision loss.
- Wearing sunglasses and practicing proper nutrition may help to prevent cataract development and AMD.
- Wearing eye protection during potentially hazardous work, hobby, and sport activities reduces the risk for eye injuries.

◆ Clinical Problems

Clinical problems for the patient with visual impairment include:

- Sensory deficit
- Difficulty coping
- Impaired role performance

◆ Planning

The overall goals are that the patient with impaired vision will (1) make a successful adjustment to the impairment, (2) discuss feelings related to the loss, (3) identify personal strengths and support systems, and (4) use appropriate coping methods. If the patient has been functioning at an appropriate or acceptable level, the goal is to maintain the current level of function.

◆ Implementation

◆ Health Promotion

Encourage the patient with preventable causes of further visual impairment to seek appropriate health care (Box 22.3). For example, the patient with vision loss from glaucoma may be able to prevent further vision loss with prescribed therapies and eye examinations.

◆ Acute Care

Provide emotional support and direct care to the patient with recent visual impairment. Allow the patient to express fear, anger, and grief. Help the patient identify positive coping methods. Caregivers are intimately involved in the experiences that occur with vision loss. With the patient's knowledge and permission, include caregivers in discussions and encourage them to express their concerns.

TABLE 22.8 Sighted-Guide Technique

- Ask the patient whether they would like help.
- Stand slightly in front and to one side of the patient and offer an elbow for the patient to hold.
- Walk slightly in front of the patient at a pace that's comfortable for them.
- Serve as the sighted guide. As you walk, describe the environment to help orient the patient. For example, "We're going through an open doorway and approaching 2 steps down."
  - Give advance notice of stairs and whether they go up or down.
  - Tell the patient when you approach ground level.
  - Give advance notice of changes in ground surface (e.g., going from hard flooring to a carpeted area).
- Never guide someone into a seat backward. Help the patient sit by placing 1 of their hands on the back of the chair. Then, allow the patient to orient themselves to the chair independently.

Many people are uncomfortable around a person with visual impairment because they are not sure what behaviors are appropriate. Being sensitive to the patient's feelings without being overly worried or smothering the patient's independence is vital in creating a therapeutic nursing presence. Communicate in a normal conversational tone and manner with the patient and address the patient, not the caregiver. Introduce yourself and all people who approach the patient. It is important to say good-bye when leaving the patient's presence. Making eye contact with the patient achieves several goals. It ensures that you are speaking while facing the patient so that the patient has no difficulty hearing. Establishing eye contact ensures that you can observe the patient's facial expressions and reactions. Help the patient using *sighted-guide technique* (Table 22.8).

Ambulatory Care

In working with the patient who is visually impaired, remember that a person classified as legally blind may have some useful vision. Rehabilitation after partial or total loss of vision can foster independence, self-esteem, and productivity. Know what services and devices are available and make appropriate referrals. For the legally blind patient the primary resource for services is the appropriate state agency for rehabilitation. Legally blind persons are often eligible for federal and state assistance and income tax benefits. A list of agencies that serve the partially sighted or blind patient is available from the American Foundation for the Blind (www.afb.org).

Braille or audio books for reading and a cane or guide dog for ambulation are examples of vision substitution techniques. These are usually best for the patient with no functional vision. For most patients who have some remaining vision, vision enhancement techniques can help in learning to ambulate, read printed material, and perform ADLs.

Optical devices for vision enhancement. A wide range of technologies are available to help people with low vision. These devices include desktop video magnification/closed circuit units, electronic hand-held magnifiers, text-to-speech scanners (material read aloud to you), E-readers, and computer tablets (material read aloud, magnification, image zooming, brighter screen, voice recognition). Many of these devices require some training by an assistive technology professional. Encourage patients to practice with the device to ensure they can use it successfully.

Nonoptical methods for vision enhancement. *Approach magnification* is a simple way to enhance the patient's residual vision. Recommend that the patient sit closer to the television or hold books closer to the eyes. Contrast enhancement techniques include watching television in black and white, using a black felt-tip marker, and using contrasting colors (e.g., a red stripe at the edge of steps or curbs). Increased lighting can be provided by halogen lamps, direct sunlight, or gooseneck lamps that are aimed directly at the reading material or other near objects. Large type is often helpful, especially when used with other vision enhancements.

Non–24-hour sleep/wake disorder. A common problem that can occur in blind people, especially those who are totally blind, is *non–24-hour sleep/wake disorder (non-24)*. It is a circadian rhythm sleep disorder in which a person's biologic clock does not synchronize to a 24-hour day.[5] It is caused by lack of light input to the circadian clock.

People with non-24 have problems falling asleep or staying asleep at night. During the day, they may have an uncontrollable urge to sleep. This can result in severe sleep issues, including insomnia, excessive sleepiness, changing patterns of when a person sleeps, and social and work consequences.

Taking melatonin can shift the circadian clock earlier (an advance) or later (a delay). Tasimelteon (Hetlioz), a melatonin receptor agonist, also can be used for treatment. It works by targeting receptors in the brain that control the timing of the sleep/wake cycle.

Evaluation

The overall expected outcomes are that the patient with visual impairment will:

- Follow treatment plan to prevent further loss of vision
- Be able to use adaptive coping methods
- Maintain self-esteem and take part in social interactions
- Function safely within their environment

Gerontologic Considerations: Visual Impairment

The older adult is at an increased risk for vision loss caused by eye disease. They may have other deficits, such as limited mobility, that further affect the ability to function in usual ways. Societal devaluation of older adults may compound the self-esteem or isolation issues associated with visual impairment. Financial resources may be inadequate to secure vision services or assistive devices.

The older patient with vision loss is more likely to have cognitive problems.[6] The combination of decreased vision and confusion increases fall risk, which can have serious consequences. Decreased vision may compromise the older patient's ability to function, resulting in concerns about independence and a diminished self-image. Decreased manual dexterity may make instilling prescribed eyedrops hard. Those with low vision are more likely to make medication errors that are potentially dangerous, such as taking too much insulin or mistaking one drug for another.

EYE TRAUMA

Although the eyes are well protected by the bony orbit and fat pads, everyday activities can result in eye trauma. The most

common eye injuries in the United States are due to falls and fights. Injuries at home may be caused by cooking cleaning, gardening, power tool use, and home repair work. Sport- and work-related injuries are other causes of eye trauma.[7]

CHECK YOUR PRACTICE

You are working in your garden when your neighbor comes running into your yard. She is screaming and waving her arms. Her husband was using a chain saw to cut down a tree when a wood chip flew into his eye. When you go to your neighbor's yard, the husband is on the ground crying in pain. You assess the wood chip embedded in his eye.

- What should you do next?

Table 22.9 outlines the emergency management of the patient with an eye injury. Chemical burns can be devastating to the eye and need immediate attention. Alkaline chemicals with a pH greater than 7 are the most harmful. They can penetrate the eye and damage the inner components. Acidic chemicals with a pH of less than 7 are unable to penetrate the eye but can damage the cornea. Both types of injury have the potential to result in blindness.

A *Morgan lens* may be used to provide continuous irrigation of an injured eye. It consists of a sterile plastic device resembling a contact lens that floats over the eye (never physically touches it). The device is connected to tubing that delivers irrigating solution. The Morgan lens provides relief for chemical or thermal burns and removes nonembedded foreign materials in the eye.

Trauma is often a preventable cause of vision loss. Many eye injuries could be prevented by wearing protective eyewear. Your role in individual and community education is very important in reducing the incidence of eye trauma.

EXTRAOCULAR INFLAMMATION AND INFECTION

One of the most common eye conditions is inflammation or infection of the external eye. Many external irritants or microorganisms can affect the eye, conjunctiva, and cornea.

An external **hordeolum** (or a *sty*) is an infection of the meibomian glands in the lid margin (Fig. 22.8). The most common bacterial infective agent is *Staphylococcus aureus.* A red, swollen, circumscribed, and acutely tender area develops rapidly.

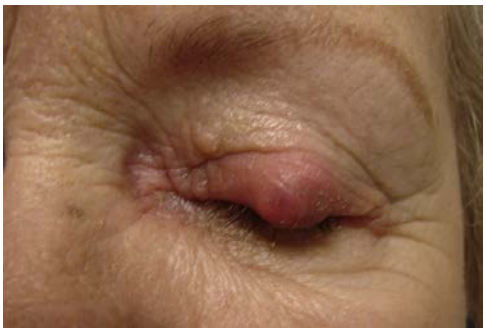

Fig. 22.8 Sty on the upper eyelid caused by staphylococcal infection. (Courtesy Stephen J. Laquis, MD, FACS Ophthalmic Facial Plastic Surgery Specialists, Fort Myers, FL.)

TABLE 22.9 EMERGENCY MANAGEMENT

Eye Injury

Etiology	Assessment Findings	Interventions
Chemical Burn • Acid • Alkaline **Foreign Bodies** • Ceramics • Glass • Metal • Plastic • Wood **Thermal Burn** • Direct burn from hot surface • Indirect burn from UV light (e.g., welding torch, looking directly at sun) **Trauma** • Blunt (e.g., fist) • Penetrating (e.g., glass, metal, or wood fragments; knife, stick, other object)	• Abnormal or decreased vision • Abnormal IOP • Absent eye movements • Blood in the anterior chamber • Fluid drainage from eye (e.g., blood, aqueous humor) • Pain • Photophobia • Prolapsed globe • Redness—diffuse or localized • Swelling • Tearing • Visible foreign body • Visual field defect	**Initial** • Determine mechanism of injury. • Ensure airway, breathing, and circulation. • Assess for other injuries. • Assess for chemical exposure. • Begin eye irrigation *immediately* in case of chemical exposure. Do not stop until emergency personnel arrive to continue irrigation. Use sterile saline or water if saline is unavailable. • Assess visual acuity. • Do not put pressure on the eye. • Tell patient not to blow nose. • Do not try to treat the injury (except as noted above for chemical exposure). • Stabilize foreign objects. • Cover the eye(s) with dry, sterile patches and a protective shield. • Do not give the patient food or fluids. • Elevate head of bed 45 degrees. • Give proper analgesia. **Ongoing Monitoring** • Reassure the patient. • Monitor pain. • Anticipate surgical repair for penetrating injury, globe rupture, or globe avulsion.

Have the patient apply warm, moist compresses at least 4 times a day until it improves. This may be the only treatment needed. If it tends to recur, teach the patient to do lid scrubs daily using eye scrub. On occasion, antibiotic ointments or drops may be needed.

A *chalazion* is a chronic inflammatory granuloma of the meibomian glands in the lid. It may evolve from a sty or occur in response to the material released into the lid when a blocked gland ruptures. The chalazion usually appears on the upper lid as a swollen, tender, reddened area that may be painful. Initial treatment is like that for a sty. If warm, moist compresses are not effective in promoting spontaneous drainage, the HCP may drain the lesion or inject it with corticosteroids.

Blepharitis is a common chronic bilateral inflammation of the lid margins. The lids are red rimmed with many scales or crusts on the lid margins and lashes. The patient mainly has itching. They may also have burning, irritation, and photophobia.

If a staphylococcal infection caused blepharitis, an eye antibiotic ointment must be used. Often blepharitis is caused by both staphylococcal and seborrheal microorganisms. The treatment must be more vigorous to avoid a sty, *keratitis* (inflammation of the cornea), and other eye infections. Emphasize good cleaning practices of the skin and scalp. Gentle cleansing of the lid margins with baby shampoo or lid scrubs can effectively soften and remove crusting.

Conjunctivitis

Conjunctivitis is an infection or inflammation of the conjunctiva. Infections may be bacterial or viral. Conjunctival inflammation may result from exposure to allergens or chemical irritants. Careful hand washing and use of individual or disposable towels help prevent spreading the condition.

Bacterial Infections

Acute bacterial conjunctivitis *(pinkeye)* is a common infection. Although it occurs in every age group, epidemics are common among children. *S. aureus* is the most common cause. The patient with pinkeye may have discomfort, pruritus, redness, and a mucopurulent drainage. Although it typically occurs initially in 1 eye, it generally spreads to the unaffected eye. It is usually self-limiting. Treatment with antibiotic drops may shorten the course. Teach patients the importance of hand washing and avoiding contact with an infected person.

Viral Infections

Many different viruses cause conjunctival infections. The patient with viral conjunctivitis may have tearing, foreign body sensation, redness, and mild photophobia. This condition is usually mild and self-limiting. However, it can be severe, with increased discomfort and subconjunctival hemorrhaging. Adenovirus conjunctivitis may be contracted in contaminated swimming pools and through direct contact with an infected patient.

Epidemic keratoconjunctivitis (EKC) is the most serious ocular adenoviral disease. EKC is spread by direct contact. In the medical setting, contaminated hands and instruments can be the source of spread. The patient may have tearing, redness, photophobia, and foreign body sensation. In most patients, the disease involves only 1 eye. Treatment is primarily palliative and includes ice packs, artificial tears, and dark glasses. Treatment for severe cases can include mild topical corticosteroids to temporarily relieve symptoms and topical antibiotic ointment. Teach the patient the importance of good hygiene practices to avoid spreading the disease.

Chlamydial Infections

Trachoma is a chronic conjunctivitis caused by *Chlamydia trachomatis* (serotypes A through C). It is a major cause of blindness worldwide. Trachoma is most often seen in underdeveloped countries. It is transmitted mainly by the hands and flies. Adult inclusion conjunctivitis (AIC) is caused by *C. trachomatis* (serotypes D through K).[8] AIC is becoming more prevalent in the United States due to the increase in sexually transmitted chlamydial infection. For unknown reasons, AIC does not carry the long-term consequences of trachoma.

Manifestations of both trachoma and AIC are mucopurulent eye discharge, irritation, redness, and lid swelling. Antibiotic therapy is usually effective for trachoma and AIC. Patients with AIC have a high risk for concurrent chlamydial genital infection and STIs that may need treatment.

Allergic Conjunctivitis

Conjunctivitis caused by exposure to an allergen can be mild and transitory, or it can be severe enough to cause significant swelling. The defining symptom of allergic conjunctivitis is itching. The patient may have burning, redness, and tearing. The patient may develop allergic conjunctivitis in response to pollens, animal dander, ocular solutions, and medications. Teach the patient to avoid known allergens if possible. Artificial tears can be effective in diluting the allergen and washing it from the eye. Topical medications include antihistamines and corticosteroids.

Keratitis

Keratitis is an inflammation or infection of the cornea. It is caused by a variety of microorganisms or by other factors. The condition may involve the conjunctiva and/or the cornea. When it involves both, the disorder is termed *keratoconjunctivitis.*

Bacterial Infections

The cornea can become infected by a variety of bacteria. Risk factors include mechanical or chemical corneal epithelial damage, contact lens wear, nutrition deficiencies, immunosuppressed states, and contaminated products (e.g., lens care solutions and cases, topical medications, cosmetics). Treatment includes topical antibiotics. In some cases, the patient may need subconjunctival antibiotic injection or, in severe cases, IV antibiotics.

Viral Infections

Herpes simplex virus keratitis (HSK) is the most common cause of corneal blindness in developed countries. It is a growing problem, especially with immunosuppressed patients. The corneal ulcer has a characteristic dendritic (tree-branching) appearance. Pain and photophobia are common.

Current treatment for HSK includes topical ganciclovir or trifluridine or oral or IV acyclovir or valacyclovir.[9] Treatment may also involve corneal debridement. Topical corticosteroids

Fig. 22.9 Exophthalmos. (Courtesy Stephen J. Laquis, MD, FACS Ophthalmic Facial Plastic Surgery Specialists, Fort Myers, FL.)

are usually contraindicated because they contribute to a longer course and possible deeper corneal ulceration.

The varicella-zoster virus (VZV) that causes chickenpox can affect the eye. Herpes zoster ophthalmicus (HZO) may occur by reactivation of a latent infection that persisted after an earlier attack of varicella or by contact with a patient with chickenpox or herpes zoster. It occurs most often in the older adult or immunosuppressed patient. Care of the patient with acute HZO includes antiviral agents. Oral antivirals started within 72 hours of symptom onset can reduce disease severity and complications. Other treatment includes analgesics for pain, topical corticosteroids to reduce inflammation, and mydriatic agents to dilate the pupil and relieve pain. The patient may apply warm compresses and povidone-iodine gel to the affected skin.

Other Causes of Keratitis

Keratitis may be caused by fungi, such as *Aspergillus, Candida,* and *Fusarium* species. This is especially true in the case of eye trauma in an outdoor setting where fungi are prevalent in the soil and moist organic matter.

Acanthamoeba keratitis is caused by a parasite that is associated with contact lens wear, usually from contaminated lens care solutions or cases. Homemade saline solution is particularly susceptible to *Acanthamoeba* contamination. Teach the patient who wears contact lenses about good lens care practices. Treatment is difficult because the organism is resistant to most drugs. Antifungal agents (e.g., ketoconazole) may be given. If antimicrobial therapy fails, the patient may need a corneal transplant.

Exposure keratitis occurs when the eyelids cannot adequately close. The patient with *exophthalmos* (protruding eyeball) from thyroid eye disease or masses posterior to the globe is susceptible to exposure keratitis (Fig. 22.9).

Corneal Ulcer

Tissue loss caused by a corneal infection produces a *corneal ulcer* (infectious keratitis) (Fig. 22.10). The infection can be due to bacteria, viruses, or fungi. Corneal ulcers are often painful. The patient may feel as if there is a foreign body in the eye. Other symptoms can include tearing, purulent or watery discharge, redness, and photophobia. Treatment is aggressive to avoid permanent vision loss. Antibiotic, antiviral, or antifungal eyedrops may be given as often as every hour for the first 24 hours. An untreated corneal ulcer can result in corneal scarring and perforation, or hole, in the cornea. A corneal transplant may be needed.

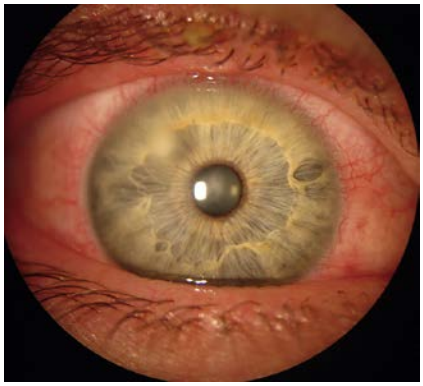

Fig. 22.10 Corneal ulcer. Infection associated with poor contact lens care. (Courtesy Cory J. Bosanko, OD, FAAO, Eye Centers of Tennessee, Crossville, TN.)

❖ NURSING MANAGEMENT: INFLAMMATION AND INFECTION

Assess for ocular changes. This include edema, redness, decreased visual acuity, feelings that a foreign body is present, and discomfort. Consider the psychosocial aspects of the patient's condition, especially when vision is impaired.

The patient's primary need is for information about prescribed care and how to perform that care. Careful asepsis and frequent, thorough hand washing are essential to prevent spreading organisms from 1 eye to the other, to other patients, to caregivers, and to health care team members. Teach the patient and caregivers how to avoid sources of eye irritation or infection and to respond appropriately if an eye problem occurs. The patient with infective disorders that may have a sexual mode of transmission needs specific information about those disorders.

Apply warm or cool compresses as needed. Darkening the room and giving an analgesic are other comfort measures. If the patient's visual acuity is decreased, modify the environment and activities for safety. Suggest alternative ways to perform daily activities and self-care.

The patient may need eyedrops as often as every hour. If the patient receives 2 or more different drops, stagger the eye drops to promote maximum absorption. For example, if 2 different eyedrops are ordered hourly, give 1 drop on the hour and 1 drop on the half hour (unless otherwise prescribed). The patient who needs to instill eyedrops frequently may have sleep deprivation. Review the proper technique for instilling eye drop.

Review the use and care of lenses and lens care products. Teach the patient who wears contact lenses and develops infections to discard all opened or used lens care products and cosmetics. This will decrease the risk for reinfection from contaminated products.

DRY EYE DISORDERS

Keratoconjunctivitis sicca (dry eyes) is a common problem, especially in older adults and people with certain systemic autoimmune diseases. These include scleroderma, systemic lupus erythematosus, and Sjögren syndrome. It is caused by a decrease in the quality or quantity of the tear film. Patients with dry eyes report irritation or "sand in my eye." The sensation typically worsens through the day.

Treatment is aimed at the underlying cause. With decreased tear secretion, the patient may use artificial tears or ointments. Cyclosporine ophthalmic emulsion (Restasis) helps to increase the eyes' natural ability to make tears. In severe cases, closure of the lacrimal puncta may be done.

STRABISMUS

Strabismus is a condition in which a person cannot consistently focus both eyes simultaneously on the same object. One eye may deviate in *(esotropia),* out *(exotropia),* up *(hypertropia),* or down *(hypotropia).* Strabismus in an adult may be caused by thyroid disease, neuromuscular problems of the eye muscles, retinal detachment repair, or cerebral lesions. The primary problem is double vision.

CORNEAL DISORDERS

Corneal Scars

Any wound (e.g., trauma, infection) to the cornea can cause it to become scarred and opacified, thus decreasing the normal transparency. The treatment is a corneal transplant.

Keratoconus

In *keratoconus,* the anterior cornea thins and bulges forward, taking on a cone shape. It usually occurs bilaterally. There is a familial tendency. Keratoconus usually appears during adolescence and slowly progresses between ages 20 and 60 years. The main symptom is blurred vision. Early treatment involves glasses or rigid contact lenses.

Intacs inserts are an option when contact lenses or glasses no longer help a patient achieve adequate vision. They are clear plastic lenses surgically inserted on the cornea to help flatten the bulge and improve vision. Collagen cross-linking uses UV light and special eye drops to strengthen collagen fibers in the cornea. Doing this helps to flatten or stiffen it, keeping it from bulging further. Sometimes, the cornea can perforate as central corneal thinning progresses. In these cases, a corneal transplant is done before the cornea can perforate.

Corneal Transplant

Around 52,000 corneal transplants (keratoplasty) are done in the United States each year. The surgery is one of the fastest and safest of all tissue or organ transplant surgeries.[10] The common indications involve corneal problems or eye injuries. These include ulceration, keratitis, scarring, and keratoconus. Types of corneal transplants include penetrating (full thickness) and lamellar (partial thickness).

Penetrating (full-thickness) cornea transplant involves transplanting all 3 layers of the cornea. In this procedure, the HCP removes the full thickness of the patient's cornea and replaces it with a donor cornea that is sutured into place (Fig. 22.11). Vision recovery may take up to 12 months.

During a *lamellar cornea transplant,* only some layers of the cornea are replaced with the transplant. This can include the deepest layer, called the *endothelium* (posterior lamellar cornea transplant). Versions of this procedure include Descemet stripping endothelial keratoplasty (DSEK) or Descemet membrane endothelial keratoplasty (DMEK). Lamellar transplants may be better than full penetrating transplants when the disease process is limited to only part of the cornea.

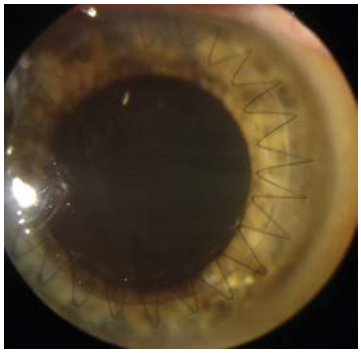

Fig. 22.11 Sutures on a donated cornea after penetrating keratoplasty (corneal transplant). (Courtesy Cory J. Bosanko, OD, FAAO, Eye Centers of Tennessee, Crossville, TN.)

The time between the donor's death and the removal of the tissue should be as short as possible. Eye banks test donors for human immunodeficiency virus (HIV), syphilis, and hepatitis B and C. The tissue is preserved in a special nutritive solution. Improved methods of tissue procurement and preservation, postoperative topical corticosteroids, and careful follow-up have decreased graft rejection. Matching the blood type of the donor and recipient improves the success rate.

INTRAOCULAR DISORDERS

CATARACT

A **cataract** is an opacity within the lens. The patient may have a cataract in 1 or both eyes. If cataracts are present in both eyes, one may affect the patient's vision more than the other. Cataract removal is the most common surgery in the United States.

Etiology and Pathophysiology

Most cataracts are age related *(senile cataracts).* Other factors include blunt or penetrating trauma, smoking, alcohol use, radiation or UV light exposure, certain drugs (e.g., steroids), and ocular inflammation. The rate of cataract development varies from patient to patient. The patient with diabetes tends to develop cataracts at a younger age.[11]

In senile cataract formation, altered metabolic processes within the lens cause an accumulation of water and changes in the lens fiber structure. These changes affect lens transparency, causing vision changes.

Clinical Manifestations and Diagnostic Studies

The patient with cataracts may have a decrease in vision, abnormal color perception, and glare. Glare is due to light scatter caused by the lens opacities. It may be significantly worse at night when the pupil dilates. Vision decline is gradual.

Diagnosis is based on decreased visual acuity or other vision problem. The opacity is directly observable by ophthalmoscopic or slit lamp microscopic examination. A totally opaque lens creates the appearance of a white pupil. Table 22.6 lists other diagnostic studies that may be helpful in evaluating a cataract.

TABLE 22.10 Interprofessional Care

Cataract

Diagnostic Assessment

- History and physical assessment
- Visual acuity measurement
- Ophthalmoscopy
- Slit lamp microscopy
- Glare testing, potential acuity testing in select patients
- Keratometry and A-scan ultrasound (if surgery is planned)
- Other tests (e.g., visual field perimetry) to determine cause of visual loss

Management

Nonsurgical

- Change in glasses prescription
- Strong reading glasses or magnifiers
- Increased lighting
- Lifestyle adjustment

Acute Care: Surgical Therapy

Preoperative

- Mydriatic, cycloplegic agents
- Nonsteroidal antiinflammatory drugs
- Topical antibiotics
- Antianxiety medications

Surgery

- Removal of lens
- Phacoemulsification
- Extracapsular extraction
- Correction of surgical aphakia
- Intraocular lens implantation (most frequent type of correction)
- Contact lenses

Postoperative

- Topical antibiotic
- Topical corticosteroid or other antiinflammatory agent
- Mild analgesia, if necessary
- Eye patch or shield and activity as prescribed

Interprofessional Care

Interprofessional care for cataracts is outlined in Table 22.10. Currently, no treatment is available to "cure" cataracts other than surgical removal. The presence of a cataract does not necessarily indicate a need for surgery. Often changing the patient's eyewear prescription can improve visual acuity, at least temporarily.

Other vision aids, such as strong reading glasses or magnifiers, may help the patient with near vision. Increasing the amount of light to read or do other near-vision tasks is useful. The patient may be willing to adjust their lifestyle to adjust to vision decline. For example, if glare makes it hard to drive at night, a patient may choose to drive only during daylight hours or to have a someone else drive at night. Sometimes, informing and reassuring the patient about the disease process makes the patient comfortable about choosing nonsurgical measures, at least temporarily.

Surgical therapy

When palliative measures no longer provide an acceptable level of vision function, the patient is a candidate for surgery. The patient's occupational needs and lifestyle changes are also factors affecting the decision to have surgery. In some instances, factors other than the patient's vision may influence the need for surgery. Lens-induced problems, such as increased IOP, may require lens removal. Opacities may prevent the HCP from getting a clear view of the retina in the patient with diabetic retinopathy or other sight-threatening problems. In those cases, the cataract is removed to allow retinal visualization and adequate management of the problem.

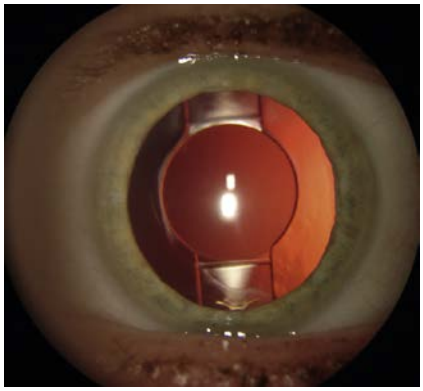

Fig. 22.12 Intraocular lens implant after cataract surgery. (Courtesy Cory J. Bosanko, OD, FAAO, Eye Centers of Tennessee, Crossville, TN.)

DRUG ALERT

Cycloplegics and Mydriatics

- Teach the patient to wear dark glasses to decrease photophobia.
- Monitor for signs of systemic toxicity (e.g., tachycardia, CNS effects).

Preoperative phase. Because most patients have local anesthesia, they do not need an extensive physical assessment. However, most patients with cataracts are older adults who may other medical problems that need evaluated and controlled before surgery. Most patients are admitted on an outpatient basis. The patient normally presents several hours before surgery to allow time for preoperative procedures.

The patient often receives 3 different eye drops before surgery. A *mydriatic* (α-adrenergic agonist) produces pupillary dilation (mydriasis) by contracting the iris dilator muscle. *Cycloplegics*, such as tropicamide (Mydriacyl), are anticholinergic agents. They block the effects of acetylcholine on the ciliary body and iris sphincter muscles. This produces mydriasis and paralysis of accommodation (cycloplegia).[11] Nonsteroidal antiinflammatory eyedrops reduce inflammation and edema. The patient may also receive antianxiety medication before surgery.

Intraoperative phase. The most common form of cataract surgery is *phacoemulsification.* In this procedure, a very small incision is made in the surface of the eye in or near the cornea. A thin ultrasound probe is inserted into the eye and ultrasonic vibrations are used to dissolve the clouded lens into fragments. These pieces are then suctioned out through the same ultrasound probe.[11] The small incisions are self-sealing and usually do not need sutures.

An *extracapsular cataract extraction procedure* is used for very advanced cataracts where the lens is too dense to dissolve into fragments. This technique requires a larger incision so that the cataract can be removed in 1 piece without being fragmented inside the eye. Sutures are needed to close the larger wound. Vision recovery is often slower.

Most patients have an IOL implanted at the time of cataract extraction surgery (Fig. 22.12). The lens of choice is a posterior chamber lens that is placed in the capsular bag behind the iris. At the end of the procedure, other drugs, such as antibiotics and corticosteroids, may be given.

Postoperative phase. Unless complications occur, the patient is usually ready to go home as soon as the effects of sedative agents have worn off. Postoperative medications include antibiotic drops to prevent infection and corticosteroid drops to decrease inflammation. The eyedrops are gradually reduced in frequency and then stopped when the eye has healed.

Recommendations for activity restrictions and nighttime eye shielding vary based on the HCP's preference. Many prefer that the patient avoid activities that increase the IOP. These include bending, stooping, coughing, and lifting.

After surgery, the HCP measures the patient's visual acuity, checks anterior chamber depth, assesses corneal clarity, and measures IOP at each visit. Even on the operative day, the patient's uncorrected visual acuity in the operative eye may be good. However, it is not unusual if the patient's visual acuity is reduced right after surgery. Multifocal IOL can correct for both near and far vision. Some patients may still need glasses or contact lenses to achieve their best visual acuity.

❖ NURSING MANAGEMENT: CATARACTS

◆ Assessment

Before surgery, obtain an appropriate history and physical assessment. Assess the patient's distance and near visual acuity. If the patient is going to have surgery, note the visual acuity in the patient's unoperated eye. Use this information to determine how visually compromised the patient may be while the operative eye is healing. Assess the psychosocial impact of the visual disability and the level of knowledge about the disease process and treatment options.

◆ Planning

Before surgery, the overall goals are that the patient with a cataract will (1) make informed decisions about treatment options and (2) have minimal anxiety. After surgery, the overall goals are that the patient with a cataract will (1) understand and follow discharge instructions, (2) maintain an acceptable level of physical and emotional comfort, and (3) remain free of infection and other complications.

◆ Implementation

◆ Health Promotion

There are no proven measures to prevent cataract development. However, it is wise to suggest that the patient wear sunglasses, avoid unnecessary radiation, and maintain appropriate intake of antioxidant vitamins (e.g., vitamins C, E) and good nutrition. Provide information about vision enhancement techniques for the patient who chooses not to have surgery.

◆ Acute Care

Before surgery, the patient with cataracts needs accurate information about the disease process and treatment options since cataract surgery is considered an elective procedure. Be available to the patient and caregiver to help them make an informed decision about treatment. For the patient having surgery, provide information, support, and reassurance about the surgical and postoperative experience to reduce anxiety. Photophobia is common when receiving pupil dilation medications. Therefore decreasing the room lighting is helpful. These medications produce transient stinging and burning.

TABLE 22.11 PATIENT & CAREGIVER TEACHING

After Eye Surgery

Include the following information in the teaching plan for the patient and caregiver after eye surgery:

- Proper hygiene and eye care techniques to ensure that dressings and/or surgical wound is not contaminated during eye care
- Signs and symptoms of infection (e.g., increased or purulent drainage, increased redness, any decrease in visual acuity) and when and how to report these to allow for early recognition and treatment of possible infection
- Importance of following restrictions on head positioning, bending, coughing, and Valsalva maneuver to optimize visual outcomes and prevent increased IOP
- How to instill eye medications using aseptic technique and adherence with prescribed eye medication routine to prevent infection
- How to take pain medication and report pain not relieved by medication
- Importance of continued follow-up to maximize potential visual outcomes
- Measures to cope with visual loss, such as large screens, audiobooks, and additional lighting, and promote safety

Patients who have cataract surgery remain at the agency for only a few hours. The patient and caregiver are responsible for almost all postoperative care. Give them written and verbal instructions before discharge. Include the caregiver in the instructions because some patients may have difficulty with self-care activities, especially if the vision in the unoperated eye is poor. Table 22.11 outlines patient and caregiver teaching after eye surgery. A nursing care plan for the patient after eye surgery (eNursing Care Plan 22.1) is available on the website for this chapter.

After cataract surgery, the patient usually has little or no pain. Mild analgesics are usually enough to relieve any pain. If the pain is intense, the patient should notify the HCP because this may indicate hemorrhage, infection, or increased IOP. They may have some scratchiness or blurriness in the operative eye. Remind them not to rub or scratch their eyes.

Most patients have little visual impairment after surgery. IOL implants provide immediate visual improvement. Many patients achieve a usable level of visual acuity within a few days after surgery.

A few patients may have significant visual impairment after surgery. They may need several weeks to achieve a usable level of visual acuity. These include patients who do not have an IOL implanted at the time of surgery and those with poor vision in their unoperated eye. For those patients, the time between surgery and receiving glasses or contacts can be a period of significant visual disability. Suggest ways the patient and caregiver can modify activities and the environment to maintain an adequate level of safe functioning. Suggestions may include getting help

with steps, removing area rugs and other potential obstacles, preparing meals for freezing before surgery, or obtaining audio books for diversion until visual acuity improves.

If a patch is used, tell patients that they will not have depth perception until the patch is removed. This makes special measures to avoid falls or other injuries necessary. The patient with significant visual impairment in the unoperated eye needs more help while the operative eye is patched. Some patients may need 1 or 2 weeks for the visual acuity in the operated eye to reach an adequate level for most vision needs. These patients need special assistance until the vision improves.

Evaluation

The overall expected outcomes are that the patient after cataract surgery will:

- Have improved vision
- Be better able to take care of self
- Have minimal to no pain
- Be optimistic about expected outcomes

Gerontologic Considerations: Cataracts

Most patients with cataracts are older. When the older patient is visually impaired, even temporarily, the patient may have a loss of independence, lack of control over their life, and a significant change in self-perception. Societal devaluation of the older adult complicates these experiences. The older patient often needs emotional support and encouragement, as well as specific suggestions to allow a maximum level of independent function. Assure the older patient that cataract surgery can be done safely and comfortably with minimal sedation.

RETINOPATHY

Retinopathy is a process of microvascular damage to the retina. It can lead to blurred vision and progressive vision loss. Retinopathy may develop slowly or rapidly. It occurs most often in adults with diabetes or hypertension.

Diabetic retinopathy is a common complication of diabetes, especially in patients with long-standing uncontrolled disease.[12] *Nonproliferative retinopathy* is the most common form of diabetic retinopathy. It is characterized by capillary microaneurysms, retinal swelling, and hard exudates. Macular edema represents a worsening of the retinopathy as plasma leaks from macular blood vessels. As capillary walls weaken, they can rupture, leading to intraretinal "dot or blot" hemorrhaging (Fig. 22.13). A severe loss in central vision can result. As the disease advances, *proliferative retinopathy* may occur. New blood vessels grow, but they are abnormal, fragile, and predisposed to leak, thus causing severe vision loss. Diagnosis and treatment of diabetic retinopathy are discussed in Chapter 53.

Hypertensive retinopathy is caused by blockages in retinal blood vessels from hypertension. These changes may not affect a person's vision at first. On a routine eye examination, retinal hemorrhages, anoxic cotton-wool spots, and macular swelling can be seen. Sustained, severe hypertension can cause sudden vision loss from swelling of the optic disc and nerve *(papilledema)*. Treatment, which may be an emergency, focuses on lowering the BP. Normal vision is usually restored by treating hypertension (see Chapter 36).

Fig. 22.13 Diabetic retinopathy. Intraretinal dot or blot hemorrhages. (Courtesy Cory J. Bosanko, OD, FAAO, Eye Centers of Tennessee, Crossville, TN.)

RETINAL DETACHMENT

A **retinal detachment** is a separation of the sensory retina and the underlying pigment epithelium, with fluid accumulation between the 2 layers. A retinal detachment is an emergency. If it is not treated quickly, more of the retina can detach. This increases the risk of permanent vision loss or blindness.

Etiology and Pathophysiology

We classify retinal detachments based on the cause. The most common is a retinal break. *Retinal breaks* are an interruption in the full thickness of the retinal tissue. They can be classified as tears or holes. *Retinal holes* are small breaks that occur spontaneously. *Retinal tears* can occur as the vitreous humor shrinks during aging and pulls on the retina. The retina tears when the traction force exceeds the strength of the retina. Once the retina has a break, liquid vitreous can enter the subretinal space between the sensory layer and the retinal pigment epithelium layer. The fluid lifts the retina away from the underlying tissue, causing a *rhegmatogenous* retinal detachment.

Nonrhegmatogenous detachments include tractional and exudative detachments.[13] Tractional detachments are caused by scar tissue that grows on the surface of the retina. It pulls the retina off the back wall of the eye. This may occur from diabetes. Exudative detachments are often caused by AMD, a tumor, blunt injury to the eye, or an inflammatory disorder.[13] Risk factors for retinal detachment are listed in Table 22.12.

Clinical Manifestations and Diagnostic Studies

Patients with a detaching retina describe symptoms that include flashes of light, floaters (small flecks), and a "cobweb," "hairnet," or ring in the field of vision. Once the retina has detached, the patient describes a gradual loss of peripheral or central vision, "like a curtain" coming across the field of vision. There is no pain.

The area of visual loss corresponds inversely to the area of detachment. For example, if the retinal detachment involves the

TABLE 22.12 Risk Factors for Retinal Detachment

- Age
- AMD
- Diabetic retinopathy
- Eye surgery
- Eye trauma
- Family or personal history of retinal detachment
- Severe myopia
- Thinning of the peripheral retina

Source: National Eye Institute, National Institutes of Health: Retinal detachment. Retrieved from https://www.nei.nih.gov/learn-about-eye-health/eye-conditions-and-diseases/retinal-detachment.

superior retina, the defect is seen in the inferior visual field. If the detachment is small or develops slowly, the patient may not be aware of a visual problem.

Visual acuity measurements should be the first diagnostic procedure with any report of vision loss (Table 22.13). The HCP can see a retinal detachment using direct and indirect ophthalmoscopy or slit lamp microscopy in conjunction with a special lens to view the far periphery of the retina. Ultrasound may be useful in finding a retinal detachment if the eye care provider cannot see retina (e.g., when the cornea, lens, or vitreous is hazy or opaque).

TABLE 22.13 Interprofessional Care

Retinal Detachment

Diagnostic Assessment
- History and physical assessment
- Visual acuity measurement
- Ophthalmoscopy
- Slit lamp microscopy
- Ultrasound if cornea, lens, or vitreous is hazy or opaque

Management

Preoperative
- Mydriatic, cycloplegic agents
- Photocoagulation of retinal break that has not progressed to detachment

Surgery
- Laser photocoagulation
- Cryopexy
- Scleral buckling
- Vitrectomy
- Intravitreal bubble

Postoperative
- Topical antibiotics
- Topical corticosteroid
- Analgesia
- Mydriatics
- Positioning and activity as prescribed

Interprofessional Care

Some retinal breaks are not likely to progress to detachment. In these situations, the HCP simply monitors the patient and teaches them to seek immediate evaluation if warning signs and symptoms of impending detachment occur. The goals of treatment are to seal any retinal breaks and reattach the retina.[11] Several techniques are used to meet these goals.

Surgical Therapy

Laser photocoagulation and cryopexy. Retinal tears or holes without accompanying detachment may be treated by sealing the retina to the posterior wall using photocoagulation or cryopexy.[13] Photocoagulation uses a laser to make small burns around the retinal tear. Cryopexy uses a special freezing probe to apply intense cold around the tear. The probe is activated with compressed nitrous oxide gas that temporarily freezes the break. The freeze-thaw reaction creates scarring in the area. In both procedures, the resulting scar tissue seals the retina to prevent a detachment.

For retinal breaks accompanied by significant detachment, photocoagulation or cryopexy may be used with scleral buckling. When used alone, laser photocoagulation and cryopexy therapy are outpatient procedures. They usually require topical anesthesia. The patient may have minimal adverse symptoms during or after the procedure.

Scleral buckling. *Scleral buckling* is an extraocular surgical procedure that involves placing a band around the globe to move the pigment epithelium, choroid, and sclera toward the detached retina. A silicone implant is sutured against the sclera, causing the sclera to buckle inward. An encircling band may be placed over the implant if there are multiple retinal breaks, if suspected breaks cannot be found, or if there is widespread inward traction on the retina (Fig. 22.14). If present, subretinal fluid may be drained using a small-gauge needle. This promotes contact between the retina and buckled sclera. Scleral buckling is usually done as an outpatient procedure.

Intraocular procedures. Intraocular procedures are used on occasion. *Pneumatic retinopexy* is the intravitreal injection of a gas to form a temporary bubble in the vitreous. The bubble closes retinal breaks and provides opposition of the separated retinal layers. Because the intravitreal bubble is temporary, this technique is combined with laser photocoagulation or cryopexy. The patient with an intravitreal bubble must position the head so that the bubble is in contact with the retinal break. The patient may need to maintain this position as much as possible for up to several weeks.

Vitrectomy is the surgical removal of the vitreous. It may relieve traction on the retina, especially when the traction results from proliferative diabetic retinopathy. Vitrectomy may be combined with scleral buckling to provide a dual effect in relieving traction.

Postoperative considerations. Vision prognosis varies. It depends on the extent, length, and area of detachment. After surgery, the patient may be on bed rest and need special positioning to maintain proper position of an intravitreal bubble. The level of activity restriction after retinal detachment surgery varies. Verify the prescribed level of activity with the HCP and help the patient plan for any help needed related to activity restrictions.

The patient may need multiple topical medications, including antibiotics, antiinflammatory agents, or dilating agents. Give prescribed pain medications. Teach the patient to take the medication as prescribed after discharge.

In most cases, retinal detachment is an urgent situation. The patient is suddenly confronted with the need for surgery. The patient needs emotional support, especially during the immediate preoperative period when surgery preparations can lead to more anxiety.

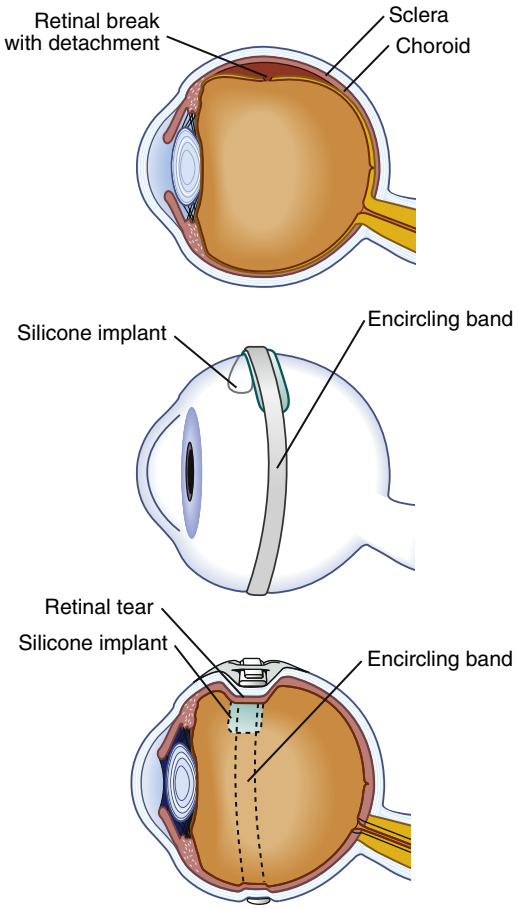

Fig. 22.14 Retinal break with detachment and surgical repair by scleral buckling technique.

The patient may go home within a few hours of surgery or stay in the hospital for several days, depending on the HCP and type of repair. Discharge planning and teaching are important and should begin early. Table 22.11 discusses patient and caregiver teaching after eye surgery. Because the patient is at increased risk for retinal detachment in the other eye, teach the patient the signs and symptoms of retinal detachment. Promote the use of protective eyewear to help avoid damage related to trauma.

AGE-RELATED MACULAR DEGENERATION

Age-related macular degeneration (AMD) is a leading cause of irreversible central vision loss. AMD is classified as dry (nonexudative) or wet (exudative). *Dry AMD* is the more common form, accounting for 90% of all cases. Those with dry AMD often notice that close vision tasks become harder. In dry AMD, the macular cells start to atrophy. This leads to a slowly progressive and painless vision loss.

Wet AMD is the more severe form. It accounts for most cases of AMD-related blindness. Wet AMD has a more rapid onset of vision loss. With wet AMD there is the development of abnormal blood vessels in or near the macula. Many patients with wet AMD have dry AMD first.

Etiology and Pathophysiology

AMD is related to retinal aging. Other risk factors include family history, obesity, hypertension, and being White. Smoking significantly increases the risk of AMD, with a dose response relationship. The risk increases with an increased number of pack-year exposure.[14]

Dry AMD starts with the abnormal accumulation of yellowish extracellular deposits called *drusen* in the retinal pigment epithelium. Over time, atrophy and degeneration of macular cells occur. In wet AMD, vascular endothelial growth factor (VEGF) promotes the growth of new blood vessels in an abnormal location in the retinal epithelium. As the new blood vessels grow, they leak fluid and can bleed. This causes scar tissue to gradually form.

Clinical Manifestations and Diagnostic Studies

The patient may have blurred and darkened vision, *scotomas* (blind spots in the visual field), and *metamorphopsia* (vision distortion). Vision distortion includes the illusion that straight lines, such as the edge of a door or sentences on a page, are wavy or that some objects are smaller than they really are. If only 1 eye is affected, the patient may not notice early changes in vision. Acute vision loss may occur from either form.

In addition to visual acuity measurement, the primary diagnostic procedure is ophthalmoscopy. The HCP looks for drusen and other fundus changes associated with AMD. The Amsler grid test may help define the involved area. It provides a baseline for future comparison (Fig. 22.15). Fundus fluorescein angiography and/or indocyanine green dyes may help to further determine the extent and type of AMD. Retinal anatomy can be analyzed using optical coherence tomography (OCT), which looks at pathology in the macula, or scanning laser ophthalmoscopy.

Interprofessional Care

The goals of care are to reverse or minimize vision loss and improve vision function. Visual prognosis varies greatly. Treatment options for patients with wet AMD include medications that are injected directly into the vitreous cavity. Ranibizumab (Lucentis), bevacizumab (Avastin), aflibercept (Eylea), and pegaptanib (Macugen) inhibit VEGF. This helps to slow vision loss by stopping new vessels from forming.[14] Side effects can include blurred vision, eye irritation, eye pain, and photosensitivity. Injections are given at 4- to 6-week intervals, depending on treatment response. Disease stability is determined by OCT. The findings determine the need for continued intravitreal injections.

Verteporfin (Visudyne) IV is part of photodynamic therapy (PDT) to treat wet AMD. Laser light shone into the eye activates verteporfin and causes it to create blood clots that block the abnormal blood vessels. By sealing the leaky blood vessels, PDT slows down central vision loss. Until the body completely excretes the drug, it can be activated by exposure to sunlight or other high-intensity light, such as halogen. The patient must avoid direct exposure to sunlight and other intense forms of light for 5 days after treatment. Exposing the skin to sunlight could activate the drug in that area, causing a chemical burn.

Taking a supplement of antioxidant vitamins (e.g., vitamin C, vitamin E), lutein, zeaxanthin, and zinc may help slow the progression of AMD.[14] Teach the patient to eat dark green, leafy vegetables

containing lutein (e.g., kale, broccoli, spinach) and foods, such as beef, pork, dairy, and whole grains, that are high in zinc. Smoking cessation may help in halting the progression of dry AMD.

The management of the patient with visual impairment is appropriate for the patient with AMD. Many patients with low-vision assistive devices can continue reading and keep a license to drive during the daytime and at lowered speeds. The permanent loss of central vision has significant psychosocial implications for nursing care. Avoid giving the impression that "nothing can be done" about the problem when caring for the patient with AMD. Although treatment may not recover lost vision, much can be done to augment the remaining vision.

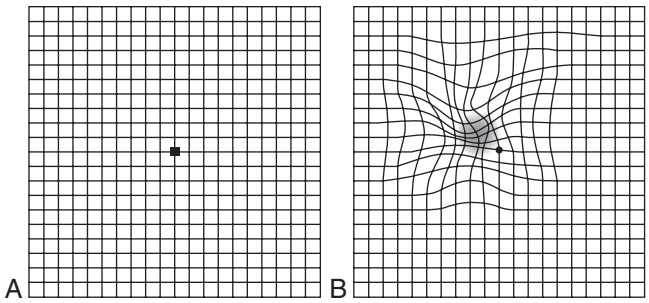

Fig. 22.15 Amsler grid. (A) Normal grid. (B) Abnormal grid as seen by person with AMD.

GLAUCOMA

Glaucoma is a group of disorders characterized by increased IOP and its consequences, optic nerve atrophy, and peripheral visual field loss. Glaucoma is the second leading cause of permanent blindness in the United States and the leading cause of blindness among Blacks.[2] Many people with glaucoma are unaware of their condition. The incidence of glaucoma increases with age. Genetic factors play a role in some types of glaucoma.

Etiology and Pathophysiology

A proper balance between the rate of aqueous production *(inflow)* and the rate of aqueous reabsorption *(outflow)* is essential to maintain the IOP within normal limits. We call the place where the outflow occurs the *angle* because it is the angle where the iris meets the cornea. When the rate of inflow is greater than the rate of outflow, IOP can increase above the normal limits. If IOP stays increased, permanent vision loss may occur.

Primary open-angle glaucoma (POAG) is the most common type of glaucoma. In POAG the outflow of aqueous humor is decreased in the trabecular meshwork. The drainage channels become clogged, like a clogged kitchen sink.[15] Damage to the optic nerve can then result.

Angle-closure glaucoma (ACG) is due to a reduction in the outflow of aqueous humor that results from angle closure. Usually, this is caused by the lens bulging forward from the aging process. Angle closure may also occur due to pupil dilation in the patient with anatomically narrow angles. Acute angle-closure glaucoma (AACG) may be precipitated by situations in which the pupil stays partially dilated long enough to cause an acute and significant rise in the IOP. This may occur with drug-induced mydriasis, emotional excitement, or darkness. Drug-induced mydriasis may occur from topical eye preparations or many systemic medications (both prescription and OTC). Check medication records before giving medications to the patient with ACG. Teach the patient not to take any mydriatic medications.

Clinical Manifestations

POAG develops slowly and without symptoms of pain or pressure. The patient usually does not notice the gradual visual field loss until peripheral vision has been severely compromised.[15] Eventually, the patient with untreated glaucoma has "tunnel vision," with only a small center visual field. All peripheral vision is absent.

AACG causes definite symptoms, including sudden, severe pain in or around the eye. The patient often has nausea and vomiting. Vision symptoms include seeing colored halos around lights, blurred vision, and eye redness.

Manifestations of subacute or chronic ACG appear more gradually. The patient who had a previous, unrecognized episode of subacute ACG may report blurred vision, seeing colored halos around lights, eye redness, or eye or brow pain.

Diagnostic Studies

IOP is usually increased in glaucoma above the normal 10 to 21 mm Hg. In POAG, IOP is usually between 22 and 32 mm Hg. In AACG, IOP may be more than 50 mm Hg. Measurements are repeated over time to verify the elevation.

In POAG, slit lamp microscopy reveals a normal angle. In ACG, there may be a markedly narrow or flat anterior chamber angle, an edematous cornea, a fixed and moderately dilated pupil, and ciliary injection (hyperemia of the ciliary blood vessels produces a red color).

Measures of peripheral and central vision provide more diagnostic information. Perimetry produces a complete map of the patient's visual field. It may reveal subtle changes in peripheral vision early in the disease process. In ACG, central visual acuity is reduced if the patient has corneal edema, and the visual fields may be markedly decreased. Central acuity may remain 20/20 even in the presence of severe peripheral visual field loss. As glaucoma progresses, *optic disc cupping* may be one of the first signs of chronic POAG. The optic disc becomes wider, deeper, and paler (light gray or white). This is visible with direct or indirect ophthalmoscopy (Fig. 22.16).

Interprofessional Care

The primary focus of treatment is to keep the IOP low enough to prevent the patient from developing optic nerve damage. Treatment varies with the type of glaucoma. The diagnostic and interprofessional care of glaucoma is outlined in Table 22.14.

Chronic Open-Angle Glaucoma

Drug therapy is the initial treatment in POAG (Table 22.15). The patient must understand that continued treatment and supervision are needed because the drugs control, but do not cure, glaucoma. Because of their superior efficacy and systemic safety, prostaglandin analogs are the preferred choice for initial treatment.

Many patients with glaucoma have systemic illnesses or take systemic medications that may affect their therapy. The patient

taking a β-adrenergic blocking glaucoma agent may have an additive effect if they also take a systemic β-adrenergic blocking drug. All β-adrenergic blocking glaucoma agents are contraindicated in the patient with bradycardia, second- or third-degree heart block, cardiogenic shock, and heart failure. The noncardioselective β-adrenergic blocking glaucoma agents are contraindicated in the patient with chronic obstructive pulmonary disease (COPD) or asthma. They may have profound effects in the older patient.

Argon laser trabeculoplasty (ALT) is a noninvasive way to lower IOP when medications are not successful or when the patient either cannot or will not use the drug therapy as recommended. ALT is an outpatient procedure that uses topical anesthetic. The laser stimulates scarring and contraction of the trabecular meshwork, which opens the outflow channels. ALT reduces IOP most of the time. The patient uses topical corticosteroids for 3 to 5 days after the procedure. The most common complication is an acute rise in IOP. The HCP examines the patient at 1 week and again at 4 to 6 weeks after surgery.

Filtration surgery, also called a *trabeculectomy,* may be used if drug and laser therapy are not successful.

Acute Angle-Closure Glaucoma

AACG is an emergency that needs immediate intervention. Carbonic anhydrase inhibitors (Table 22.15) and oral or IV hyperosmotic agents, including glycerin (Ophthalgan), isosorbide (Ismotic), and mannitol (Osmitrol), are usually successful in immediately lowering IOP. A laser peripheral iridotomy or surgical iridectomy is necessary for long-term treatment and prevention of more episodes. These procedures allow the aqueous humor to flow through a newly created opening in the iris and into normal outflow channels. A procedure may be done on the other eye as a precaution because many patients often have an acute attack in the other eye.

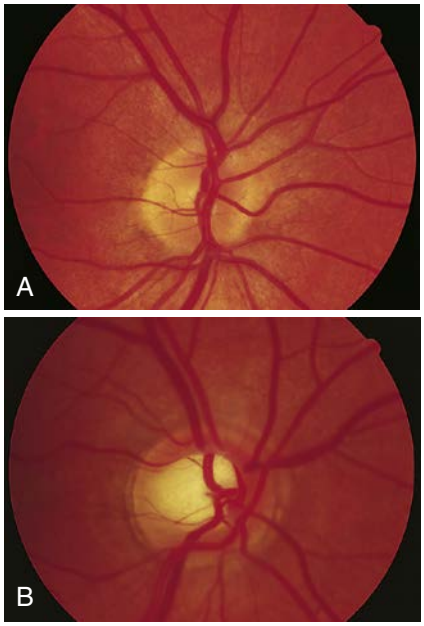

Fig. 22.16 (A) In the normal eye the optic cup is pink with little cupping. (B) In glaucoma the optic cup is bleached, and optic cupping is present. Note the appearance of the retinal vessels, which travel over the edge of the optic cup and appear to dip into it.

Management

Chronic Open-Angle Glaucoma

Drug Therapy (Table 22.15)
- α-Adrenergic agonists
- β-Adrenergic blockers
- Carbonic anhydrase inhibitors
- Miotics
- Prostaglandin agonists

Surgical Therapy
- Argon laser trabeculoplasty (ALT)
- Trabeculectomy with or without filtering implant

Acute Angle-Closure Glaucoma
- Carbonic anhydrase inhibitors
- Hyperosmotic agent
- Laser peripheral iridotomy
- Surgical iridectomy

NURSING MANAGEMENT: GLAUCOMA

Assessment

Because glaucoma is a chronic condition requiring long-term management, assess the patient's ability to understand and adhere to the treatment plan. Assess the patient's psychologic reaction to the diagnosis of a potentially sight-threatening chronic disorder. Include the patient's caregiver in the assessment because the chronic nature of this disorder also affects them. For example, caregivers may have to administer eyedrops if the patient is unwilling or unable.

Clinical Problems

Clinical problems for the patient with glaucoma include:
- Sensory deficit
- Pain
- Impaired role performance

Planning

The overall goals are that the patient with glaucoma will (1) have no progression of visual impairment, (2) follow the treatment plan, and (3) have no complications.

Implementation

Health Promotion

Loss of vision from glaucoma is preventable. Teach the patient and caregiver about the risk for glaucoma and that it

TABLE 22.15 Drug Therapy

Acute and Chronic Glaucoma

apraclonidine (Iopidine), brimonidine (Alphagan)	↓ Aqueous humor production	Eye redness, irregular heart rate, dry mouth, fatigue	Topical drops Used to control or prevent acute postlaser IOP rise (used before and immediately after ALT and iridotomy, Nd:YAG laser capsulotomy) Teach patient at risk for systemic reactions to occlude puncta
β-Adrenergic Blockers			
betaxolol (Betoptic)	β_1 cardioselective ↓ IOP, ↓ aqueous humor production	Eye discomfort Systemic reactions rare but include bradycardia, heart block, pulmonary distress, headache, depression	Topical drugs Contraindicated in patient with bradycardia, cardiogenic shock, or heart failure Systemic absorption can have additive effect with systemic β_1-blocking agents
carteolol levobunolol (Betagan) optipranolol timolol maleate (Timoptic, Istalol)	β_1 and β_2 noncardioselective blockers ↓ IOP, ↓ aqueous humor production	Same as betaxolol	Topical drops Same as betaxolol Contraindicated in patients with asthma or COPD
Carbonic Anhydrase Inhibitors			
Systemic			
acetazolamide (Diamox) methazolamide	↓ Aqueous humor production	Paresthesias, hearing problems, tinnitus, anorexia, taste changes, GI problems, headache, drowsiness, depression, kidney stones	Sulfa-type allergic reactions may occur in patient allergic to sulfa Diuretic effect can alter fluid and electrolyte balance Do not give to patient on high-dose aspirin therapy May cause gout attacks
Topical			
brinzolamide (Azopt) dorzolamide (Trusopt)	↓ Aqueous humor production	Transient stinging, blurred vision, redness	Sulfa-type allergic reactions may occur in patient allergic to sulfa
Miotics			
pilocarpine (Isopto Carpine, Pilocar)	Parasympathomimetic Stimulates ciliary muscle contraction, causing miosis and opening of trabecular meshwork, ↑ aqueous outflow Partially inhibits cholinesterase	Eye pain and burning, headache, blurred vision, decreased adaptation to the dark, syncope, dysrhythmias, hypotension	Topical drops Caution patient about ↓ visual acuity caused by miosis, particularly in dim light
Prostaglandin Agonists			
bimatoprost (Lumigan) latanoprost (Xalatan) tafluprost (Zioptan) travoprost	↑ Outflow of aqueous humor between the uvea and sclera and the usual exit through the trabecular meshwork	Increased brown iris pigmentation, stinging, redness, dryness, itching, and foreign body sensation	Topical drops Teach patient to only administer 1 drop per day Have patient remove contact lens 15 min before instilling
Rho Kinase Inhibitors			
netarsudil (Rhopressa)	↓ Aqueous humor production and ↑ outflow	Redness, blurred vision, headache	Topical drops Teach patient to only administer 1 drop per day

ALT, Argon laser trabeculoplasty; *Nd:YAG,* neodymium-doped yttrium aluminum garnet (laser).

increases with age. Stress the importance of early detection and treatment in preventing visual impairment. A comprehensive eye examination is important in identifying people with glaucoma or those at risk for developing glaucoma. The current recommendations for an eye examination are (1) every 2 to 4 years between ages 40 to 54 years, (2) every 1 to 3 years between ages 55 to 64 years, and (3) every 1 to 2 years for people age 65 years or older.[16] Those at higher risk for glaucoma and other problems should have their eyes checked more often.

Acute Care

Acute nursing interventions are directed primarily toward the patient with AACG and the surgical patient. The patient with AACG needs medication immediately to lower the IOP. Most surgeries for glaucoma are outpatient procedures. Provide care to relieve any discomfort related to the procedure. Patient and caregiver teaching after eye surgery is discussed in Table 22.11.

Ambulatory care. Because of the chronic nature of glaucoma, teach the patient to follow the treatment plan and follow-up recommendations prescribed by the HCP. Provide accurate information about the disease process and treatment options, including the reason for each option. The patient needs information about the purpose, frequency, and technique for administering antiglaucoma drugs. Encourage adherence by helping the patient set up a medication administration schedule and advocating a change in therapy if the patient reports unacceptable side effects.

Evaluation

The overall expected outcomes are that the patient with glaucoma will:

- Have no further loss of vision
- Adhere to the treatment plan
- Safely function within own environment
- Have relief from pain associated with the disease and surgery

INTRAOCULAR INFLAMMATION AND INFECTION

The term *uveitis* is used to describe inflammation of the uveal tract, retina, vitreous body, or optic nerve. Inflammation may be caused by bacteria, viruses, fungi, or parasites. *Cytomegalovirus retinitis* (CMV retinitis) is an opportunistic infection that occurs in patients with AIDS or immunosuppression. The cause of sterile intraocular inflammation includes autoimmune disorders, AIDS, cancer, or disorders associated with systemic diseases, such as inflammatory bowel disease. Pain and photophobia are common symptoms.

Endophthalmitis is an extensive intraocular inflammation of the vitreous cavity. Bacteria, viruses, fungi, or parasites can induce this serious inflammatory response. The mechanism of infection may be endogenous, in which the infecting agent arrives at the eye through the bloodstream, or exogenous. In that case the infecting agent is introduced through a surgical wound or a penetrating injury. Although rare, endophthalmitis is a devastating complication of intraocular surgery or penetrating eye injury. It can lead to irreversible blindness within hours or days. Manifestations include eye pain, photophobia, decreased visual acuity, headaches, reddened and swollen conjunctiva, and corneal edema.

Treatment depends on the underlying cause. Intraocular infections require antimicrobial agents. They may be delivered topically, subconjunctivally, intravitreally, systemically, or in some combination. Inflammatory responses require antiinflammatory medications (e.g., corticosteroids). The patient is usually uncomfortable and may be anxious and frightened. Provide accurate information and emotional support. In severe cases, the patient may need enucleation. When the patient has lost visual function or even the entire eye, the patient will grieve the loss. Your role includes helping the patient through the grieving process.

Fig. 22.17 Uveal melanoma. A large tumor in the choroid, the most common location in the eye for melanoma. (Courtesy Cory J. Bosanko, OD, FAAO, Eye Centers of Tennessee, Crossville, TN.)

OCULAR TUMORS

Benign and cancerous tumors can occur in many areas of the eye, including the conjunctiva, retina, and orbit. Eyelid cancers include basal cell and squamous cell cancers (see Chapter 25).

Uveal melanoma is a cancer of the iris, choroid, or ciliary body. It more often occurs in light-skinned people with light eye color, who are over age 60, and have chronic UV exposure.[17] Uveal melanoma can arise from preexisting nevi in the eye. Tumors may be asymptomatic or there may be vision loss. This depends on their size and location and presence of hemorrhage and retinal detachment. As with other cancers, cancer stage and cell type are important variables in the prognosis. Diagnostic testing may include ultrasound, MRI, angiography, and fine-needle aspiration biopsy. Uveal melanoma often appears as a dome-shaped, well-circumscribed, solid brown to golden pigment in the iris, choroid, or ciliary body (Fig. 20.17).

Depending on the status of the involved eye, treatment options can include radiation therapy, photocoagulation, thermotherapy, resection, and eye removal. Many patients do not lose their eye. Some may have good vision after treatment in the affected eye.

ENUCLEATION

Enucleation is the removal of the eye. The primary reason for enucleation is a blind, painful eye. This may result from glaucoma, infection, or trauma. Enucleation may be used to treat ocular cancer. The surgery includes severing the extraocular muscles close to their insertion on the globe, inserting an implant to maintain the intraorbital anatomy, and suturing the ends of the muscles over the implant. The conjunctiva covers the joined muscles. A clear conformer is placed over the conjunctiva until the permanent prosthesis is fitted. A pressure dressing helps prevent bleeding.

After surgery, observe the patient for signs of complications, including excess bleeding or swelling, increased pain, displacement of the implant, and fever. Teaching should include how to instill topical ointments or drops and wound cleansing. Teach the patient how to insert the conformer into the socket in case it falls out. The loss of an eye is often devastating, even when enucleation occurs after a lengthy period of painful blindness. Recognize the patient's emotional response and provide support to the patient and caregivers.

About 6 weeks after surgery, the wound is sufficiently healed for the permanent prosthesis. An ocularist fits the prosthesis and designs it to match the remaining eye. Teach the patient how to remove, cleanse, and insert the prosthesis. Special polishing is needed periodically to remove dried protein secretions.

Case Study

Glaucoma and Diabetic Retinopathy

(© Kevin Peterson/Stockbyte/Thinkstock.)

Patient Profile

J.K. is a 68-year-old woman with a history of osteoarthritis and type 2 diabetes for the past 15 years. She now has diabetic retinopathy. She returns to the eye clinic with her daughter for continued care of primary open-angle glaucoma (POAG) and reexamination for changes in diabetic retinopathy. Her current drug therapy for POAG includes topical timolol maleate 0.5% extended (Timoptic-XE) and latanoprost (Xalatan) 0.005% once daily in both eyes. At her last examination, she had microaneurysms and hard exudates of the retina.

Subjective Data

- Can no longer read the newspaper and reports that medication labels are difficult to read.
- States she is not always successful in getting the eyedrops instilled because her hands are gnarled and painful from osteoarthritis.

Objective Data

- Distant and near visual acuity: 20/60 (right eye) and 20/50 (left eye), with a reduction from 20/40 (both eyes) at her last visit
- Intraocular pressure (IOP) 20 mm Hg in each eye
- A new blind spot with visual field testing in the left eye
- Fluorescein angiography reveals diabetic macular edema in both eyes

Interprofessional Care

- Brimonidine 0.15% (left eye) 15 min before and immediately after argon laser trabeculoplasty (ALT)
- Argon laser to left eye to seal leaking microaneurysms from macular edema
- Check IOP 1 hr after ALT
- Continue previous glaucoma drop regimen
- Follow-up examination in 2 wk for possible ALT of right eye

Discussion Questions

1. ***Recognize:*** Explain the cause of the new blind spot.
2. ***Recognize:*** What is the cause of the vision loss from diabetic retinopathy?
3. ***Analyze:*** What main complication is J.K. at risk for?
4. ***Plan:*** Why is ALT an appropriate treatment for J.K.?
5. ***Prioritize:*** Based on the assessment data, what are the priority clinical problems?
6. ***Prioritize:*** What are the priority nursing interventions for J.K.?
7. ***Act:*** What is the purpose of the eyedrops before and immediately after ALT?
8. ***Act:*** What teaching will you provide so J.K. can manage her care?
9. ***Evaluate:*** What outcomes would indicate interprofessional care was effective?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. In a patient with a hemorrhage in the posterior cavity of the eye, the nurse knows that blood is accumulating
   a. in the aqueous humor.
   b. between the lens and retina.
   c. between the cornea and lens.
   d. in the space between the iris and lens.
2. Increased intraocular pressure may occur due to
   a. edema of the corneal stroma.
   b. dilation of the retinal arterioles.
   c. blockage of the lacrimal canals and ducts.
   d. increased aqueous humor production by the ciliary process.
3. Ask patients using eyedrops to treat their glaucoma about
   a. use of corrective lenses.
   b. their usual sleep pattern.
   c. a history of heart or lung disease.
   d. sensitivity to opioids or depressants.
4. Always assess the patient with an eye problem for
   a. visual acuity.
   b. pupillary reactions.
   c. intraocular pressure.
   d. confrontation visual fields.
5. When examining the patient's eyes, which finding would be of *most* concern to the nurse?
   a. Intraocular pressure of 16 mm Hg
   b. Slightly yellowish cast of the sclera
   c. Outward turning of the lower lid margin
   d. Small, white nodule on the upper lid margin
6. Presbyopia occurs in older people because
   a. the eyeball elongates.
   b. the lens becomes inflexible.
   c. the corneal curvature becomes irregular.
   d. light rays are focusing in front of the retina.
7. Before injecting fluorescein for angiography, it is important for the nurse to *(select all that apply)*
   a. obtain an emesis basin.
   b. ask if the patient is fatigued.
   c. administer a topical anesthetic.
   d. inform patient that skin may turn yellow.
   e. assess for allergies to iodine-based contrast media.
8. A patient says she was diagnosed with astigmatism. When she asks what that is, what is the best explanation the nurse can give to the patient?
   a. "It happens because the lens of the eye is absent."
   b. "People with astigmatism have abnormally long eyeballs."

c. "The cornea of the eye is uneven or irregular with astigmatism."
d. "Astigmatism occurs because the eye muscles weaken with age."

9. Which intervention would be part of the plan of care for a patient who has new vision loss?
a. Allow the patient to express feelings of grief and anger.
b. Have the AP perform all self-care activities for the patient.
c. Address any family present first when discussing care concerns.
d. Speak loudly and clearly, addressing the patient with each contact.

10. Which patient behaviors would the nurse promote for healthy eyes? *(select all that apply)*
a. Protective sunglasses when bicycling
b. Taking part in a smoking cessation program
c. Supplementing diet intake of vitamin C and beta-carotene
d. Washing hands thoroughly before putting in or taking out contact lenses
e. A woman avoiding pregnancy for 4 weeks after receiving MMR immunization

11. The *most* important intervention for the patient with epidemic keratoconjunctivitis is
a. cleansing the affected area with baby shampoo.
b. monitoring spread of infection to the opposing eye.
c. regular instillation of artificial tears to the affected eye.
d. teaching the patient and caregivers good hygiene techniques.

12. What should be included in the discharge teaching for the patient who had cataract surgery? *(Select all that apply.)*
a. Eye discomfort is often relieved with mild analgesics.
b. A decline in visual acuity is common for the first month.
c. Stay on bed rest and limit activity for the first few weeks.
d. Notify the provider if an increase in redness or drainage occurs.
e. Following activity restrictions is essential to reduce intraocular pressure.

1. b; 2. d; 3. c; 4. a; 5. d; 6. b; 7. a, d; 8. c; 9. a; 10. a, b, c, d; 11. d; 12. a, d, e.

Assessment and Management: Auditory Problems

Mariann M. Harding

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Functional Ability
Infection
Sensory Perception
Stress and Coping

LEARNING OUTCOMES

1. Describe the structures and functions of the auditory system.
2. Obtain significant subjective and objective assessment data related to the auditory system from a patient.
3. Perform a physical assessment of the auditory system using the appropriate techniques.
4. Distinguish normal from common abnormal findings of a physical assessment of the auditory system.
5. Link the age-related changes in the auditory system to differences in assessment findings.
6. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the auditory system.
7. Explain the pathophysiology, clinical manifestations, and nursing and interprofessional management of common ear problems.
8. Compare the common causes, management, and rehabilitative potential of conductive and sensorineural hearing loss.
9. Explain the use, care, and patient teaching related to assistive hearing devices.
10. Describe measures used to assist the patient in adapting to decreased hearing.

KEY TERMS

acoustic neuroma
benign paroxysmal positional vertigo (BPPV)
external otitis
Ménière disease
nystagmus
otosclerosis
presbycusis
tinnitus
vertigo

AUDITORY SYSTEM

Hearing is a complex process that allows us to interact with the environment. It is the basis for social interaction and communication. Having a hearing impairment can lead to major challenges that can adversely affect well-being. Difficulties with related concepts, including functional ability and cognition, may be present with hearing loss. Problems with equilibrium can impair coordination, balance, and orientation. This chapter presents an overview of auditory function and discusses care when problems occur.

STRUCTURES AND FUNCTIONS OF AUDITORY SYSTEM

The auditory system is composed of the peripheral auditory system and central auditory system. The peripheral auditory system includes the structures of the ear itself: external, middle, and inner ear (Fig. 23.1). This system is involved with the reception and perception of sound. The inner ear functions in hearing and balance.

The central auditory system integrates and assigns meaning to what you hear. This system includes the vestibulocochlear

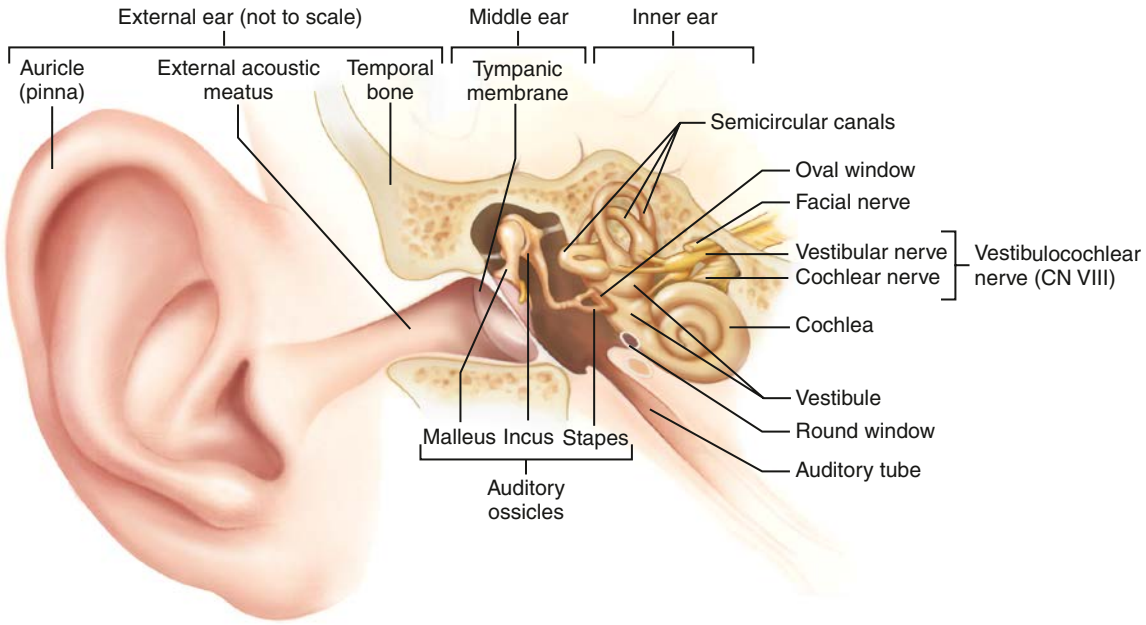

Fig. 23.1 External, middle, and inner ear. (Modified from Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 8, St Louis, 2013, Mosby.)

nerve (cranial nerve [CN] VIII) and auditory cortex of the brain. The brain and its pathways transmit and process sound and sensations that maintain your equilibrium.

The role of the external and middle part of the ear is to conduct and amplify sound waves from the environment. This part of sound conduction is termed *air conduction.* Problems in these parts of the ear may cause *conductive hearing loss,* resulting in a decrease in sound intensity and/or a distortion in sound.

Damage to or a problem of the inner ear or along the nerve pathways results in *sensorineural hearing loss.* Besides causing distortion or faintness of sound, sensorineural hearing loss may affect the ability to understand speech or cause complete hearing loss. Impairment within the auditory pathways of the brain causes *central hearing loss.* Central hearing loss causes difficulty in understanding the meaning of words the person heard. Types of hearing loss are discussed later in this chapter.

External Ear

The external ear consists of the *auricle* (pinna), external auditory canal, and *tympanic membrane (TM),* or eardrum. The auricle is composed of cartilage and connective tissue covered with epithelium, which also lines the external auditory canal (Fig. 23.1). The external auditory canal is a slightly S-shaped tube about 1 inch (2.5 cm) in length in the adult. The lining of the first one-third of the canal contains fine hairs (cilia), sebaceous (oil) glands, and ceruminous (wax) glands. The oil and wax lubricate the ear canal, keep it free from debris, and kill bacteria. Thin epithelium lines the distal two-thirds of the canal. It is over bone and very sensitive.

The function of the external ear and canal is to collect and transmit sound waves to the TM. The TM is a shiny, translucent, pearl-gray membrane. It is made up of epithelial cells, connective tissue, and mucous membrane. It serves as a partition and transmits sounds between the external auditory canal and middle ear.

Middle Ear

The middle ear cavity is an air space in the temporal bone. Mucous membrane lines the middle ear and is continuous from the nasal pharynx via the eustachian (auditory) tube. The eustachian tube equalizes atmospheric air pressure between the middle ear and throat. This allows the TM to move freely. It is normally closed, opening only with yawning, swallowing, and chewing. Blockage of the tube can occur with allergies, nasopharyngeal infections, or enlarged adenoids. A tube that stays open is *patulous.* When this occurs, *autophony,* or hearing your own voice, may be present.

The middle ear contains the *ossicles,* the 3 smallest bones in the body: *malleus, incus,* and *stapes.* Vibrations of the TM cause the ossicles to move and transmit sound waves to the oval window. The superior part of the middle ear is the *epitympanum,* or the attic. It also communicates with air cells within the mastoid bone. The mastoid is the posterior part of the temporal bone. The facial nerve (CN VII) traverses above the oval window of the middle ear. The thin, bony covering of the facial nerve can become damaged by chronic ear infection, skull fracture, or trauma during ear surgery. Problems may occur with voluntary facial movements, eyelid closure, and taste discrimination. Permanent damage to the facial nerve can result.

Inner Ear

The inner ear consists of 3 spaces in the temporal bone, assembled in a system called the bony labyrinth. The space is filled with watery fluid called perilymph. Within the perilymph is the membranous labyrinth. It follows the shape of the bony labyrinth and holds a thicker fluid called *endolymph.*

The inner ear holds the functional organs for hearing and balance. The receptor organ for hearing is the *organ of Corti.* It lies on the basilar membrane in the *cochlea.* Its tiny hair cells transform fluid vibrations from sounds into electrical impulses.

These are transmitted by the acoustic part of the vestibulocochlear nerve (CN VIII) to the temporal lobe of the brain to process and interpret the sound.

Three *semicircular canals* and the *vestibule* make up the organ of balance. The semicircular canals sit at right angles to each other. Structures in each canal and the vestibule generate nerve impulses in response to our movements. The vestibule is beside the oval window between the semicircular canals and the cochlea. Nerves from receptors in the vestibule join those from the semicircular canals to form the vestibular nerve. It joins with the cochlear nerve to form the *vestibulocochlear nerve,* or CN VIII.

Hearing Sound

Hearing depends on a series of complex steps that change sound waves in the air into electrical signals. Sound waves travel by air (air conduction) and are picked up by the auricles and auditory canal. Sound waves strike the TM, causing it to vibrate. The central part of the TM is connected to the malleus, which then starts to vibrate. The malleus transmits the vibration to the incus and then the stapes. As the stapes moves back and forth, it pushes the membrane of the oval window in and out.

Movement of the oval window makes waves in the perilymph. These vibrations are picked up by the tiny sensory hair cells of the cochlea, which initiate nerve impulses. These impulses are carried by nerve fibers to the main branch of the acoustic portion of CN VIII and then to the brain. The bones of the skull can also transmit sound directly to the inner ear (bone conduction).

We measure sound waves in 2 ways, intensity or strength and frequency or pitch. We measure the intensity in terms of decibels (dB). The lowest hearing decibel level is 0 dB, which is nearly total silence and the softest sound that we can hear. Normal speech is around 40 to 65 dB; a soft whisper is 20 dB. Sounds above 90 dB can lead to hearing damage if people are exposed to them every day or all the time. Hearing becomes uncomfortable if the sound pressure level is above 110 dB.

Frequency is the measurement of the number of sound vibrations in 1 second. We measure it in hertz (Hz). The higher the frequency is, the higher the pitch. Normally, a child and a young adult can hear frequencies from about 16 to 20,000 Hz, but hearing is most sensitive between 500 and 4000 Hz. This is similar to normal speech frequencies.

Gerontologic Considerations: Effects of Aging on Auditory System

Presbycusis, or hearing loss due to aging, is the third most common health issue in older adults, after arthritis and heart disease.[1] Calcification of the ossicles diminishes sound transmission. **Tinnitus**, or ringing in the ears, may accompany the hearing loss that results from the aging process. Cerumen glands atrophy, causing cerumen (earwax) to be much drier. The hair in the ear becomes thicker and coarser, trapping the hard, dry earwax in the canal. Accumulation of dry earwax in the external canal can interfere with the transmission of sound. Atrophy of vestibular structures in the inner ear causes a decline in balance, slowing of motor responses, and musculoskeletal limitations.

Age-related changes in the auditory system and differences in assessment findings are outlined in Table 23.1.

Case Study

Patient Introduction

(© iStock.com/EyeMark.)

R.S. is a 57-year-old woman who comes to the emergency department with extreme dizziness. R.S. states that she is so dizzy she "can't do anything but lie down." She reports feeling like her right ear is "plugged" and is having ringing in that ear.

Discussion Questions

1. What are the possible causes of R.M.'s hearing and balance problems?
2. Is her condition stable or an emergency?
3. What assessment questions will you ask?

You will learn more about R.S. and her condition as you read this chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg

ASSESSMENT OF AUDITORY SYSTEM

Assessment of the auditory system should include assessment of hearing and equilibrium because the auditory and *vestibular* (balance) systems are closely related. It is often hard to separate symptoms related to these 2 systems. Help the patient describe symptoms and problems to determine the source of the problems. Health history questions to ask a patient with an auditory problem are listed in Table 23.2.

TABLE 23.1 GERONTOLOGIC ASSESSMENT DIFFERENCES

Auditory System

Changes	Differences in Assessment Findings
External Ear	
Increased hair growth	Visible hair, especially in men
Loss of elasticity in cartilage	Collapsed ear canal
Thicker, drier earwax	Impacted earwax, potential hearing loss
Middle Ear	
Atrophy of TM	Conductive hearing loss
Inner Ear	
Hair cell degeneration, neuron degeneration in auditory nerve and central pathways, reduced blood supply to cochlea, calcification of ossicles	Presbycusis, diminished sensitivity to high-pitched sounds, impaired speech reception, tinnitus
Less effective vestibular apparatus in semicircular canals	Alterations in balance and body orientation
Brain	
Decline in ability to filter out unwanted and unnecessary sound	Difficulty hearing in a noisy environment, heightened sensitivity to loud sounds

TABLE 23.2 HEALTH HISTORY

Auditory System

Health Perception–Health Management

Hearing

- Have you had a change in your hearing?[a] If yes, how does this change affect your daily life?
- Do you use any devices to improve your hearing, such as a hearing aid, special volume control, or headphones?[a]
- How do you protect your hearing?
- Do you have any allergies that result in ear problems?[a]

Equilibrium

- When did the dizziness or spinning sensation first occur?
- Does this sensation occur when you first stand up, when you are lying down, or both?
- Have you ever fallen because of the dizziness?[a]
- Can you drive or walk alone? If no, elaborate.
- Are there any times of the day when your symptoms are worse?[a]

Tinnitus

- How long have you had ringing in your ears? Has it changed?[a] Describe the ringing (e.g., buzzing, ringing, roaring). Do you also have a feeling of fullness or pressure?[a]
- When does it bother you the most?
- What things have you tried that help or have not helped?
- What medications are you taking?

Nutritional-Metabolic

- Do you notice any change in symptoms with changes in diet?[a]
- Does your ear problem cause nausea that interferes with your food intake?[a]
- Does chewing or swallowing cause you any ear discomfort?[a]

Elimination

- Does straining during a bowel movement cause ear pain?[a]

Activity-Exercise

- Do you need help with certain activities, like lifting, bending, climbing stairs, driving, or speaking because of symptoms?[a]

Sleep-Rest

- Is your sleep disturbed by noises or ringing in the ears or by a sensation of spinning?[a]

Cognitive-Perceptual

- Do you have ear pain?[a] What relieves the pain? What makes it worse? Does the pain affect your hearing or balance?
- Have you noticed any problem with communicating or understanding what people are saying?[a]

Self-Perception–Self-Concept

- Have changes in your hearing affected how you feel about yourself or your feeling of independence?[a]

Role-Relationship

- What effect has your ear problem had on your work, family, or social life?
- Do you notice any effects of your ear problems on your life?[a]

Sexuality-Reproductive

- Has your ear problem caused a change in your sex life?[a]

Coping–Stress Tolerance

- Do you consider your ear problem a source of stress?[a]
- How do you cope when you are having symptoms?

Value-Belief

- Do you have a conflict between what your HCP would like you to do and what you believe you should do?

[a]If yes, describe.

Problems with balance may manifest as vertigo or nystagmus. **Vertigo** is a sense that the person or objects around the person are moving or spinning. It is usually stimulated by head movement. *Dizziness* is a sensation of being off-balance that occurs when standing or walking. **Nystagmus** is an abnormal eye movement that may be seen as a twitching of the eyeball or described by the patient as a blurring of vision with head or eye movement.

At first, try to determine symptoms that are related to balance and separate them from those related to hearing loss or tinnitus. The symptoms can be combined later in the assessment to help make a diagnosis and care plan for the patient.

Subjective Data

Important Health Information

Many ear problems result from childhood illnesses or problems of adjacent organs. This makes a careful assessment of past health problems important. Ask the patient about previous ear problems, especially during childhood. Note the (1) frequency of acute middle ear infections (otitis media); (2) surgeries (e.g., myringotomy, tonsillectomy, tympanoplasty); (3) TM perforations; (4) drainage; and (5) history of mumps, measles, or scarlet fever. Assess for systemic conditions, including diabetes, rheumatoid arthritis, and multiple sclerosis, that are associated with hearing loss.[2] Note head injury because it may result in hearing loss. Information about food and environment allergies is important because they can cause edema of the eustachian tube and prevent aeration of the middle ear.

Record symptoms such as vertigo, tinnitus, and hearing loss in the patient's words. Ask for specific details of the sensations and situations that cause them or make them worse. Details about family members with hearing loss and type of hearing loss is important. Some congenital hearing loss is hereditary. The age of onset of presbycusis follows a familial pattern. Record the use of and satisfaction with a hearing aid. Note any problems with impacted earwax.

Medications

Obtain information about present or past use of ototoxic drugs. More than 200 drugs that are ototoxic and have the potential to cause hearing loss, tinnitus, and vertigo. These include

aspirin, some antibiotics (aminoglycosides, erythromycin, vancomycin), loop diuretics, nonsteroidal antiinflammatory drugs (NSAIDs), antimalarial agents, and certain chemotherapy drugs (e.g., bleomycin, cyclophosphamide, cisplatin). Ask about hearing and balance problems, in patients receiving these drugs. For many, the hearing loss may be reversible if treatment is stopped. Chemicals used in industry (e.g., toluene, carbon disulfide, mercury) may damage the inner ear.

Functional Health Patterns

Hearing and balance problems can affect all aspects of a person's life. To assess the impact of hearing loss, ask health history questions based on a functional health patterns approach (Table 23.2).

Health perception–health management pattern. Note the onset of hearing loss, whether sudden or gradual, and who noted the onset (e.g., patient, family, significant others). Gradual hearing losses are often noted by those who communicate with the patient. The patient often notes sudden losses and those worsened by other problems.

Assess the patient for personal measures used to preserve hearing. The use of protective ear covers or earplugs is good practice for people in high-noise environments. Note if the patient is a swimmer and the frequency and duration of swimming and use of ear protection. Knowing the type of water (pool, lake, ocean) in which the swimming takes place helps identify contact with contaminated water. Assess for the placement of any item in the ear which can cause trauma to the canal and TM.

Nutritional-metabolic pattern. Ask the patient about any ear pain (otalgia) or discomfort when chewing or swallowing. These symptoms may occur with middle ear problems. Note changes in symptoms with food intake. Alcohol, sodium, and diet supplements affect the amount of endolymph in the inner ear system. Patients with Ménière disease may notice some symptom improvement with alcohol restriction and a low-sodium diet.

Clenching or grinding of the teeth helps distinguish problems of the ear from referred pain of the temporomandibular joint (TMJ). Ask about dental problems and dentures. Referred pain from the teeth, gums, or throat can cause ear pain.

Elimination pattern. Elimination patterns are of interest in the patient with perilymph fistula and after surgery. Frequent constipation or straining with bowel or bladder elimination may interfere with healing or repair of a perilymph fistula. After middle ear surgery (stapedectomy), the patient needs to prevent increased intracranial (and consequent inner ear) pressure from straining during bowel movements. Stool softeners may be needed after surgery for the patient who reports chronic problems with constipation.

Activity-exercise pattern. A review of the patient's activity-exercise pattern is essential when assessing for balance problems. Ask about the onset, duration, and frequency of symptoms. Identify activities that relieve or worsen symptoms and how they relate to the time of the day. For example, patients with Ménière disease are less able to compensate as the day progresses.

Sleep-rest pattern. Ask the patient with chronic tinnitus about sleep problems. Find out if they have tried anything to minimize the tinnitus, such as having a fan on or using white noise devices. Assess for snoring. It can be caused by swelling or hypertrophy of tissue in the nasopharynx. This excess tissue can impair eustachian tube function and cause the sensation of ear fullness or pain.

Cognitive-perceptual pattern. Pain occurs with some ear problems, especially those involving the middle ear and auditory canal. If pain is present, ask the patient to describe the pain, any drainage present *(otorrhea),* history of teeth grinding, and treatments used for relief. Note the effect on the pain level when you move the auricle and palpate the tragus.

Note the patient's ability to pay attention and follow directions. Problems with these tasks may be an early sign of hearing loss. The patient may not recognize a gradual hearing loss. Ask caregivers if they have noted any change in the patient's hearing.

Self-perception–self-concept pattern. Ask the patient to describe how the ear problem has affected their personal life and feelings about themselves. Hearing loss and chronic vertigo are particularly distressing for the patient. Hearing loss can result in embarrassing social situations that affect the patient's self-concept. People may think a person with chronic vertigo is intoxicated. Question the patient gently about such situations. Clarify the symptom history with the patient and consider an evaluation with a hearing specialist.

Role-relationship pattern. Ask the patient about the effect that an ear problem or vertigo has had on family life, work responsibilities, and social relationships. Hearing loss can result in strained relationships and misunderstandings.

Ask about employment or contact with environments that have excessive noise levels, such as work with jet engines and machinery and amplified music. Document the use of preventive devices worn in noisy environments. Many jobs rely on the ability to hear accurately and respond appropriately. If hearing loss is present, assess the effect this has on the patient's job. The unpredictability of vertigo attacks can have devastating effects on all aspects of life. Ordinary activities which require balance, such as driving, cooking, and work, all have an element of danger.

Sexuality-reproductive pattern. Determine whether hearing loss or vertigo has interfered with having a satisfactory sex life. Although intimacy does not depend on the ability to hear, hearing loss can interfere with establishing or maintaining a relationship.

Coping–stress tolerance pattern. Ask about coping style, stress management strategies, and available support. If the patient seems unable to manage the situation, outside intervention may be needed. Denial is a common response to a hearing problem and should be assessed.

Value-belief pattern. Ask the patient about any conflicts produced by the problem or treatment related to values or beliefs. Make every effort to resolve the problem so that the patient does not have added stress. Ask about the use of home remedies such as hot oil in the ear.

Objective Data

Physical Assessment

During the interview to obtain a health history, obtain objective data about the patient's ability to hear. Look for cues that a patient cannot hear (Table 23.3). Record these observations. This is important because the patient is often unaware of hearing loss

Case Study

Subjective Data

(© iStock.com/EyeMark.)

A focused subjective assessment of R.S. revealed the following information:

- ***History:*** Mild osteoarthritis. Hysterectomy 5 years ago. Last saw HCP 6 months ago.
- ***Medications:*** Multivitamin 1 PO daily, ASA 81 mg PO daily, ibuprofen 200 mg PO every 6 hours as needed.
- ***Health Perception–Health Management:*** She says last night she felt like she had the start of a cold. The symptoms were present this morning when she woke up. She tried to clear her ear by blowing her nose and could not use that ear to talk on the phone. Had excellent hearing until today. Denies any syncope. Does not have allergies.
- ***Nutritional-Metabolic:*** States she is nauseous but has not vomited. Has only had a few sips of water since the symptoms started.
- ***Activity-Exercise:*** Dizziness worse when standing. It is still present when lying down but is less. Her husband drove her to the emergency room since she was unable to drive. Normally walks 1–2 miles 5 times a week and attends yoga class 2 times a week.
- ***Cognitive-Perceptual:*** Denies any ear pain, headache.
- ***Coping–Stress Tolerance:*** Concerned she is having a stroke.

Discussion Questions

1. Which subjective assessment findings concern you most?
2. Based on the subjective assessment findings, what should you include in the physical assessment? For what would you be looking?

You will learn more about the physical assessment of the auditory system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

or does not admit to changes in hearing until moderate losses have occurred.

A normal assessment of the auditory system is shown in Table 23.4. Age-related changes of the auditory system and differences in assessment findings are found in Table 23.1.

A *focused assessment* is used to evaluate the status of previously identified auditory problems and monitor for signs of new problems. A focused assessment of the auditory system is shown in Box 23.1.

External ear. Inspect and palpate the external ear before assessing the external canal and TM. Observe the auricle, preauricular area, and mastoid area for symmetry, color of skin, swelling, redness, and lesions. Then palpate the auricle and mastoid areas for tenderness and nodules. Grasping the auricle or pressing on the tragus may cause pain, especially if the external ear or canal is inflamed.

External auditory canal and tympanic membrane. Before inserting an otoscope, inspect the canal opening for patency, palpate the tragus, and gently move the auricle to check for discomfort. Select a speculum slightly smaller than the size of the ear canal. Tip the patient's head to the opposite shoulder. Grasp the top of the auricle and gently pull up and backward to straighten the canal. Hold the otoscope while stabilizing it with your fingers on the patient's cheek, and then insert it slowly. A tight seal of the speculum is essential during this step of the assessment. Observe the canal for size and shape and the color, amount, and type of earwax. Be careful when clearing the canal of earwax. Damage can occur to the middle ear if the TM is perforated.

Inspect the TM for color, fluid behind the membrane, landmarks, contour, and intactness (Fig. 23.2). The TM is normally pearl gray, white, or pink; shiny; and translucent. The handle (manubrium) of the malleus and its short process (umbo) should be visible through the membrane. The position and dome (concave) shape of the TM cause the light from the otoscope to reflect in a cone shape with crisp edges. If the TM is bulging or retracted, the edges of the light reflex will be fuzzy (diffuse) and may spread over the TM. A pneumatic otoscope creates negative pressure to pull at the TM. It is helpful in confirming TM retraction or fluid behind the

TABLE 23.3 Signs of Possible Hearing Loss

- Does not respond to or understand oral communication
- Has excessively loud or soft speech
- Answers questions inappropriately
- Tilts head, leans forward when listening
- Constantly needs to clarify conversation
- States other people mumble all the time
- Increases the volume of radio or TV
- Difficulty hearing over the phone

TABLE 23.4 Normal Physical Assessment of Auditory System

- Ears symmetric in location and shape
- Auricles and tragus nontender, without lesions
- Canal clear, TM intact, landmarks and light reflex intact
- Able to hear low whisper at 30 cm.
- Weber test results, no lateralization. Rinne test results: Air conduction > Bone conduction

BOX 23.1 FOCUSED ASSESSMENT

Auditory System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Changes in hearing	Y	N
Ear pain	Y	N
Ear drainage	Y	N
Tinnitus	Y	N

Objective: Physical Assessment

Inspect

Alignment and position of ears on head	✓
Size, shape, symmetry, color, and skin intactness	✓
External auditory meatus for discharge or lesions	✓

Assess

Hearing based on ability to respond to conversation, respond to a whisper, or hear a ticking watch	✓

Case Study

Objective Data: Physical Assessment

(© iStock.com/EyeMark.)

Physical assessment findings of R.S. were as follows:

- Neurologic and otoscopic assessments normal
- Unable to hear whisper on the right at 30 cm
- Vision normal. PERRLA (pupils equal, round, and reactive to light and accommodation) without nystagmus
- Gait unsteady. No motor weakness
- Skin pale, warm, and dry
- Heart rate 84 beats/min, temperature 97.4°F (36.3°C)

Discussion Questions

1. What physical assessment findings concern you most?
2. What diagnostic studies might you expect to be ordered?

As you continue to read this chapter, consider diagnostic studies that you would expect being performed for R.S.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

TM. You cannot examine the middle and inner ear with the otoscope.

Table 23.5 summarizes assessment abnormalities of the auditory system.

DIAGNOSTIC STUDIES OF AUDITORY SYSTEM

Table 23.6 describes common diagnostic studies used to assess the auditory system. Several tests are available to determine the cause of certain hearing losses. CT scan and MRI can detect lesions such as a tumor of the auditory nerve.

Audiometry

Audiometry is used as a screening test for hearing acuity and as a diagnostic test to determine the degree and type of hearing loss. The most common test performed by the audiologist is pure-tone audiometry. The audiometer produces pure tones at varying intensities to which the patient can respond. Hearing loss can affect certain sound frequencies. The specific pattern produced on the audiogram by these losses can help diagnose the type of hearing loss. Threshold refers to the signal level at which pure tones are detected (pure-tone thresholds) or the signal level at which the patient correctly hears 50% of the signals (speech detection thresholds).

Case Study

Objective Data: Diagnostic Studies

(© iStock.com/EyeMark.)

The Weber's test shows lateralization to the left. An audiogram confirms low-frequency, sensorineural hearing loss with normal speech discrimination. An MRI of the head is normal.

Discussion Questions

1. Are these the diagnostic studies that you expected to be ordered?
2. Which diagnostic study results are of most concern to you?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

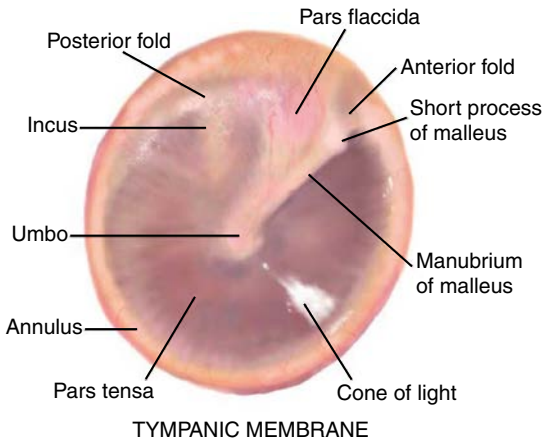

Fig. 23.2 Normal tympanic membrane. (From Jarvis C: *Physical examination and health assessment,* ed 7, St Louis, 2015, Elsevier.)

EXTERNAL EAR AND CANAL PROBLEMS

EXTERNAL OTITIS

The skin of the external ear and canal is subject to the same problems as skin anywhere on the body. **External otitis** involves inflammation or infection of the epithelium of the auricle and ear canal. Swimming may change the flora of the external canal because of chemicals and contaminated water. This can result in an infection often referred to as "swimmer's ear." Trauma from picking the ear or using sharp objects (e.g., hairpins) often causes the initial break in the skin. Piercing of cartilage in the upper part of the auricle increases the risk for infection.

The warm, dark environment of the ear canal provides a good growth medium for microorganisms. Bacteria or fungal infection may cause external otitis. *Staphylococcus aureus* is the most common bacterial cause. Fungi, especially *Candida albicans* and *Aspergillus,* thrive in the warm, moist climate.

Malignant external otitis is a serious infection caused by *P. aeruginosa.* It occurs mainly in older patients with diabetes. The infection, which can spread from the external ear to the parotid gland and temporal bone (osteomyelitis), is usually treated with antibiotics.

Ear pain *(otalgia)* is an early sign of external otitis. Even in mild cases, the patient may have significant pain with chewing, moving the auricle, or pressing on the tragus. Swelling of the ear canal can muffle hearing. There may be serosanguineous (blood-tinged) or purulent (white to thick green) drainage. Fever occurs when the infection spreads to surrounding tissue.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: EXTERNAL OTITIS

External otitis is diagnosed by otoscopic examination of the ear canal. Take care to avoid pain when pulling on the pinna to straighten out the canal or when inserting the otoscope speculum. The TM may be hard to see due to swelling in the canal. Culture and sensitivity studies of the drainage may be done. Moist heat, mild analgesics, and topical anesthetic drops usually control the pain. Topical treatments may include

TABLE 23.5 ASSESSMENT ABNORMALITIES

Auditory System

Finding	Description	Possible Cause and Significance
External Ear and Canal		
Discharge	Infection of external ear, usually painful	Swimmer's ear, infection of external ear. Possibly caused by ruptured TM and otitis media
Exostosis	Bony growth extending into canal causing narrowing of canal	May interfere with seeing TM. Usually asymptomatic
Impacted earwax	Wax that was not normally excreted from the ear. Cannot see TM	Decreased hearing possible, pain, sensation of fullness in auditory canal, removal necessary before otoscopic examination
Scaling or lesions	Change in usual appearance of skin	Seborrheic dermatitis, actinic keratosis, basal or squamous cell carcinoma
Sebaceous cyst behind ear	Usually within skin, may see a black dot (opening to sebaceous gland)	Removal or incision and drainage if painful
Swelling of pinna, pain	Infection of glands of skin, hematoma caused by trauma	Aspiration (for hematoma)
Tophi	Hard nodules in the helix or antihelix consisting of uric acid crystals	Occur with gout, metabolic disorders. Further diagnosis needed
Tympanic Membrane (TM)		
Hairline fluid level, yellow-amber bubbles above fluid level	Caused by transudate of blood and serum, meniscus of fluid producing hairline appearance	Serous otitis media
Lack of landmarks, bulging red or blue TM (Fig. 23.3)	Fluid-filled middle ear, pus, blood	Acute otitis media, perforation
Perforated TM	Previous TM perforations that have failed to heal. Thin, transparent layer of epithelium surrounding TM	Chronic otitis media, mastoiditis, drainage
Recruitment	Perception that sounds are getting too loud too fast	Sensorineural hearing loss. Hearing aid hard to use
Retracted TM	Appearance of shorter, more horizontal malleus. Absent or bent cone of light	Vacuum in middle ear, blockage of eustachian tube, negative pressure in middle ear

TABLE 23.6 Diagnostic Studies

Auditory System

Study	Description, Purpose, and Considerations
Auditory	
Audiometry	*Pure-tone audiometry* quantifies hearing loss. Sounds are presented through earphones in soundproof room. Patient responds when sound is heard. Response is recorded on an audiogram. Purpose is to determine patient's hearing range in terms of decibels (dB) and Hertz (Hz) for diagnosing hearing loss. Tinnitus can cause inconsistent results. *Speech audiometry* includes speech reception threshold (measure of intensity at which speech is recognized) and word recognition score (ability to discriminate among various speech sounds).
Auditory brainstem response (ABR)	Measures electrical peaks along auditory pathway of inner ear to brain. Provides information related to acoustic neuromas, brainstem problems, and stroke.
Auditory evoked potential (AEP)	Similar to an electroencephalogram (see Chapter 60 and Table 60.10). Electrodes are placed typically at vertex, mastoid process, and forehead. A computer is used to isolate auditory from other electrical activity of brain. Patient should avoid loud noises for 24 hr before the test.
Electrocochleography	Test records electrical activity in cochlea and auditory nerve. Electrode placed on or through the TM. Used to assess and monitor patients with dizziness.
Tympanometry	Used to check middle ear and mobility of TM. A probe is placed snugly into external ear canal, and positive and negative pressures are applied. Measurements are made of TM movement.
Tuning Fork Tests	
Rinne test	Compares hearing by bone conduction (BC) and air conduction (AC). Stem of vibrating tuning fork held against mastoid bone (for BC of sound) and time noted. When the sound is no longer perceived behind the ear (BC of sound), time is noted once again and the still-vibrating fork is moved close to the pinna (AC of sound). Have the patient report when the sound next to the ear canal (AC) is no longer heard and note time. Normally, sound is heard twice as long in front of the ear as it is on the bone. With conductive hearing loss, the relationship is reversed; BC is longer than AC. With sensorineural hearing loss, both AC and BC are reduced, but AC is longer.
Weber test	Stem of vibrating tuning fork is placed on midline of skull or forehead. Patient asked to indicate where the sound is heard best. In normal auditory function, the patient perceives a midline tone, and the sound is heard equally in both ears. If a patient has conductive hearing loss in 1 ear, the sound will be heard louder (lateralizes) in that ear. If sensorineural loss is present, the sound is louder (lateralizes) in the normal (unaffected) ear.

Continued

TABLE 23.6 Diagnostic Studies—cont'd

Auditory System

Study	Description, Purpose, and Considerations
Vestibular Tests	
Electronystagmography (ENG)	Used to diagnose diseases of vestibular system such as dizziness and balance disorders. Electrodes are placed near patient's eyes. Eye movement (nystagmus) is recorded on graph during specific eye movements and when ear is irrigated. Caloric test may be part of testing to measure responses to warm and cold water circulated into the ear canal. Have patient eat a light meal before test to avoid nausea. Observe patient for vomiting. Ensure patient safety.
Posturography	Balance test that can isolate one semicircular canal from others to determine site of lesion. Done in a boxlike device in which floor moves in response to a correction in balance by patient. Tell patient that test may be uncomfortable. Can be stopped at any time at patient's request.
Rotary chair testing	Evaluates peripheral vestibular system. Patient is seated in a chair driven by a motor under computer control. Test is usually done in the dark. Tell patient to eat light meal before test to avoid nausea. Observe patient for vomiting. Ensure patient safety.

antibiotics for infection and corticosteroids for inflammation. If the surrounding tissue is involved, systemic antibiotics are used. Improvement should occur in 48 hours. The patient needs to adhere to the prescribed therapy for 7 to 14 days for complete resolution (see Table 15.3).

Wash hands before and after applying eardrops (otic drops). The drops should be at room temperature. Cold drops can cause vertigo due to stimulation of the semicircular canals. Heated drops can burn the TM. The tip of the dropper should not touch the ear during application to prevent contamination of the entire bottles. Position the ear so that the drops can run into the canal. The patient should stay in this position for 2 minutes to allow the drops to spread. Sometimes you can place the drops onto a wick of cotton, then place the wick in the canal. Tell the patient not to push the cotton farther into the ear. Careful handling and disposal of material saturated with drainage are important. Teach the patient ways to reduce the risk for external otitis (Table 23.7).

TABLE 23.7 PATIENT & CAREGIVER TEACHING

Preventing External Otitis

Include the following instructions when teaching the patient and caregiver:

1. Do not put anything in your ear canal unless requested by your HCP.
2. Report itching if it becomes a problem.
3. Earwax is normal.
   - It lubricates and protects the canal.
   - Report chronic excess earwax if it impairs your hearing.
4. Keep your ears as dry as possible.
   - Use earplugs if you are prone to swimmer's ear.
   - Turn your head to each side for 30 seconds at a time to help water run out of the ears.
   - Do not dry with cotton-tipped applicators.
   - A hair dryer set to low and held at least 6 inches from the ear can speed water evaporation.

CERUMEN AND FOREIGN BODIES IN EXTERNAL EAR CANAL

The ear canal may be obstructed by cerumen (earwax) or a foreign object. Impacted earwax can cause discomfort and decreased hearing. Other symptoms include tinnitus and vertigo. Remove an impaction by irrigating the canal with body-temperature solutions to soften the earwax. Special syringes may be used. These vary from a simple bulb syringe to special irrigating equipment. Place the patient in a sitting position with an emesis basin under the ear. Pull the auricle up and back, and direct the flow of solution above or below the impaction. Do not completely occlude the ear canal with the syringe tip. If irrigation does not remove the wax, use mild lubricant drops to soften the earwax. The HCP may need to remove severe impactions.

Attempts to remove a foreign object from the ear may result in pushing it farther into the canal. Vegetable matter in the ear tends to swell. This can create a secondary inflammation, making removal more difficult. Mineral oil or lidocaine drops can be used to kill an insect before removal under microscope guidance. The HCP should remove impacted objects.

Cleanse ears with a washcloth and finger. Avoid using cotton-tipped applicators. Penetration of the middle ear by a cotton-tipped applicator can cause serious injury to the TM and ossicles. Their use can also cause earwax to become impacted against the TM and impair hearing.

TRAUMA

Trauma to the external ear can cause injury to the subcutaneous tissue and result in a hematoma. If a hematoma is not aspirated, inflammation of the membranes of the ear cartilage (perichondritis) can result. Blows to the ear can cause conductive hearing loss if the ossicles in the middle ear are damaged or the TM is perforated. Head trauma that injures the temporal lobe of the cerebral cortex can impair the ability to understand the meaning of sounds.

MALIGNANCY OF EXTERNAL EAR

Skin cancers are the only common cancers of the ear. Precancerous actinic keratoses, rough sandpaper-like lesions on the upper border of the auricle, are associated with chronic sun exposure. They are often treated with liquid nitrogen. Cancers in the external ear canal include basal cell carcinoma in the pinna and squamous cell carcinoma in the ear canal. If left untreated,

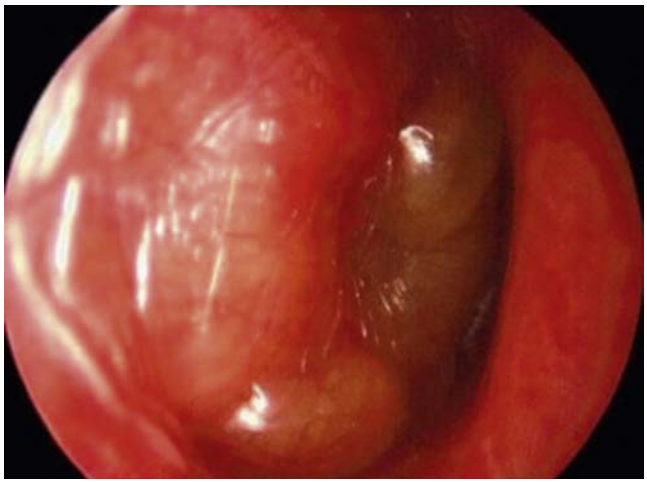

Fig. 23.3 Acute otitis media. (From Bourayou R, et al: Otitis, sinusitis, and related conditions. In Cohen J, et al, editors: *Infectious disease*, ed 4, St Louis, 2017, Mosby.)

they can invade underlying tissue. Teach the patient about the dangers of sun exposure and the importance of using hats and sunscreen when outdoors. See Chapter 25 for more about skin cancer.

MIDDLE EAR AND MASTOID PROBLEMS

OTITIS MEDIA

Acute Otitis Media

Acute otitis media is an infection of the TM, ossicles, and space of the middle ear. Swelling of the auditory tube from colds or allergies can trap bacteria, causing a middle ear infection. Pressure from the inflammation pushes on the TM, causing it to become red, bulging, and painful (Fig. 23.3). Acute otitis media is usually a childhood disease. In children, the auditory tube that normally drains fluid and mucus from the middle ear is shorter and narrower, and its position is flatter than in adults. Infection can be due to viruses or bacteria. Pain, fever, malaise, drainage, and reduced hearing are signs and symptoms of infection.

Oral antibiotics and eardrops are used if an infection is present (see Table 15.3). Surgery is reserved for the patient who does not respond to medical treatment. A *myringotomy* involves an incision in the TM to release the increased pressure and exudate from the middle ear. A tympanostomy tube may be placed short- or long-term for ventilation of the ear. Prompt treatment of acute otitis media can help prevent spontaneous perforation of the TM. If allergies are a causative factor, the patient may receive antihistamines and a nasal corticosteroid spray.

Otitis Media With Effusion

Otitis media with effusion is an inflammation of the middle ear with a collection of fluid in the middle ear space. The fluid may be thin, mucoid, or purulent. If the auditory tube does not open and allow equalization of atmospheric pressure, negative pressure within the middle ear pulls fluid from surrounding tissues. This problem often follows upper respiratory tract or chronic sinus infections, barotrauma (caused by pressure change), or otitis media.

Symptoms include a feeling of fullness of the ear, a "plugged" feeling or popping, and decreased hearing. The patient does not have pain, fever, or discharge from the ear. It is common to have otitis media with effusion for weeks to months after an episode of acute otitis media. It usually resolves without treatment but may recur.

Chronic Otitis Media and Mastoiditis

Repeated attacks of otitis media may lead to chronic otitis media, especially in adults who have a history of recurrent otitis media in childhood. Because the mucous membrane of the middle ear is continuous with the air cells of the mastoid bone, both can be involved in the chronic infectious process.

In *chronic otitis media* there is purulent exudate and inflammation that can involve the ossicles, auditory tube, and mastoid bone. It is often painless. Hearing loss, nausea, and episodes of dizziness can occur. Hearing loss is a complication from inflammatory destruction of the ossicles, TM perforation, or accumulation of fluid in the middle ear space. A mass of epithelial cells and cholesterol in the middle ear *(cholesteatoma)* may develop. As the cholesteatoma enlarges it can destroy the adjacent bones. Unless removed surgically, it can cause extensive damage to the ossicles and impair hearing.

Otoscopic examination of the TM may reveal changes in color and mobility or a perforation. Culture and sensitivity tests of the drainage are necessary to identify the organisms involved so the patient may receive the right antibiotic therapy. The audiogram may show a hearing loss as great as 50 to 60 dB if the ossicles are damaged or separated. Sinus x-rays, MRI, or a CT scan of the temporal bone can assess for bone destruction and the presence of a mass.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: CHRONIC OTITIS MEDIA

The goals of treatment are to clear the middle ear of infection, repair any perforations, and preserve hearing (Table 23.8). Otic and systemic (oral, IV) antibiotic therapy is started based on the culture and sensitivity results. In many cases of chronic otitis media, antibiotic resistance is present. The patient may need to have frequent evacuation of drainage and debris in an outpatient setting.

Often chronic TM perforations do not heal with conservative treatment, and surgery is necessary. *Tympanoplasty (myringoplasty)* involves reconstruction of the TM and/or the ossicles. A *mastoidectomy* is often done with a tympanoplasty to remove infected portions of the mastoid bone. Removal of tissue stops at the middle ear structures that appear capable of conducting sound. Sudden pressure changes in the ear and postoperative infections can disrupt healing or cause facial nerve paralysis.

Expect impaired hearing during the postoperative period if there is packing in the ear. A cotton ball dressing is used if an incision was made through the external auditory canal. Teach the patient to change the cotton packing as needed (Table 23.9). If a postauricular (behind the ear) incision was used and a drain is in place, place a dressing over that area. Then, place a soft outer dressing over the top of that dressing. This will prevent putting pressure on the auricle. Monitor the tightness of the

- Audiometry
- Imaging: Mastoid x-ray, CT scan, MRI

Management
- Ear irrigations
- Otic, oral, or IV antibiotics (see Table 15.3)
- Analgesics
- Antiemetics (see Table 46.1)
- Surgery
  - Tympanoplasty
  - Mastoidectomy

TABLE 23.9 PATIENT & CAREGIVER TEACHING

After Ear Surgery

Include the following information in the teaching plan for the patient and caregiver after ear surgery:

1. Sleep on your back or the unoperated ear for 1 week.
2. Avoid air travel and sun exposure for 6 weeks.
3. If you need to cough or sneeze, keep your mouth open.
4. Blow your nose gently, without blocking either nostril.
5. Do not shampoo your hair for 5 days. Wear a shower cap when bathing.
6. No swimming. Keep your ear dry for 6 weeks.
7. You may resume strenuous activity and contact sports in 1 month.
8. Change your ear dressing daily as prescribed.
9. Report excess drainage or severe dizziness to the HCP.

outer dressing to prevent tissue necrosis. Assess the amount and type of drainage. Keep the suture line dry.

OTOSCLEROSIS

Otosclerosis is a hereditary autosomal dominant disease. It is the most common cause of hearing loss in young adults. Spongy bone develops from the bony labyrinth, preventing movement of the footplate of the stapes in the oval window. This reduces the transmission of vibrations to the inner ear fluids and results in conductive hearing loss. Otosclerosis is typically bilateral, though 1 ear may show faster progression of hearing loss. The patient is often unaware of the problem until the loss becomes so severe that communication is difficult.

Otoscopic examination may reveal a reddish blush of the TM (Schwartz sign). It is caused by the vascular and bony changes within the middle ear. Tuning fork tests (e.g., Rinne) and an audiogram show good hearing by bone conduction with poor hearing by air conduction (air-bone gap) (Table 23.6). Usually, a difference of at least 20 to 25 dB between air and bone conduction levels of hearing occurs with otosclerosis.

TABLE 23.10 Interprofessional Care

Otosclerosis

Diagnostic Assessment
- History and physical assessment
- Otoscopic examination
- Rinne test
- Weber test
- Audiometry
- Tympanometry

Management
- Hearing aid
- Surgery (stapedectomy, stapes prosthesis)
- Sodium fluoride drug therapy

Interprofessional care of otosclerosis is outlined in Table 23.10. Microdrill or laser surgical treatment involves opening the footplate (stapedotomy) or replacing the stapes with a metal or Teflon substitute (prosthesis). These procedures are usually done with the patient under conscious sedation. The ear with poorer hearing is repaired first. The other ear may be operated on within a year. Right after surgery the patient often reports a significant improvement in hearing in the operative ear. Because blood and fluid accumulate in the middle ear during the postoperative period, the hearing level decreases somewhat, but it improves gradually with healing.

The hearing loss from otosclerosis may be stabilized by giving oral sodium fluoride supplements. They slow bone resorption and promote the calcification of bony lesions. Amplifying sound with a hearing aid may be helpful in mild disease.

Nursing management of the patient undergoing surgery for otosclerosis is like that of the patient having a tympanoplasty. Place a cotton ball in the ear canal and cover the ear with a small dressing. The patient may have dizziness, nausea, and vomiting because of stimulation of the labyrinth during surgery. Disturbing the perilymph fluid can cause nystagmus. Teach the patient to avoid sudden movements that may bring on or worsen vertigo and actions that increase inner ear pressure. These include coughing, sneezing, lifting, bending, and straining during bowel movements. The patient with nausea and vomiting often needs antiemetic drugs (see Table 46.1).

INNER EAR PROBLEMS

Three manifestations that indicate disease of the inner ear are vertigo, sensorineural hearing loss, and tinnitus. Symptoms of vertigo arise from the vestibular labyrinth, while hearing loss and tinnitus arise from the auditory labyrinth. There is an overlap between manifestations of inner ear problems and central nervous system (CNS) disorders.

MÉNIÈRE DISEASE

Ménière disease is a progressive disorder leading to an accumulation of endolymph in the membranous labyrinth. Although it usually affects only 1 ear, it can affect both. The cause is unknown.

TABLE 23.11 Interprofessional Care

Ménière Disease

Diagnostic Assessment
- History and physical assessment
- Audiometry
- Vestibular tests (including caloric test, positional test)
- Electronystagmography
- Glycerol test

Management

Acute Care

Drug Therapy
- Anticholinergics
- Antihistamines
- Antiemetics (see Table 46.1)
- Benzodiazepines

Surgical Therapy
- Endolymphatic sac decompression
- Endolymphatic shunt
- Labyrinthectomy
- Vestibular nerve section

Ambulatory Care
- Diuretics (see Table 36.7)
- Antihistamines
- Diet restriction of sodium, caffeine, nicotine, alcohol
- Vestibular exercises
- Vestibular rehabilitation

Genetic, immune, and environmental factors may play a role. Symptoms usually begin between 40 and 60 years of age.[3]

The excess fluid and resulting pressure lead to hearing and balance problems, including episodic vertigo, tinnitus, and ear pressure or fullness. Sensorineural hearing loss occurs gradually over time. The patient has significant disability because of sudden, severe attacks of vertigo with nausea, vomiting, and nystagmus. A sense of fullness in the ear, increasing tinnitus, and muffled hearing may precede an attack.[3] The patient may have the feeling of being pulled to the ground ("drop attacks"). Some patients report feeling like they are whirling in space. Attacks may last minutes to hours and may occur several times a year. The clinical course is highly variable.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: MÉNIÈRE DISEASE

Interprofessional care of Ménière disease (Table 23.11) includes diagnostic tests to rule out other causes of the symptoms, including CNS disease. Results that suggest Ménière disease include low-frequency sensorineural hearing loss on audiogram, 2 or more spontaneous episodes of vertigo, and abnormal vestibular tests.[3] A glycerol test may aid in diagnosis. The patient receives an oral dose of glycerol, followed by serial audiograms over 3 hours. Improved hearing or speech discrimination supports a diagnosis of Ménière disease. This is attributed to the osmotic effect of glycerol pulling fluid from the inner ear.

No cure exists for Ménière disease. The primary goal is to treat symptoms and reduce the number of attacks. During acute vertigo attacks, antihistamines (e.g., meclizine, diphenhydramine), anticholinergics (e.g., scopolamine), and benzodiazepines (e.g., lorazepam) can decrease vertigo and lessen nausea and vomiting.[4] Those with severe vomiting may need IV hydration and antiemetics (e.g., ondansetron). Plan nursing interventions to minimize vertigo and maintain patient safety (Table 23.12). Management between attacks may include diuretics and antihistamines. A low-salt diet with limited caffeine and alcohol intake often helps. Vestibular exercises may be recommended.

TABLE 23.12 NURSING MANAGEMENT

Care of the Patient With Acute Ménière Disease
- Administer medications and IV hydration as ordered.
- Keep patient in a quiet, darkened room in a comfortable position.
- Have patient avoid sudden head movements and position changes.
- Teach the patient to close the eyes until vertigo stops.
- Avoid fluorescent or flickering lights and television.
- Implement fall precautions.
- Implement measures to address nausea and vomiting.
- Monitor intake and output and daily weights.
- Help the patient with ambulation as needed.

Frequent and incapacitating attacks are indications for surgical intervention. Decompression of the endolymphatic sac and shunting can reduce the pressure on the cochlear hair cells and prevent further damage and hearing loss. If relief is not achieved, a vestibular nerve section (cutting the nerve) may be done. When involvement is unilateral, surgical ablation of the labyrinth, resulting in the loss of vestibular and hearing cochlear function, is an option. Some patients with severe attacks of vertigo have shown improvement with the injection of gentamicin through the TM. This results in inner ear damage that reduces endolymph production.

Discharge teaching should emphasize ways to protect the patient from injury between attacks. Review with the patient the need to sit or lie down at the onset of any dizziness. Discuss home safety and measures to decrease fall risk. Teach the need to avoid swimming under water and being on high places, like ladders, until vertigo is under control. Encourage the patient to practice any balance therapy exercises daily.

BENIGN PAROXYSMAL POSITIONAL VERTIGO

Benign paroxysmal positional vertigo (BPPV) is a common cause of vertigo. About 50% of the cases of vertigo may be due to BPPV. In BPPV, free-floating debris ("ear rocks") in the semicircular canal causes vertigo with specific head movements, such as getting out of bed, rolling over in bed, and sitting up from lying down. The debris is composed of small crystals of calcium carbonate that come from the utricle in the inner ear. The utricle may have been injured by head trauma, infection, or degeneration from the aging process. However, for many patients, we do not know the cause.

Symptoms of BPPV include nystagmus, vertigo, light-headedness, loss of balance, and nausea. There is no hearing loss. Symptoms tend to be intermittent and may be confused with those of Ménière disease. Diagnosis is based on the results of auditory and vestibular tests.

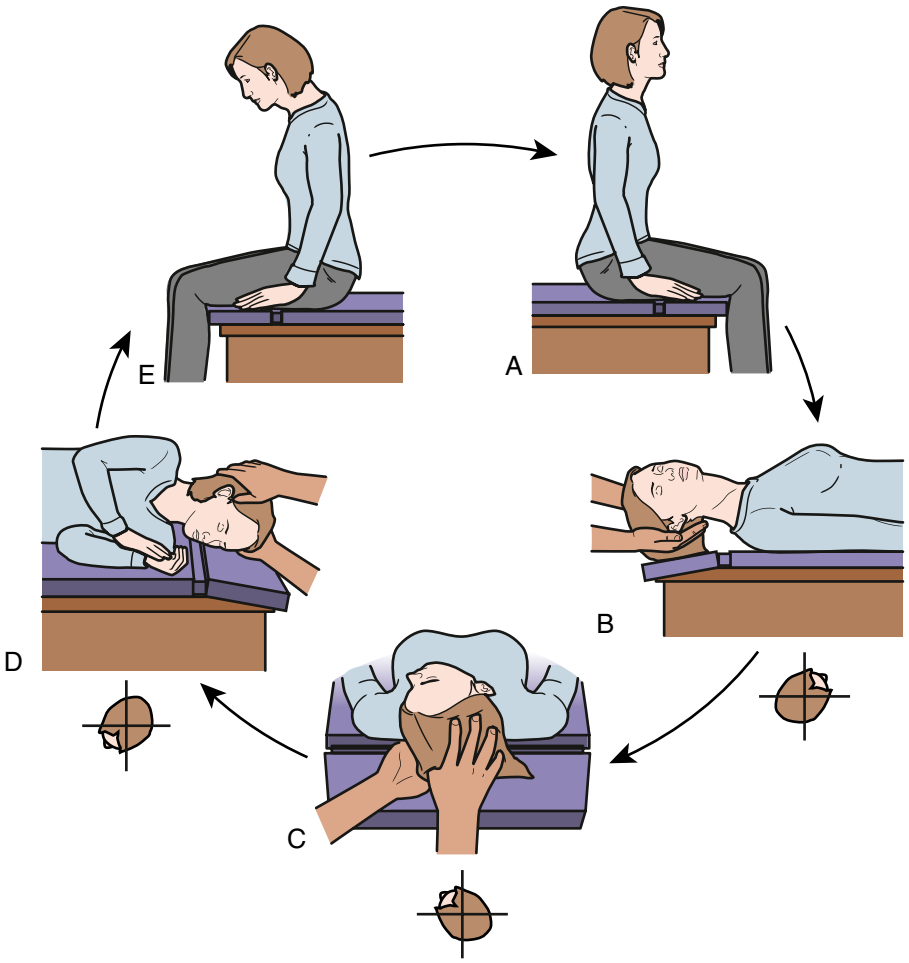

Fig. 23.4 Epley maneuver.

Although BPPV is bothersome, it is rarely serious unless a person falls. The Epley maneuver, or canalith repositioning procedure, is effective in providing symptom relief for many patients. This maneuver does not change the presence of debris but changes the location. It moves ear debris from areas in the inner ear that cause symptoms into less sensitive areas where they do not cause these problems. A trained HCP can teach the patient how to perform the maneuver (Fig. 23.4).

ACOUSTIC NEUROMA

An **acoustic neuroma** is a unilateral benign tumor that occurs where the vestibulocochlear nerve (CN VIII) enters the internal auditory canal. Early diagnosis is important because the tumor can compress the trigeminal and facial nerves and arteries within the internal auditory canal. Symptoms usually begin between 40 and 60 years of age.

Early symptoms are due to CN VIII compression and destruction. They include unilateral, progressive, sensorineural hearing loss, reduced touch sensation in the posterior ear canal, unilateral tinnitus, and mild, intermittent vertigo. Diagnostic tests include neurologic and audiometric tests and MRI.

Radiation therapy for small tumors can preserve hearing and vestibular function. Surgical treatment is effective for all tumors. Surgery on tumors larger than 3 cm can leave the patient with permanent hearing loss and facial paralysis. Stereotactic radiosurgery may slow tumor growth and preserve the facial nerve. Follow-up care after surgery is important to monitor hearing and tumor recurrence. Teach the patient to report any clear, colorless discharge from the nose. This may be cerebrospinal fluid (CSF), which increases the risk for infection.

HEARING LOSS AND DEAFNESS

Hearing disorders are a common cause of disability. Age is the strongest predictor of impaired hearing. In the United States, about 25% of those ages 65 to 74 and 50% of those 75 and older have hearing loss.[5] Causes of hearing loss are shown in Fig. 23.5.

Types of Hearing Loss

Conductive Hearing Loss

Conductive hearing loss occurs when outer or middle ear problems impair the transmission of sound waves to the inner ear. Common causes of conductive hearing loss in adults include impacted earwax, otitis media, TM perforation, otosclerosis, allergies, and benign tumors.[6]

The audiogram shows better hearing through bone than through air (air-bone gap). The patient often speaks softly because hearing their own voice (which is conducted by bone) seems loud. The patient may seem to hear better in a noisy environment. The first step is to identify and treat the cause if

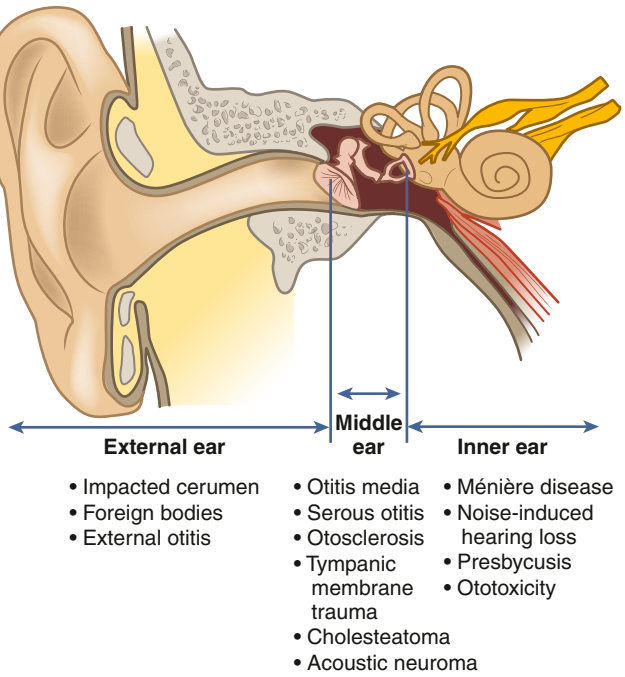

Fig. 23.5 Causes of hearing loss.

possible. If correction of the cause is not possible, a hearing aid may help if the loss is greater than 40 to 50 dB.

Sensorineural Hearing Loss

Sensorineural hearing loss is caused by damage in the inner ear or the vestibulocochlear nerve (CN VIII). Congenital and hereditary factors, noise exposure, aging (presbycusis), Ménière disease, trauma, and ototoxicity can cause sensorineural hearing loss. The main problems are the ability to hear sound but not to understand speech and the lack of understanding of the problem by others. The ability to hear high-pitched sounds (including consonants) diminishes. Sounds become muffled and hard to understand. An audiogram shows a loss in decibel levels of the 4000-Hz range and eventually the 2000-Hz range. A hearing aid may help some patients, but it only makes sounds and speech louder, not clearer.

Mixed Hearing Loss

Mixed hearing loss occurs from a combination of conductive damage in the outer or middle ear and sensorineural damage in the inner ear or auditory nerve. Conductive loss can often be treated surgically. Sensorineural loss is usually treated with hearing aids.

Central and Functional Hearing Loss

Central hearing loss involves an inability to interpret sound, including speech, because of a problem in the brain (CNS). A careful history is helpful because there are usually cases of deafness in the family. Refer the patient to a qualified hearing and speech service if needed.

An emotional or a psychologic factor can cause functional hearing loss. The patient does not seem to hear or respond to pure-tone subjective hearing tests, but no physical reason for hearing loss can be found. Psychologic counseling may help.

Genetic Link

Hereditary hearing loss is labeled non-syndromic or syndromic. Most persons have *non-syndromic hearing impairment,* in which hearing loss is the only problem. *GJB2* gene mutations are one of the most common causes of non-syndromic hearing loss. These result in changes in the production of the protein Connexin 26, which has a role in the cochlear function. Other genetic mutations increase the risk for ototoxicity or result in malformations of structures in the middle and/or inner ear. *Syndromic hearing impairment* is part of a syndrome associated with other problems. These often involve the eye, kidney, musculoskeletal, and nervous systems. There are more than 400 syndromes that include hearing loss.

Clinical Manifestations

Common early signs of hearing loss are answering questions inappropriately and not responding when not looking at the speaker (Table 23.3). Other behaviors that suggest hearing loss include straining to hear, cupping the hand around the ear, reading lips, and an increased sensitivity to slight increases in noise level. Often the patient is unaware of minimal hearing loss. Family and friends who get tired of repeating or talking loudly are often the first to notice the hearing loss. Pressure exerted by significant others is a significant factor in whether the patient seeks help for impaired hearing.

Sudden hearing loss, or sudden deafness, occurs as an unexplained, rapid loss of hearing (usually in 1 ear) either at once or over several days. It is a medical emergency. The patient should see an HCP at once.

Classification of Hearing Loss

We often classify hearing loss by the decibel level or loss as recorded on the audiogram. Normal hearing is in the 0- to 15-dB range at all frequencies. Most people with a hearing loss of 90 dB or greater have been deaf since birth (congenitally deaf). Table 23.13 describes the levels of hearing loss.

Tinnitus

Tinnitus is the perception of sound that originates in the head. It is often called "ringing in the ears" or "head noise." Bilateral tinnitus is sometimes the first symptom of hearing loss, especially in older adults. It may be soft or loud, high pitched or low pitched. Often, tinnitus occurs because of noise exposure. It also can be a drug side effect. More than 200 drugs are known to cause tinnitus. It can also occur with TMJ, stroke, and head and neck injuries.[7]

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: HEARING LOSS AND DEAFNESS

Deafness is often called an "invisible disability" because you cannot tell someone has hearing loss by looking at them. The disability usually is noted when you communicate with the person. You need to establish good communication so the patient has needed health information and feels included in their care.

TABLE 23.13 Diagnostic Criteria

Classification of Hearing Loss

Decibel (dB) Loss	Meaning
0–15	Normal hearing
16–25	Slight hearing loss
26–40	Mild impairment
41–55	Moderate impairment
56–70	Moderately severe impairment
71–90	Severe impairment
>90	Profound deafness

Hearing level, communication style, and language varies greatly. Assess these factors so you are aware of the patient's needs.

Problems with communication and interaction with others can be the source of many problems for the patient and caregiver. Hearing loss can affect the ability to understand and follow the advice of HCPs. You need to confirm the patient's understanding of health teaching. Descriptive visual aids can be helpful. If the patient uses sign language to communicate, the Americans with Disabilities Act requires using an interpreter when presenting significant information, such as consent or discharge teaching. Use and teach verbal and nonverbal communication techniques as described in Table 23.14.

Sometimes the patient refuses to admit or may be unaware of impaired hearing. Irritability is common because the patient must concentrate so hard to understand speech. The loss of clarity of speech in the patient with sensorineural hearing loss is frustrating. The patient may hear what is said but not understand it. Loneliness, depression, and cognitive decline can occur with advanced hearing loss.[8]

CHECK YOUR PRACTICE

Your newly assigned 68-year-old female patient is being discharged today after a hip replacement. Before going to her room, you prepared the materials and information for her discharge. You sit down by her bed and start talking with her. She shakes her head and says, "No, no." You are perplexed until she flashes a bracelet that says *I am deaf.*

- How will you proceed?

Health Promotion

Environmental Noise Control

Noise is the most preventable cause of hearing loss. Fig. 23.6 shows the dB levels of common indoor and outdoor sounds. Sudden severe loud noise (acoustic trauma) and chronic exposure to loud noise (noise-induced hearing loss) can damage hearing. Acoustic trauma causes hearing loss by destroying the hair cells of the organ of Corti. Sensorineural hearing loss from increased and prolonged environmental noise, such as amplified sound, is occurring at an increasing rate. Three factors affect noise-induced hearing loss: how loud the noise is, how close you are to the noise, and how long you hear the noise. Health teaching about avoiding continued exposure to noise levels greater than 70 dB is essential (Box 23.2).

TABLE 23.14 Communicating With Patients With Hearing Impairment

Nonverbal Aids	• Draw attention with hand movements. • Have speaker's face in good light. • Avoid light behind the speaker. • Maintain eye contact. • Use a face shield or clear mask if a face covering is needed. • Avoid chewing, eating, smoking while talking. • Remove background noise. • Move close to better ear.
Verbal Aids	• Speak normally and slowly. Do not shout. • Do not exaggerate facial expressions. • Do not overenunciate. • Use simple sentences. • Rephrase sentence. Use different words. • Write name or difficult words. • Speak in normal voice directly into better ear.

In work environments known to have high noise levels, Occupational Safety and Health Administration (OSHA) standards require employers to implement a hearing conservation program. Such programs should include noise exposure analysis, ways to control noise exposure, and employee-employer education. OSHA mandates ear protection for workers in environments where the noise levels consistently exceed 85 dB. Periodic audiometric screening provides baseline data on hearing and a way to measure later hearing loss.

Immunizations

Various viruses can cause deafness because of fetal damage and malformations affecting the ear. Promote childhood and adult immunizations, including the measles, mumps, and rubella (MMR) vaccine. Rubella infection during the first 8 weeks of pregnancy is associated with a high incidence of congenital rubella syndrome, which causes sensorineural deafness. Women of childbearing age should be tested for antibodies to these viral diseases. Women should avoid pregnancy for at least 3 months after being immunized. Immunization must be delayed if a woman is pregnant. Women can be vaccinated safely for rubella during the postpartum period.

Ototoxic Substances

Monitor the patient who is receiving ototoxic drugs or exposed to ototoxic agents for signs and symptoms of ototoxicity. These include tinnitus, diminished hearing, and balance problems. If symptoms develop, stopping the drug may prevent further damage and allow the symptoms to disappear.

Assistive Devices and Techniques

Hearing Aids

Hearing aids are sound-amplifying devices designed to improve hearing in people with hearing loss. The patient with suspected hearing loss should have a hearing assessment by a qualified audiologist. If a hearing aid is needed, it should be fitted by an audiologist or a speech and hearing specialist. Many types of hearing aids are available, each with advantages

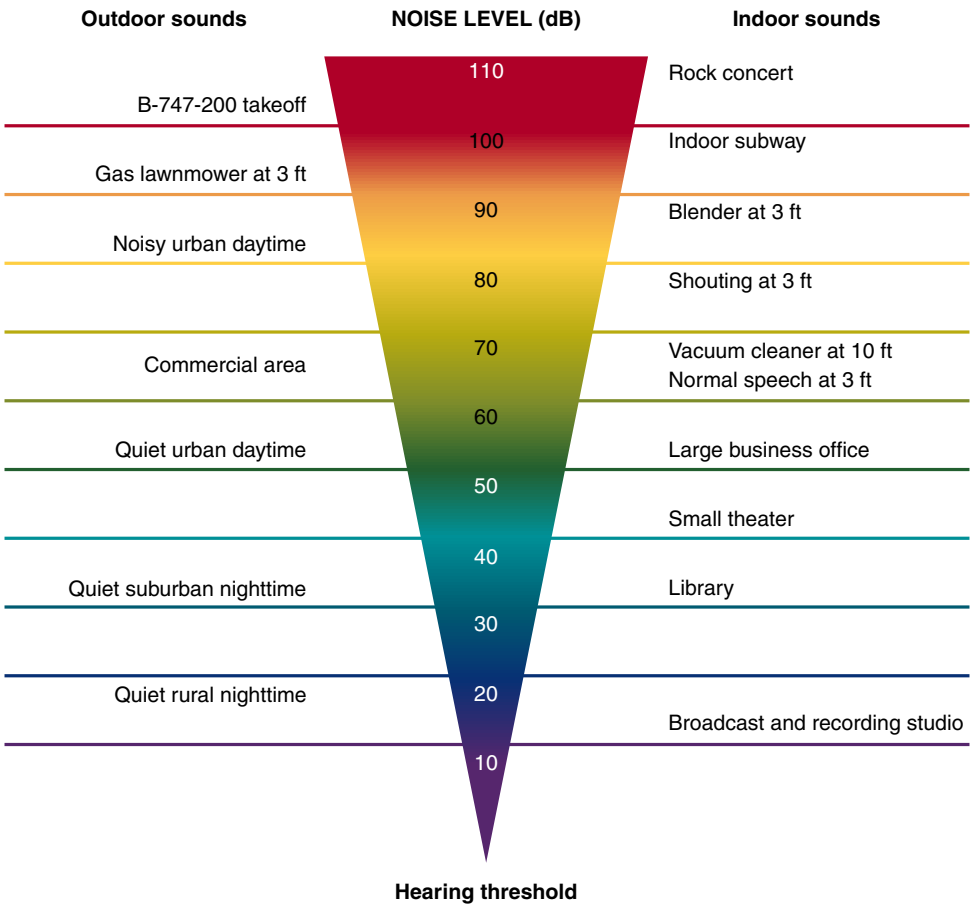

Fig. 23.6 Decibel levels of common sounds.

BOX 23.2 PROMOTING POPULATION HEALTH

Promoting Healthy Hearing

- Wear ear protection during recreational and work activities involving high noise levels.
- Monitor your audio level and how long you use personal listening devices.
- Avoid exposure to excessively loud noise whenever possible.
- Keep amplified music at a reasonable level.
- Undergo audiometric screening to detect hearing loss before it progresses.
- Avoid injury from cotton-tipped applicators and other cleaning materials.

and disadvantages (Table 23.15). The type of hearing aid chosen is based on the type and severity of hearing loss, financial resources, and patient's lifestyle.[9]

Patients who are motivated and optimistic about using a hearing aid are more successful users. Determine the patient's readiness for hearing aid therapy (Box 23.3). Assess their acknowledgment of a hearing problem, their feelings about wearing a hearing aid, the degree to which the hearing loss affects life, and any problems the patient has manipulating small objects, such as putting a battery in a hearing aid.

At first, the patient should wear hearing aids at home or quiet environments. The patient must first adjust to voices (including their own voice) and household sounds. Then, they should try increasing and decreasing the volume as situations require. As the patient adjusts to the increase in sounds and background noise, they can progress to situations in which several people will be talking at once. Next, the environment is expanded to the outdoors and then a shopping mall or grocery store. Adjustment to different environments occurs gradually, depending on the patient.

When a hearing aid is not being worn, it should be placed in a dry, cool area. The battery should be disconnected or removed when not in use. Battery life averages 1 week, depending on the hearing aid, battery, and amount of use. Ear molds should be cleaned weekly or as needed. Toothpicks or pipe cleaners can easily clear a clogged ear tip.

An *implantable hearing device* may be an option for those with mild to severe hearing loss who are unable or do not wish to wear regular hearing aids. There are 2 types: bone-anchored and implantable middle-ear devices. Bone-anchored devices are mainly used for conductive hearing loss or single-sided deafness. They are implanted into the bone of the skull. The sound signal bypasses the middle and outer ear, sending it straight to the cochlea.

Implantable middle-ear hearing devices help increase the transmission of sound vibrations reaching the inner ear. They involve a small prosthesis attached to one of the bones of the middle ear. Rather than amplifying the sound traveling to the TM like a hearing aid, these devices help move the bones directly.

TABLE 23.15 Types of Hearing Aids

Type	Advantages	Disadvantages
Completely in the canal (mild to moderate hearing loss)	Smallest and least visible aid. Protected from sounds such as wind noise	Costly. No space for add-ons such as directional microphones or volume controls. Small size may be hard to use.
In the canal (mild to severe hearing loss) 	Small, discrete. Easy to use controls. Has adjustable features such as noise reduction	Small size with added features may be hard to use. Not the best in noisy environments.
In the ear (mild to severe hearing loss) 	Inserts and adjusts easily. Good for those who wear glasses and during sports and activities.	Visible. May pick up wind noise. Susceptible to moisture.
Behind the ear (all types of hearing loss) 	Most powerful. Adjusts easily. Easy to clean. Longest battery life. Can fit many features.	Largest, most visible. Newer models may be smaller and less obvious. May pick up wind.

BOX 23.3 EVIDENCE-BASED PRACTICE

Hearing Aid Rehabilitation

As a nurse in a community-based health clinic, you provide medication education for patients with new prescriptions. S.T. is a 76-year-old patient who has been prescribed a metered dose inhaler for treatment of chronic bronchitis. As you prepare to review medication use with S.T., you quickly discern he has marked bilateral hearing loss. When you ask about the hearing loss, he says he does not use hearing aids.

Making Clinical Decisions

Synthesis of Best Available Evidence

Age-related hearing loss (presbycusis) is one of the most common problems affecting older adults. Research findings suggest the way in which hearing aid use is introduced may have impact on a patient's readiness to adopt hearing aid use. For example, one HCP may recommend hearing aid use as part of their expert opinion based on test results. Another HCP may ask the patient's opinion about hearing aid use, recognizing the patient's responsibility and right in decision making.

Clinician Expertise

While you provide S.T. written materials and use a demonstration inhaler to explain inhaler administration, you realize his hearing loss may affect his ability to get all needed information to use his medications safely and effectively. You ask him to tell you more about how hearing loss has affected his life, especially situations in which he has had problems with his hearing.

Patient Preferences and Values

S.T. tells you he often feels isolated due to his hearing loss. However, he is concerned about the cost because he does not have a hearing health care benefit on his Medicare plan. He states he does not like the visibility of hearing aids. They would "tell everyone that I'm hard of hearing."

Implications for Nursing Practice

1. What options besides hearing aid use could you discuss with S.T. to address his hearing loss?
2. How would you introduce a hearing clinic referral to S.T. to ensure he remains the decision maker about his own health?

Reference for Evidence

Ruusuvuori J, Aaltonen T, Lonka E, et al.: Discussing hearing aid rehabilitation at the hearing clinic: patient involvement in deciding upon the need for a hearing aid, *Health Commun* 35:1146, 2020.

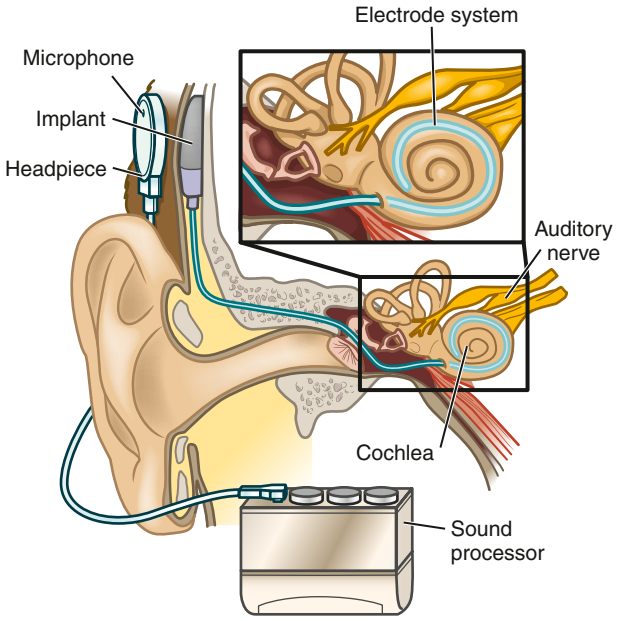

Fig. 23.7 Cochlear implant.

Cochlear Implant

A *cochlear implant* may be used for some people with severe to profound sensorineural hearing loss in one or both ears.[10] The implant bypasses damaged or missing portions of the ear and directly activates CN VIII. The ideal patient is one who became deaf after they acquired speech and language. The system has an external portion consisting of a microphone, sound processor, and transmitter, and an internal portion that includes a receiver and several electrodes (Fig. 23.7). The microphone picks up sounds in the environment. The processor then converts the sounds into electronic signals that are sent to the transmitter. The transmitter forwards these signals to the receiver, where they are passed on to the electrodes. The electrodes stimulate the auditory nerve, which carries the information directly to the brain, where it is interpreted as sound.

Extensive training and rehabilitation are essential to receive the most benefit from an implant. Besides providing sound to the person who heard none, cochlear implants improve speech-reading ability, allow self-monitoring of the loudness of speech, improve the sense of security, and decrease feelings of isolation.

Speech Reading

Speech reading, or *lip reading,* involves trying to understand speech from observing the speaker's lip movements. It can be helpful in increasing communication by supplementing what the patient can hear. It allows for about 40% understanding of the spoken word. The patient uses visual cues associated with speech, such as gestures and facial expressions, to help clarify the spoken message.

Sign Language

Sign language is a visual language for people with profound hearing impairment. It involves specific hand gestures along with facial expressions, head movements, shoulder raises, and other body movements. There are many different sign languages. American Sign Language (ASL) is used in the United States and the English-speaking parts of Canada.

TABLE 23.16 Classification of Presbycusis

Type	Hearing Change and Prognosis
Cochlear	
Stiffening of basilar membrane, which interferes with sound transmission in the cochlea	Hearing loss increases from low to high frequencies. Speech discrimination affected with higher frequency losses. Helped by appropriate forms of amplification
Metabolic	
Atrophy of blood vessels in wall of cochlea with interruption of essential nutrient supply	Uniform loss for all frequencies accompanied by recruitment. Good response to hearing aid
Neural	
Degenerative changes in cochlea and spinal ganglion	Loss of speech discrimination. Amplification alone not sufficient
Sensory	
Atrophy of auditory nerve. Loss of sensory hair cells	Loss of high-pitched sounds. Little effect on speech understanding. Good response to sound amplification

Assistive Listening Devices

Assistive listening devices (ALDs) are helpful in specific situations. Amplified telephones are the most common type of ALDs. Direct amplification devices, FM systems, and television listeners send sound directly to a hearing aid or other receiver. Notification systems take the place of alarms, such as doorbells and smoke detectors. They use amplified sounds, visual light cues, or vibration to notify the patient about their surroundings. People with profound deafness may be helped by text-telephone alerting systems that flash when activated by sound, closed captioning on television, and a specially trained dog. The dogs are trained to alert their owners to specific sounds within the environment, thus increasing the person's safety and independence.

Gerontologic Considerations: Hearing Loss

Presbycusis, hearing loss associated with aging, includes the loss of peripheral auditory sensitivity and a decline in word recognition ability. The person hears vowels but cannot distinguish consonants because they are in the high-frequency range. Because consonants help us recognize spoken words, this causes a decreased ability to understand speech. This may lead to confusion and embarrassment because of the difference in what was said and what was heard. Hearing loss in older adults is also associated with poorer cognitive and physical function and higher healthcare use. It can contribute to feelings of isolation as it becomes harder to enjoy talking to family or friends.

Degenerative changes in the inner ear cause presbycusis. Noise exposure is a common factor. Table 23.16 describes the classification of specific causes and associated hearing changes of presbycusis. Often, a person may have more than one type of presbycusis. The prognosis for hearing depends on the cause of the loss. Sound amplification with the right device is often

helpful in improving the understanding of speech. In other situations, an audiologic rehabilitation program can be valuable.

The older adult is often reluctant to use a hearing aid. Reasons cited most often include cost, appearance, lack of knowledge about hearing aids, amplification of competing noise, and unrealistic expectations. Some older adults may tend to accept their losses as part of getting older and believe there is no need for improvement. Most hearing aids and batteries are small. Neuromuscular changes such as stiff fingers, enlarged joints, and decreased sensory perception often make the care and handling of a hearing aid frustrating for an older person.

Case Study

Ménière Disease

(© iStock.com/EyeMark.)

Patient Profile

While R.S. is in the emergency department, she starts violently vomiting. She tells you that any movement is making her feel like she is "spinning like crazy." The HCP decides to admit her under observation with plans to administer an intratympanic injection of dexamethasone.

Objective Data

- Skin pale, extremely diaphoretic
- Heart rate 112 beats/min, respirations 22 breaths/min, BP 100/64

Interprofessional Care

- 1000 mg sodium diet as tolerated
- Ondansetron 2 mg IV now
- Lorazepam 1 mg IV every 6 hours
- Meclizine 25 mg PO every 6 hours
- Electronystagmogram and glycerol test
- Dextrose 5% with 0.45% NaCl at 75 mL/hr

Discussion Questions

1. ***Analyze:*** Explain the cause of Ménière disease.
2. ***Analyze***: What manifestations of Ménière disease does R.S. have?
3. ***Plan:*** Give the rationale for each treatment ordered.
4. ***Prioritize:*** Based on the assessment data, what are the priority clinical problems?
5. ***Prioritize:*** What are the priority nursing interventions for R.S.?
6. ***Act:*** Identify interventions that you can delegate to assistive personnel.
7. ***Safety:*** Name an area of risk for injury. What actions will you take to ensure patient safety?
8. ***Act:*** What teaching will you provide so R.S. can successfully self-manage her condition after discharge?
9. ***Evaluate:*** What outcomes would indicate care was effective?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. In a patient with vertigo, the parts of the ear most likely involved are the *(select all that apply)*
   - **a.** cochlea.
   - **b.** ossicles.
   - **c.** vestibule.
   - **d.** semicircular canals.
   - **e.** tympanic membrane.
2. A patient reports tinnitus and balance problems. The medication that may be responsible is
   - **a.** digoxin.
   - **b.** warfarin.
   - **c.** furosemide.
   - **d.** acetaminophen.
3. What assessment technique should the nurse use to assess an adult patient's tympanic membrane?
   - **a.** Have the patient tilt the head toward the nurse.
   - **b.** Stabilize the otoscope with your fingers on the patient's cheek.
   - **c.** Pull the auricle down and back to straighten the auditory canal.
   - **d.** Use a speculum slightly larger than the size of the patient's ear canal.
4. A normal finding the nurse would expect when assessing hearing would be
   - **a.** absent cone of light.
   - **b.** bluish purple tympanic membrane.
   - **c.** midline tone heard equally in both ears.
   - **d.** fluid level at hairline in the tympanic membrane.
5. Common age-related changes in the auditory system include *(select all that apply)*
   - **a.** drier earwax.
   - **b.** tinnitus in both ears.
   - **c.** auditory nerve degeneration.
   - **d.** atrophy of the tympanic membrane.
   - **e.** greater ability to hear high-pitched sounds.
6. The nurse teaches a patient scheduled for an electronystagmography that the test involves
   - **a.** measuring ear drum movement in response to pressure.
   - **b.** recording eye movements associated with ear irrigation.
   - **c.** placing an electrode on the eardrum and assessing for dizziness.
   - **d.** wearing headphones and determining which sounds can be heard.
7. Care of the patient with an acute attack of Ménière disease includes *(select all that apply)*
   - **a.** giving antiemetics as needed.
   - **b.** implementing fall precautions.
   - **c.** keeping the room dark and quiet.
   - **d.** placing the patient on NPO status.
   - **e.** ambulating in the hall independently.

8. The patient who has a conductive hearing loss
   a. hears better in a noisy environment.
   b. hears sound but does not understand speech.
   c. often speaks loudly because their own voice seems low.
   d. has clearer sound with a hearing aid if the loss is less than 30 dB.
9. Teach the patient who is newly fitted with bilateral hearing aids to *(select all that apply)*
   a. replace the batteries monthly.
   b. clean the ear molds weekly or as needed.
   c. clean ears with cotton-tipped applicators daily.
   d. disconnect or remove the batteries when not in use.
   e. initially restrict usage to quiet listening in the home.
10. Which strategies would *best* aid the nurse communicate with a patient who has a hearing loss? *(select all that apply)*
    a. Overenunciate speech.
    b. Speak normally and slowly.
    c. Exaggerate facial expressions.
    d. Raise the voice to a higher pitch.
    e. Write out names or difficult words.

1. c, d; 2. c; 3. b; 4. c; 5. a, b, c, d; 6. b; 7. a, b, c; 8. a; 9. b, d, e; 10. b, e.

Assessment: Integumentary System

Margaret R. Rateau

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Health Promotion

Tissue Integrity

LEARNING OUTCOMES

1. Describe the structures and functions of the integumentary system.
2. Link the age-related changes in the integumentary system to differences in assessment findings.
3. Obtain significant subjective and objective data related to the integumentary system from a patient.
4. Compare the components for describing primary and secondary lesions.
5. Perform a physical assessment of the integumentary system using appropriate techniques.
6. Specify the structural and assessment differences in light- and dark-skinned persons.
7. Distinguish normal from common abnormal findings of a physical assessment of the integumentary system.
8. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the integumentary system.

KEY TERMS

alopecia, Table 24.8
dermis
epidermis
erythema, Table 24.8
hirsutism, Table 24.8
intertriginous
keloid
keratinocytes
melanocytes
mole (nevus), Table 24.8
pruritus
sebaceous glands

The integumentary system is the largest organ of the body. It is composed of the skin, hair, nails, and certain glands. The skin has 2 major layers: the epidermis (outer layer) and the dermis (inner layer). The subcutaneous tissue (layer) lies under the dermis (Fig. 24.1). The skin is as complex as any organ, but, unlike the others, it is readily visible. Being able to see and touch the skin helps you assess your patients. You can see abnormalities, understand their significance, and intervene early.

STRUCTURES AND FUNCTIONS OF SKIN AND APPENDAGES

Structures

Epidermis

The **epidermis**, the outer layer of the skin, is relatively thin. Its thickness ranges from 0.5 mm on the eyelids to 1.5 mm on the palms of the hands and soles of the feet.[1] There are no lymphatic or vascular structures in the epidermis. It is supported by passive circulation from the dermis.

The epidermis is divided into 5 distinct but interrelated layers. Two of the layers are the stratum corneum (the surface layer) and the stratum germinativum (deepest, basal layer) (Fig. 24.1).

Most epithelial cells are keratinocytes (90%). The remaining cells are melanocytes, Langerhans' cells, and Merkel cells. **Keratinocytes** form in the basal layer. Initially, they are undifferentiated and shaped like columns. As they mature (keratinize), they move to the surface. There they flatten and die, forming the outer skin layer (stratum corneum). Keratinocytes make a fibrous protein, keratin, which is vital to the skin's protective barrier function. The upward movement of keratinocytes from the basal layer to the outermost levels of the stratum corneum takes about 14 days. The keratinocytes stay there for another 14 days, allowing the epidermis to regenerate every 28 days. Thus, each month you have a new layer of skin.

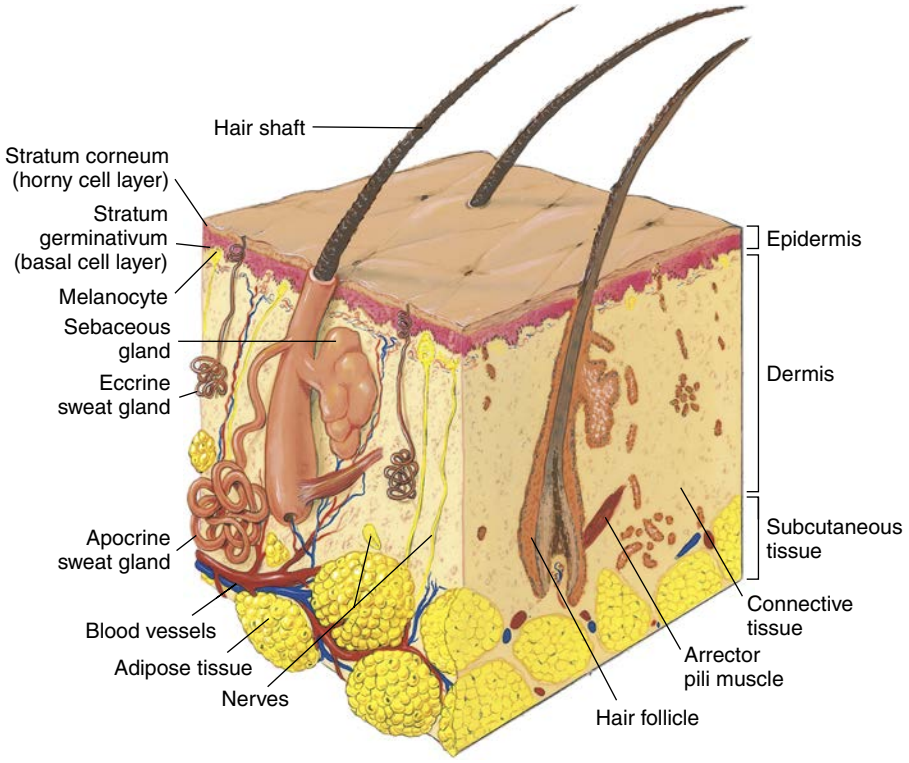

Fig. 24.1 Longitudinal view of the skin. (From Jarvis C: *Physical examination and health assessment,* ed 6, St Louis, 2012, Saunders.)

Many skin problems result from changes in this cell cycle. If dead cells slough off too rapidly, the skin appears thin and eroded. If new cells form faster than you shed old cells, the skin becomes scaly and thickened. The epidermis fails to function normally with skin cancer and psoriasis (discussed in Chapter 25).

Melanocytes are found in the deep, basal layer. They contain melanin, a pigment that gives color to the skin and hair and protects the body from damaging ultraviolet (UV) sunlight. Sunlight and hormones stimulate the melanosome (within the melanocyte) to increase the production of melanin. People of all races have similar numbers of melanocytes. In darker skin, the melanosomes are larger and more numerous. They make more eumelanin, the form of melanin that gives us the coloring of our skin.[2] Increased melanin forms a natural sun shield for dark skin and results in a decreased incidence of skin cancer. The distribution of melanocytes varies from one area of the body to another. For example, the face has more melanocytes than the abdomen.

Langerhans' cells are a type of dendritic cell. They are immunocompetent cells that recognize antigens. When they are depleted, the skin cannot initiate an immune response. The Langerhans cells in bioengineered skin grafts are removed to prevent graft rejection. We find decreased numbers of Langerhans cells with skin diseases such as psoriasis and sarcoidosis. *Merkel cells* are found in the basal layer. They are involved in the sensation of light touch. We use them when feeling the texture of an object and figuring out what it is.

The basement membrane zone is between the epidermis and dermis. It provides for the (1) exchange of fluids between the epidermis and dermis and (2) structural support for the epidermis. The basement membrane helps to secure the 2 layers together. Inflammation and separation of the epidermal and dermal layers result in the blisters seen with problems such as burns, full-thickness wounds, and mechanical trauma.

Dermis

The **dermis** is the connective tissue below the epidermis. Its thickness ranges from 0.6 mm on the eyelid to 3.0 mm on the back, palms of the hands, and soles of the feet.[1] The dermis is very vascular, containing many blood vessels. It also contains nerves, lymphatic vessels, hair follicles, sebaceous glands, and specialized cells such as mast cells and macrophages that protect the body from external stimuli.

The dermis is made of 3 types of connective tissue: collagen, elastic fibers, and reticular fibers. Collagen forms the greatest part of the dermis. It gives the skin toughness and strength. Collagen is critical in wound healing. The primary cell type in the dermis is the *fibroblast,* which makes collagen and elastin.

The dermis has 2 layers: an upper, thin papillary layer and a deeper, thicker reticular layer. The papillary layer is arranged haphazardly in ridges, or papillae, which extend into the outer epidermal layer. These elevated surface ridges form fingerprints and footprints. The reticular layer forms the bulk of the dermis. It is made up of thick collagen bundles arranged parallel to the skin's surface.

Subcutaneous Tissue

The subcutaneous tissue lies below the dermis. It is made of loose connective tissue and fat cells that provide insulation,

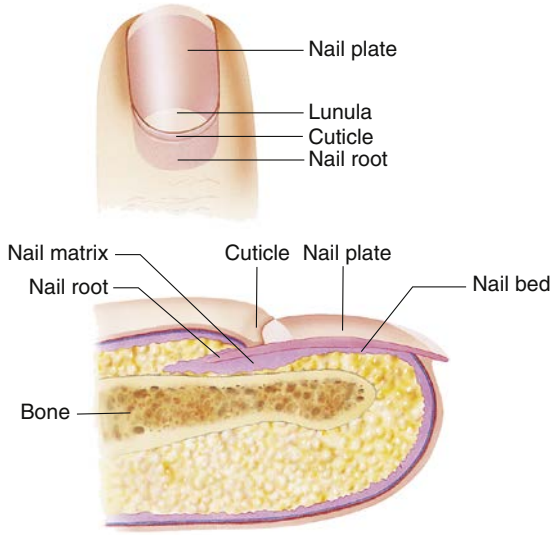

Fig. 24.2 Structure of a nail. (From Patton KT, Thibodeau GA, Douglas M: *Essentials of anatomy and physiology,* St Louis, 2014, Mosby.)

Fig. 24.3 Pigmented nail bands normally seen with dark skin color. (From Ball J, Dains J, Flynn J, et al.: *Seidel's guide to physical examination,* ed 8, St Louis, 2014, Mosby.)

cushioning, temperature regulation, and energy storage. The subcutaneous tissue attaches the skin to underlying tissues, such as muscle and bone. The distribution pattern of subcutaneous tissue varies with gender, heredity, age, and nutrition status.

Skin Appendages

Skin appendages include the hair, nails, and glands (sebaceous, apocrine, and eccrine). These appendages are epidermal extensions that have their roots in the dermis. They receive nutrients, electrolytes, and fluids from the dermis. Hair and nails form from specialized keratin. Systemic diseases can affect the condition and health of both hair and nails.

Hair grows on most of the body except for the lips, palms of the hands, interdigital spaces, portions of the genitalia, and soles of the feet. The density and pattern of distribution varies depending on age, sex, and race. Hair color is a result of heredity. It is determined by the type and amount of melanin in the hair shaft. Hair grows about 1 cm per month. People lose about 50 to 100 hairs each day.[3] Baldness, or **alopecia**, results when we do not replace lost hair.

Nails are made of heavily keratinized cells. The part of the nail that you can see is the nail body. The rest is the nail root. A fold of skin hides most of the nail root. The cuticle borders this skinfold. Nail growth begins in the nail root. The part of the nail root you can see is the *lunula*. This white, crescent-shaped area is the site of mitosis and nail growth (Fig. 24.2). Under the nail is an area of epidermis called the *nail bed.* The nail bed has many blood vessels. Nails grow slowly but continuously. Fingernails grow much faster than toenails, on average of 0.1 mm/day.[4] It takes 3 to 6 months to replace a fingernail. A toenail may take 12 months or longer to replace. Nail color ranges from pink to yellow or brown depending on skin color. Color and texture variations in nails may be normal or represent an abnormal condition. Pigmented longitudinal bands *(melanonychia striata)* occur in the nail bed in 90% or more of people with dark skin (Fig. 24.3).[5]

There are 2 major types of glands in the skin: sebaceous and sweat (apocrine and eccrine) glands. **Sebaceous glands** secrete *sebum,* which is emptied into the hair follicles. Sebum waterproofs and lubricates the skin and promotes the absorption of fat-soluble substances. Sebum is somewhat bacteriostatic and fungistatic. These glands depend on sex hormones, particularly testosterone, to regulate sebum secretion and production. Actual production varies depending on age, sex, and testosterone and estrogen levels. Sebaceous glands are present on all areas of the skin except the palms and soles and dorsum of the feet. These glands are most abundant on the face, scalp, upper chest, and back.

The *apocrine sweat glands* are mainly found in the axillary, genital, and breast areas. They are always connected to a hair follicle. These glands enlarge and become active at puberty because of reproductive hormones. They secrete a thick milky substance that is naturally odorless. Odor occurs when skin surface bacteria alter the secretions.

The *eccrine sweat glands* are found on most of the body, except the lips, ear canals, nail beds, labia minora, glans penis, and prepuce. One square inch of skin has about 3000 eccrine sweat glands. Their main function is to cool the body by evaporation, excrete waste products, and moisturize surface cells. Sweat is a transparent watery solution composed of salts, ammonia, urea, and other wastes. In extreme situations, the body can make 2 to 4 L of sweat per hour or up to 12 L in 24 hours. Heat, certain mental stimuli, and ingesting hot, spicy foods stimulate sweat secretion.

Functions of Integumentary System

The skin's main function is to protect the underlying body tissues by serving as a barrier to the external environment. The skin acts as a barrier against invasion by bacteria and viruses and prevents excess water loss. The fat in the subcutaneous layer insulates the body and provides protection from trauma. Melanin screens and absorbs UV radiation.

The skin with its nerve endings and special receptors collects sensory information from environmental stimuli. These highly specialized nerve endings give information to the brain related to pain, heat and cold, touch, pressure, and vibration.

TABLE 24.1 GERONTOLOGIC ASSESSMENT DIFFERENCES

Integumentary System

Changes	Differences in Assessment Findings
Skin	
↓ Subcutaneous fat, muscle laxity, degeneration of elastic fibers, collagen stiffening	Wrinkling, sagging breasts and abdomen, redundant flesh around eyes, slowness of skin to flatten when pinched (tenting)
↓ Extracellular water, surface lipids, and sebaceous gland activity	Dry, flaking skin
↓ Activity of apocrine and sebaceous glands	Dry skin with minimal to no perspiration, skin color uneven
Increased capillary fragility and permeability	Bruising
Increased focal melanocytes in basal layer with pigment accumulation	Solar lentigines on face and back of hands
↓ Blood supply	↓ In rosy appearance of skin and mucous membranes. Skin cool to touch. ↓ Awareness of pain, touch, temperature, peripheral vibration
↓ Proliferative capacity	Delayed wound healing
↓ Immunocompetence	↑ In skin cancers
Hair	
↓ Melanin and melanocytes	Gray or white hair
↓ Oil	Dry, coarse hair. Scaly scalp
↓ Hair density	Thinning and hair loss
Cumulative androgen effect; decreasing estrogen levels	Facial hirsutism, baldness
Nails	
↓ Peripheral blood supply	Thick, brittle nails, ↓ nail growth
Increased keratin	Longitudinal ridging
↓ Circulation	Prolonged return of blood to nails on blanching

The skin controls heat regulation by responding to changes in internal and external temperature with vasoconstriction or vasodilation. The skin's excretory function and heat regulation are related. We lose between 600 and 900 mL of water daily through insensible water loss (invisible vaporization from the lungs and skin), which helps regulate body temperature. Sebum and sweat lubricate the skin surface. Endogenous synthesis of vitamin D, which is critical to calcium and phosphorus balance, occurs in the epidermis. We make Vitamin D in the epidermis when UV light acts on vitamin D precursor cells.

Gerontologic Considerations: Effects of Aging on Integumentary System

Many skin changes occur with aging. Depending on how you view yourself, the normal, visible effects of aging on the skin and hair may have a profound psychologic effect. Having a youthful look may affect a person's self-image. The appearance of the signs of aging can be a threat to self-concept. Other changes in skin structure related to aging can pose a serious risk. Table 24.1 outlines age-related changes of the integumentary system and differences in assessment findings.

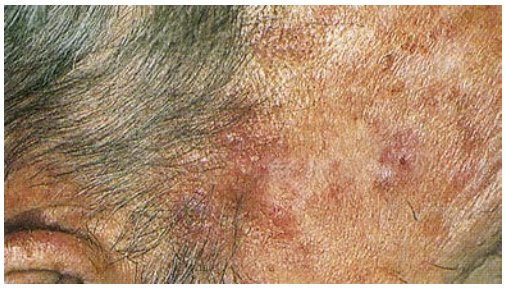

Fig. 24.4 Photoaging. Irregular pigmentation and keratoses occur in sun-damaged skin on forehead. (From Gawkrodger D, Ardern-Jones MR: *Dermatology,* ed 5, Edinburgh, 2012, Churchill Livingstone.)

Chronic UV exposure is the major cause of premature aging or photoaging and wrinkling of skin.[6] Sun damage to the skin is cumulative (Fig. 24.4). The wrinkling of sun-exposed areas such as the face and hands is more marked than in a sun-shielded area, such as the buttocks. A photoaged person is more susceptible to skin cancers because UV exposure decreases the ability to repair cellular damage. Chronic UV exposure from tanning beds causes the same damage as UV from the sun. Other factors that influence skin aging include diabetes, smoking, and alcohol use.

The junction between the dermis and epidermis flattens. This causes the layers to lose their tight bond. Skin tears and other trauma become common as the epidermis slides separately from the dermis. Collagen fibers stiffen, and elastic fibers degenerate. The amount of subcutaneous tissue decreases. These changes, with the added effects of gravity, lead to wrinkling. Fewer free fatty acids in the epidermis result in dry, scaly, itchy skin. Dryness, combined with trauma caused by scratching, increases the risk for cracks in the skin and secondary infections. Decreased subcutaneous fat increases the risk for traumatic injury, hypothermia, and skin shearing, which may lead to a pressure injury.

Fewer melanocytes are present. With decreased levels of melanin, hair color fades. Hormonal and vitamin deficiencies can cause dry, thin hair and alopecia. The growth rate of the hair and nails decreases. The nail plate thins. Nails become brittle and more prone to splitting and yellowing. Nails, especially the toenails, may thicken with age. With aging, the apocrine and eccrine sweat glands atrophy. This causes dry skin and decreased body odor.

Benign neoplasms related to the aging process can occur. These growths include seborrheic keratoses, vascular lesions such as cherry angiomas, and skin tags. *Actinic keratoses* appear on areas of chronic sun exposure, especially in the person who has a fair complexion and light eyes (blue, green, hazel). These premalignant skin lesions place a person at increased risk for squamous and basal cell cancers.

ASSESSMENT OF INTEGUMENTARY SYSTEM

The general skin assessment begins with your first contact with the patient and continues throughout the examination. As you are meeting your patient for the first time, take a moment to note the overall condition of the patient's skin and hair. You will assess specific areas of the skin when examining other body systems unless the chief complaint is a skin problem. Record a general statement about the skin's physical condition (Table 24.2).

TABLE 24.2 Normal Physical Assessment of Integumentary System

Skin	• Evenly pigmented. No petechiae, purpura, lesions, or excoriations • Warm, good turgor
Nails	• Pink, oval, adhere to nail bed with 160-degree angle
Hair	• Shiny and full; amount and distribution appropriate for age and gender • No flaking of scalp, forehead, or pinna

In addition, ask the health history questions outlined in Table 24.3 when you note a skin problem.

Case Study

Patient Introduction

(© iStockphoto/Thinkstock.)

D.A. is a 74-year-old woman who comes to the medical clinic with concerns related to "spots" on her face. She says they have been there for a while, and she thought they were just "age spots." She became concerned after her friend was diagnosed with a malignant melanoma.

Discussion Questions

1. Which type of assessment should you perform: comprehensive, focused, or emergency?
2. What are the possible causes of D.A.'s facial lesions?
3. What questions would you ask D.A. to determine the possible causes?

You will learn more about D.A. and her condition as you read this chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Subjective Data

Perform the interview using a sensitive and nonjudgmental attitude. The problem may be the result of poor hygiene or unhealthy behaviors. Some problems are highly visible and affect the patient's body image and self-concept. A thorough health history yields information about possible causes and the effect of the problem on the person's life.

Important Health Information

Health history. A health history reveals previous trauma, surgery, or disease that involves the skin. Many diseases have skin manifestations (Table 24.4). Determine if the patient has noticed any problems such as jaundice (liver disease), delayed wound healing (diabetes), cyanosis (respiratory, cardiovascular disorder), or pallor (anemia). Obtain specific information related to food sensitivities, pet or drug allergies, and skin reactions to insect bites and stings. Note any history of chronic or unprotected exposure to UV light, including tanning bed use and radiation treatments.

Medications. A thorough medication history is important. Ask the patient about skin-related problems that occurred because of taking a medication. Many hormones, antibiotics, corticosteroids, and antimetabolites have side effects that manifest in the skin. Medications may contain fragrances and preservatives that can cause skin reactions. Document the use of medications specifically used to treat a primary skin problem, such as acne, or a secondary skin problem, such as itching. Record the drug's name, length of use, method of application, and effectiveness.

TABLE 24.3 HEALTH HISTORY

Integumentary System

Health Perception–Health Management
- Describe your daily hygiene practices.
- What skin products are you now using?
- Describe any current skin problems, including onset, course, and treatment (if any).

Nutritional-Metabolic
- Describe any changes in your skin, hair, nails, and mucous membranes.
- Have you noticed any recent changes in the way sores or wounds heal?[a]
- Have you had any weight loss or dietary changes?[a]

Elimination
- Have you noticed recent changes in your skin related to excess sweating, dryness, or swelling?[a]

Activity-Exercise
- Do your leisure or work activities involve using any chemicals that might irritate your skin?[a]
- Do you do anything to protect yourself from the sun?[a]

Sleep-Rest
- Does your skin problem keep you awake or awaken you from sleep?[a]

Cognitive-Perceptual
- Do you have any unusual sensations of heat, cold, or touch?[a]
- Do you have any pain associated with your skin problem?[a]
- Do you have any joint pain?[a]

Self-Perception–Self-Concept
- How does your skin make you feel about yourself?

Role-Relationship
- Has your skin problem changed your relationships with others?[a]
- Have you changed your lifestyle because of your skin problem?[a]

Sexuality-Reproductive
- Has your skin problem changed your intimate relationships with others?[a]
- Has your birth control method (if used) caused a skin problem?[a]

Coping–Stress Tolerance
- Are you aware of any situation or stressor that changes your skin problem?[a]
- Do you think that stress plays a role in your skin problem?[a]
- How do you handle stress?

Value-Belief
- Are there any cultural beliefs that influence your thinking or feelings about your skin problem?[a]
- Are there any treatment options that you would be opposed to using?

[a] If yes, describe.

Surgery or other treatments. Determine if any surgeries, including cosmetic surgery, were done on the skin. Record any biopsy results. Note any treatments specific for a skin problem (e.g., phototherapy) or for a health problem (e.g., radiation therapy). Document any treatments undergone primarily for cosmetic purposes, such as tanning booth use, laser resurfacing, or cosmetic "peels."

Functional Health Patterns

Health perception–health management pattern. Ask about health practices, such as self-care habits related to daily hygiene. Assess the frequency of use and sun protection factor (SPF) of sunscreen products. Note the use of personal care products (e.g., shampoos, moisturizing agents, cosmetics), including brand name, quantity, and frequency. Record a

TABLE 24.4 Diseases With Skin Manifestations

Systemic Problem	Skin Manifestations
Cardiovascular	
Peripheral vascular disease	Loss of hair on hands and feet. Delayed capillary filling. Dependent rubor (redness), pain
Rheumatic heart disease	Petechiae, urticaria, nodules, erythema
Thromboangiitis obliterans (Buerger disease)	Pallor or cyanosis, gangrene, ulceration
Venous ulcers	Leathery, brownish skin on lower leg; itching, concave lesion with edema. Scar tissue with healing
Endocrine	
Addison disease	Loss of body hair (especially axillary), generalized hyperpigmentation (accentuated in folds)
Androgen deficiency	Development of sparse hair. Marked ↓ in sebum production
Androgen excess	Enlarged facial pores, male sex characteristics, acne, acceleration of coarse hair growth
Diabetes	Erythematous plaques of shins, delayed wound healing, neuropathy, acanthosis nigricans (velvety, dark skin on the neck and in skin folds)
Glucocorticoid excess (Cushing syndrome)	Atrophy, striae, epidermal thinning, telangiectasia, acne. ↓ Subcutaneous fat over extremities. Thin, loose dermis. Impaired wound healing. Increased vascular fragility. Mild hirsutism. Excess collection of fat over clavicles, back of neck, abdomen, and face
Hyperpituitarism (acromegaly)	Coarsened skin, deepened lines. ↑ Oiliness and sweating, acne. ↑ Number of nevi, hyperpigmentation; hypertrichosis (excess hair growth)
Hyperthyroidism	↑ Sweating, warm skin with persistent flush, thin nails, alopecia. Fine, soft hair
Hypoparathyroidism	Opaque, brittle nails with transverse ridges. Coarse, sparse hair with patchy alopecia
Hypothyroidism	Cold, dry, pale to yellow skin. Generalized nonpitting edema. Dry, coarse, brittle hair. Brittle, slow-growing nails
Gastrointestinal	
Cystic fibrosis	Abnormal sweat gland function
Deficiency of essential fatty acids	Scaly skin
Inflammatory bowel disease	Mouth ulcers, erythema nodosum
Liver disease and biliary tract obstruction	Jaundice, itching, pigmentary abnormalities, changes in nails and hair, spider angiomas, telangiectasia
Malabsorption syndrome	Acquired ichthyosis (dry, scaly skin)
Hematologic	
Anemia	Pallor, hyperpigmentation, pale mucous membranes, hair loss, nail dystrophy
Clotting disorders	Purpura, petechiae, bruising
Immune	
HIV infection	Kaposi sarcoma, eosinophilic folliculitis
Hodgkin lymphoma	Itching, sensitive skin
Non-Hodgkin lymphoma	Papules, nodules, plaques, itching
Metabolic	
Nicotinic acid (niacin) deficiency	Redness of exposed areas of skin of hand or foot, face, or neck; infected dermatitis
Vitamin B_1 (thiamine) deficiency	Edema, redness of soles of feet
Vitamin B_2 (riboflavin) deficiency	Red fissures at corner of mouth, glossitis
Vitamin C deficiency	Petechiae, purpura, bleeding gums
Musculoskeletal and Connective Tissue	
Dermatomyositis	Edema; purplish-red upper eyelids; scaly, macular erythema over knuckles
Scleroderma	Leathery hardening and stiffness of skin
Systemic lupus erythematosus	Discoid lesions, maculopapular semiconfluent rash (butterfly rash), alopecia, mouth ulcers
Neurologic	
Chronic sensory polyneuropathies, spinal cord trauma	Trophic changes in skin resulting from sensory denervation, pressure injuries, anesthesia, paresthesias
Renal	
Chronic kidney disease	Dry skin, itching, uremic frost, pallor, bruises
Reproductive Organs	
Paget disease	Eczematous patch of nipple and areola
Primary syphilis	Chancre
Secondary syphilis	Generalized skin lesions, alopecia
Tertiary syphilis	Gummas
Respiratory	
↓ Oxygenation due to respiratory disease	Cyanosis

BOX 24.1 GENETIC RISK ALERT

- The primary risk factor leading to skin cancer and melanoma is environmental exposure to UV radiation. UV radiation damages DNA, causing genetic defects. The resulting abnormal skin cells can lead to cancer.[7]
- Inherited genetic factors can increase skin cancer risk. A person has an increased risk for developing melanoma if they have a first-degree relative (e.g., parent, full sibling) who had a melanoma.
- People with a fair complexion (light-colored skin that easily freckles, red or blond hair, and blue or light-colored eyes) have an increased risk for skin cancer.

description of any current skin problem, including onset, symptoms, course, and treatment. Note any medications used for treating hair loss.

Obtain information about the family history of any skin diseases (Box 24.1). Include congenital and familial diseases (e.g., alopecia, psoriasis) and systemic diseases with skin manifestations (e.g., diabetes, thyroid disease, cardiovascular diseases, immune disorders). Note any family and personal history of skin cancer, particularly melanoma.

Nutritional-metabolic pattern. Ask about the condition of skin, hair, nails, and mucous membranes. Have there been any changes related to diet? A diet history reveals the adequacy of nutrients essential to healthy skin and wound healing, such as protein and vitamins A, D, E, and C. Note any food allergies that cause a skin reaction. Ask obese patients if they have areas of chafing or a rash in **intertriginous** areas. This is where skin surfaces overlap and rub on each other (e.g., below the breasts, axillae, groin). Skin in these areas is predisposed to skin tags *(acrochordons)* and candidiasis (yeast), intertrigo (bacteria, fungi, yeast), and erythrasma (bacteria) infections. Note any excess or absent sweating. Ask the patient about poor or delayed wound healing.

Elimination pattern. Ask the patient about skin problems, such as dehydration, edema, and **pruritus** (itching). These can indicate changes in fluid balance. If urinary or fecal incontinence is a problem, ask about the condition of the skin in the anal and perineal areas.

Activity-exercise pattern. Obtain information about environmental hazards in relation to hobbies and recreational activities, including exposure to known carcinogens, chemical irritants, and allergens. Ask the patient if any changes occur in the skin during exercise or other activities.

Sleep-rest pattern. Ask the patient about changes in sleep patterns caused by a skin problem. For example, itching can be distressing and interfere with normal sleep. Poor sleep and resulting tiredness can be reflected in a patient's face by dark circles under the eyes and a decreased firmness in the facial skin.

Cognitive-perceptual pattern. Assess the perception of the sensations of heat, cold, pain, and touch. Note any discomfort associated with a skin problem, especially when observed in intact skin. Are there any reports of unusual skin sensations? Patients with neuropathy may describe numbness, tingling, or crawling sensations in their arms or legs. Ask about joint pain. Assess the mobility of the joints since a skin problem may cause changes in mobility.

Self-perception–self-concept pattern. Assess any feelings related to having a skin problem, such as sadness, anxiety, despair, or altered body image. These feelings can occur with classic signs of aging or visible skin problems such as acne, rosacea, and psoriasis, which alter physical appearance.

Role-relationship pattern. Determine how the skin problem affects relationships with family members, peers, and work associates. Ask the patient about the effect of environmental factors on the skin, such as occupational exposure to irritants, sun, and unusually cold or unhygienic conditions. Contact dermatitis caused by allergens and irritants is a common problem associated with occupation.

Sexuality-reproductive pattern. Assess the effect of the patient's skin problem on sexual activity. Note the reproductive status of the female patient relative to possible therapeutic interventions. For example, isotretinoin used to treat acne, and topical fluorouracil used to treat actinic keratoses, are teratogenic drugs that may cause abnormal fetal development. Pregnant women or women who could become pregnant should not use them.

Coping–stress tolerance pattern. Assess the role that stress may play in creating or worsening a skin problem. Discuss what coping strategies the patient uses to manage the problem.

Value-belief pattern. Assess cultural or religious beliefs that could influence the patient's self-image as related to the skin problem. Values and beliefs that may influence or limit the choice of treatment options.

Case Study

Subjective Data

(© iStockphoto/Thinkstock.)

A focused subjective assessment of D.A. reveals the following:

- ***History:*** Negative except for an appendectomy at age 16.
- ***Medications:*** None at present. NKA.
- ***Health Perception–Health Management:*** Washes her face with a skin cleanser in the morning and nighttime. After cleansing, she applies a moisturizer with SPF 15. She has used these facial products for the past 3 years since she first started noticing small age spots appearing. Before that, she just used soap and water.
- ***Nutritional:*** D.A. reports that her skin seems drier as she ages but otherwise no changes besides the "age spots" or "whatever they are." Denies any changes in the way cuts or sores heal. No weight loss. Does not take any vitamins or mineral supplements.
- ***Elimination:*** Although skin is a little dry, D.A. does not perceive it to be excessively dry. Denies excess sweating or any swelling.
- ***Activity-Exercise:*** Loves to garden and go for walks outdoors. Reports a history of frequent, sometimes severe, sunburns as a child. No use of sunscreen growing up but does remember her mother making her wear T-shirts over her bathing suits to help prevent sunburn. Has used sunscreen for the past 20 years when outdoors. Reapplies as needed.
- ***Cognitive-Perceptual:*** Denies any pain or discomfort associated with skin lesions.
- ***Coping–Stress Tolerance:*** Fearful that she might have skin cancer.

Discussion Questions

1. Which subjective assessment findings concern you most?
2. What should you include in the physical assessment? What specific characteristics of the skin lesions would you be looking for?

You will learn more about the physical assessment of the skin in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Objective Data

Physical Assessment

The physical assessment begins with a systematic, general inspection and then a more specific assessment of problem areas. A normal range of differences exists in the skin, hair, and nails. Note normal skin changes related to age, genetic factors, and environmental exposures from other changes. Look for changes in the color of the skin, turgor, temperature, dryness, thickness, and vascularity. General principles when assessing the skin are:

- Have a private room of moderate temperature with good lighting. A room with exposure to daylight is preferred.
- Ensure that the patient is comfortable and in a dressing gown that allows easy access to all skin areas.
- Perform a general inspection and then a lesion-specific assessment.
- Use the metric system when taking measurements.
- Use the right terminology when documenting.

Clinical photography. Photographs are an adjunct to documentation and promote communication among the interprofessional team. We use them to assess and monitor skin problems and determine if the problem has improved or declined with treatment. They can be used to track moles and precancerous lesions and detect any changes early. Follow agency protocol for obtaining the patient's consent to photograph lesions.

Inspection. Inspect the skin for general color and pigmentation, vascularity, bruising, lesions, and discolorations. The critical factor in assessing skin color is change. A skin color that is normal for one patient can be a sign of a pathologic problem in another patient. The skin color depends on the amount of melanin (brown), carotene (yellow), oxyhemoglobin (red), and reduced hemoglobin (bluish-red) present at a particular time. The most reliable areas to assess erythema, cyanosis, pallor, and jaundice are the areas of least pigmentation. These include the sclera, conjunctivae, nail beds, lips, and buccal mucosa. We see true skin color best in photo-protected areas such as the buttocks. Activity, sun (UV) exposure, emotions, cigarette smoking, and edema, as well as respiratory, renal, cardiovascular, and hepatic disorders, can directly affect skin color.

Note the presence of body art such as piercings and tattoos. The nose, ears, eyebrows, lips, navel, and nipples are common sites of piercing. Examine tattoos and needle-track marks. Note the location and characteristics of the surrounding skin area. Tattoo pigments deposited in the skin may cause itching, pain, and sensitivity for several weeks after the tattoo is placed.

Examine the skin for problems related to vascularity (see Table 33.6). Is there any bruising? Note vascular and purpuric lesions such as *angioma* (benign tumor of blood or lymph vessels), *petechiae* (tiny, flat, purplish-red pinpoint lesions), or *purpura* (purple or reddish areas with bruising that do not blanche). Note the reaction to direct pressure on the lesion. If a lesion blanches on direct pressure and then refills, the redness is due to dilated blood vessels. If the discoloration stays, it is the result of subcutaneous or intradermal bleeding or a nonvascular lesion. Note any pattern of bruising. Is the discoloration in the shape of the hand or fingers? Are bruises at different stages of resolution? These may indicate other health problems or abuse and need further investigation.

Record the color, size, height, distribution, location, and shape of any lesions. Lesions may be primary or secondary lesions. *Primary skin lesions* develop on previously unaltered skin. The common characteristics of primary skin lesions are shown in Table 24.5. *Secondary skin lesions* are lesions that change with time or occur because of scratching or infection (Table 24.6).

We usually describe skin lesions in terms related to the lesions' configuration (solitary or pattern in relation to other lesions) and distribution (arrangement of lesions over an area of skin) (Table 24.7). Note any unusual odors. Skin sites with lesions, such as rashes, may be colonized with yeast or bacteria, which can cause distinctive odors in areas where skin rubs together (Fig. 24.5).

Inspect all body hair. Note the distribution, texture, and quantity of hair. Changes in the normal distribution of body hair and growth may indicate an endocrine or vascular problem. Inspect the nails, including nail shape, thickness, curvature, and surface. Note any grooves, pitting, ridges, or detachment from the nail bed. Changes in nail smoothness or thickness can occur with anemia, psoriasis, thyroid problems, decreased circulation, and some infections.

Palpation. Palpate the skin to obtain information about temperature, turgor, moisture, and texture. Use the back of your hand to gauge skin temperature. The skin should be warm, not hot; skin temperature increases when blood flow to the dermis increases. A local temperature increase occurs with burns and local inflammation. A general increase occurs when a person has a fever. A decreased body temperature may occur when shock or other circulatory problems, chilling, or infection are present.

Turgor refers to the elasticity of the skin. Assess turgor by gently pinching an area of skin under the clavicle or on the back of the hand. Skin with good turgor should easily move when lifted and immediately return to its original position when released. In older or patients with dehydration, a loss of turgor occurs and can cause tenting of the skin.

Skin moisture (dampness or dryness of the skin) increases in areas where skin rubs together. Skin moisture varies with environmental temperature, muscular activity, body weight, and body temperature. The skin should be intact with no flaking, scaling, or cracking. Skin generally becomes drier with increasing age.

Texture refers to the fineness or coarseness of the skin. The skin should feel smooth and firm, with the surface evenly thin in most areas. Thickened callus areas are normal on the soles and palms and relate to weight bearing. Increased skin thickness is often work related and the result of excess pressure. Excess calluses on the soles of patients with neuropathy or diabetes predispose them to developing lesions.

Use a focused assessment (Box 24.2) to evaluate the status of previously identified skin problems and monitor for signs of new problems. Assessment abnormalities of the skin are described in Table 24.8.

Assessment of Dark Skin

The structures of dark skin are often harder to assess (Table 24.9). Color is easiest to assess in areas where the epidermis is thin, and

TABLE 24.5 Primary Skin Lesions

Lesion	Description
Macule 	Circumscribed, flat discoloration that is blue, red, brown, or hypopigmented. <0.5 cm in diameter. If lesion >0.5 cm, it is a patch *Examples:* freckles, petechiae, measles, flat mole (nevus), café-au-lait spots, vitiligo (complete depigmentation)
Papule 	Elevated, solid lesion. <0.5 cm in diameter. Color varies. If lesion is >0.5 cm in diameter, it is a nodule *Examples:* wart (verruca), elevated moles, lipoma, basal cell cancer
Plaque 	Circumscribed, elevated, superficial, solid lesion. >0.5 cm in diameter *Examples:* psoriasis, seborrheic and actinic keratoses
Pustule 	Elevated, superficial lesion filled with purulent fluid *Examples:* acne, impetigo
Vesicle 	Circumscribed, superficial collection of serous fluid. <0.5 cm in diameter. If lesion >0.5 cm, it is a bulla *Examples:* varicella (chickenpox), herpes zoster (shingles), second-degree burn
Wheal 	Firm, edematous, irregularly shaped area. Size varies. May last only a few hours *Examples:* insect bite, urticaria, angioedema

TABLE 24.6 Secondary Skin Lesions

	Description
Atrophy 	Depression in skin resulting from thinning of the epidermis or dermis *Examples:* aged skin, striae
Excoriation 	Area in which epidermis is missing, exposing the dermis *Examples:* abrasion, scratch
Fissure 	Linear crack or break from the epidermis to the dermis. Dry or moist *Examples:* athlete's foot, chapping, eczema
Scale 	Excess, dead epidermal cells made by abnormal keratinization and shedding *Examples:* flaking of skin after a drug reaction or sunburn
Scar 	Abnormal formation of connective tissue that replaces normal skin *Examples:* surgical incision, healed wound
Ulcer 	Loss of the epidermis and dermis. Crater-like, irregular shape. Heals with scarring *Examples:* pressure injury, chancre

TABLE 24.7 Lesion Distribution Terminology

Term	Description
Annular	Circular, begins in center and spreads to periphery (e.g., tinea corporis [ringworm])
Asymmetric	Unilateral distribution
Confluent	Merging together (e.g., urticaria [hives])
Discrete	Distinct individual lesions that are separate (e.g., acne)
Gyrate	Twisted, coiled spiral, snakelike
Grouped	Clusters of lesions (e.g., vesicles of contact dermatitis)
Localized	Clearly defined, limited areas of involvement (confined to one area)
Polycyclic	Annular lesions grow together (e.g., psoriasis)
Solitary	Single lesion
Symmetric	Bilateral distribution
Zosteriform	Linear arrangement along a dermatome area (e.g., herpes zoster)

Fig. 24.5 Intertrigo. Rash in body folds with *Candida* infection. (From Graham-Brown R, Bourke J, Cunliffe T: *Dermatology: Fundamentals of practice,* Edinburgh, 2008, Mosby.)

pigmentation is not influenced by sun exposure, such as the lips, mucous membranes, nail beds, and protected areas (e.g., buttocks). Palmar and plantar surfaces are lighter than other skin areas in darker-skinned persons. Rashes are often harder to see and may have to be palpated. Wrinkling is less apparent in those with dark skin.

Persons with dark skin are predisposed to certain skin and hair problems. **Keloid** is an overgrowth of collagenous tissue at the site of a skin injury (e.g., ear piercing) (Fig. 24.6). *Vitiligo* is a total loss of pigment in the affected area (Fig. 24.7). In *dermatosis papulosa nigra,* the person has small, pigmented wart-like papules, often on the face (Fig. 24.8). *Nevus of Ota* is a slate-gray or blue-gray birthmark found on the forehead and face around the eye area. It may involve the sclera. *Traction alopecia* may be the result of trauma from hair rollers or from tight braiding of the hair (Fig. 24.9). The hair loss may be temporary or permanent. *Pseudofolliculitis* is an inflammatory response to ingrown hairs that occurs after shaving too closely in the beard area. The ingrown hairs result in pustules and papules.

Because of the darkness of the skin in some people, color may not be a reliable indicator of systemic conditions (e.g., flushed skin with fever). Cyanosis may be hard to detect because a normal bluish hue occurs in dark-skinned people. Dark skin rarely shows a blanch response, making it harder to identify pressure injuries.

BOX 24.2 FOCUSED ASSESSMENT

Integumentary System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about the following and note responses.

Hair loss (unusual or rapid)	Y	N
Changes in skin (e.g., lesions, bruising)	Y	N
Nail discoloration	Y	N

Objective: Diagnostic

Check the following for results and critical values.

Biopsy results	✓
Albumin	✓

Objective: Physical Assessment

Inspect

Skin for color, integrity, scars, lesions, signs of breakdown	✓
Facial and body hair for distribution, color, quantity, hygiene	✓
Nails for shape, contour, color, thickness, cleanliness	✓
Dressings, if present	✓

Palpate

Skin for temperature, texture, moisture, thickness, turgor, mobility	✓

Case Study

Objective Data: Physical Examination

(© iStockphoto/Thinkstock.)

Physical assessment findings of D.A.'s skin are as follows:

- Complexion fair. Wrinkles around eyes, above upper lip, and on sides of cheeks bilaterally. Normal skin temperature and turgor.
- Lesions: on upper right forehead measuring 2 × 3 mm; on left forehead near hairline measuring 1 × 2 mm; and on left lower cheek measuring 2 × 2.5 mm.

Cheek lesion. (From Bolognia JL, Schaffer JV, Duncan KO, et al: *Dermatology essentials,* Philadelphia, 2014, Saunders.)

- The lesions are slightly erythematous and do not blanch with direct pressure. Borders are distinct. The lesions on the forehead have minimal elevation noted on palpation. The lesion on the cheek is slightly elevated.
- No other skin lesions noted elsewhere.

Discussion Questions

1. Which physical assessment findings concern you most?
2. What diagnostic studies do you think may be ordered for D.A.?
   You will learn more about diagnostic studies related to the skin in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

TABLE 24.8 ASSESSMENT ABNORMALITIES

Integumentary System

Finding	Description	Possible Etiology and Significance
Alopecia	Hair loss (local or general)	Heredity, friction, rubbing, traction, trauma, stress, infection, inflammation, chemotherapy, pregnancy, emotional shock, tinea capitis, immunologic factors
Angioma	Tumor consisting of blood or lymph vessels	Normal increase in incidence with aging, liver disease, pregnancy, varicose veins
Carotenemia (carotenosis)	Yellow discoloration of skin, no yellowing of sclerae, most noticeable on palms and soles	Vegetables containing carotene (e.g., carrots, squash), hypothyroidism
Comedo (acne lesion)	Enlarged hair follicle plugged with sebum, bacteria, and skin cells; can be open (blackhead) or closed (whitehead)	Heredity, certain drugs, hormonal changes with puberty and pregnancy
Cyanosis	Slightly bluish-gray or dark purple discoloration of the skin and mucous membranes caused by excess amounts of reduced hemoglobin in capillaries	Cardiorespiratory problems, vasoconstriction, asphyxiation, anemia, leukemia, and cancers
Cyst	Sac containing fluid or semisolid material	Obstruction of a duct or gland, parasitic infection
Ecchymosis (bruising)	Large, bruise-like lesion caused by collection of extravascular blood in dermis and subcutaneous tissue	Trauma, bleeding disorders
Erythema	Redness occurring in patches of variable size and shape	Heat, certain drugs, alcohol, UV rays, any problem that causes dilation of blood vessels in the skin
Hematoma	Extravasation of blood of enough size to cause visible swelling	Trauma, bleeding disorders
Hirsutism	Male distribution of hair in women	Abnormality of ovaries or adrenal glands, decrease in estrogen level, familial trait
Hypopigmentation	Loss of pigmentation resulting in lighter patches than the normal skin	Chemical agents, nutrition, burns, inflammation, infection
Intertrigo	Dermatitis of overlying surfaces of the skin (Fig. 24.5)	Moisture, irritation, obesity; may be complicated by *Candida* infection
Jaundice	Yellow (in white patients) or yellowish-brown (in dark-skinned patients) discoloration of the skin, best seen in the sclera, due to increased bilirubin in the blood	Liver disease, red blood cell hemolysis, pancreatic cancer, common bile duct obstruction
Keloid	Hypertrophied scar beyond wound margins (Fig. 24.6)	Predisposition more common in dark-skinned persons
Lichenification	Thickening of the skin with accentuated normal skin markings	Repeated scratching, rubbing, and irritation usually because of itching or neurosis
Mole (nevus)	Benign overgrowth of melanocytes	Defects of development; excess numbers and large, irregular moles; often familial
Petechiae	Pinpoint, discrete deposits of blood <1–2 mm in the extravascular tissues and visible through the skin or mucous membrane	Inflammation, marked vasodilation, blood vessel trauma, blood dyscrasia that results in bleeding tendencies (e.g., thrombocytopenia)
Telangiectasia	Visibly dilated, superficial, small blood vessels, often found on face and thighs	Aging, acne, sun exposure, alcohol, liver failure, corticosteroids, radiation, certain systemic diseases, skin tumors
Tenting	Failure of skin to return immediately to normal position after gentle pinching	Aging, dehydration, cachexia
Varicosity	Increased prominence of superficial veins	Interruption of venous return (e.g., from tumor, incompetent valves, inflammation), often found on lower legs with aging
Vitiligo	Complete absence of melanin (pigment) resulting in chalky-white patch (Fig. 24.7)	Autoimmune, familial, thyroid disease

TABLE 24.9 NURSING ASSESSMENT

Assessment Variations in Light- and Dark-Skinned Persons

Light Skin	Dark Skin
Cyanosis	
Grayish blue tone, especially in nail beds, earlobes, lips, mucous membranes, palms, and soles	Ashen or gray color most easily seen in the conjunctiva of the eye, mucous membranes, and nail beds
Ecchymosis	
Dark red, purple, yellow, or green color, depending on age of bruise	Purple to brownish-black. Hard to see unless occurring in an area of light pigmentation
Erythema	
Reddish tone, increased skin temperature may be present from inflammation	Deeper brown or purple skin tone, increased skin temperature may be present from inflammation

Continued

TABLE 24.9 NURSING ASSESSMENT—cont'd

Assessment Variations in Light- and Dark-Skinned Persons

Light Skin	Dark Skin
Jaundice	
Yellowish color of skin, sclera, fingernails, palms, and oral mucosa	Yellowish green color most obviously seen in sclera of eye (do not confuse with yellow eye pigmentation, which may be seen in patients with dark skin), palms, and soles
Pallor	
Pale skin color that may appear white or ashen; also seen on lips, nail beds, and mucous membranes	Lack of underlying red tone in brown or black skin. In lighter dark-skinned persons, yellowish-brown skin. In darker dark-skinned persons, ashen or gray skin
Petechiae	
Lesions appearing as small, reddish-purple pinpoints, best seen on abdomen and buttocks	Hard to see. May be seen in the buccal mucosa of the mouth or conjunctiva of the eye
Rash	
May be seen and felt with light palpation	Not easily seen. May be felt with light palpation
Scar	
Generally heals, showing narrow scar line	Higher incidence of keloid development, resulting in a thickened, raised scar (Fig. 24.6)

Fig. 24.6 Keloid. Hypertrophic scarring after skin injury, which is more common in dark-skinned persons. (From Kliegman RM et al.: *Nelson textbook of pediatrics,* Philadelphia, 2011, Saunders.)

Fig. 24.7 Vitiligo. Total loss of pigment in the affected area. (From Marks JG, Miller JJ: *Principles of dermatology,* St. Louis, 2019, Elsevier.)

Fig. 24.8 Dermatosis papulosa nigra. Small, pigmented wart-like papules, often on the face. (From James W, Berger T, Elston D: *Andrews' diseases of the skin,* ed 12, Edinburgh, 2016, Elsevier.)

Fig. 24.9 Traction alopecia. Hair loss in scalp because of prolonged tension from hair rollers, braiding, or straightening combs. (From Ahanogbe I, Gavino A: Evaluation and management of the hair loss patient in the primary care setting, *Prim Care* 42:569, 2015.)

DIAGNOSTIC STUDIES OF INTEGUMENTARY SYSTEM

Table 24.10 presents common diagnostic studies used for the integumentary system. The main diagnostic techniques related to skin problems are inspection of an individual lesion and a careful history related to the problem. If we cannot make a definitive diagnosis with these techniques, other tests may be needed. With *dermatoscopy*, the HCP uses a lighted instrument with optical magnification up to 10 times normal to see skin structures and colors not visible to the naked eye.[8] These devices can help the HCP determine if a lesion should be biopsied.

Biopsy is one of the most common diagnostic tests used to evaluate a skin lesion. A biopsy is needed when we suspect cancer or the specific diagnosis is questionable. Techniques include punch, incisional, excisional, and shave biopsies. The method used depends on factors such as the site of the biopsy, cosmetic result desired, and type of tissue needed.

TABLE 24.10 Diagnostic Studies

Integumentary System

Study	Description and Purpose	Nursing Responsibility
Biopsy		
Excisional	Used when good cosmetic results and/or entire lesion removal desired. Skin closed with subcutaneous and skin sutures.	*Before:* Verify that consent form is signed (if needed). *During:* Help with site preparation, anesthesia, procedure, and hemostasis. Properly identify specimen. *After:* Apply dressing, give postprocedure instructions to patient.
Incisional	Wedge-shaped incision made in lesion too large for excisional biopsy. Useful when specimen needed is larger than shave or punch biopsy.	
Punch	Special punch biopsy instrument of appropriate size used. Instrument rotated to appropriate level to include dermis and some fat. Suturing depends on size and site. Provides full-thickness skin for diagnostic purposes.	
Shave	Single-edged razor blade used to shave off superficial lesions or small sample of a large lesion. Provides thin specimen for diagnostic purposes.	
Microscopic Tests		
Culture	Test identifies fungal, bacterial, and viral organisms. For *fungi,* scraping or swab of skin performed. For *bacteria,* material obtained from intact pustules, bullae, or abscesses. For *viruses,* vesicle or bulla and exudate taken from base of lesion.	*Before:* Teach patient the purpose of test. *During:* Properly identify specimen. Follow instructions for storing specimen if not immediately sent to laboratory.
Immunofluorescence studies	Some skin diseases have specific, abnormal antibody proteins that we can identify with fluorescence studies. Can examine both skin tissue and serum.	*Before:* Teach patient the purpose of test. *During:* Help obtain specimen. For punch biopsy, place specimen in special fixative (e.g., Michel's) and not formalin.
Mineral oil slides	To check for infestations, place scrapings on slide with mineral oil and view microscopically.	*Before:* Teach patient the purpose of test. *During:* Prepare slide.
Potassium hydroxide (KOH)	Hair, scales, or nails examined for superficial fungal infection. Put specimen on glass slide and add 10%–20% concentration of KOH.	*Before:* Teach patient the purpose of test. *During:* Prepare slide.
Tzanck test (Wright's and Giemsa's stain)	Fluid and cells from vesicles examined. Used to diagnose herpes infections. Specimen put on slide, stained, and examined microscopically.	*Before:* Teach patient the purpose of test. *During:* Use sterile technique for collecting fluid.
Miscellaneous		
Patch test (Fig. 24.10)	Used to assess for allergic dermatitis and photoallergic reactions. Application of allergens to the patient's skin (usually on the back) for 48 hr. Test sites examined 48 hr later for a reaction, characterized by the presence of erythema, papules, and/or vesicles. May do additional readings beyond 48 hr.	*Before:* Teach patient the purpose of test and procedure. *After:* Tell patient to leave patches in place for 48 hr. During this time, it is important not to wash the area or play vigorous sports because if the adhesive tape peels off, the process will need to be repeated. Do not expose the patches to sunlight or other sources of UV light.
Wood's lamp (blacklight)	Examination of skin with long-wave UV light causes specific substances to fluoresce (e.g., *Pseudomonas* organisms, fungal infections, vitiligo).	*Before:* Teach patient the purpose of test and procedure. Tell patient it is not painful. *During:* Darken room.

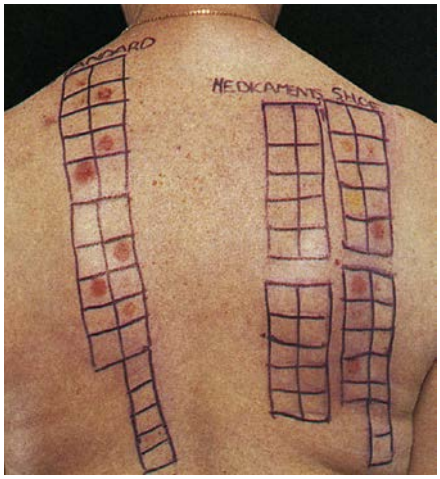

Fig. 24.10 Patch test. Results from applying possible allergens to the skin show positive reactions in the sites labeled "standard" and "shoe." (From Graham-Brown R, Bourke J, Cunliffe T: *Dermatology: Fundamentals of practice,* Edinburgh, 2008, Mosby.)

Other diagnostic procedures include stains and cultures for fungal, bacterial, and viral infections. Direct immunofluorescence is a special diagnostic technique used on biopsy specimens. It may be done in certain conditions such as bullous diseases and systemic lupus erythematosus. Indirect immunofluorescence is done on blood samples.

Case Study

Objective Data: Diagnostic Studies

(© iStockphoto/ Thinkstock.)

The HCP examines the lesion via dermatoscopy and uses a Wood's lamp to rule out a fungal infection. The HCP suspects basal cell cancer.

Discussion Questions

1. Are these the diagnostic tests you expected the HCP to perform?
2. What, if any, other diagnostic studies would you expect the HCP to order?
3. What are the interprofessional team's priorities for D.A. at this time?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The nurse provides diligent skincare because the primary function of the skin is
   - **a.** insulation.
   - **b.** protection.
   - **c.** sensation.
   - **d.** absorption.
2. Age-related assessment findings of the hair and nails include *(select all that apply)*
   - **a.** oily scalp.
   - **b.** scaly scalp.
   - **c.** thinner nails.
   - **d.** thicker, brittle nails.
   - **e.** longitudinal nail ridging.
3. When assessing the nutritional-metabolic pattern in relation to the skin, the nurse asks the patient about
   - **a.** joint pain.
   - **b.** the use of moisturizing shampoo.
   - **c.** recent changes in wound healing.
   - **d.** self-care habits related to daily hygiene.
4. The nurse assessed a patient's skin lesions as firm, edematous, and irregularly shaped with a variable diameter. They would be called
   - **a.** wheals.
   - **b.** papules.
   - **c.** fissures.
   - **d.** plaques.
5. During the physical assessment of a patient's skin, the nurse would
   - **a.** use a flashlight in a poorly lit room.
   - **b.** note cool, moist skin as a normal finding.
   - **c.** pinch up a fold of skin to assess for turgor.
   - **d.** perform a lesion-specific assessment and then a general inspection.
6. Patients with dark skin are more likely to develop
   - **a.** keloids.
   - **b.** wrinkles.
   - **c.** skin rashes.
   - **d.** skin cancer.
7. On inspection of a patient's dark skin, the nurse notes a blue-gray birthmark on the forehead and eye area. This assessment finding is called
   - **a.** vitiligo.
   - **b.** intertrigo.
   - **c.** Nevus of Ota.
   - **d.** telangiectasia.
8. Diagnostic testing is recommended for skin lesions when
   - **a.** a health history cannot be obtained.
   - **b.** a more definitive diagnosis is needed.
   - **c.** percussion reveals an abnormal finding.
   - **d.** treatment with prescribed medication has failed.

1. b; 2. b, d, e; 3. c; 4. a; 5. c; 6. a; 7. c; 8. b.

Integumentary Problems

Mary M. Cameron

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Cellular Regulation
Coping
Infection
Pain
Tissue Integrity

LEARNING OUTCOMES

1. Outline health promotion practices related to environmental hazards.
2. Explain the etiology, clinical manifestations, and interprofessional and nursing management of skin cancers.
3. Relate the etiology, clinical manifestations, and interprofessional and nursing management of bacterial, viral, and fungal skin infections.
4. Describe the etiology, clinical manifestations, and interprofessional and nursing management of infestations and insect bites.
5. Discuss the etiology, clinical manifestations, and interprofessional and nursing management of allergic skin disorders.
6. Explain the etiology, clinical manifestations, and interprofessional and nursing management related to benign skin disorders.
7. Select appropriate nursing interventions to manage the patient with a skin problem.
8. Explain the indications and nursing management related to common cosmetic procedures and skin grafts.

KEY TERMS

acne vulgaris, Table 25.10
actinic keratosis
basal cell carcinoma (BCC)
cellulitis, Table 25.5
cryosurgery
curettage
dysplastic nevi (DN)
herpes zoster, Table 25.6
impetigo, Table 25.5
lichenification
melanoma
psoriasis
rosacea, Table 25.10
squamous cell carcinoma (SCC)
sun protection factor (SPF)

This chapter discusses common skin problems and skin cancer. Impaired skin integrity affects many body functions. The skin reflects both physical and psychologic well-being. Many skin problems leave underlying tissues unprotected from infection and chemical dangers. Lesions can be painful because the skin has many sensory nerve endings. Skin problems are often highly visible, potentially affecting body image and causing distress.

ENVIRONMENTAL HAZARDS

Sun exposure comes with serious risk and results in permanent skin damage. Sunlight is made up of visible light and ultraviolet (UV) light. There are 2 types of UV light: UVA and UVB. Specific wavelengths (Table 25.1) have different effects on the skin. UVA light is responsible for tanning, UVB for sunburn. The damage caused by UV rays is cumulative. It results in degenerative changes in the dermis and premature aging (e.g., loss of elasticity, thinning, wrinkling). Prolonged and repeated sun exposure increases risk for actinic keratosis (AK), basal and squamous cell cancers, and melanoma.

Provide teaching on sun protection. People often do not understand the risks of sun exposure. Following sun safety guidelines beginning early in life can help avoid the damaging effects of the sun and prevent skin cancer later in life.

TABLE 25.1 Wavelengths of Sun and Effects on Skin

Wavelength	Effect
Long (ultraviolet A [UVA])	Can cause elastic tissue damage and actinic skin damage Contributes to skin cancer
Middle (ultraviolet B [UVB])	Causes sunburn and cumulative effect of sun damage Major factor in developing skin cancer
Short (ultraviolet C [UVC])	Blocked by the atmosphere and does not reach earth

Fair-skinned persons and those with light-colored eyes should be especially cautious about sun exposure. They have less melanin and thus less natural protection.

Teach the patient ways to avoid the damaging effects of the sun. This includes wearing protective clothing, including sunglasses, a large-brimmed hat, and a darker colored, long-sleeved shirt of a tightly woven fabric or carrying an umbrella. The greatest risk is with midday sun, between the hours of 10:00 a.m. and 2:00 p.m., regardless of the latitude. This is when 80% of UV rays occur. Even on overcast days, serious sunburn can occur because up to 80% of the sun's UV rays can penetrate the clouds. Warn people of the dangers of tanning booths and sun lamps, which emit UVA. Tanning booths increase the risk for sunburn, cataracts, and skin cancer (Box 25.1).[1]

Sunscreens can filter both UVA and UVB wavelengths. The 2 types of topical sunscreens are chemical and physical. Chemical sunscreens absorb into the skin. There they absorb or filter UV light, resulting in decreased UV light penetration. Physical sunscreens sit on top of the skin. They reflect UV radiation away from the skin. Regular sunscreen use decreases the risk for melanoma.

The US Food and Drug Administration (FDA) rates sunscreen products on their **sun protection factor (SPF)**. The SPF measures the effectiveness of a sunscreen in filtering and absorbing UV radiation. All sunscreen labels in the United States must say which rays they protect against. Products labeled with "broad spectrum" block both UVA and UVB.[2] Sunscreens with broad spectrum labeling must have an SPF of at least 15. Sunscreens with an SPF of 15 or more filter 92% of the UVB rays and make sunburn unlikely when applied appropriately.

People need to select the right sunscreen for their needs. The general suggestion is that everyone should use daily sunscreen with a minimum SPF of 15. Teach patients to look for the term *broad spectrum* on sunscreen packaging. People with a history of skin cancer or problems with sun sensitivity should use a product with an SPF of at least 30. Sunscreens should be applied 20 to 30 minutes before going outdoors, even in cloudy weather. The SPF value of all sunscreens decreases with time. Sunscreen should be reapplied every 2 hours. You should apply 1 ounce per total body application. The ears, toes, and lips also need sunscreen. Sunscreens are not "waterproof" and must be reapplied after swimming.

Some drugs potentiate the sun's effects, even with brief exposure. The chemicals in these drugs absorb light when exposed to natural sunlight and release energy that harms cells and tissues. Common photosensitizing drugs are shown in Table 25.2. The manifestations of drug-induced photosensitivity (Fig. 25.1) are like those of a sunburn. These include swelling, redness, vesicles, and papular, plaque-like lesions. Assess the photosensitivity of each drug. Teach patients who are taking these drugs about their photosensitizing effect and the need to protect the skin from photosensitivity reactions by using sunscreen products.

Teach patients to assess their skin monthly. They should have a periodic professional assessment of areas that are hard to see. The cornerstone of skin assessment is the ABCDE rule. Assess lesions for ***A**symmetry, **B**order* irregularity, ***C**olor* change and variation, ***D**iameter* of 6 mm or more, and ***E**volving* in

BOX 25.1 EVIDENCE-BASED PRACTICE

Tanning Booths and Skin Cancer

You are a nurse working in a dermatology clinic. D.F., a 30-year-old woman with fair skin and blue eyes, is completing her health history before her annual skin screening. She says she visits an indoor tanning salon every other week. She tells you that being tan makes her feel "healthier and prettier."

Making Clinical Decisions

Best Available Evidence

There is a strong link between exposure to UVA from indoor tanning booth use and increased risk for all skin cancers. Skin damage starts with the 1st visit. 95% of persons with melanoma who are diagnosed before age 30 report having used tanning booths. Melanoma risk increases with the number of years, hours, and sessions of indoor tanning independent of outdoor exposure.

Clinician Expertise

You note that D.F. has several skin cancer risk factors: fair skin, blue eyes, frequent use of tanning booths.

Patient Preferences and Values

After listening, D.F. tells you that she will consider reducing the frequency of her visits—going only when she has an important event to attend.

Implications for Nursing Practice

1. How would you respond to D.F., given the information that she shared with you?
2. What resources can help address her view that a "tan looks healthy?"
3. What sun safety guidelines should she follow to prevent skin cancer?

TABLE 25.2 Drug Therapy

Drugs That May Cause Photosensitivity

Categories	Examples
Antidepressants	fluoxetine, paroxetine, venlafaxine
Antidysrhythmics	amiodarone (Cordarone), quinidine
Antihistamines	cetirizine (Zyrtec), chlorpheniramine, clemastine, diphenhydramine, loratadine
Antimicrobials	tetracycline, azithromycin (Zithromax), ciprofloxacin, sulfonamides
Antifungals	griseofulvin, ketoconazole
Antipsychotics	chlorpromazine, haloperidol
Cholesterol-lowering agents	atorvastatin, simvastatin
Diuretics	furosemide (Lasix), thiazides
Hypoglycemics	glipizide, glyburide
Nonsteroidal antiinflammatory drugs	diclofenac (Voltaren), ibuprofen, naproxen, piroxicam (Feldene),

Fig. 25.1 Photosensitivity reaction in a patient taking methotrexate. (From Valeyrie-Allanore L, Obeid O, Revuz J: *Dermatology*, ed 4, St. Louis, 2018, Elsevier.)

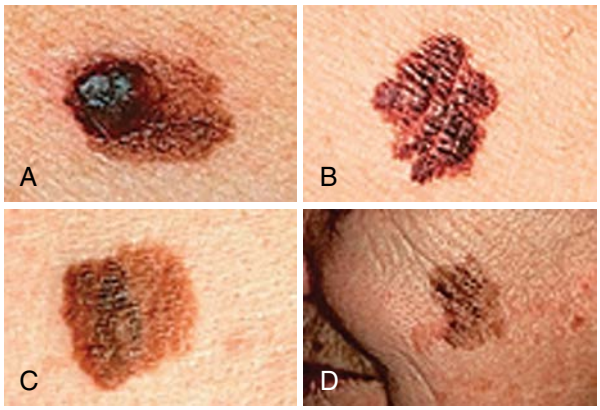

Fig. 25.2 The ABCDEs of melanoma. (A) Asymmetry: one half unlike the other half. (B) Border irregularity: edges are ragged, notched, or blurred. (C) Color: varied pigmentation; shades of tan, brown, and black. (D) Diameter: greater than 6 mm (diameter of a pencil eraser). (E, *not pictured*) Evolving; changing appearance (change in shape, size, color, or other characteristic noted over time). (From The Skin Cancer Foundation, New York, NY.)

appearance (Fig. 25.2). Emphasize that a persistent lesion that does not heal and lesions once flat and now raised, once small and recently growing, or changing in appearance are warning signs. Patients should consult their HCP at once if any lesions or moles show any clinical signs (ABCDEs).

SKIN CANCER

Skin cancer is the most commonly diagnosed cancer.[3] Skin cancers are either nonmelanoma or melanoma. The fact that skin lesions are so visible increases the chance of early detection and diagnosis. This often leads to a highly favorable prognosis.

Risk Factors

Risk factors for skin cancer include (1) having fair skin, blond or red hair with blue eye color; (2) history of outdoor sunbathing; (3) living near the equator or at high altitudes; (4) family or personal history of skin cancer; (5) having an outdoor occupation; (6) spending a lot of time in outdoor recreation activities; and (7) indoor tanning.[3] The Fitzpatrick Classification of Skin Type can help you determine a person's skin complexion and their risk for skin cancer (Table 25.3). Patients treated with oral methoxsalen (psoralen) and psoralen plus ultraviolet A radiation (PUVA) have a higher risk.

Dark-skinned persons are less susceptible to skin cancer because of their increased melanin, which acts like a sunscreen (Box 25.2). However, there is still a risk, and they need to wear sunscreen. They often have melanomas on areas with less melanin, such as the palms, soles, mucous membranes, and under the nails. Since it is common for people with dark skin to have pigmented, longitudinal bands on their nails, assess for nail discoloration.

NONMELANOMA SKIN CANCER

Nonmelanoma skin cancers (basal cell and squamous cell cancers) are the most common forms of skin cancer. More than 5.4 million new cases are diagnosed each year.[3] Nonmelanoma skin cancers do not develop from melanocytes. They develop in the basement membrane of the skin. Although there are few deaths from nonmelanoma skin cancer, they have the potential for severe local destruction, disfigurement, and disability.

Nonmelanoma skin cancers usually develop in sun-exposed areas, such as the face, head, neck, back of the hands, and arms. The most common causative factor is sun exposure. There are some differences between basal and squamous cell cancers. Squamous cell cancers usually occur on the head and neck, where there is the highest degree of UV radiation. Basal cell cancers do not follow that pattern and may occur in sun-protected areas.

Actinic Keratosis

Actinic keratosis (AK), or *solar keratosis,* is the most common precancerous skin lesion. They affect most of the older White population. Sun exposure is a key factor. AKs appear most often on skin that has been exposed to the sun or to artificial UV light. They may spontaneously resolve if a person reduces exposure to sunlight.

TABLE 25.3 Fitzpatrick Classification of Skin Type

Skin Type	Skin Color	Characteristics
I	White, freckles, very fair. Red or blond hair. Blue eyes	Always burns, never tans
II	White, fair. Red or blond hair. Blue, hazel, or green eyes	Usually burns, tans with difficulty
III	Cream white, fair. Any eye or hair color	Sometimes mild burn, gradually tan
IV	Brown, typical Mediterranean skin	Rarely burns, tans with ease
V	Deep brown, Middle Eastern skin types	Very rarely burns, tans very easily
VI	Black	Never burns, tans very easily

BOX 25.2 PROMOTING HEALTH EQUITY

Skin Cancer

- Blacks, Asians, and Hispanics have a lower incidence of skin cancer than Whites.
- Melanoma in dark-skinned persons often goes unrecognized until the advanced stages.

The clinical appearance of AK can be highly varied. The typical lesion is an irregularly shaped, flat, slightly red papule with indistinct borders and an overlying hard keratotic scale or horn (Table 25.4). Because AK is impossible to distinguish from squamous cell cancer, treatment should be aggressive. Nonsurgical procedures are the first-line treatment. Any lesion that persists should be evaluated for a biopsy.

Basal Cell Carcinoma

Basal cell carcinoma (BCC) is a locally invasive cancer arising from epidermal basal cells. It is the most common type of skin cancer but the least deadly. BCC usually occurs in middle-aged to older adults. Most BCCs occur in the head and neck area (e.g., sun-exposed), followed by the trunk and extremities.[4]

Table 25.4 describes manifestations of BCC. Some BCCs are pigmented, with curled borders and an opaque appearance. They may be hard to distinguish from melanoma. A tissue biopsy is needed to confirm the diagnosis. BCCs rarely metastasize (Fig. 25.3). However, untreated BCC may result in massive tissue destruction. Treatment depends on the tumor location and histologic type, size, history of recurrence, and patient characteristics (Table 25.4).

Squamous Cell Carcinoma

Squamous cell carcinoma (SCC) is a cancer arising from keratinizing epidermal cells. SCC can be aggressive and has the potential to metastasize. It may lead to death if not treated early. SCC often occurs at the base of an AK or another lesion. The main risk factors are sun exposure and immunosuppression after an organ transplant.[5] Pipe, cigar, and cigarette smoking contribute to SCC on the mouth and lips. Table 25.4 outlines the manifestations of SCC. A biopsy should always be done when a lesion is thought to be SCC.

MELANOMA

Melanoma is a tumor arising from melanocytes, the cells that make melanin. It causes most skin cancer deaths. The incidence of melanoma is steadily rising.[1] More than 107,000 new cases are diagnosed each year in the United States, and almost 8000 people die from the disease.[6] Melanoma can metastasize to any organ, including the brain and heart.

A combination of environmental and genetic factors is likely involved in the development of melanoma. UV radiation from the sun is the main cause. Artificial sources of UV radiation, such as sunlamps and tanning booths, also play a role. UV radiation damages the deoxyribonucleic acid (DNA) in skin cells, causing "misspellings" (mutations) in their genetic code. This alters the cells. Although anyone can develop melanoma, the risk is greatest for people who have red or blond hair, blue or light-colored eyes, and light-colored skin that freckles easily. These people have less melanin and thus less protection from UV radiation. The use of immunosuppressive drugs and a history of dysplastic nevi (DN) also increase risk.

A person may have a genetic predisposition toward getting melanoma. Of those with melanoma, 5% to 10% have a first-degree relative (e.g., parent, full sibling) who had melanoma.[1] This risk greatly increases if multiple relatives had melanoma. Mutated genes have been found in some families who have a high familial incidence of melanoma.

Cutaneous melanoma begins in the skin. There are 4 subtypes of melanoma: (1) superficial spreading melanoma, (2) nodular melanoma, (3) lentigo maligna melanoma, and (4) acral lentiginous melanoma.

Clinical Manifestations

Melanoma often occurs on the lower legs in women and on the trunk and head in men. About 25% occur in existing nevi or moles. About 20% occur in DN. Rarely, it occurs in the mouth, intestines, and eyes.

The cornerstone of skin assessment is the ABCDE rule (Fig. 25.2). Because most melanoma cells continue to make melanin, melanoma tumors are often deep brown or black (Table 25.4). Lesions showing any sudden or progressive change in the ABCDE rule need evaluated.

Interprofessional Care

One of the first steps in diagnosing a suspicious lesion is dermoscopic examination. Dermoscopy can help the HCP decide if a lesion should be biopsied. Biopsy can determine the type of lesion. A biopsy should be done using an excisional biopsy technique. Shave biopsy, shave excision, or electrocauterization are avoided because they do not measure the depth of the lesion.

The most important prognostic factor is tumor thickness at the time of diagnosis. We assess tumor thickness with the *Breslow measurement.* It indicates tumor depth in millimeters (Fig. 25.4). Melanomas less than 1 mm thick have a small chance of spreading. As the melanoma becomes thicker, it has a greater chance of spreading.

Treatment depends on the site of the original tumor and the stage of the cancer. Melanoma staging (stages 0 to IV) is based on tumor size (thickness), nodal involvement, and metastasis. In stage 0, melanoma is confined to 1 place (in situ) in the epidermis. Melanoma is nearly 100% curable by excision if diagnosed at stage 0. Unfortunately, those with deep tumors or disease that has already spread to lymph nodes often develop metastases. The 5-year survival rate for those with advanced disease is around 27%.[6]

The initial treatment of melanoma is wide surgical excision. Melanoma that has spread to the lymph nodes or nearby sites usually requires additional (adjuvant) therapy with combinations of immunotherapy, targeted therapy, chemotherapy, and/or radiation therapy.

TABLE 25.4 Premalignant and Malignant Skin Problems

Etiology and Pathophysiology	Clinical Manifestations	Treatment
Actinic Keratosis		
• Actinic (sun) damage • Premalignant skin lesions • Common in older Whites • Increase in number with age	• Flat or elevated, dry, hyperkeratotic scaly papule. Often multiple • May be rough or wart-like • Rough adherent scale on red base, which returns when removed • Often on sun-exposed area	• Excision (cryosurgery, laser, chemical peel). Topical fluorouracil, imiquimod, ingenol mebutate. Photodynamic therapy • Recurrence possible even with adequate treatment
Atypical or Dysplastic Nevi		
• Morphologically between common acquired nevi and melanoma • May be precursor of melanoma	• Often >5 mm. Irregular border, possibly notched. Frequently multiple • Varying colors of tan, brown, black, red, or pink within single mole • Central part often raised with flat edges • Most common site on back, but possible in uncommon mole sites such as scalp or buttocks (Fig. 25.5)	• Careful monitoring of those with a familial tendency to melanoma or dysplastic nevi • Excisional biopsy for suspicious lesions
Basal Cell Carcinoma		
• Change in basal cells. • No maturation or normal keratinization • Continuing division of basal cells and formation of enlarging mass • Related to sun exposure, skin type, x-ray radiation, scars, some types of nevi • Slow-growing tumor that invades local tissue • Metastasis rare, 90% cure rate with primary lesions	*Nodular and ulcerative*: • Small, slowly enlarging papule • Borders semitranslucent or "pearly" with overlying telangiectasia • Erosion, ulceration, and depression of center • Normal skin markings lost (Fig. 25.3) *Superficial*: • Red, pearly, sharply defined, barely elevated plaques	• Surgical excision, electrodessication and curettage, cryosurgery, radiation therapy, laser therapy, photodynamic therapy • Vismodegib (Erivedge), sonidegib (Odomzo) for metastatic or recurrent locally invasive lesions • Fluorouracil, imiquimod for superficial lesions
Cutaneous T-Cell Lymphoma		
• Origins in skin. Localized chronic, slowly progressing disease • Possibly related to environmental toxins and chemical exposure • Mycosis fungoides (MF) is most common form • Sézary syndrome is an advanced form of MF • Prevalence twice as high in men • Disease course is unpredictable. 10% have progressive disease	• Classic presentation involves 3 stages: patch (early), plaque, and tumor (advanced) • History of persistent macules followed by gradual appearance of indurated red plaques on trunk • Appears similar to psoriasis • Itching, lymphadenopathy	• Treatment usually controls symptoms but is not curative • Phototherapy, radiation therapy, extracorporeal photopheresis, chemotherapy, biologic therapy (interferon) • Medications include corticosteroids, topical nitrogen mustard, imiquimod, retinoids, romidepsin (Istodax), denileukin diftitox (Ontak), vorinostat (Zolinza)
Melanoma		
• Neoplastic growth of melanocytes anywhere on skin, eyes, or mucous membranes • Classified by major histologic mode of spread • Correlation between survival rate and depth of invasion • Poor prognosis unless diagnosed and treated early • Spreading by local extension, regional lymphatic vessels, and bloodstream	• Irregular color, surface, and border • Variegated color, including red, white, blue, black, gray, brown • Flat or elevated. Eroded or ulcerated • Often <1 cm in size • Most common sites in males are back, then chest. In females are legs, then back (Fig. 25.2)	• Surgical excision and possible sentinel lymph node evaluation • Adjuvant therapy after surgery if lesion >1.5 mm in depth • Key adjuvant therapies include immunotherapy (cytokines, PD-1 inhibitors, CTLA-4 inhibitors), targeted therapy (BRAF and MEK inhibitors)

Continued

TABLE 25.4 Premalignant and Malignant Skin Problems—cont'd

Etiology and Pathophysiology	Clinical Manifestations	Treatment
Squamous Cell Carcinoma (SCC)		
• Often occurs on previously damaged skin (e.g., from sun, radiation, scar) • Cancer of squamous cell of epidermis. Invades dermis, surrounding skin • Most common on sun-exposed areas such as face and hands • High cure rate with early detection and treatment	• *Superficial:* Thin, scaly, red plaque without invasion into the dermis • *Early:* Firm nodules with indistinct borders, scaling, ulceration • *Late:* Covering of lesion with scale or horn from keratinization, ulceration	• Surgical excision, cryosurgery, radiation therapy, electrosurgery, laser therapy, photodynamic therapy • Untreated lesion may metastasize to regional lymph nodes and distant organs • Fluorouracil, imiquimod for noninvasive SCC • Immunotherapy for metastatic lesions

Fig. 25.3 Basal cell carcinoma. Rolled, well-defined border and central erosion. (From Goldman L, Schafer A: *Goldman-Cecil medicine*, ed 25, Philadelphia, 2016, Saunders.)

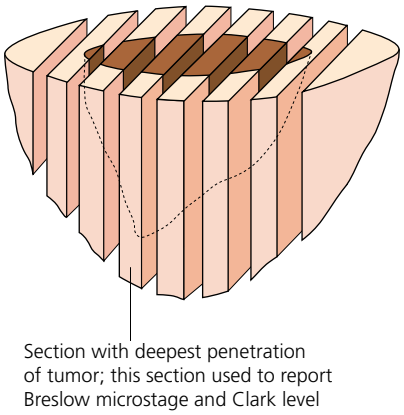

Fig. 25.4 Breslow measurement of tumor thickness. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 6, St Louis, 2016, Mosby.)

Immunotherapy can include cytokines (α-interferon, interleukin-2), PD-1 inhibitors, and CTLA-4 inhibitors. Cytokines enhance the production of many immune system cells, including T cells and B cells. Drugs that block PD-1 or CTLA-4 boost the immune response against melanoma cells.[7] Anti–PD-1 agents include nivolumab (Opdivo) and pembrolizumab (Keytruda). They block PD-1, a protein on T cells that keeps T cells from attacking other cells in the body. Atezolizumab (Tecentriq) targets PD-L1, a protein related to PD-1 that is found on some tumor cells. Ipilimumab (Yervoy) blocks the action of CTLA-4, another protein that normally suppresses the action of T cells.

Fig. 25.5 Dysplastic nevus. Irregular border and color. (From Graham-Brown R, Bourke J, Cunliffe T: *Dermatology: fundamentals of practice,* Edinburgh, 2008, Mosby.)

Targeted therapy for melanoma includes BRAF and MEK inhibitors. About half of melanomas have *BRAF* gene mutations, which make an altered BRAF protein that signals melanoma cells to proliferate. Vemurafenib (Zelboraf), dabrafenib (Tafinlar), and encorafenib (Braftovi) directly target BRAF genes. The MEK gene works with the BRAF gene, so drugs that block MEK proteins also help treat melanomas with BRAF gene changes. MEK inhibitors include Trametinib (Mekinist), binimetinib (Mektovi), and cobimetinib (Cotellic).[6,7]

Chemotherapy is not as effective for melanoma as it is for most other cancers. It is usually used only with advanced disease. Drugs used include dacarbazine and temozolomide.[6] Radiation therapy has a role in treating lymph node and brain metastases.

Atypical or Dysplastic Nevus

Dysplastic nevi (DN), or atypical moles, are nevi that are larger than usual (greater than 5 mm across) with irregular borders and various shades of color (Fig. 25.5). DN may have the same ABCDE characteristics as melanoma, but they are less pronounced. About 5% to 17% of the White population have DN.[8] Those with DN have an increased risk for developing melanoma in a mole or elsewhere on the body. The more DN a person has, the higher the risk. Those with 10 or more DN have 12 times the risk for developing melanoma.

CHECK YOUR PRACTICE

You are working in an HCP office, and your next patient is a 64-year-old White man. He is worried about the many "brown" spots on his face and arms. He tells you that they probably happened because he worked outside in construction most of his life.

- How do you distinguish among an age spot (lentigo), normal mole, and melanoma?
- What risk factors would you assess for in a patient with a suspected cancerous lesion?

SKIN INFECTIONS AND INFESTATIONS

Bacterial Infections

Bacterial infection can occur as a primary infection after a break in the skin. A secondary infection can occur in already damaged skin or as a sign of a systemic disease (Table 25.5). Risk factors include the presence of excess moisture, obesity, having atopic dermatitis, systemic corticosteroid or antibiotic use, and having a chronic disease, such as diabetes.

Staphylococcus aureus and group A β-hemolytic streptococci are the main types of bacteria that cause primary and secondary skin infections. Streptococci cause impetigo, erysipelas, cellulitis, and lymphangitis. *S. aureus* causes impetigo, folliculitis, cellulitis, and furuncles (Fig. 25.6). When an infection is present, the resulting drainage is infectious. Good skin hygiene and infection control practices help prevent the spread of the infection.

Viral Infections

Viral infections of the skin are hard to treat. When a virus infects a cell, a skin lesion may develop. Lesions can also result from an inflammatory response to viral infections. Herpes simplex, herpes zoster (Fig. 25.7), and warts (Fig. 25.8) are the most common viral infections affecting the skin (Table 25.6).

Infestations and Insect Bites

There are many opportunities for exposure to *infestations* (harboring insects or worms) and insect bites (Table 25.7). In many instances, an allergy to the venom plays a key role in the reaction. In other cases, the clinical manifestations are a reaction to the eggs, feces, or body parts of the invading organism. Some people react with a severe hypersensitivity (anaphylaxis), which can be life threatening (see Chapter 14).

Preventing insect bites by avoidance or using repellents is somewhat effective. Meticulous hygiene related to care of personal articles, clothing, bedding, and pets can reduce the incidence of infestations. Prompt, routine skin inspection is necessary in areas where there is a risk for tick bite. Lyme disease, caused by a tick, is discussed in Chapter 69.

Fungal Infections

Because of the large number of fungi that are present everywhere, exposure to some pathologic varieties may occur. Skin, hair, and nails can become infected with fungi, including candidiasis and tinea unguium. Common fungal infections of the skin are described in Table 25.8. Most infections are harmless in healthy adults, but they can cause embarrassment and distress.

Fungal infections are easy to diagnose. A microscopic examination showing the appearance of hyphae (thread-like structures) in a skin scraping mounted in 10% to 20% potassium hydroxide (KOH) indicates a fungal infection. A Wood light examination of hair infected with certain fungi will fluoresce blue to green.

ALLERGIC SKIN PROBLEMS

Patients often seek treatment for irritant or allergic dermatitis, 2 common types of contact dermatitis. *Irritant contact dermatitis* results from direct chemical injury to the skin. *Allergic contact dermatitis* is an antigen-specific, type IV delayed hypersensitivity response. Allergic and contact dermatitis is discussed in Chapter 14. Skin problems from allergies and hypersensitivity reactions can be challenging (Table 25.9). A careful history and discussion of exposure to possible offending agents can provide valuable data. Patch testing can help determine possible causative agents (see Fig. 24.10). The best treatment of allergic dermatitis is to avoid known irritants. The extreme itching and its potential for chronicity make it a frustrating problem for you and the patient, especially if we cannot find the offending agent.

Skin Drug Reactions

Stevens-Johnson syndrome (SJS) and *toxic epidermal necrolysis* (TEN) are rare, life-threatening diseases. They are violent immune responses that often occur as a severe adverse reaction to either a drug or, more rarely, an infection. The result is the acute destruction of the epithelium of the skin and mucous membranes. SJS, SJS-TEN overlap, and TEN represents a spectrum of disease severity. SJS involves less than 10% of total body surface area. SJS-TEN overlap involves 10% to 29%. TEN involves more than 30% of total body surface area.[9]

SJS and TEN typically occur 4 to 21 days after starting use of the offending drug. Systemic symptoms, including fever, cough, headache, anorexia, myalgia, and nausea, precede skin and mucous membrane findings by 1 to 3 days. Skin involvement starts as a red, macular rash with purpuric centers. Over a period of hours to days, the rash merges to form blisters with sheet-like epidermal detachment (Fig. 25.9). The lesions usually start on the palms, soles, and trunk, then spread to the face and extremities. They are very painful. Most people have mucosal lesions in the eye, mouth, and genital areas.

Identifying and stopping the offending drug(s) is the most important action in caring for a patient with SJS/TEN. Common drugs involved include sulfonamides, fluoroquinolones, NSAIDs, allopurinol, antiseizure drugs, and antiretroviral drugs. Immunotherapy may play a role in slowing disease progression and promoting skin repair.

The patient receives supportive care, often in an intensive care unit. Interventions focus on airway management, preserving renal function, maintaining fluid and electrolyte balance, and pain control. Fluid replacement is given to maintain urine output. Proper wound care helps prevent infection and promote healing. Dressing with petrolatum gauze or other nonadhesive material provides a barrier and offers moisture to help the skin repair.

TABLE 25.5 Common Bacterial Skin Infections

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Carbuncle		
• Multiple, interconnecting furuncles	• Many pustules appearing in reddened area • Most common at nape of neck	• Incision and drainage (possibly with packing), antibiotics, meticulous care of involved skin, frequent application of warm, moist compresses • Heal slowly with scar formation
Cellulitis		
• Inflammation of subcutaneous tissues • May be a primary infection or secondary complication • Often following break in skin • *Staphylococcus aureus* and streptococci usual causative agents • Deep inflammation of subcutaneous tissue from enzymes produced by bacteria	• Hot, tender, red, edematous area with diffuse borders • Chills, malaise, fever (Fig. 25.6)	*Topical:* • Moist heat, immobilization, and elevation *Systemic:* • Systemic antibiotic therapy • Hospitalization if severe for IV antibiotic therapy based on culture and sensitivity • Progression to gangrene possible if untreated
Erysipelas		
• Superficial cellulitis mainly involving the dermis • Group A β-hemolytic streptococci	• Red, hot, sharply demarcated plaque, Indurated, painful • Bacteremia possible • Most common on face and extremities • Toxic signs: fever, ↑ WBC count, headache, malaise	• Systemic antibiotics, usually penicillin • Hospitalization often needed
Folliculitis		
• Usually staphylococci • Present in areas subjected to friction, moisture, rubbing, oil • Increased incidence in patients with diabetes	• Small pustule at hair follicle opening with minimal redness • Development of crusting • Most common on scalp, beard, extremities in men • Tender to touch	• Topical antibiotics (e.g., mupirocin) • Cleanse with chlorhexidine • Warm saline compresses • Usually heals without scarring • If lesions extensive and deep, possible scarring, loss of involved hair follicles, and treatment with systemic antibiotics
Furuncle		
• Deep infection with staphylococci around hair follicle • Often occurs with severe acne or seborrheic dermatitis	• Tender, red, painful area around hair follicle • Draining pus and core of necrotic debris on rupture • Most common on face, back of neck, axillae, breasts, buttocks, perineum, thighs	• Same as for carbuncles
Furunculosis		
• Increased incidence in patients who are obese, diabetic, chronically ill, regularly exposed to moisture, pressure	• Lesions as above • Malaise, regional adenopathy, fever	*Topical:* • Incision and drainage of painful nodules • Warm, moist compresses to reddened plaques • Measures to reduce surface staphylococci include antimicrobial cream to nares, armpits, groin and antiseptic to entire skin • Meticulous personal hygiene *Systemic:* • Systemic antibiotic effective against MRSA pending culture and sensitivity results • Often recurrent with scarring
Impetigo		
• Streptococci, staphylococci, or combination of both • Primary or secondary infection. • Contagious	• Vesiculopustular lesions that develop thick, honey-colored crust surrounded by redness • Itches • Most common on face as primary infection	*Topical:* • Wound care with warm saline or aluminum acetate soaks followed by soap-and-water removal of crusts • Topical antibiotic cream or ointment (mupirocin, retapamulin) • Good personal hygiene *Systemic:* • Systemic antibiotics (e.g., cephalexin, doxycycline, dicloxacillin, clindamycin) for widespread infections or systemic manifestations

Fig. 25.6 Cellulitis with characteristic redness, tenderness, and edema. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 5, St Louis, 2011, Mosby.)

Fig. 25.7 Herpes zoster (shingles) involving the lumbar dermatome. (From Elsevier Point of Care, 2020, Elsevier.)

Because of painful oral lesions, most patients need parenteral or enteral nutrition to meet nutrient needs. Apply eyedrops, lubricating ointment, and antibiotic drops to those with conjunctivitis.

BENIGN SKIN PROBLEMS

The list of benign skin problems is long. Some of the most common and distressing ones include acne (Fig. 25.10), psoriasis, and seborrheic keratoses. Benign skin problems are outlined in Table 25.10.

Psoriasis is a chronic autoimmune disease. It is fairly common, affecting around 7.5 million Americans.[9] Men and women develop psoriasis at equal rates. The rate is highest in Whites.[9] It usually develops in those 15 to 35 years old. One-third of people with psoriasis have at least 1 relative with the disease. Psoriasis is associated with metabolic syndrome, heart disease, and type 2 diabetes. Up to 40% of people also have psoriatic arthritis. Psoriatic arthritis is discussed in Chapter 69.

The diagnosis of plaque psoriasis, the most common form, is based on the skin's appearance (Fig. 25.11). Lesions are distinct

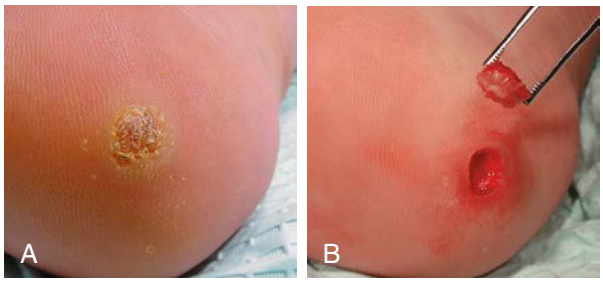

Fig. 25.8 Plantar wart. (A) Keratotic lesion. (B) After excision. (From Swartz MH: *Textbook of physical diagnosis: history and examination*, ed 6, Philadelphia, 2010, Saunders.)

and appear as red, scaling papules that merge to form plaques. The affected area is normally rounded, with adherent silver scales that bleed easily when removed. Plaques are common on the knees, elbows, scalp, hands, feet, and lower back. They are often itchy and may be painful. The extent of the disease varies. Most people have mild disease. Some have psoriasis on much of their skin surface.

We tailor treatment to the person's needs. This varies depending on the location of lesions, severity, patient preferences, and comorbidities. Goals range from improved quality of life to complete disease resolution. Psoriasis for most is more emotionally than physically disabling. It erodes the self-image. The person may be self-conscious and withdraw from social contacts. Quality of life can diminish as people avoid activities. Depression is common.

DRUG ALERT

Isotretinoin

- Used to treat acne (Table 25.10)
- Can cause serious damage to fetus
- Contraindicated in women who are pregnant or want to become pregnant
- Cannot donate blood during treatment and for 1 month after treatment ends
- May cause depression and suicidal ideation

INTERPROFESSIONAL CARE: SKIN PROBLEMS

Many different treatments are used in dermatology. Advances in this field have brought relief to many previously chronic, untreatable problems. Many of the specific treatments require specialized equipment. They are usually used by a dermatologist or specially trained nurse. The history, physical assessment, and diagnostic test results guide therapy.

Phototherapy

UV light therapy is a part of treating many skin problems, including psoriasis, cutaneous T-cell lymphoma, atopic dermatitis, vitiligo, and itching. Light sources available include broadband UVB, narrowband UVB, and long-wave UV (UVA1). One form of phototherapy combines the use of the photosensitizing drug methoxsalen with UVA light (PUVA). With PUVA, patients receive methoxsalen and then are exposed to UVA.

Treatments are generally given 2 to 3 times a week. Side effects include nausea, itching, and redness. Taking methoxsalen with

TABLE 25.6 Common Viral Skin Infections

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Herpes Simplex Virus (HSV) Types 1 and 2		
• Oral or genital HSV infections serotyped as either HSV-1 or HSV-2 • Both are recurrent lifelong viral infections • Worsened by sunlight, trauma, menses, stress, and systemic infection • Contagious to those not previously infected • Transmitted by respiratory droplets or virus-containing fluid (e.g., saliva, cervical secretions) • Infection in one area readily transmitted to another site by contact	*First episode:* • Symptoms occurring 2 days to 2 weeks after contact • Painful local reaction • Single or grouped vesicles on reddened base • Systemic symptoms (e.g., fever, malaise) possible or no symptoms possible *Recurrent:* • Recurrence in similar spot • Characteristic grouped vesicles on reddened base	• Symptomatic • Soothing, moist compresses. Petroleum jelly to lesions • Scarring not usual result • Antiviral agents such as acyclovir (Zovirax), famciclovir, valacyclovir (Valtrex)
Herpes Zoster (Shingles)		
• Activation of the varicella-zoster virus • Incidence increases with age • Potentially contagious to anyone who has not had varicella or who is immunosuppressed	• Linear distribution along a dermatome of grouped vesicles and pustules on reddened base (see Fig. 25.7) • Usually unilateral on trunk, face, and lumbosacral areas • Burning, pain, and neuralgia preceding outbreak • Mild to severe pain during outbreak	*Topical:* • Wet compresses, silver sulfadiazine (Silvadene) to ruptured vesicles *Systemic:* • Antiviral agents (e.g., acyclovir, famciclovir, valacyclovir) within 72 h of onset to prevent postherpetic neuralgia • Analgesia. Mild sedation at bedtime • Gabapentin (Neurontin) to treat postherpetic neuralgia • Usually heals without complications, but scarring and postherpetic neuralgia possible • Vaccine (Zostavax) to prevent shingles one-time dose for adults ≥60 year
Plantar Warts		
• Caused by human papillomavirus (HPV)	• Wart on bottom surface of foot, growing inward because of pressure of walking or standing (Fig. 25.8) • Painful when pressure applied • Interrupted skin markings • Cone shaped with black dots (thrombosed vessels) when wart removed	• Topical immunotherapy (imiquimod), cryosurgery, salicylic acid, duct tape
Verruca Vulgaris		
• Caused by HPV • May disappear spontaneously in 1–2 years • Mildly contagious by autoinoculation • Specific response dependent on body part affected • Prevalence greater in youth and immunosuppressed	• Circumscribed, hypertrophic, flesh-colored papule limited to epidermis • Painful on lateral compression	• Multiple treatments, including surgery using blunt dissection with scissors or curette • Liquid nitrogen therapy • Blistering agent (cantharidin) • Keratolytic agent (salicylic acid) • CO_2 laser destruction

food and milk may reduce nausea. Caution patients about taking methoxsalen and exposure during therapy to UV rays from sunlight or artificial UV light. Because of the risk for cataracts, patients receiving PUVA need to wear prescription goggles that block 100% of UV light. Teach patients to wear the eyewear for 24 hours after taking the medication when outdoors or near a bright window (UVA penetrates glass). Perform frequent skin assessments on all patients receiving phototherapy. The immunosuppressive effects of PUVA increase the risk for SCC, BCC, and melanoma.

Photodynamic therapy is a special type of phototherapy used to treat AK and some skin cancers. This therapy uses a photosensitizing agent in a different way than other phototherapy treatments. The patient receives the photosensitizing agent IV or topically, depending on the area treated. Time is allowed for the drug to be absorbed by the target cells. Light is then applied to the area, causing the drug to react with oxygen. This starts a reaction that kills the cells.

CHECK YOUR PRACTICE

You are working in a dermatology clinic, preparing a 64-year-old woman for phototherapy to treat multiple actinic keratoses on her nose and both cheeks. She says the first lesion appeared a few years ago. She then started to worry about all the time she spent in her garden without sunscreen. She thought the lesions were just "age spots" and was unconcerned until a few started to grow and periodically bleed.

- What teaching will you do to get her ready for the procedure and to take care of herself after?

TABLE 25.7 Common Infestations and Insect Bites

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Bedbugs		
• Cimicidae species • Feeding periodic, usually at night • Present in furniture, walls during day	• Wheal surrounded by vivid flare • Firm hives transforming into persistent lesion • Severe itching • Often grouped in threes appearing on uncovered parts of body	• Lesions usually require no treatment • Severe itching may require use of antihistamines or topical corticosteroids
Bees and Wasps		
• Hymenoptera species	• Intense, burning, local pain • Swelling and itching • Severe hypersensitivity may lead to anaphylaxis	• Cool compresses • Local application of antipruritic lotion • Antihistamines if indicated • Usually uneventful recovery
Pediculosis (Head Lice, Body Lice, Pubic Lice)		
• *Pediculus humanus* var. *capitis, Pediculus humanus* var. *corporis, Phthirus pubis* • Parasites that suck blood, leave excrement and eggs on skin and hair, live in seams of clothing (if body lice) and in hair as nits. Transmission of pubic lice often by sexual contact	• Minute, red, noninflammatory • Points flush with skin. Progression to papular wheal-like lesions • Itching • Secondary excoriation, especially parallel linear excoriations in intrascapular region • Nits and eggs firmly attached to hair shaft in head and body	• γ-Benzene hexachloride or pyrethrins to treat various parts of body • Spinosad (Natroba) topical suspension 0.9% to treat scalp and hair • Screen and treat close contacts (e.g., bed partners and playmates) as needed • Do not share head gear
Scabies		
• *Sarcoptes scabiei* • Mite penetrates stratum corneum, deposits eggs • Allergic reaction to eggs, feces, mite parts • Transmission by direct physical contact, sometimes by shared personal items • Rarely seen in dark-skinned people	• Severe itching, especially at night, usually not on face • Presence of burrows, especially in interdigital webs, flexor surface of wrists, genitalia, and anterior axillary folds • Red papules (may be crusted), possible vesiculation, interdigital web crusting	• 5% permethrin topical lotion, 1 overnight application with second application 1 wk later, may yield 95% eradication • Treat all family members, treat environment with plastic covering for 5 days, launder all clothes and linen with bleach • Treat sexual partner • Antibiotics, if secondary infections present • Possible residual itching up to 4 wk after treatment • Recurrence possible if not adequately treated
Ticks		
• *Borrelia burgdorferi* (spirochete transmitted by ticks in certain areas) causes Lyme disease • Endemic areas include Northeast, Mid-Atlantic states, parts of Midwest and West (see Chapter 69)	• Spreading, ring-like rash 3–4 wk after bite (see Fig. 69.7) • Rash common in groin, buttocks, axillae, trunk, and upper arms and legs • Warm, itchy, or painful rash • Flu-like symptoms • Cardiac, arthritic, and neurologic manifestations possible • Unreliable laboratory test	• Oral antibiotics, such as doxycycline • IV antibiotics for arthritic, neurologic, and cardiac symptoms • Rest and healthy diet • Most patients recover

Radiation Therapy

The use of radiation therapy to treat BCC and SCC varies. The best candidates are those with lesions in challenging locations, such as the ear, nose, scalp, neck, and shin; those who may have trouble with wound healing; or those with medical comorbidities who cannot have surgery.[10] Use is limited in those with melanoma to palliative pain control or treating brain metastases.

Radiation therapy requires multiple visits to a radiology department. It can cause permanent hair loss *(alopecia)* of the irradiated areas. Other adverse effects depend on the location and dose of radiation delivered. They include telangiectasia, atrophy, changes in pigmentation, ulceration, hearing loss, eye damage, atrophy, and mucositis. Shielding is needed to prevent lens damage if the irradiated area is around the eyes. See Chapter 16 for more on radiation therapy.

Total body skin radiation is a treatment for cutaneous T-cell lymphoma. Treatment follows a lengthy course and causes premature skin aging. Patients have varying degrees of permanent alopecia and radiation dermatitis with a transient loss of sweat gland function.

TABLE 25.8 Common Fungal Infections of the Skin and Nails

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Candidiasis		
• Caused by *Candida albicans* • Also known as moniliasis • 50% of adults are symptom-free carriers • Appears in warm, moist areas such as groin area, oral mucosa, and submammary folds • Immunosuppression (e.g., from HIV infection, chemotherapy, radiation, and organ transplantation) allows yeast to become pathogenic	*Mouth:* White, cheesy plaque, resembles milk curds *Vagina:* Vaginitis with red, edematous, painful vaginal wall, white patches. Vaginal discharge. Itching. Pain on urination and intercourse *Skin:* Diffuse, popular, red rash with pinpoint satellite lesions around edges of affected area	• Azole antifungals (e.g., fluconazole, ketoconazole) or other specific medication such as vaginal suppository or oral lozenge • Sexual abstinence or use of condom • Skin hygiene to keep area clean and dry • Powder is effective on nonmucosal surfaces of skin to prevent recurrence
Tinea Corporis		
• Various dermatophytes, often called *ringworm*	• Typical annular (ring-like) scaly appearance, well-defined margins • Reddened	• Cool compresses • Topical antifungals for isolated patches. Creams or solutions of miconazole, ketoconazole, clotrimazole, butenafine
Tinea Cruris		
• Various dermatophytes • Often called *jock itch*	• Well-defined scaly plaque in groin area • Does not affect mucous membranes	• Topical antifungal cream or solution
Tinea Pedis		
• Various dermatophytes • Often called *athlete's foot*	• Interdigital scaling and maceration • Scaly plantar surfaces sometimes with redness and blistering • May be itchy and painful	• Topical antifungal cream, gel, solution, spray, powder
Tinea Unguium (Onychomycosis)		
• Various dermatophytes • Incidence increases with age	• May affect only a few nails on 1 hand • Affects toenails most often • Scaliness under distal nail plate • Brittle, thickened, broken, or crumbling nails with yellowish discoloration	• Oral antifungal (terbinafine [Lamisil], itraconazole [Sporanox]) • Topical antifungal cream or solution (minimal effectiveness) if unable to tolerate systemic treatment • Thinning of toenails if needed • Nail avulsion (removal) is an option

Laser Technology

Laser treatment is expanding rapidly as an efficient treatment for many types of skin problems (Table 25.11). Depending on the type of laser and the wavelength, lasers serve a wide variety of functions. Lasers can make measurable, repeatable, consistent zones of tissue damage. They can cut, coagulate, and vaporize tissue to some degree. Laser light does not accumulate in body cells and cannot cause cumulative cellular changes or damage. With less damage to surrounding tissue, there is a decreased risk for scarring.

The surgical use of laser energy requires a focusing device to produce a small, high-density spot of energy. Several types of lasers are available. The CO_2 laser, the most common, has many applications as a vaporizing and cutting tool for most tissues. The argon laser emits light that is mainly absorbed by hemoglobin. It helps in the treatment of vascular and other pigmented lesions. Other, less common lasers include copper and gold vapors and neodymium:yttrium-aluminum-garnet (Nd:YAG). Those who work with laser equipment must be familiar with agency procedures on laser safety.

Drug Therapy

Antibiotics

We use several topical and systemic antibiotics to treat skin problems. Sometimes they are used concurrently. Common OTC topical antibiotics include bacitracin-neomycin-polymyxin (Neosporin), bacitracin, and polymyxin B. Prescription topical antibiotics include (1) mupirocin (for superficial *Staphylococcus* infections such as impetigo), (2) gentamicin (used for *Staphylococcus,* many gram-negative organisms), and (3) erythromycin (used for gram-positive cocci [staphylococci, streptococci] and gram-negative cocci and bacilli). Metronidazole is a common therapy for rosacea. Topical erythromycin and clindamycin are options for acne.

Systemic infections require systemic antibiotics. They have a role in treating acne and bacterial infections, such as erysipelas, cellulitis, abscesses, and certain wound infections. Frequently used oral drugs include penicillin, erythromycin, doxycycline, clindamycin, and linezolid. Vancomycin is the drug of choice for severe infections.[11]

Corticosteroids

Corticosteroids are effective in treating a wide variety of skin problems. They can be used topically, intralesionally, or systemically. Topical corticosteroids have local antiinflammatory and antipruritic effects. Since corticosteroids may change the manifestations, try to diagnose a skin problem before applying a corticosteroid preparation.

The potency of a preparation depends on the concentration of active drug. With prolonged use, high-potency corticosteroids

TABLE 25.9 Common Allergic Skin Problems

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Allergic Contact Dermatitis		
• Type IV delayed hypersensitivity response (see Chapter 14) • Absorbed agent acts as antigen • Sensitization occurs after one or more exposures • Appearance of lesions 2–7 days after contact with allergen	• Red papules and plaques • Sharply circumscribed with occasional vesicles • Itching • Area of dermatitis often takes shape of causative agent (e.g., metal allergy and band-like dermatitis on ring finger).	• Topical or oral corticosteroids, antihistamines • Skin lubrication • Elimination of contact allergen • Avoidance of irritating affected area • Systemic corticosteroids if sensitivity severe
Atopic Dermatitis		
• Type 1 hypersensitivity response (see Chapter 14) • Genetically influenced, chronic, relapsing disease • Exaggerated by a skin response to environmental allergens • Associated with allergic rhinitis and asthma	• Multiple presentations, including acute, subacute, and chronic stages. • *Acute stage:* Redness, oozing vesicles, with extreme itching • *Subacute stage:* Scaly, light red to red-brown plaques. Itching • *Chronic stage:* Thickened skin with accentuation of skin markings (lichenification), possible hypopigmentation or hyperpigmentation. Dry skin. Itching. Common in antecubital and popliteal space	• Lubrication of dry skin • Topical immunomodulators (pimecrolimus [Elidel], tacrolimus [Protopic]) • Stress reduction reduces flares • Corticosteroids, phototherapy for severe inflammation and itching • Antibiotics for secondary infection as needed
Drug Reaction		
• May be caused by any drug that acts as antigen and causes hypersensitivity reaction • Certain drugs (e.g., penicillin) more likely to cause reactions • Not all reactions are allergic, some are intolerance (e.g., gastric upset)	• Rash of any morphology • Often red, macular and papular, semiconfluent, generalized rash with abrupt onset • Appearance as late as 14 days after cessation of drug. May be itchy • Some reactions may be life threatening requiring immediate and intensive care	• Withdrawal of drug if possible • Antihistamines, topical or systemic corticosteroids may be necessary depending on severity of symptoms
Urticaria (Hives)		
• Often an allergic event • Redness and edema in upper dermis resulting from a local increase in permeability of capillaries (usually from histamine release)	• Spontaneously occurring, raised or irregularly shaped wheals, varying size, usually multiple • A single lesion usually resolves in 24 hr • Can occur anywhere on the body	• Removal of triggering agent, if known • Oral antihistamine therapy • Possibly systemic corticosteroids

can cause adrenal suppression, especially if a large surface area is covered and occlusive dressings are used. Other side effects include skin atrophy from impaired cell mitosis, capillary fragility, rosacea, acne, and bruising. In general, atrophy does not occur until a corticosteroid has been in use for 2 to 3 weeks. If drug use is stopped at the first sign of atrophy, recovery usually occurs in several weeks. Rebound dermatitis can occur when therapy is stopped. Tapering the use of high-potency topical corticosteroids when improvement is noted reduces the risk.

Low-potency corticosteroids act more slowly. They can be used for a longer time without producing serious side effects. Low-potency corticosteroids are safe to use on the face and areas where skin may touch or rub together, such as the axillae and groin.

The most potent delivery system for a topical corticosteroid is an ointment. Apply creams and ointments in thin layers and slowly massage into the site 1 to 3 times a day.

Intralesional corticosteroids are injected directly into or just beneath the lesion. This method provides a reservoir of medication with an effect lasting several weeks to months. Intralesional injection is common in the treatment of psoriasis, alopecia areata (patchy hair loss), cystic acne, hypertrophic scars, and keloids. Triamcinolone acetonide (Kenalog) is the most common drug used for intralesional injection.

Systemic corticosteroids can have remarkable results in treating a skin problem. However, they often have undesirable systemic effects (see Chapter 54). Corticosteroids are helpful in short-term therapy for acute problems such as contact dermatitis caused by poison ivy. Long-term therapy is reserved for those with severe disease such as bullous (blistering) disorders.

Antihistamines

Oral antihistamines are helpful in treating urticaria (hives), angioedema, and itching that can occur in problems such as atopic dermatitis, allergic dermatitis, and other allergic skin reactions. Several antihistamines may be tried before getting an acceptable effect. Antihistamines with sedative effects, such as diphenhydramine, may be better with itching because the tranquilizing and sedative effects enhance symptom relief. Warn the patient about sedative effects, a problem when driving or using heavy machinery. Antihistamines, such as loratadine (Claritin), fexofenadine (Allegra), and cetirizine (Zyrtec), bind to peripheral histamine receptors, giving antihistamine action without sedation. They are not effective for controlling itching. Use antihistamines with caution in older adults because of their long half-life and anticholinergic effects.

Fig. 25.9 Toxic epidermal necrolysis. (From *Ferri's clinical advisor 2018.* Dabiri, G, Rüenger T. Published January 1, 2018. Page 1282.e2. © 2018.)

Fig. 25.10 Acne with papules and pustules. (From James WD, Berger T, Elston DMD: *Andrews' diseases of the skin,* ed 11, Philadelphia, 2011, Saunders.)

Topical Fluorouracil

Fluorouracil is a topical cytotoxic agent with selective toxicity for sun-damaged cells. It is used to treat precancerous lesions (especially AK) and some skin cancers. Patient adherence is a consideration in the use of fluorouracil. Use causes redness, burning, and itching within 3 to 5 days. Painful, eroded areas over the damaged skin occur within 1 to 3 weeks, depending on skin thickness at the site. Reduce redness and itching by applying a low-potency topical corticosteroid 20 minutes after dosing. Treatment must continue with applications 1 or 2 times a day for 2 to 4 weeks. Healing may take up to 4 weeks after stopping treatment.

Adherence to therapy depends on your teaching. Tell the patient that they will look worse before they look better. Teach them about the side effects. Because fluorouracil is a photosensitizing drug, tell the patient to avoid sunlight during treatment. After treatment, skin should be smooth and free of AK. AK may recur in treated areas. Multiple courses of therapy may be necessary over the years for those with severely sun-damaged skin.

Immunomodulators

Topical immunomodulators, such as pimecrolimus (Elidel) and tacrolimus (Protopic), are used to treat atopic dermatitis, psoriasis, and rosacea.[12] They work by suppressing an overreactive immune system. The side effects are minimal. They include a transient burning or feeling of heat at the application site. Use may increase the risk for skin cancer and precancerous lesions.

The topical immunomodulator imiquimod (Aldara) is used to treat external genital warts, AK, and superficial BCC. It stimulates the production of α-interferon and other cytokines to enhance cell-mediated immunity. It boosts the immune response only where applied. Most patients using this cream have skin reactions, including redness, swelling, blistering, peeling, itching, and burning. Dosing varies depending on the type of lesion treated and the strength prescribed.

Diagnostic and Surgical Therapy

Skin Scraping

Scraping with a scalpel blade can yield a sample of surface cells (stratum corneum) for microscopic inspection and diagnosis. The most common tests of skin scrapings are mineral oil examination for scabies and 10% to 20% KOH for fungus.

Electrodessication and Electrocoagulation

Electrical energy can be converted to heat that burns and destroys tissue. The major uses of these therapies are coagulation of bleeding vessels to obtain hemostasis and destruction of small *telangiectasias* (dilation of groups of superficial capillaries and venules). *Electrodessication* usually involves more superficial destruction. It uses a monopolar electrode. *Electrocoagulation* uses a bipolar electrode. It has a deeper effect, with better hemostasis, but an increased chance of scarring. While minor electrosurgery on patients with a pacemaker poses minimal risk, the electrical energy can affect both pacemakers and internal defibrillators.

Curettage

Curettage is the removal and scooping away of tissue using an instrument called a *curette.* A curette looks like a small spoon with very sharp edges. A curette can remove many types of small, soft skin tumors and superficial lesions, such as warts, AK, seborrheic keratosis, and small BCCs and SCCs. The area to be curetted is anesthetized before the procedure. The HCP removes the lesion and then cauterizes the skin. The removed tissue is usually sent for biopsy. A dressing may be applied. You will need to teach the patient wound care. A small scar and hypopigmentation can result.

Punch Biopsy

Punch biopsy is a common procedure used to obtain a tissue sample for histologic study or to remove small lesions (Fig. 25.12).

TABLE 25.10 Common Benign Skin Problems

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Acne Vulgaris		
• Inflammatory disorder of sebaceous glands • More common in teenagers • May begin and persist into adulthood • Flare can occur with use of corticosteroids and androgen-dominant birth control pills and before menses.	• Noninflammatory lesions, including open comedones (blackheads) and closed comedones (whiteheads) • Inflammatory lesions, including papules and pustules • Most common on face, neck, and upper back (Fig. 25.10)	*Topical:* • Mechanical removal of multiple lesions with comedo extractor • Topical benzoyl peroxide, retinoids, antimicrobials (clindamycin, minocycline, erythromycin) *Systemic*: • Systemic antibiotics • Use of isotretinoin for severe nodulocystic acne may provide lasting remission. Pregnancy tests, monitor liver function, cholesterol, triglycerides, and for depression • Aim is to suppress new lesions and minimize scarring • Spontaneous remission possible • Often improves with sun exposure
Acrochordons (Skin Tags)		
• Common after midlife • Appearance on neck, axillae, and upper trunk from mechanical friction or redundant skin (associated with obesity)	• Small, skin-colored, soft, pedunculated papules • May become irritated	• No treatment medically necessary • Surgical removal when needed. Usually just snipping without anesthesia
Lentigo		
• Increased number of normal melanocytes in basal layer of epidermis from sun exposure and aging • Also called "liver spots" or "age spots"	• Hyperpigmented, brown to black macule or patch (flat lesion) on sun-exposed areas	• Evaluate carefully for progression • Treatment only for cosmetic purposes: liquid nitrogen, laser resurfacing • May recur • Biopsy when suspicious of melanoma
Lipoma		
• Benign tumor of adipose tissue, often encapsulated • Most common in 40- to 60-year-old age group	• Rubbery, compressible, round mass of adipose tissue • Single or multiple • Variable in size, may be very large • Most common on trunk, back of neck, forearms	• Usually no treatment • Biopsy to distinguish from liposarcoma • Excision usual treatment (when indicated)
Nevi (Moles)		
• Grouping of normal cells derived from melanocyte-like precursor cells	• Hyperpigmented areas that vary in form and color • Flat, slightly elevated, verrucoid, polypoid, dome-shaped, sessile, papillomatous • Preservation of normal skin markings • Hair growth possible	• No treatment necessary except for cosmetic reasons • Skin biopsy for suspicious nevi
Psoriasis		
• Autoimmune chronic dermatitis that involves very rapid turnover of epidermal cells • Family predisposition • Usually develops before age 40	• Sharply demarcated silvery scaling plaques on reddish skin often on the scalp, elbows, knees, palms, soles, and fingernails (Fig. 25.11) • Itching, burning, pain • Localized or general, intermittent or continuous • Symptoms vary in intensity from mild to severe	• Goal to reduce inflammation and suppress rapid turnover of epidermal cells. No cure, but control is possible *Topical treatments:* • Corticosteroids, tazarotene, calcipotriene, anthralin, tacrolimus, halobetasol propionate and tazarotene (Duobrii) • Intralesional injection of corticosteroids for chronic plaques *Systemic treatments:* • Natural or artificial UVB. PUVA (UVA with topical or systemic photosensitizer) • Traditional and oral therapies: methotrexate, retinoid (acitretin), apremilast (Otezla), cyclosporine • Biologic therapies for moderate to severe plaque disease: adalimumab (Humira), brodalumab (Siliq), certolizumab pegol (Cimzia), etanercept (Enbrel), golimumab (Simponi), guselkumab (Tremfya), infliximab (Remicade), ixekizumab (Taltz), risankizumab-rzaa (Skyrizi), secukinumab (Cosentyx), ustekinumab (Stelara)

Continued

TABLE 25.10 Common Benign Skin Problems—cont'd

Etiology and Pathophysiology	Clinical Manifestations	Treatment and Prognosis
Rosacea		
• Common disorder of the central face • Cause is unclear	4 major subtypes: • Erythematotelangiectatic (ETR): Telangiectasia (thread-like red lines or patterns on the skin), redness, flushing. • Papulopustular (PPR): Redness, flushing, papules, pustules. • Phymatous (PHY): Thickening of the skin, hypertrophy of the nose. • Ocular rosacea (OR): Tearing, stinging, itching, dryness of the lids.	• Avoid triggers: sun, extreme heat/cold, heavy exercise, spicy foods, alcohol use, smoking • Ablative laser surgery • Oral treatments: azithromycin, doxycycline, isotretinoin, minocycline, trimethoprim/sulfamethoxazole • Topical treatments: Brimonidine, oxymetazoline hydrochloride cream, azelaic acid, ivermectin, metronidazole, sodium sulfacetamide
Seborrheic Keratoses		
• Benign, familial, exact etiology unknown • Usually occur after age 40, increase in number with age	• Irregularly round or oval, often warty papules or plaques • Well-defined shape, appearance of being stuck on • Increase in pigmentation with time • Usually multiple, may be itchy	• Removal by curettage or cryosurgery for cosmetic reasons or to eliminate source of irritation • Biopsy if unable to distinguish from melanoma

PUVA, Psoralen ultraviolet A; *UVA,* ultraviolet A; *UVB,* ultraviolet B.

Fig. 25.11 Psoriasis. Characteristic inflammation and scaling. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy,* ed 5, St Louis, 2011, Mosby.)

TABLE 25.11 Skin Problems Treated by Laser

- Acne scars
- Hair removal
- Hemangiomas
- Leg veins
- Pigment discoloration in epidermis
- Pigmented nevi
- Port wine stain
- Psoriasis
- Resurfacing of skin
- Rosacea
- Skin lesions
- Tattoo removal
- Vascular lesions
- Warts
- Wrinkles

The procedure is simple. The HCP marks the biopsy area and then anesthetizes it so that the anesthetic will not obscure the landmarks. The HCP rotates the punch into the skin and removes a small cylinder of skin. Hemostasis is achieved with pressure or absorbable gelatin (Gelfoam) packing. Sites of 4 mm or larger are usually closed with sutures. Punch biopsies are not done below the knee if other sites are available. Circulatory changes can make evaluating the tissue sample difficult.

Cryosurgery

Cryosurgery is the use of subfreezing temperatures to destroy epidermal lesions. Cryosurgery is used to treat common and genital warts, skin tags, thin seborrheic keratoses, AK, BCC, and SCC. Topical liquid nitrogen is the agent most often used for cryosurgery. Damage occurs in treated tissue because of intracellular ice formation. It causes the cell to rupture during thaw, leading to cell death and necrosis. The degree of damage depends on the rate of cooling and the minimum temperature achieved.

Liquid nitrogen is applied topically (directly onto the lesion) with a direct spray or contact probe. Tell patients that they will feel a painful, stinging cold sensation. The lesion first becomes swollen and red. It may blister. A scab forms and falls off in 1 to 3 weeks. The skin lesion sloughs along with the scab. Growth of new skin follows.

The size of an affected area may limit the use of cryotherapy. Other disadvantages include the potential for harming adjacent healthy tissue and the low temperature of liquid nitrogen destroying melanocytes, leaving an area of hypopigmentation resembling a scar.

Excision

Excision is an option if the lesion involves the dermis. Complete closure of the excised area usually results in a good cosmetic result.

A specific type of excision is *Mohs surgery,* the microscopically controlled removal of a skin cancer. In this procedure, the HCP removes tissue sections in thin horizontal layers.

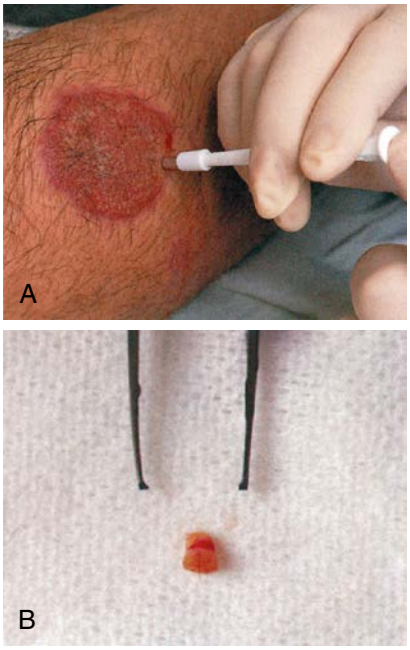

Fig. 25.12 Punch biopsy. (A) Removal of skin for diagnostic purposes. (B) Specimen obtained. (From Graham-Brown R, Bourke J, Cunliffe T: *Dermatology: fundamentals of practice,* Edinburgh, 2008, Mosby.)

Fig. 25.13 (A) Removal of melanoma by Mohs surgery. (B) After plastic surgery using a skin flap to repair defect. (Courtesy Peter Bonner, Placitas, NM.)

All the specimen's margins are examined to see if any cancer cells remain (Fig. 25.13). Any residual tumor not removed by the first excision is removed in serial excisions done the same day. Benefits of Mohs surgery are that it preserves normal tissue, produces the smallest possible wound, and can completely remove the cancer. Although it can be a lengthy procedure, it is done in an outpatient setting using local anesthesia.

❖ NURSING MANAGEMENT: SKIN PROBLEMS

A careful history is important in diagnosing skin problems. You must be skilled at detecting findings that could lead to finding the cause of many skin problems. After a careful history and physical assessment, inspect the lesions.

Nursing interventions for skin problems fall into broad categories (Table 25.12). They apply to many problems in both inpatient and outpatient settings. A nursing care plan for the patient with chronic skin lesions (eNursing Care Plan 25.1) is available on the website for this chapter.

In your patient teaching, stress the duration of the treatment. Review specific instructions about each therapy. Skin problems may be slow to resolve. Tell the patient to follow package directions when using OTC drugs. If the package insert says use should not exceed 7 days, patients should heed this warning. Teach the patient to stop care and notify the HCP if any systemic signs of inflammation or extensions of the skin problem (e.g., more lesions, increased redness or swelling) develop.

◆ Wet Compresses

It is important to know how to apply a wet compress (Table 25.13). We often apply wet compresses for superficial skin problems that involve inflammation, itching, and infection. They are appropriate for damaged, oozing skin. Wet compresses

TABLE 25.12 NURSING MANAGEMENT

Skin Problems

- Assess patient's skin for acute and chronic skin problems.
- Assess patient's risk factors for skin problems.
- Document skin problems and risk factor assessment and develop a plan of care.
- Determine whether patient is taking drugs that increase photosensitivity.
- Teach about risks associated with sun exposure and methods for decreasing exposure to the sun.
- Administer prescribed therapies such as dressings and oral or topical medications.
- Teach about therapies used for skin disorders, including dressings, baths, and oral or topical medications used on an outpatient basis.
- Evaluate treatment for effectiveness and any adverse effects.

TABLE 25.13 NURSING MANAGEMENT

Applying a Wet Compress

- Select compress material that is 4 to 8 layers thick and slightly larger than the area being treated. Use gauze or any clean material. Do not use gauze sponges with fillers as they retain too much solution.
- Use tap water at room temperature. If drinkable water is not available, use filtered, bottled, or sterile water. Add ordered additives.
- The temperature of the fluid should be tepid. However, when an antiinflammatory effect is desired, the fluid should be cool.
- When using continuous compresses, remove the compress and replace with a new one as needed. Do not add solution to a compress as this can change the fluid's concentration and damage the skin.
- Intermittent compresses are placed for 10–30 min, several times a day.
- Assess the skin at regular intervals. If the skin appears macerated, stop the compresses for 2–3 days.
- Change and wash daily any material used repeatedly throughout the day.
- Protect the patient from discomfort and chilling.
- Use a water-resistant pad to help protect the mattress, linens, and furniture.

are a good way to remove crusts and scabs that are adhering to the wound surface. They provide comfort and treatment of problems such as poison ivy, insect bites, and skin infections. Depending on the problem, we may use additives. Common solutions include (1) saline, (2) Burow solution (Domeboro powder [aluminum acetate; calcium acetate]), (3) acetic acid (vinegar), and (4) silver nitrate.

Baths

Baths are an appropriate intervention when large areas of the body need treatment. Baths may be relaxing and will help decrease itching. Agents such as colloidal oatmeal (Aveeno) and sodium bicarbonate can be added directly to bath water. Fill the tub with tepid water to cover the affected areas. Depending on the severity of the problem and the patient's discomfort, have the patient soak for 15 to 20 minutes 3 or 4 times a day. Tell the patient not to rub the skin dry with a towel but gently pat to prevent increased irritation and inflammation. To sustain the hydrating effect, apply cream, ointment emollients (moisturizers), or other prescribed topical agents after the bath. This helps seal the moisture in the hydrated cells and increases the absorption of any topical agents.

Hygienic Practices

The patient's skin type, lifestyle, culture, age, and gender influence hygienic practices. The normal acidity of the skin and perspiration protect against bacterial overgrowth. Most soaps are alkaline and neutralize the skin surface, leading to a loss of protection. Using mild, moisturizing soaps and lipid-free cleansers and avoiding hot water and vigorous scrubbing can noticeably decrease local skin irritation and inflammation. Skin piercings in which jewelry has been inserted can be cared for with antibacterial soaps that do not contain sulfites.

In general, skin and hair must be washed often enough to remove excess oil and excretions and prevent odor. Older persons should avoid harsh soaps and shampoos and frequent bathing because of the dryness of their skin and scalp. Using moisturizers right after a bath or shower (while the skin is still damp) seals in the moisture.

Topical Medications

Topical medications are often used to treat skin problems. The effectiveness of topical therapy depends on which base the medication is prepared in. Table 25.14 describes common bases for topical preparations and their considerations. The base selected depends on the properties needed.

Apply topical agents as directed. As a rule, apply a topical agent in a thin film to clean skin and spread evenly in a downward motion in the direction of hair growth. Thick creams will spread easier if the skin is still damp. If you are using a secondary dressing, you can apply the agent directly onto a dressing. Teach the patient and caregiver proper dosing, application technique, expected results, and common reactions.

Occlusion with a plastic wrap is an effective way to increase the absorption of topical corticosteroids or simple emollients. The plastic wrap traps perspiration against the outer layer of the epidermis. Applying agents to moist skin increases absorption 10-fold. Use tape or stretch wraps to keep the plastic wrap in place. For lesions on the feet or lower legs, the patient can wear socks over the plastic wrap. Wraps applied multiple times daily are kept in place for 2 to 8 hours. Some patients choose to use the occlusion technique at bedtime. Occlusion is not appropriate in areas prone to infection, such as skin creases.

TABLE 25.14 Drug Therapy

Common Bases for Topical Medications

Agent	Considerations
Cream	Emulsions of oil and water. Most common base for topical medications. Versatile. Lubrication and protection
Gel	Nongreasy combination of propylene glycol and water. May contain alcohol. Work well on the scalp. Good for acute exudative problems (e.g., poison ivy)
Lotion	Emulsions of water, alcohol, and/or oil. Cooling and drying. Some leave residual powder film after evaporation of water. May cause stinging when used in skinfolds. Useful with subacute itching problems
Ointment	Oil with differing amounts of water added in suspension. Lubrication and prevention of dehydration. More lubricating than a cream. May be too occlusive for problems with lots of exudate or in body creases. Petrolatum most common
Paste	Mixture of powder and ointment. Used when drying effect necessary because moisture is absorbed
Powder	Promotion of dryness. Lubricates skinfold areas to prevent irritation. Base for antifungal preparations. Protect patient from inhaling

Control of Pruritus

Many problems cause *pruritus* (itching). This includes dry skin, almost any physical or chemical stimulus to the skin (e.g., drugs or insects), and any scaling skin problem. The itch sensation is carried by the same nonmyelinated nerve fibers as pain and temperature. The patient will have pain rather than an itch if the epidermis is damaged or absent. It is important to figure out if itching preceded a skin lesion. Itching can lead to scratching that results in an excoriated and inflamed lesion.

Certain circumstances make itching worse. Teach the patient ways to help break the itch/scratch cycle. A cool environment may cause vasoconstriction and decrease itching. Hydration, wet compresses, and moisturizers (including antipruritic lotions) are normally helpful. Apply wet compresses for 30 to 60 minutes, pat the skin dry, and apply a lubricant or medication. Topical and injectable corticosteroids are sometimes used. Topically applied menthol, camphor, or phenol numb itch receptors. Systemic antihistamines may give relief. The main side effect of most antihistamines is sedation. This may be desirable because itching is often worse at night and can interfere with sleep. Adequate rest increases the patient's ability to tolerate itching, thereby decreasing skin damage from scratching. Have the patient avoid anything that causes vasodilation, such as heat or rubbing. Dry skin lowers the itch threshold and increases the itch sensation.

Lichenification is a thickening of epidermis with exaggerated markings resembling a washboard. It is caused by chronic scratching or rubbing of the skin. Lichenification often occurs with atopic dermatoses and other itching problems. The hands, forearms, shins, and nape of the neck are common sites. Scratching may become a habit. Persistent scratching can cause excoriations. Treating the cause of the itching is the key to preventing lichenification.

Preventing Spread

Although most skin problems are not contagious, infection control precautions indicate wearing gloves when working with any open wounds or lesions with drainage. Not all infected drainage is purulent. Careful hand washing and properly disposing of soiled dressings are the best means of preventing the spread of infections or infestations. The most common contagious lesions include impetigo, streptococcal infections, staphylococcal infections (e.g., methicillin-resistant *S. aureus* [MRSA]), fungal infections, primary chancre, scabies, and pediculosis.

Preventing Secondary Infections

Open skin lesions are susceptible to invasion by other viral, bacterial, or fungal organisms. Meticulous hygiene, hand washing, and dressing changes are important to minimize the risk for secondary infections. Warn the patient about scratching lesions, which can cause excoriations and create a portal of entry for pathogens. Trim the patient's nails short to minimize trauma from scratching.

Postprocedure Care

Provide teaching about skin care after simple procedures, such as skin biopsy, excision, and cryosurgery. In general, review cleansing, dressing changes, topical agent use, and the signs and symptoms of infection. Teach the patient how to tell normal inflammation from an infection. A slight red border first few days after is normal. Signs and symptoms of infection include redness that persists longer than a week or extends beyond a 1-cm border, a fever greater than 101°F, increased pain, pronounced swelling, and purulent drainage. If these occur, they should be reported to the HCP at once.

After a skin procedure, cleanse any oozing wound with a saline solution twice daily or as ordered by the HCP. Safe drinking water is a safe alternative in some situations. Apply antibiotic or ordered ointment with a nonadherent secondary dressing. Wounds that are kept moist and covered heal more rapidly and with less scarring. The initial crust that forms should be left undisturbed as a protective coating for the damaged skin beneath it. Healing crusts that have been moisturized and protected will separate naturally from healed epidermis.

We can cover a sutured wound with a variety of dressings. Sutures are generally removed in 4 to 14 days, depending on the placement site. Sometimes alternating sutures are removed after the third day. Incision lines may need daily cleansing, usually with plain water. If necessary, a topical antibiotic is applied and the wound either is covered with a dry dressing or left open to air. The patient may have some swelling and discomfort in the first 24 hours. Intermittent application of cold (ice packs) over the dressing may reduce edema. Mild analgesics, such as acetaminophen, should control discomfort.[13]

Psychologic Effects of Chronic Skin Problems

Emotional stress can occur for those who suffer from chronic skin problems, such as psoriasis, atopic dermatitis, or acne. The visibility of skin lesions often presents a real problem to the patient. The sequelae could result in social and employment problems with subsequent financial implications, a poor self-image, and problems with sexuality.

Help the patient to follow the treatment plan. Allow the patient to verbalize the "Why me?" question, even though there is no ready answer. Refer the patient to dermatology support groups. Many are listed on the American Academy of Dermatology website (www.aad.org). These groups are helpful with patient support and education.

The location of lesions and scars is the determining factor with respect to their cosmetic implications. Facial scars are the most damaging psychologically because they are so visible. Creative use of cosmetics can do much to mask lesions and scarring. Consider the patient's sensitivity to product ingredients when selecting cosmetics. Oil-free, hypoallergenic cosmetics may help the patient with allergies. Rehabilitative cosmetics are available to help camouflage and deemphasize such lesions as *vitiligo* (loss of pigmentation), *melasma* (tan to brown patches on the face), and healed wound sites. These commercially available products are opaque, smudge resistant, and water resistant.

COSMETIC PROCEDURES

A vast array of cosmetic procedures is available. Common ones include chemical peels, toxin injections, fillers, laser surgery, breast enlargement and reduction (see Chapter 56), face-lift, eyelid-lift, brow-forehead lift, and liposuction. Common cosmetic topical procedures are outlined in Table 25.15. Other common procedures include the injection of botulinum (e.g., Botox, Dysport) and dermal fillers (e.g., collagen, calcium hydroxyapatite, hyaluronic acid fillers [Restylane, Juvéderm]).[14] Transitory side effects may occur, such as mild redness, pain, swelling, and bruising. Uncommon side effects from cosmetic procedures include allergic reaction, infection, grayish skin discoloration, or lumps at the injection sites. Tell the patient that the procedure will need repeating at prescribed intervals to maintain the desired appearance.

The reasons for undergoing these procedures are as varied as the techniques. The most common reason is to improve body image. If someone feels better about themselves after having cosmetic procedures, they often act more confident and self-assured. Often social position and economic considerations are part of the decision. Maintain a supportive, nonjudgmental attitude. If the patient wishes to change or enhance a body feature perceived as unattractive and has realistic expectations about the outcome, you should support this decision.[15]

Surgical Therapies

Laser Surgery

Laser surgery is used to treat congenital and acquired vascular lesions (cherry angiomas, spider leg veins, hemangiomas,

TABLE 25.15 Common Cosmetic Topical Procedures

Tretinoin (Retin-A, Renova)	Chemical Peels (e.g., Jessner, Trichloroacetic Acid [TCA], Salicylic Acid)	Microdermabrasion	α-Hydroxy Acids (e.g., Glycolic Acid, Lactic Acid)
Indications			
Improves appearance of photodamaged skin, especially fine wrinkling. Reduces actinic keratoses	Improves appearance of photodamaged skin, acne scarring, actinic and seborrheic keratoses	Smooths appearance of photodamaged and wrinkled skin, acne scarring	Smooths appearance of photodamaged and wrinkled skin, acne scarring
Description			
Initially applied every 2–3 days. Treatment stopped if severe inflammation occurs. Maximum response in 8–12 mo	Solution applied in varying amounts to the skin, causing a controlled burn with a loss of melanin	Epidermis and top dermal layer removed by applying aluminum oxide or baking soda crystals. Reepithelialization of abraded surface then occurs	Low concentrations (<10%) in many skin care products consumers can apply to the skin. Higher concentrations (50%–70%) applied only by an HCP
Side Effects			
Redness, swelling, flaking, pigmentation changes. Teratogenic. Increases phototoxicity if taking other photosensitive drugs	Moderate swelling and crusting for 1 wk. Redness for 6–8 wk. Pink tone possible for several mo. Photosensitivity	Light pink tone that resolves within 24 hr. Photosensitivity	Photosensitivity, slight irritation at lower concentrations, severe redness, oozing, and flaking skin possible with higher concentrations
Patient Teaching			
Apply at night since preparation is inactivated by light. Apply emollients, use sunscreen, use sun avoidance measures, avoid abrasive or drying facial cleansers for severe sensitivity (e.g., excess irritation)	Use sunscreen. Avoid sun for 6 mo to prevent hyperpigmentation	Generous application of emollients and sunscreen	Use sunscreen and sun avoidance measures

port-wine stains, and tattoo removal) and for skin resurfacing and hair removal. Lasers can reduce scarring and fine wrinkles around the lips or eyes and remove facial lesions (Table 25.11). Swelling, redness, and bruising are common after treatment. The treated areas usually are kept moist with ointment or occlusive dressings for the first few days. The patient must protect treated skin from the sun.

Face-Lift

A face-lift *(rhytidectomy)* is the lifting and repositioning of the lower two-thirds of the face and neck to improve appearance (Fig. 25.14). Indications for this procedure include:

- Redundant soft tissue or scarring resulting from disease (e.g., acne scarring)
- Asymmetric redundancy of soft tissues (e.g., facial palsy)
- Redundant soft tissue resulting from trauma
- Preauricular lesions
- Redundant soft tissues resulting from *solar elastosis* (sagging of the skin from sun damage), changes in body weight, and the effects of gravity
- Restore body image

The surgical approach and lines of incisions vary according to the desired correction and the position of the hairline. Eyelid-lifts *(blepharoplasty)* can remove redundant tissue and possibly improve the field of vision. Preventing hematoma formation is important after surgery. Ice packs are usually applied for the first 24 to 48 hours to reduce swelling and bruising. The pain is often minimal. Antibiotics are used at the HCP's discretion. Complications can occur if the person smokes or does not follow activity restrictions.

Liposuction

Liposuction is a technique for removing subcutaneous fat to improve facial and body contours. Although not a substitute for diet and exercise, it can be successful in removing areas of fat from almost any body area that is resistant to other techniques.

Liposuction is relatively free of complications. Possible contraindications include the use of anticoagulants, uncontrolled hypertension, diabetes, and poor cardiovascular status. Those younger than 50 years of age with good skin elasticity are the best candidates. However, patients older than 50 can be treated successfully.

The procedure is usually done on an outpatient basis under local anesthesia. One or more sessions may be needed, depending on the size of the area. The HCP inserts a blunt-tipped cannula through a small incision and pushes into the fat to break it loose from the fibrous stroma. Multiple repeated thrusts disrupt the fat and create tunnels. The loosened fat is removed with a powerful suction. Afterward, firm pressure is applied to the wounds until drainage stops. It may take several months for the results to be evident.

❖ NURSING MANAGEMENT: COSMETIC SURGERY

Many cosmetic surgeries are done in well-equipped day-surgery units or in dermatologist or plastic surgeon in-office surgery suites.

Fig. 25.14 Face-lift. (A) Preoperative. (B) Postoperative. (From Cuzalina A, Copty TV, Khan H: *Current therapy in oral and maxillofacial surgery,* St Louis, 2012, Elsevier.)

◆ Preoperative Management

A major consideration before surgery relates to informed consent and realistic expectations of what cosmetic surgery can accomplish.[15] Although the HCP should provide this information, reinforce as needed and answer questions and concerns. For instance, a face-lift has little or no effect on deep wrinkling of the forehead and temples, deep nasolabial grooves, or vertical lip wrinkles. Before-and-after treatment photographs of similar cases are often useful in helping the patient to set realistic expectations.

Review the timeframe for healing. Explain the oozing, crusting stage of an abrasive procedure so the patient can plan time off from work if necessary. Since wound healing may not be complete for 1 year, the patient should not expect complete results at once. The final result is affected by the patient's age, general health, and skin type and the extent (severity) of the problem being treated. Efforts should be made to correct or control any existing health problem before the procedure.

◆ Postoperative Management

Most cosmetic procedures are not very painful. Usually, mild analgesics are enough to keep the patient comfortable.[13] Although infection is not a common problem after cosmetic surgery, assess the sites for signs of infection. Teach the patient signs and symptoms of infection. Stress that it is important to report them at once so that treatment can be started.

If the surgery involved a change in the skin's circulation, as in a face-lift, carefully monitor for adequate circulation. Warm, pink skin that blanches on pressure shows that adequate circulation is present in the surgical area. Supportive, compressive dressings and ice packs may be applied early in the postoperative period.

SKIN GRAFTS

Uses

Skin grafts may be necessary to protect underlying structures or to reconstruct areas for cosmetic or functional purposes. They may be used to facilitate rapid closure and minimize complications. Ideally, wounds heal by primary intention. However, large wounds, surgically created wounds, trauma, and chronic wounds can result in extensive tissue destruction, making healing by primary intention impossible. In these cases, skin grafting may be necessary to close the defect. Improved surgical techniques make it possible to graft skin, bone, cartilage, fat, fascia, muscles, and nerves. For cosmetically pleasing results, the color, thickness, texture, and hair-growing nature of skin used for grafting should match the recipient site. See Chapter 26 for more about skin grafting for patients with burn injuries.

Types

The 2 types of traditional skin grafts are free grafts and skin flaps. We describe free grafts by how they supply blood to the grafted skin. One method is to transfer the graft (epidermis and part or all the dermis) to the recipient site from the donor site. The *autograft* (from the patient's own body) or *isograft* (from an identical twin) revascularizes and becomes fixed to the new site. The other method of free skin grafting is by *reconstructive microsurgery.* With the use of an operating microscope, the HCP establishes circulation immediately in the graft by connecting blood vessels in the skin flap to vessels in the recipient site.

Skin flaps involve moving a section of skin and subcutaneous tissue from one part of the body to another without terminating the vascular attachment *(pedicle).* Skin flaps are used to cover wounds with a poor vascular bed, provide padding when needed, and cover wounds over cartilage and bone. The patient may need intermediate flap placement if the recipient site is far removed from the donor site. For instance, a skin flap from the thigh to the head would require an intermediate graft. The flap is advanced to the recipient site when circulation is well established at the intermediate site. The patient's needs and the type of defect determine the type of flap and the route of transfer.

Soft tissue expansion is a technique for providing skin (1) for resurfacing of a defect, such as a burn scar; (2) for removal of a disfiguring mark (e.g., a tattoo); or (3) as a preliminary step in breast reconstruction. A subcutaneous tissue expander of a proper size and shape is placed under the skin, usually as an outpatient procedure. Weekly expansion with saline solution can be done in a health care setting or by the patient at home. This expansion procedure is repeated until the skin reaches the size needed for the repair. This may take from several weeks to 3 to 4 months. Once enough skin is available, the old incision is opened, the expander is removed, and the soft tissue is ready to be used as an advancement flap. The tissue expander next to a defect has the primary tissue characteristics, such as color and texture.

Engineered skin substitutes (e.g., Apligraf, Dermagraft, Integra) are gaining popularity. There are several available, each with its own indications and benefits. Some are 2-layered membranes with both dermal and epidermal components. Others are only 1 layer. The skin is engineered from neonatal foreskins and cadavers. Skin substitutes do not contain structures such as blood vessels, hair follicles, sweat glands, or cells such as melanocytes, Langerhans cells, macrophages, and lymphocytes.[16] Engineered skin grafts have an extended shelf life. Some are cryopreserved. Others shipped overnight as they are needed. Advantages include ready availability, no donor site, application in outpatient settings, minimal scarring, and less pain.

Case Study

Melanoma and Dysplastic Nevi

(© Dimedrol68/iStock/Thinkstock.)

Patient Profile

G.L. is a 48-year-old White, fair-skinned man who is a long-distance truck driver. In his leisure time, he enjoys swimming and bicycling. He comes to the clinic because of a changing lesion on his left arm.

Subjective Data

- History of a basal cell cancer (BCC) on his left ear in the last 4 years
- Father treated for metastatic melanoma in the past 2 years
- First noted the lesion 1 month ago when it started changing size
- Anxious that removing the lesion will require extensive, disfiguring surgery

Objective Data

Physical Assessment

- Has a 4-mm lesion, deep brown, scalloped with vaguely defined borders
- 5 dysplastic nevi found on back

Diagnostic Studies

- Excisional biopsy confirmed superficial spreading melanoma.
- Sentinel node biopsy results were negative.
- Diagnostic tests indicate melanoma stage I.

Discussion Questions

1. ***Recognize***: What risk factors for melanoma does G.L. have?
2. ***Recognize***: What manifestations of melanoma are present?
3. ***Analyze***: What is the prognosis for a patient with this stage of melanoma?
4. ***Plan***: What treatment options are available for him?
5. ***Prioritize:*** What is the priority of care for G.L.?
6. ***Prioritize:*** Based on the assessment data presented, what are the priority clinical problems?
7. ***Act:*** How would you help G.L. deal with his anxiety over the treatment outcomes?
8. ***Act:*** What would you include in his teaching plan to address future sun exposure?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which safe sun practices would the nurse include in a teaching plan for a patient with photosensitivity? *(select all that apply)*
   - **a.** Wear protective clothing.
   - **b.** Apply sunscreen liberally and often.
   - **c.** Emphasize the short-term use of a tanning booth.
   - **d.** Avoid exposure to the sun, especially during midday.
   - **e.** Wear any sunscreen that is available from the drugstore.
2. When teaching a patient with melanoma, the nurse recognizes that the patient's prognosis is *most* dependent on
   - **a.** the thickness of the lesion.
   - **b.** the degree of asymmetry in the lesion.
   - **c.** the amount of ulceration in the surrounding skin.
   - **d.** how much color variation is present in the lesion.
3. The nurse determines that a patient with which disorder is *most* at risk for spreading the disease?
   - **a.** Tinea pedis
   - **b.** Impetigo on the face
   - **c.** Candidiasis of the nails
   - **d.** Psoriasis on the palms and soles
4. A mother and her children have been diagnosed with pediculosis corporis at a health care center. An appropriate treatment is
   - **a.** applying pyrethrins to the body.
   - **b.** topical application of griseofulvin.
   - **c.** moist compresses applied frequently.
   - **d.** administration of systemic antibiotics.
5. A common site for the lesions caused by atopic dermatitis is the
   - **a.** buttocks.
   - **b.** temporal area.
   - **c.** antecubital space.
   - **d.** plantar surface of the feet.
6. During the assessment of a patient, you note an area of red, sharply defined plaques covered with silvery scales that are mildly itchy on the patient's knees and elbows. You would describe this finding as
   - **a.** lentigo.
   - **b.** psoriasis.
   - **c.** actinic keratosis.
   - **d.** seborrheic keratosis.

7. In teaching a patient who is using topical corticosteroids to treat acute dermatitis, the nurse should tell the patient that *(select all that apply)*
   a. the cream form is the most efficient system of delivery.
   b. short-term topical corticosteroid use usually does not cause systemic side effects.
   c. use a glove to apply a large amount of topical ointment to prevent further infection.
   d. abruptly stopping the use of topical corticosteroids may cause the dermatitis to reappear.
   e. systemic side effects from topical corticosteroids are likely if the patient is malnourished.
8. Important patient teaching after a chemical peel includes
   a. avoidance of sun exposure.
   b. application of firm bandages.
   c. limitation of vigorous exercise.
   d. use of moist heat to relieve discomfort.

1. a b, d; 2. a; 3. b; 4. a; 5. c; 6. b; 7. b, d; 8. a.

CONCEPTUAL FOCUS

Coping
Fluids and Electrolytes
Gas Exchange
Infection
Nutrition
Pain
Perfusion
Tissue Integrity

LEARNING OUTCOMES

1. Relate the causes of burns to prevention strategies for burn injuries.
2. Distinguish between partial-thickness and full-thickness burns.
3. Apply tools used to determine the severity of burns.
4. Compare the pathophysiology, clinical manifestations, complications, and interprofessional care throughout the 3 burn phases.
5. Compare the fluid and electrolyte shifts during the emergent and acute burn phases.
6. Outline the nutrition needs of the burn patient.
7. Compare burn wound care techniques and surgical options for partial-thickness and full-thickness burn wounds.
8. Prioritize nursing interventions in the management of the burn patient's physiologic and psychosocial needs.
9. Examine the physiologic and psychosocial aspects of burn rehabilitation.
10. Develop a plan of care to prepare the burn patient and caregiver for discharge.

KEY TERMS

chemical burns
debridement
electrical burns
eschar
escharotomy
excision
full-thickness burns
inhalation injuries
partial-thickness burns
thermal burns

The focus of this chapter is the nursing care of patients with burn injuries. Heat, chemicals, electric current, or radiation can cause significant burns. Injury severity ranges from mild to life-threatening. Patients with less serious burns are managed in outpatient clinics. Those with major burn injuries will require prolonged hospitalization in a specialty burn center.

A burn injury affects many body systems. A patient exposed to smoke may have problems with gas exchange. Expect to see fluid and electrolyte imbalances. Full-thickness burns can alter perfusion to limbs. Patients with burns are at risk for malnutrition and immobility. Infection is a constant threat. The most common cause of death after a major burn injury is multiple organ dysfunction syndrome as a response to sepsis.

Patients and caregivers often experience overwhelming emotions, including fear, anger, guilt, or depression. Patients often have anxiety when anticipating painful dressing changes. Coping with pain daily can affect the patient physically and mentally. Others fear possible permanent lifestyle changes and disfigurement.

The needs of patients with major burns are extensive. They require the expertise of many health care team members. These include nurses, health care providers (HCP), occupational (OT) and physical (PT) therapists, dietitians, social workers, psychologists, and clergy. Nurses caring for burn patients usually have extensive specialized training. Providing care to burn patients can be emotionally and physically challenging. However, it is very rewarding to work as a burn team member and contribute to the recovery of patients with devastating injuries.

An estimated 486,000 Americans seek medical care each year for burns.[1] Around 40,000 people are hospitalized, with

TABLE 26.1 Common Sources of Burn Injury

Home Hazards

Bathroom and Kitchen

- Water heaters set at 120°F (60°C) or higher
- Microwaved food
- Steam, hot grease, or liquids from cooking

General Household

- Carelessness with cigarettes, matches, candles
- Heat lamps
- Fireplaces (e.g., gas, wood)
- Flammables (e.g., starter fluid, gasoline, kerosene)
- Frayed or defective wiring
- Multiple extension cords per outlet
- Open space heaters
- Outdoor grills (e.g., propane, charcoal)

Occupational Hazards

- Cement
- Chemicals
- Combustible fuels
- Electricity from power lines
- Fertilizers, pesticides
- Hot metals
- Sparks from live electric sources
- Steam pipes
- Tar

TABLE 26.2 PROMOTING POPULATION HEALTH

Strategies to Reduce Burn Injury in Homes

- Install and maintain smoke alarms in your home—on every floor and near all rooms family members sleep in. Test your smoke alarms once a month to make sure they are working properly. Use long-life batteries when possible.
- Create and practice a family fire escape plan. Involve kids in the planning. Make sure everyone knows at least 2 ways out of every room. Identify a central meeting place outside.
- Use safe cooking practices, such as never leaving food unattended on the stove. Supervise or restrict children's use of stoves, ovens, and especially microwaves.
- Set your water heater's thermostat to 120°F or lower.
- Store chemicals in approved, labeled containers
- Replace or repair frayed wiring.
- Avoid outdoor activities during electrical (e.g., lightning) storms.
- Ensure the electrical power source is off before beginning repairs.
- Never use gasoline or other flammable liquids to start a fire.
- Never leave candles unattended or near open windows or curtains.
- Consider a flame-retardant smoking apron for older or "at-risk" people.
- Before placing a child in the bath or getting in the bath yourself, test the water.
- Have a "kid-free zone" of at least 3 feet around the stove and areas where hot food or drink is prepared or carried.
- Never hold a child while you are cooking, drinking a hot liquid, or carrying hot foods or liquids.

60% receiving care in specialized burn centers. About 3275 Americans die each year from their injuries. Worldwide, over 11 million people seek medical attention annually for burn injuries, and about 180,000 die.[2] Although burn injuries in the United States have decreased over the past 20 years, injuries still occur, often to those living in low- and middle-income counties.[3]

Most burn accidents are preventable when safety policies are in place. Coordinated national burn prevention programs in higher-income countries have focused on child-resistant lighters, tap water anti-scald devices, stricter building codes, having smoke detectors, and burn safety education curriculums in schools.[4] As a nurse, you can advocate for and teach about burn prevention strategies (Tables 26.1 and 26.2).

TYPES OF BURN INJURY

Thermal Burns

Thermal burns are due to exposure to external heat sources such as hot metals, scalding liquids, steam, or flames. The severity of the injury depends on the temperature of the burning agent and duration of skin contact. This is the most common type of burn injury. Causes of thermal injury include grease fires when cooking, house fires, smoking, and the use of gasoline for cleaning or incineration.

Chemical Burns

Contact with acids, alkalines, or organic compounds can cause **chemical burns** through absorption, inhalation, or ingestion. Dangerous chemicals are in homes, businesses, and industries. For example, severe injury can occur with exposure to lye and sulfuric acid, common chemicals used to unclog sinks in homes. Exposure to wet cement, oven cleaners, and heavy industrial cleaners can cause chemical burns. Chemicals such as phenols (chemical disinfectants) and petroleum products (creosote and gasoline) cause not only external burns but also systemic toxicity. Acid chemicals cause tissue necrosis. Alkaline chemicals cause liquefaction necrosis, which can be more damaging. Some chemicals will have heat-producing reactions once exposed to the skin, causing superficial blisters or even deep burns.

Electrical Burns

Electrical burns result from the intense heat generated from an electric current. Direct damage to nerves and vessels can cause tissue anoxia and cell death. The severity of an electrical injury depends on the voltage, tissue resistance, current pathways, surface area in contact with the current, and length of time that the current flow was sustained (Fig. 26.1). Current that passes through vital organs (e.g., brain, heart, kidneys) causes more life-threatening sequela when compared to a current passing through other tissues. The severity of an electrical injury can be hard to determine initially since most of the damage is below the skin.

Contact with an electric current can cause muscle contractions strong enough to fracture the long bones and vertebrae. Forceful propulsion of the body from an electrical source can cause injuries such as spinal and limb fractures. For this reason, consider cervical spine injury for all patients with electrical burns.

Fig. 26.1 Types of burn injury. (A) Superficial, partial-thickness scald burn to the thigh. (B) Deep, partial-thickness flame burn to the hand. (C) Full-thickness flame burn to posterior chest and arm. (Courtesy Judy Knighton, Toronto, Canada.)

Electrical injury puts the patient at risk for respiratory arrest, severe metabolic acidosis, and myoglobinuria. An electric shock can cause immediate cardiac standstill or ventricular fibrillation. Massive muscle and blood vessel damage can release myoglobin from injured muscle and hemoglobin from damaged red blood cells (RBCs). Myoglobin can block the renal tubules resulting in acute kidney injury (AKI; see Chapter 51).

Cold Thermal Injury

Cold thermal injury, or frostbite, is discussed in Chapter 21.

CLASSIFICATION OF BURN INJURY

Severity is determined by (1) depth of burn, (2) extent of burn calculated in percent of total body surface area (TBSA), (3) location of the burn, (4) preexisting health issues, and (5) associated injuries. The American Burn Association (ABA) provides referral criteria based on injury severity to determine which patients need specialized treatment in a burn center (Table 26.3).[5]

Burn Depth Classification

Four factors influence burn depth: (1) temperature of the agent, (2) duration of contact, (3) thickness of the epidermis and dermis, and (4) blood supply to the area. Burn injury is determined according to the extent of injury through the epidermis, dermis, and underlying structures. One method describes an injury as first, second, third, or fourth degree. The ABA recommends using the terms partial-thickness burns and full-thickness burns to classify burns (Figs. 26.2 and 26.3). **Partial-thickness burns** involve the epidermis and sometimes part of the dermis. A **full-thickness injury** occurs if the epidermis and dermis are destroyed. **Eschar** is another name for full-thickness nonviable burn tissue. Burns can extend beyond the skin and involve tendons, ligaments, muscle, and adipose. Table 26.4 compares the various burn classifications according to the depth of injury

TABLE 26.3 Burn Center Referral Criteria

Burn injuries that should be referred to a burn center include the following:

- Partial-thickness burns greater than 10% total body surface area (TBSA)
- Burns that involve the face, hands, feet, genitalia, perineum, or major joints
- Third-degree burns in any age-group
- Electrical burns, including lightning injury
- Chemical burns
- Inhalation injury
- Injury in patients with preexisting medical disorders that could complicate management, prolong recovery, or affect mortality
- Any patient with burns and concomitant trauma (e.g., fractures) in which the burn injury poses the greatest risk for morbidity or mortality. In such cases, if the trauma poses a greater immediate risk, the patient may be stabilized in a trauma center before being transferred to a burn unit. HCP judgment is necessary in such situations and would be in concert with the regional medical control plan and triage protocols.
- Burned children in hospitals without qualified personnel or equipment for the care of children
- Burn injury in patients who will need special social, emotional, or rehabilitative intervention

Source: American Burn Association: Guidelines for the operation of burn centers. Retrieved from http://ameriburn.org/wp-content/uploads/2017/05/burncenterreferralcriteria.pdf.

Extent of Burn

Nurses are responsible for estimating the extent of burn injury. The *Lund-Browder chart* (Fig. 26.4A) and the *Rule of Nines* (Fig. 26.4B) are common methods used to determine burn TBSA. We often use the Rule of 9's for initial adult triage. Use the Lund-Browder formula for children because it considers the patient's age in proportion to relative body-area size. Electronic tools (e.g., the *Sage Burn Diagram* at www.sagediagram.com) and mobile applications (e.g., BurnMed, Mersey Burns) are available for estimating TBSA.

Location of Burn

The location of the burn injury influences the severity. Face, neck, and circumferential torso burns may interfere with gas exchange. Circumferential leathery eschar can restrict chest movement. Edema from inflammation and fluid resuscitation can narrow the airway.

Hand, foot, and joint burns can limit mobility and function. Full-thickness circumferential extremity burns can impair

perfusion distal to the injury. Injured hands and feet are challenging to manage because of the superficial vascular and nerve supplies that require protection. Infection is a risk for patients with ear or nose burns with exposed cartilage since the skin and subcutaneous tissues are thin and there are no blood vessels. Patients with buttocks or perineum burns are at high risk for infection from urine or feces contamination.

Fig. 26.2 Electrical injury produces heat coagulation of blood supply and contact area as electric current passes through the skin. (A) Back and buttock *(arrows)*. (B) Leg *(arrow)*. (Courtesy Judy Knighton, Toronto, Canada.)

Patient Risk Factors

Patients with preexisting chronic diseases have a poorer prognosis for recovery because of the increased demands placed on the body by burn injury.[6] Patients with diabetes or peripheral vascular disease are at high risk for delayed healing, especially with foot and leg burns.

PREHOSPITAL AND EMERGENCY CARE

Scene safety is a priority at the time of the injury. Once assured, first responders will remove the person from the source of the burn and stop the burning process.[7] The wounds are flushed with copious amounts of water. Cooling the burn tissue helps minimize the depth of the injury. Afterward, wrapping the

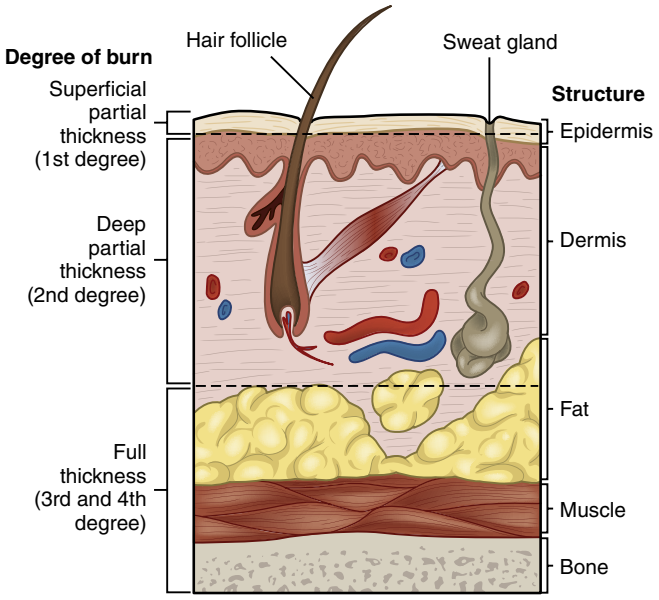

Fig. 26.3 Cross-section of skin showing the depth of burn and structures involved.

TABLE 26.4 Classification of Burn Injury Depth

Classification	Appearance	Possible Cause	Structures Involved
Partial-Thickness Skin Destruction			
Superficial (first-degree) burn	Erythema, blanching on pressure, pain and mild swelling, no vesicles or blisters (although after 24 hr, skin may blister and peel)	Quick heat flash Superficial sunburn	Superficial epidermal damage with hyperemia. Tactile and pain sensation intact
Deep (second-degree) burn	Fluid-filled vesicles that are red, shiny, wet (if vesicles have ruptured). Severe pain caused by nerve injury. Mild to moderate edema	Chemicals Contact burns Electric current Flame Flash Scald Tar, cement	Epidermis and dermis are involved in varying depths. Skin elements, from which epithelial regeneration occurs, remain viable
Full-Thickness Skin Destruction			
Third- and fourth-degree burns	Dry, waxy white, brown or charred, leathery, or hard skin. Visible thrombosed vessels. Insensitivity to pain because of nerve destruction. Possible muscle, tendon, and bone involvement	Chemical Electric current Flame Scald Tar, cement	All skin elements and local nerve endings destroyed. Coagulation necrosis present. Surgical intervention required for healing

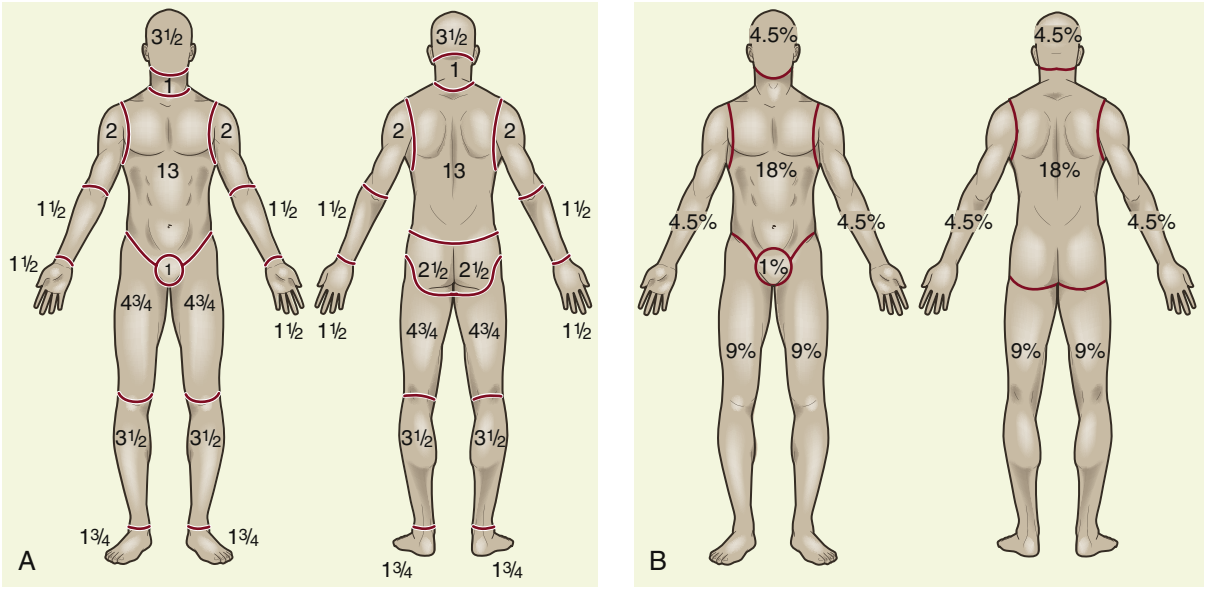

Fig. 26.4 (A) Lund-Browder chart. By convention, areas of partial-thickness injury are in *blue* and areas of full-thickness injury in *red*. Superficial partial-thickness burns are not calculated. (B) Rule of Nines chart.

patient in a dry, clean sheet or blanket will prevent further wound contamination and provide warmth. Dressings moistened with water can reduce burn pain, but too many wet dressings can cause hypothermia.

Remember that the patient may have other injuries that take priority over the burn injury. First responders must fully explain the circumstances of the injury to the emergency department (ED) team. This is especially important if an injury occurred in an enclosed space, involved hazardous chemicals, or a traumatic injury (e.g., fall).

PHASES OF BURN MANAGEMENT

Burn management for those with significant injuries can be organized chronologically into 3 phases: (1) emergent (resuscitative), (2) acute (wound healing), and (3) rehabilitative (restorative). A nursing care plan for the patient with burn injury (eNursing Care Plan 26.1) is available on the website for this chapter.

EMERGENT PHASE

During the emergent (resuscitative) phase, the health care team prioritizes life-threatening problems. This phase usually lasts up to 72 hours after the initial injury for patients with burns extending over 20% of their bodies. The priority nursing concerns are fluid and electrolyte shifts and gas exchange.

Pathophysiology

Fluid and Electrolyte Shifts

Burn shock is a combination of distributive and hypovolemic shock. It is a significant threat to a patient with a major burn (Fig. 26.5). Increased capillary permeability will cause a massive shift of fluids from the intravascular to interstitial spaces. The patient's vital signs will begin to change as water, sodium, and

PATHOPHYSIOLOGY MAP

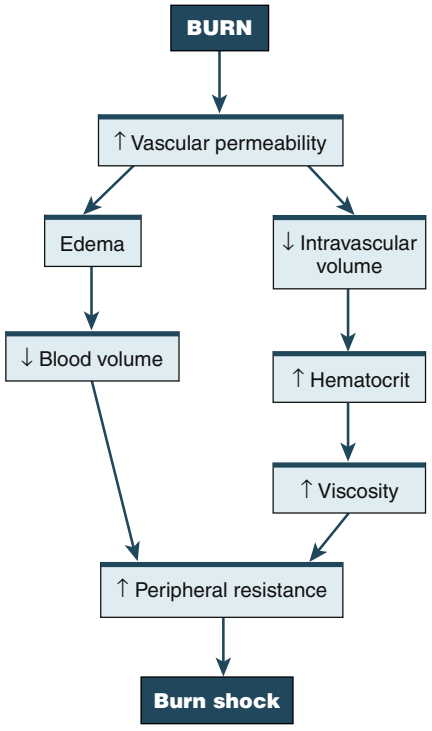

Fig. 26.5 At the time of major burn injury, capillary permeability increases. All fluid components of the blood begin to leak into the interstitium, causing edema and a decreased blood volume. Hematocrit increases. The blood becomes more viscous. The combination of decreased blood volume and increased viscosity increases peripheral resistance. Burn shock, a type of hypovolemic shock, rapidly ensues and, if not corrected, can result in death.

plasma proteins move into the interstitial spaces. The progressive loss of protein from the vascular space will reduce colloidal osmotic pressure. This causes more fluid to shift out of the

Fig. 26.6 (A) Facial edema before fluid resuscitation. (B) Facial edema after 24 hours. (Courtesy Judy Knighton, Toronto, Canada.)

vascular space into the interstitial spaces (Fig. 26.6). We call this *third spacing*. The patient may have massive edema and significant wound drainage. Loss of intravascular fluid can cause burn shock. Monitor for hypotension, tachycardia, and tachypnea. Report changes to the HCP. Patients can develop AKI and ultimately death if not resuscitated sufficiently.

Hemolysis of RBCs from circulating factors released at the time of injury from the burned tissue affects perfusion. Thrombosis in the capillaries of burned tissue causes the loss of additional circulating RBCs. Monitor for a high hematocrit from hemoconcentration due to fluid loss. Hematocrit levels will return to normal after burn shock resolves.

Major electrolyte shifts of sodium and potassium occur during this phase. A potassium shift develops first when injured cells and hemolyzed RBCs release potassium into the circulation. Sodium rapidly moves to the interstitial spaces (Fig. 26.7).

The emergent phase ends once capillary membrane permeability is restored after successful fluid resuscitation. Interstitial fluid gradually returns to the vascular space (Fig. 26.7). Potassium levels decline and sodium levels increase.

Inflammation and Healing

Burn injury causes coagulation necrosis. Neutrophils and monocytes accumulate at the site of injury. Fibroblasts and newly formed collagen fibrils appear and begin wound repair within the first 6 to 12 hours after injury. (The inflammatory response is discussed in Chapter 12.)

Immunologic Changes

A burn injury challenges the body's immune system by altering the skin's barrier to invading organisms. Bone marrow depression occurs and circulating levels of immunoglobulins decrease. Defects occur in white blood cell (WBC) function. The inflammatory cytokine cascade, triggered by tissue damage, impairs the function of lymphocytes, monocytes, and neutrophils. Therefore the patient is at high risk of infection.

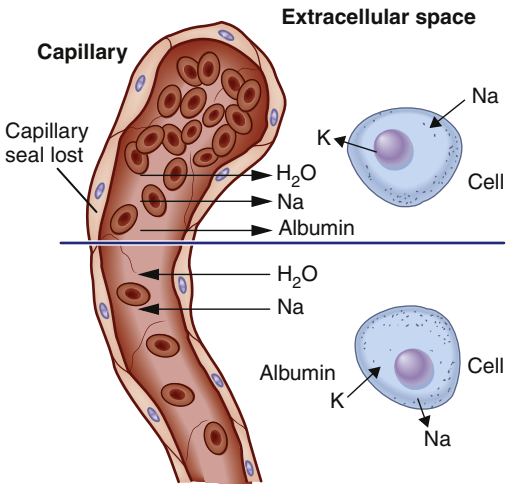

Fig. 26.7 The effects of burn shock are shown above the *purple line*. As the capillary seal is lost, interstitial edema develops. Cellular integrity is altered. Sodium *(Na)* moves into the cell in abnormal amounts and potassium *(K)* leaves the cell. The shifts after the resolution of burn shock are shown below the *blue line*. Water and sodium move back into the circulating volume through the capillary. Albumin stays in the interstitium. Potassium is transported into the cell and sodium is transported out as the cellular integrity returns.

Clinical Manifestations

Seeing a patient with major burns can be overwhelming due to the burns and the smell of burned tissue and hair. The patient is normally alert and able to answer questions during admission or until intubated (if there is respiratory compromise). Monitor cognition and report any changes. Unconsciousness or altered mental status usually results from hypoxia due to inhalation injury. Other possibilities include head trauma, substance use, or the side effects of sedation or pain medication. Patients are often frightened and need your calm reassurances. Give the patient simple explanations of what to expect.

Often patients will shiver from heat loss, anxiety, or pain. Provide warm blankets and increase the room temperature or turn on heat lamps. Full thickness burns are painless since nerves in the dermis are destroyed. Partial-thickness burns are very painful.

Complications

The 3 systems most susceptible to complications during the emergent phase of burn injury are the respiratory, cardiovascular, and renal systems.

Respiratory

Inhalation injuries from breathing noxious chemicals or hot air will damage the respiratory tract. Three types of inhalation injuries can occur:

- Injury from exposure to toxic gases, including carbon monoxide and/or cyanide
- Above the glottis injury from direct heat or chemicals causing severe mucosal edema
- Below the glottis injury causing airway inflammation and edema resulting in atelectasis and pneumonia

TABLE 26.5 EMERGENCY MANAGEMENT

Inhalation Injury

Etiology	Assessment Findings	Interventions
• Exposure of the respiratory tract to intense heat or flames • Inhalation of noxious chemicals, smoke, or carbon monoxide (CO) • Occurs with being trapped in an enclosed space, being in an explosion, or having clothing catch fire	• Altered mental status, including confusion, coma • Carbonaceous sputum • Cherry-red skin color (CO levels >20%) • Coughing • Darkened oral or nasal membranes • Decreased O_2 saturation • Difficulty swallowing • Dysrhythmias • Increasing hoarseness • Irritation of upper airways or burning pain in throat or chest • Productive cough with black, gray, or bloody sputum • Rapid, shallow respirations • Restlessness, anxiety • Singed nasal or facial hair • Smoky breath	**Initial** • If unresponsive, assess circulation, airway, and breathing. • If responsive, monitor the airway, breathing, and circulation. • Assess for a thermal burn. • Provide 100% humidified O_2. • Anticipate endotracheal intubation and mechanical ventilation with significant inhalation injury. • Monitor vital signs, level of consciousness, O_2 saturation, and heart rhythm. • Obtain ABGs, carboxyhemoglobin levels, and chest x-ray. • Remove non-adherent clothing, jewelry, glasses, or contact lenses (if the face was exposed). • Establish IV access with 2 large-bore catheters if burn >20% TBSA. • Begin fluid replacement. • Insert indwelling urinary catheter if burn >20% TBSA. • Elevate burned limb(s) above the heart to decrease edema. • Give IV analgesia and assess effectiveness frequently. • Identify and treat other injuries (e.g., fractures, pneumothorax, head injury). • Cover concurrent burned areas with dry dressings or clean sheets. • Anticipate the need for fiberoptic bronchoscopy or intubation. **Ongoing Monitoring** • Monitor airway, breathing, and circulation. • Monitor vital signs, O_2 saturation, heart rhythm, and level of consciousness. • Monitor pain level. • Monitor urine output.

TBSA, Total body surface area.

The severity of inhalation injury ranges from mild to severe (Table 26.5). Rapid initial and ongoing assessment is critical. Airway compromise and pulmonary edema can quickly develop within hours of injury. The patient may need a fiberoptic bronchoscopy and carboxyhemoglobin blood levels to confirm a suspected inhalation injury. Patients exposed to carbon monoxide from smoke will have elevated carboxyhemoglobin levels. Examine sputum for carbon particles. Watch for signs of respiratory distress, such as increased agitation, anxiety, restlessness, or a change in the rate or character of breathing. Symptoms may not be present at first.

Patients with preexisting lung disease are more likely to develop a respiratory infection. Pneumonia, a common complication of major burns, is the leading cause of death in patients with an inhalation injury.

Cardiovascular

Other complications can affect perfusion besides burn shock. Deep circumferential burns and subsequent edema formation can impair blood flow to the extremities. If untreated, ischemia, paresthesia, and necrosis can occur. An **escharotomy** (an incision through the full-thickness eschar) will restore circulation to compromised extremities or improve chest expansion (Fig. 26.8).[8] HCPs perform this procedure.

Fig. 26.8 Escharotomies of the lower leg. (Source: Sheridan R: Medical aspects of trauma and burns. In Goldman L, Schafer A [Eds], *Goldman-Cecil medicine*, ed 26, Philadelphia, 2020, Elsevier.)

Burn patients are at risk for venous thromboembolism (VTE), especially if other risk factors are present. These include advanced age, obesity, extensive or lower extremity burns, concomitant lower extremity trauma, and prolonged immobility. It is recommended the patient receive low-molecular-weight heparin (enoxaparin) or low-dose unfractionated heparin if there are no contraindications. Apply intermittent pneumatic compression devices if the patient is immobile.

TABLE 26.6 Interprofessional Care

Burn Injury

Emergent Phase	Acute Phase	Rehabilitation Phase
Fluid Therapy (Table 26.7) • Assess fluid needs. • Begin IV fluid replacement. • Insert an indwelling urinary catheter. • Monitor urine output. **Wound Care** • Start daily shower and wound care. • Debride as needed. • Assess the extent and depth of burns. • Give tetanus toxoid or tetanus antitoxin. **Pain and Anxiety** • Assess and manage pain and anxiety. **Physical and Occupational Therapy** • Place the patient in a position that prevents contracture formation and reduces edema. • Assess the need for splints. **Nutrition Therapy** • Assess nutrition needs and begin feeding patients by the most appropriate route as soon as possible. **Respiratory Therapy** • Assess oxygenation needs. • Provide supplemental O_2 as needed. • Intubate if needed. • Monitor respiratory status. **Psychosocial Care** • Provide support to patients and caregivers during the initial crisis phase.	**Fluid Therapy** • Continue to replace fluids, depending on the patient's clinical response. **Wound Care** • Continue daily shower and wound care. • Continue debridement (if needed). • Assess wound daily and adjust dressing protocols as needed. • Observe for complications (e.g., infection). **Early Excision and Grafting (Table 26.9)** • Provide temporary allografts. • Provide permanent autografts. • Care for donor sites. **Pain and Anxiety** • Continue to assess for and treat pain and anxiety. **Physical and Occupational Therapy** • Begin a daily therapy program for maintenance of a range of motion. • Assess the need for splints and anti-contracture positioning. • Encourage and aid patients with self-care as possible. **Nutrition Therapy** • Continue to assess diet to support wound healing. **Respiratory Therapy** • Continue to assess oxygenation needs. • Continue to monitor respiratory status. • Monitor for signs of complications (e.g., pneumonia). **Psychosocial Care** • Provide ongoing support, counseling, and teaching to patients and caregiver about physical and emotional aspects of care and recovery. • Begin discharge planning. **Drug Therapy (Table 26.8)** • Assess the need for drugs (e.g., antibiotics). • Continue to monitor effectiveness and adjust dosage as needed.	• Continue to teach patients and caregivers about wound care. • Continue to encourage and aid the patient in resuming self-care. • Continue to prevent or minimize contractures. • Assess risk for scarring (surgery, physical and occupational therapy, splinting, pressure garments). • Discuss possible reconstructive surgery. • Prepare for discharge home or transfer to a rehabilitation hospital. • Discuss the possible need for home care nursing.

Renal

The most common renal complication during the emergent phase is AKI.[9] If the patient becomes hypovolemic, blood flow to the kidneys will decrease, causing renal ischemia. If this continues, AKI will develop.

With full-thickness and major electrical burns, released myoglobin (from muscle cell breakdown) and hemoglobin (from RBC breakdown) can block renal tubules. Monitor the adequacy of fluid replacement because this can prevent the tubule obstruction.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: EMERGENT PHASE

In the emergent phase, the patient's survival depends on a rapid and thorough assessment, analyzing findings, planning and prioritizing interventions, and evaluating the results. Nurses, HCPs, and other clinicians initially focus on airway management, fluid and electrolyte balance, wound care, and nutrition (Table 26.6).

◆ Airway Management

Work with respiratory therapists to monitor the patient's airway and breathing pattern (Table 26.5). Place the patient in a high Fowler's position unless contraindicated (e.g., spinal injury). The treatment for inhalation injury includes administering 100% O_2 with a non-rebreather mask, aerosolized heparin, N-acetylcysteine, and albuterol. Encourage deep breathing and coughing every hour. Reposition the patient every 1 to 2 hours. Suction if needed. Draw ABGs to assess the adequacy of gas exchange. Make sure to place the patient on telemetry. Monitor pulse oximetry and capnography. Evaluate the patient's response to interventions. Report adverse responses or declines to HCPs.

TABLE 26.7 Fluid Resuscitation Formulas

American Burn Association

2 mL lactated Ringer's solution per kilogram (kg) of body weight per percent of total body surface area (% TBSA) burned = Total fluid requirements for the first 24 hr after burn injury

Application

- ½ of the total in the first 8 hr
- ¼ of the total in the second 8 hr
- ¼ of the total in third 8 hr

Example

For a 70-kg patient with a 50% TBSA burn: mL × 70 × 50 (TBSA burned) = 7000 mL in 24 hr

- ½ of the total in first 8 hr = 3500 mL (438 mL/hr)
- ¼ of the total in second 8 hr = 1750 mL (219 mL/hr)
- ¼ of the total in third 8 hr = 1750 mL (219 mL/hr)

American Burn Association Consensus Fluid Resuscitation

2–4 mL lactated Ringer's solution per kilogram (kg) of body weight per percent of total body surface area (% TBSA) burned = Total fluid requirements for the first 24 hr after burn

In general, the patient with significant face and neck burns needs intubation within 1 to 2 hours after injury. Early intubation prevents the need for an emergency cricothyrotomy. Other patients will need intubation if symptoms of severe respiratory distress (e.g., hoarseness, shortness of breath) develop (see Chapters 28 and 32). Extubation may occur at the end of the emergent phase when airway edema resolves. This is usually 3 to 5 days after the initial injury. Other patients will be intubated for many weeks or months due to extensive lung damage.

! SAFETY ALERT

Pulse CO-Oximetry Monitoring

- Standard pulse oximetry (SpO_2) does not distinguish oxyhemoglobin from carboxyhemoglobin.
- A patient with CO poisoning will have normal SpO_2 readings despite high carboxyhemoglobin levels.
- For patients with suspected or confirmed CO poisoning, use a pulse CO oximetry (SpCO) device.

Fluid Therapy

Nurses have many responsibilities during fluid resuscitation.[10] Insert at least 2 large-bore IVs when burns are greater than 20% TBSA. The HCP may elect to insert a central line. It is critical to select IVs that can handle large volumes of fluid. Central lines are discussed in Chapter 17.

You will need to estimate the TBSA of the burn wounds to calculate the initial IV fluid requirements for resuscitation (Fig. 26.4). Use the ABA formula to calculate the fluid needs for the first 24 hours after injury (Table 26.7 or www.mdcalc.com/parkland-formula-for-burns).[11] For adults with thermal burns, multiplying 2 mL lactated Ringer's/patient's weight in kg/TBSA burned to calculate fluid needs. Remember that formulas are estimates. Fluids are titrated based on the patient's response. Crystalloid solutions and sometimes colloids (albumin) are used for resuscitation. Insert an indwelling catheter for patients with burns greater than 20% TBSA. Monitor the patient for early signs of fluid overload, especially older patients or those with chronic heart, lung, or kidney diseases. Assess for the adequacy of fluid resuscitation hourly using urine output and cardiac parameters:

- *Urine output for adults:* 0.5 to 1 mL/kg/hr; *for children*: 1 to 1.5 mg/kg/hr.
- *Cardiac parameters:* Mean arterial pressure (MAP) greater than 65 mm Hg, systolic BP greater than 90 mm Hg, heart rate less than 120 beats/min. MAP and BP are best measured by an arterial line. Manual BP measurement is often invalid because of edema and vasoconstriction.

Patients with an electrical injury have greater than normal fluid needs to prevent AKI. They often require an osmotic diuretic (mannitol [Osmitrol]) to increase urine output and overcome hemoglobinuria or myoglobinuria. A higher hourly output of 75 to 100 mL/hr is best.

Fig. 26.9 Shower trolley. Showering presents an opportunity for PT and wound care. (Courtesy Judy Knighton, Toronto, Canada.)

CHECK YOUR PRACTICE

You are admitting an adult with thermal burns who weighs 72 kg and has 45% TBSA burn. Calculate the patient's fluid requirements for the first 24 hrs using the ABA Formula (2 mL/kg/% total body surface area burn).

Wound Care

A patient with significant burns is admitted or transferred to a burn unit after being stabilizing in the ED. The patient will shower or receive a trolley bath (Fig. 26.9). Patients can lose body heat through their wounds. Prevent shivering by keeping the room warm (around 85°F [29.4°C]). Always wear personal protective equipment (PPE) (e.g., disposable hats, masks, gowns, gloves) when the patient's burn wounds are exposed. Wear non-sterile disposable gloves when removing contaminated dressings and washing wounds. Patients find wound care

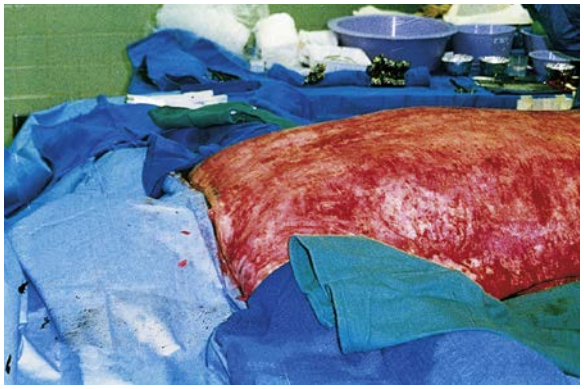

Fig. 26.10 Surgical debridement of full-thickness burns is necessary to prepare the wound for grafting. (Courtesy Judy Knighton, Toronto, Canada.)

Fig. 26.11 Application of silver sulfadiazine cream to saline-moistened gauze. (Courtesy Judy Knighton, Toronto, Canada.)

to be physically and emotionally demanding. Provide emotional support and begin to build trust during this activity.

Partial-thickness burn wounds appear pink to cherry-red and are wet and shiny with serous exudate. These painful wounds may or may not have intact blisters. Most partial thickness burns will heal within several weeks or months. Full-thickness burns can be white, red, brown, or charred. Patients may not have pain since the nerves in the dermis are destroyed. Patients with large full-thickness burns will require skin grafts. Give analgesia to manage pain during wound cleansing, debridement, and dressing application.

Use a mild cleanser and washcloths and perform cleansing and gentle wound debridement. **Debridement** is the removal of necrotic tissue from the wound bed. Skilled nurses will use scissors and forceps to remove loose burn tissue and blisters. Extensive surgical debridement occurs in the operating room (Fig. 26.10). Once the bathing is finished, the skin and burns are dried, and the total burn percentage is re-estimated. Next, we apply dressings.

Many different types of dressings and topical agents are available. These include antimicrobial creams, hydrocolloids, alginates, hydrogels, collagen, and hyaluronic acid (Fig. 26.11).[12] HCPs will prescribe topical agents based on the burn depth, bacterial count, and cost. Some burns are treated with a topical ointment and left open to the air. Others will be dressed with various products and covered with secondary dressings such as gauze. Dressing changes continue once or twice a day depending on the severity of the burn and type of dressings. Patients may have a specific specialty dressing that is changed every 5 to 7 days. Some burn centers use ace wraps or tubular elastic dressings to hold all burn dressings in place and reduce edema.

! SAFETY ALERT

Drug Allergy Check

- Check the patient for any allergies to sulfa since many burn antimicrobial creams contain sulfa.

Other Care Measures

Certain parts of the body (e.g., face, eyes, hands, arms, ears, perineum) need vigilant nursing care. The face is vascular and can become very swollen. Facial burns are often covered with ointments and gauze but not wrapped to limit pressure on delicate facial structures. An eye exam should occur soon after admission for all patients with facial burns. Periorbital edema can temporarily prevent eye-opening and is often frightening for the patient. Assure that the swelling is not permanent. Instill artificial tears into the eyes for moisture and comfort.

Keep the ears free from pressure because of their poor vascularization and the tendency to become infected. Do not use pillows for the patient with ear burns. The pressure on the cartilage may cause chondritis. The ear may stick to the pillowcase, causing pain and bleeding. Raise the patient's head using a rolled towel placed under the shoulders to avoid pressure necrosis. Follow the same strategy for the patient with neck burns to hyperextend the neck and prevent neck contracture.

Extend burned hands and arms and raise them on pillows or foam wedges to reduce edema. The PT will evaluate and provide splints to keep burned joints in positions of function. Remove the splints often and inspect the skin and bony prominences to avoid areas of pressure from inappropriate or prolonged application. Collaborate with PT/OT to schedule therapy sessions. Work with PT and OT to provide range-of-motion (ROM) exercises during dressing changes and throughout the day. ROM aids the shift of the interstitial fluid back into the vascular bed, maintains function, and prevents skin and joint contractures.

Keep the patient's perineum clean and dry after voiding or bowel movements. Remove indwelling catheters used for fluid resuscitation as soon as possible. If the patient has frequent, loose stools, consider using a fecal diversion device.

Drug Therapy

Analgesics and Sedatives

Provide analgesics for the patient's comfort. Early in the postburn period, give IV pain medications. The onset of action is fast. Common drugs used for pain control are shown in Table 26.8. Opioids are the drug of choice for severe pain. When given appropriately, these drugs should provide adequate pain relief.

Evaluate the pain management plan often since the patient's needs may change and tolerance to drugs may develop, especially

TABLE 26.8 Drug Therapy

Burns

Drugs	Purpose
Analgesics	
morphine	Relieve pain
sustained-release morphine (MS Contin)	
hydromorphone (Dilaudid)	
sustained-release hydromorphone (Dilaudid CR)	
fentanyl (Sublimaze)	
oxycodone and acetaminophen (Percocet)	
nonsteroidal antiinflammatory (e.g., ketorolac)	
adjuvant analgesics (e.g., gabapentin)	
Anticoagulants	
enoxaparin (Lovenox)	Prevent venous thromboembolism
heparin	
Antidepressants	
citalopram (Celexa)	Reduce depression, improve mood
sertraline (Zoloft)	
Gastrointestinal Support	
aluminum hydroxide and magnesium hydroxide (Maalox)	Neutralize stomach acid
calcium carbonate and magnesium carbonate (Mylanta)	
esomeprazole (Nexium)	Decrease stomach acid and risk for Curling ulcer
cimetidine (Tagamet)	
nystatin	Prevent overgrowth of *Candida albicans* in oral mucosa
Nutrition Support	
Minerals: zinc, iron (ferrous sulfate)	Promote cell integrity and hemoglobin formation
Vitamins A, C, E, and multivitamins	Promote wound healing
Sedatives/Hypnotics	
lorazepam (Ativan)	Reduce anxiety
midazolam (Versed)	Provide short-acting amnesic effects
zolpidem (Ambien)	Promote sleep

during the acute phase. Remember that the patient's pain level may not directly correlate with the extent and depth of the burn. Analgesic needs vary from one patient to another. Consider a multimodal approach to pain control. Sedatives/hypnotics and antidepressants given with analgesics help with anxiety, insomnia, or depression. Include nondrug methods such as digital technology distraction.[13]

◆ Tetanus Immunization

Patients routinely receive tetanus toxoid because of the risk of exposure to clostridium tetani. Tetanus immunoglobulin would be considered if the patient has not received an active immunization within 10 years before the burn injury. Tetanus immunization is discussed in Table 21.6.

◆ Nutrition Therapy

A hypermetabolic state proportional to the size of the wound occurs after a major burn injury. Resting metabolic expenditure may increase by 50% to 100% above normal.[14] The core temperature increases. Catecholamine release stimulates catabolism and heat production. Massive catabolism occurs with protein breakdown and increased gluconeogenesis. Failure to supply adequate calories and protein leads to weight loss, malnutrition, and delayed healing.

Early nutrition support within several hours of the burn injury can reduce complications and mortality, optimize burn wound healing, and minimize the negative effects of hypermetabolism and catabolism. Dietitians will calculate nutrition needs and recommend supplements or enteral nutrition (EN). Non-intubated patients with a burn of less than 20% TBSA will usually be able to consume enough calories to meet their nutrition needs. Work with the dietitian to provide a high protein, high carbohydrate diet. Patients with major burns may develop an ileus and need a gastro-jejunal tube for decompression and EN. Calorie-containing nutrition supplements are given to meet the caloric needs. We may give supplemental vitamins (see Table 26.8).

Intubated patients and those with larger burns need more support. Early EN, usually with smaller bore tubes, preserves GI function, increases intestinal blood flow, and promotes optimal conditions for wound healing. In general, begin the feedings slowly at a rate of 20 to 40 mL/hr and increase to the goal rate within 24 to 48 hours. Assess bowel sounds every 8 hours.

ACUTE PHASE

The acute phase of burn care begins with the mobilization of interstitial fluid and subsequent diuresis and continues until wounds are nearly healed. This may take weeks or months depending on the burn severity and the patient's response to treatment.

Pathophysiology

Oxygenation problems may resolve. However, sometimes inhalation injuries will not resolve for many days, weeks, or months. Vital signs are more stable. Wound healing begins as WBCs surround the burn wound and phagocytosis occurs. Necrotic tissue begins to slough. Unfortunately, many patients with major burns will have complications during this phase. The patient may now become more aware of the enormity of the situation.

Clinical Manifestations

Partial-thickness wounds begin to heal at the wound margins. Epithelial buds, from the hair follicles and glands in the dermal bed, eventually close the wound. Healing is spontaneous and usually occurs within 10 to 21 days. Patients often have more pain during the acute phase due to repeated dressing changes, therapy exercises, opioid tolerance, fatigue, and reduced coping ability. Surgical procedures continue for extensive debridement and skin grafting.

Fluid and Electrolytes

Because the body is trying to reestablish fluid and electrolyte balance in the initial acute phase, it is important to follow serum electrolyte levels closely.

Sodium

Hyponatremia can develop from excess GI suction and diarrhea. Manifestations include headache, irritability, confusion, vomiting, seizures, and even coma. The patient may develop *dilutional hyponatremia* from excess water intake. To avoid this condition, offer the patient fluids other than water, such as juice or nutrition supplements.

Hypernatremia may occur after successful fluid resuscitation if large amounts of hypertonic solutions were given. EN or inappropriate fluid administration can cause hypernatremia. Manifestations include changes in mental status, ranging from drowsiness, restlessness, confusion, and lethargy to seizures and coma. Restricting sodium in IV fluids and EN can reduce levels.

Potassium

Hyperkalemia may occur if the patient has renal failure, adrenocortical insufficiency, or massive deep muscle injury (e.g., electrical burn). Damaged cells release large amounts of potassium. Dysrhythmias and arrest can occur with high potassium levels. The patient may have confusion, tetany, muscle cramps, paresthesia, and weakness.

Hypokalemia occurs with vomiting, diarrhea, prolonged GI suction, and IV therapy without potassium supplementation. The patient loses potassium through their burn wounds. Besides dysrhythmias, the patient may have muscle weakness, paresthesia, decreased GI motility, and decreased reflexes (see Chapter 17).

Complications

Infection

A burn injury destroys the body's first line of defense, the skin. The person's normal flora will quickly colonize the burn wound. The WBCs have functional defects. The patient is immunosuppressed for many months after the burn injury.

Localized inflammation, induration, and sometimes purulent drainage can be seen at the burn wound margins. Watch for signs and symptoms of systemic infection, including hypothermia or hyperthermia, increased heart and respiratory rate, decreased BP, and decreased urine output. The patient may have mild confusion, chills, malaise, and loss of appetite. The WBC count can rise over 20,000/μL (20×10^9/L). The causative organisms of sepsis are usually gram-negative bacteria (e.g., *Pseudomonas, Proteus*), putting the patient at risk for septic shock. Sepsis is a leading cause of death in the patient with major burns. It may lead to multiple organ dysfunction syndrome (see Chapter 42).

Fungal infections may develop in the patient's mucous membranes (mouth, genitalia) due to systemic antibiotic therapy and low resistance. In severe cases, fungal infections spread to the blood. The offending organism is usually *Candida albicans.* Administer antifungals such as nystatin and fluconazole as ordered.

Cardiovascular and Respiratory

The same cardiovascular and respiratory complications present in the emergent phase may continue into the acute phase of care. New problems, such as pneumonia, might arise, requiring prompt intervention.

Neurologic

Neurologic problems may result due to severe hypoxia from respiratory injuries or as a complication from electrical injuries. Other causes of neurologic problems include electrolyte imbalance, stress, cerebral edema, sepsis, sleep problems, and the use of analgesics and antianxiety drugs.

Some patients may become disoriented, withdraw, be combative, hallucinate, or have frequent nightmare-like episodes. Delirium is more acute at night and occurs more often in older patients. Use a screening tool to diagnose delirium (see Table 64.19). Start nursing interventions to prevent delirium. Orient and reassure a patient who is confused or agitated. This state is usually transient, lasting from a day or 2 to several weeks. However, some complications can last for years and be serious.

Musculoskeletal

The musculoskeletal system is especially prone to complications during the acute phase. PT and OT are vitally important. As the burns begin to heal and scar tissue forms, the skin is less supple and pliant. ROM may be affected. Skin and joint contractures can occur. Because of pain, the patient prefers a flexed position for comfort. Have the patient stretch and move the burned body parts as much as possible. Consult with PT or OT about proper positioning and splinting to prevent or reduce contracture formation.

Gastrointestinal

The GI system may develop complications during this phase. Diarrhea may result from the use of EN or antibiotics. Constipation can occur as a side effect of opioids, decreased mobility, and a low-fiber diet. *Curling ulcer* is a type of gastroduodenal ulcer characterized by diffuse superficial lesions (including mucosal erosion). The stress response can decrease blood flow to the GI tract.

Aim to prevent Curling ulcer by feeding the patient as soon as possible after the burn injury. Antacids, H_2-histamine blockers (e.g., cimetidine), and proton pump inhibitors (e.g., omeprazole) are used prophylactically to neutralize stomach acids and inhibit histamine and the secretion of hydrochloric acid (Table 26.8). Patients with major burns may have occult blood in their stools during the acute phase and require close monitoring for bleeding.

Endocrine

Watch for transient increases in the patient's blood glucose levels because of stress-mediated cortisol and catecholamine release. There is increased mobilization of glycogen stores and gluconeogenesis. Subsequently, glucose is produced with an increase in insulin production. However, insulin's effectiveness decreases because of relative insulin insensitivity. This results in a high blood glucose level. The increased caloric intake needed to meet metabolic requirements can increase blood glucose levels. When hyperglycemia occurs, check glucose levels and administer insulin. Monitor blood glucose testing results. This stress-induced condition reverses as metabolic demands are met, and less stress is placed on the entire system.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: ACUTE PHASE

The major therapeutic interventions in the acute phase are (1) wound care, (2) excision and grafting, (3) pain management, (4) physical and occupational therapy, and (5) nutrition therapy.

◆ Wound Care

The goals of wound care are to (1) prevent infection by cleansing and debriding the area of necrotic tissue that would promote bacterial growth and (2) promote wound re-epithelialization and/or successful skin grafting.

Wound care consists of ongoing observation, assessment, cleansing, debridement, and dressing reapplication. Dressing changes, topical antimicrobial therapy, graft care, and donor site care is done as often as needed, depending on the topical cream or dressing. Collagenase is used for *enzymatic debridement* of burn wounds. It promotes the removal of nonviable tissue from the healthy wound bed.[15]

Gently cleanse wounds to remove the old antimicrobial agent and any loose necrotic tissue, scabs, or dried blood. After cleansing, cover the wound with topical antimicrobial creams (e.g., silver sulfadiazine) or silver-impregnated dressings. Avoid silver sulfadiazine if the patient has an allergy or sensitivity to sulfa.

◆ Excision and Grafting

Many patients, especially those with major burns, have surgery on day 1 or 2 (emergent phase). With **excision**, devitalized tissue (eschar) is surgically removed down to the subcutaneous tissue or fascia. Surgical excision can result in massive blood loss.

A *dermatome* is used to remove the donor skin for grafting (Fig. 26.12B). An autograft is the patient's skin used for grafting. The abdomen and thighs are common donor sites. The donor skin can be meshed to allow for greater wound coverage. Sometimes it is applied as an unmeshed sheet for a better cosmetic result when grafting the face, neck, and hands. Sometimes wounds are covered with a biologic dressing or allograft for temporary coverage until permanent grafting can occur (Table 26.9).

The graft is placed on clean, viable tissue to achieve good adherence. Grafts can be stapled or sutured into place (Fig. 26.12A). Negative pressure wound therapy dressings are often placed on top of skin grafts to optimize adherence of the graft to the excised wound bed. Outer occlusive dressings apply just enough pressure to promote adherence of the graft to the wound bed and help control bleeding.

The goals of donor site care are to promote rapid, moist wound healing, decrease pain at the site, and prevent infection. The choices of dressings for donor sites include transparent dressings (e.g., OpSite), xenograft, silver sulfadiazine, silver-impregnated dressings, calcium alginate, and hydrophilic foam dressings (Fig. 26.12C).[16] Nursing care of the donor site is specific to the dressing used. Many newer dressings decrease healing time, which allows earlier harvesting of skin at the same site. The average healing time for a donor site is 10 to 14 days (Fig. 26.12D).

Recell is a newer burn treatment product for partial and full-thickness wounds. It uses a small sample of the patient's skin to produce a sprayed-on suspension.[17] Meshed autografts are required with Recell for full-thickness wounds.

◆ Cultured Epidermal Autografts

In the patient with large body burns, only a limited amount of unburned skin may be available as donor sites for grafting, and some of that skin may not be suitable for harvesting. Cultured epidermal autograft (CEA) is a method of getting permanent

TABLE 26.9 Skin Grafts Used for Burn Injury

Graft Type	Source and Description	Coverage
Allograft (or homograft) (same species)	Cadaveric skin	Temporary (3 days to 2 weeks)
Autografts		
Autograft	Patient's skin	Permanent
Cultured epithelial autograft (CEA)–Epical Recell	Patient's own skin cell cultures	Permanent
Dermal Substitutes		
Allover	Acellular dermal matrix derived from donated human skin	Permanent
Apligraf	Donated neonatal foreskin fibroblasts and keratinocytes in bovine collagen gel	Permanent
Biobrane	Semipermeable silicone membrane bonded to nylon fabric	Temporary (10–21 days)
Integra	Biodegradable dermal layer made of bovine collagen and glycosaminoglycan bonded to silicone membrane	Permanent
Matriderm	Bovine collagen and elastin matrix	Permanent
OrCel	Donated neonatal foreskin fibroblasts and keratinocytes in bovine collagen sponge	Permanent
Xenograft (or heterograft) (different species)	Porcine skin	Temporary (3 days to 2 weeks)

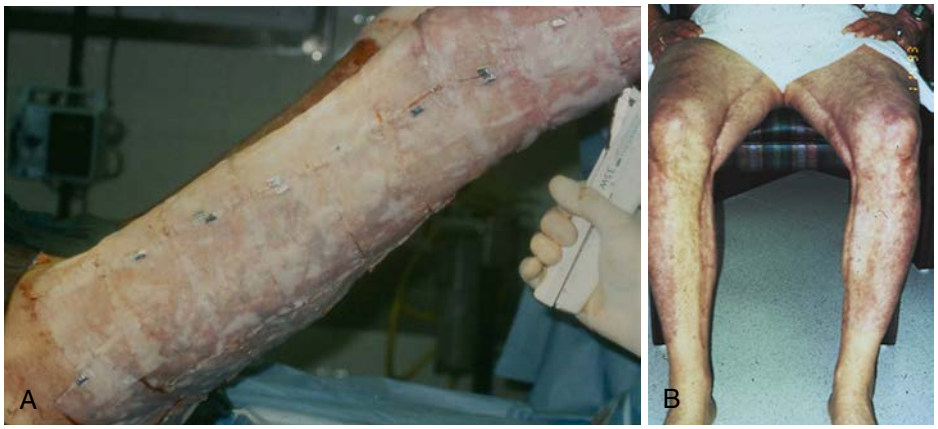

Fig. 26.13 Patient with cultured epithelial autograft (CEA). (A) Intraoperative application of CEA. (B) Healed CEA.

skin from a person with limited skin available for harvesting.[18] CEA is grown from biopsy samples obtained from the patient's unburned skin. The specimens are sent to a commercial laboratory, where the biopsied keratinocytes are grown in a culture medium containing epidermal growth factor. After about 18 to 25 days, the keratinocytes have expanded up to 10,000 times. They form sheets that we can use as skin grafts on excised burn wounds (Fig. 26.13A). CEA grafts generally form a seamless, smooth replacement skin tissue (Fig. 26.13B). However, problems include a poor graft take because of thin epidermal skin, graft loss during healing, infection, and contractures.

Dermal Substitutes

Dermal substitutes act as a synthetic dermis and are covered by a skin graft. The Integra artificial skin dermal regeneration template is an example of a skin replacement system. As with CEA, it is used in the treatment of life-threatening full-thickness or deep partial-thickness burn wounds when a conventional autograft is not available or advisable, as in older or high anesthetic-risk patients. It also is used in reconstructive burn surgery procedures.

Integra artificial skin has a 2-layer membrane composed of acellular dermis and silicone. After the wound is excised, the bilayer membrane is placed dermal layer down, and the wound is wrapped with dressings in the OR. The dermal layer functions as a biodegradable template that induces the organized regeneration of new dermis by the body. The silicone layer stays intact for 3 weeks as the dermal layer degrades and epidermal autograft becomes available. At this point, the silicone is removed during a second surgery and replaced by the patient's epidermal autograft.

Pain Management

Many aspects of burn care cause pain. Eliminating all pain is difficult, but most patients will have acceptable levels of relative comfort if they receive adequate analgesia. To provide effective pain management, you must understand both the physiologic and psychological aspects of pain. Pain management is discussed in Chapter 9.

Burn patients have 2 kinds of pain: (1) *continuous, background pain* that might be present throughout the day and night, and (2) *treatment-induced pain* caused by dressing

changes, ambulation, and rehabilitation activities. The first line of treatment is medication (Table 26.8). With background pain, frequent IV administration of an opioid (e.g., hydromorphone) provides a steady, therapeutic level of the drug. If tolerating food, slow-release, twice-daily opioids (e.g., morphine) can be used. Patient-controlled analgesia (PCA) is used in some burn centers. Anxiolytics (e.g., lorazepam, midazolam) and adjuvant analgesics (e.g., gabapentin, pregabalin) can enhance opioid effectiveness. Their use can help reduce opioid dosage and undesirable side effects.

Breakthrough doses of analgesia must be available. Additional doses of opioids are usually given. For treatment-induced pain, pre-medicate with an analgesic, and possibly an anxiolytic, via the IV or oral route.

Some patients respond to complementary therapy. Relaxation breathing, guided imagery, hypnosis, biofeedback, computerized gaming, and music therapy can help patients cope with pain (see Chapter 7).

Remember, the more control the patient has in managing pain, the more successful the chosen strategies will be. Active participation in asking for time-outs and scheduling treatments and rest periods can help the patient reduce feelings of anticipatory pain.

CHECK YOUR PRACTICE

A patient with a burn injury is prescribed fentanyl (Sublimaze) before a dressing change. The patient has multiple IV lines. You are not sure which line to use to give the drug. You know that mixing up IV lines can lead to serious drug errors.

- How would you determine which IV line to use to give the drug?

Physical and Occupational Therapy

Continuous therapy throughout burn recovery is critical if the patient is to regain and maintain muscle strength and optimal joint function. A good time for exercise is during dressing changes when bulky dressings are removed and patients are medicated for pain. Passive and active ROM should be performed on all joints. PT and OT may provide exercises after dressing changes. Maintain the schedule for wearing custom-fitted splints designed to keep joints in a functional position. Check the skin to make sure the splints are not causing excessive pressure.

Nutrition Therapy

The goal of nutrition therapy during the acute burn phase is to provide adequate calories and protein to promote healing. When the wounds are still open, the burn patient is in a hypermetabolic and catabolic state.

The patient may benefit from an antioxidant protocol, which includes selenium, vitamin E, acetylcysteine, ascorbic acid, zinc, and a multivitamin. Meeting daily caloric requirements is crucial and should start within the first 1 to 2 days post-burn. The dietitian regularly calculates the daily caloric requirements and makes adjustments as the patient's condition changes (e.g., wound healing improves, sepsis develops). Monitor laboratory values (e.g., albumin, prealbumin, total protein, transferrin) as available.

Encourage the patient to eat high-protein, high-carbohydrate foods to meet caloric goals. Ask caregivers to bring in their favorite foods from home. Appetite is usually reduced. You will need to reinforce the steps being taken to achieve adequate intake. Ideally, weight loss should not be more than 10% of the pre-burn weight. Record the patient's daily caloric intake using calorie count sheets. Review the sheets with the dietitian. Weigh the patient weekly to evaluate progress.

REHABILITATION PHASE

The formal rehabilitation phase begins when the patient's wounds have nearly healed, and they are engaging in some level of self-care. This may happen as early as 2 weeks or as long as 7 to 8 months after a major burn injury. Goals for the patient now are to (1) work toward resuming a functional role in society and (2) rehabilitate from any functional and cosmetic postburn reconstructive surgery.

Pathophysiologic Changes and Clinical Manifestations

Burn wounds heal by either spontaneous re-epithelialization or skin grafting. Layers of keratinocytes begin rebuilding the tissue structure destroyed by the burn injury. Collagen fibers, present in the new scar tissue, help with healing and add strength to weakened areas. The new skin appears flat and pink. In about 4 to 6 weeks, the area becomes raised and hyperemic. If adequate ROM is not continued, the new tissue will shorten, causing a contracture. Mature healing is reached in about 12 months when suppleness has returned, and the pink or red color has faded to a slightly lighter hue than the surrounding unburned tissue.

Scarring has 2 characteristics: (1) discoloration and (2) contour. Discoloration fades with time. Tell patients with heavily pigmented skin that it will take longer for it to regain tone because of altered melanocytes. Often, the skin does not regain its original tone, though this is impossible to predict. Provide teaching and emotional support to help the patient with grieving about these body changes. Cosmetic camouflage or pigment implantation can help even out unequal skin tones and improve the patient's overall appearance and self-image.

Scar tissue tends to develop altered contours. That is, it is no longer flat or slightly raised but becomes elevated and enlarged above the original burned area. Some HCPs believe that pressure can help keep a scar flat. Gentle pressure is maintained on the healed burn with custom-fitted pressure garments and clear, thermoplastic facemasks.[19] Pressure garments and masks should never be worn over unhealed wounds. Pressure garments are worn up to 23 hours a day for as long as 12 to 18 months.

The patient typically reports discomfort from itching where healing is occurring. Teach the patient that water-based moisturizers and short-term use of oral antihistamines (e.g., hydroxyzine [Atarax]) can help reduce itching. Massage, cooling, emollients, gabapentin, antidepressants, and anesthetic creams also may help.

Skin flaking occurs as the epithelium is replaced by new cells. The newly formed skin is very sensitive to trauma. Blisters and

Fig. 26.14 Neck contracture. (Courtesy Linda Bucher, RN, PhD, CEN, CNE, Staff Nurse, Virtua Memorial Hospital, Mt. Holly, NJ.)

skin tears are likely to develop from slight pressure or friction. These newly healed areas can be more or less sensitive to cold, heat, and touch. Grafted areas are more likely to be less sensitive until peripheral nerve regeneration occurs. Have patients protect healed burn areas from direct sunlight for about 3 months to prevent hyperpigmentation and sunburn injury. Tell patients to wear sunscreen when exposing healed skin to the sun.

Complications

The most common complications during the rehabilitation phase are skin and joint contractures and hypertrophic scarring. Joint contractures may develop because of the shortening of scar tissue in the flexor tissues of a joint. Areas that are most susceptible to contractures include the anterior and lateral neck areas, axillae, antecubital fossae, fingers, groin areas, popliteal fossae, knees, and ankles (Fig. 26.14). Some involve ligaments and tendons.

Carefully watch the patient for these potential problems. Encourage proper positioning, splinting, and exercise. Tell the patient to continue with these strategies until the skin matures at around 1-year post healing. Rehabilitative therapy is aimed at the extension of body parts because the flexors are stronger than the extensors.

Burned legs may be wrapped with elastic (e.g., tensor, ACE) bandages to assist with circulation to leg-graft and donor sites before ambulation. Burned arms can be wrapped with a layer of tubular elastic gauze (e.g., Tubigrip). This interim pressure prevents blister formation, promotes venous return, and decreases pain and itchiness. Custom-fitted pressure garments replace the elastic bandages and tubular gauze once the skin is healed.

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: REHABILITATION PHASE

The first step is to ask the patient about thoughts and feelings about discharge. Encourage both the patient and caregiver to take part in care. The patient and caregiver may need wound care instructions. Tell the patient to take a shower, not a bath, to wash the wounds. Have the patient or caregiver demonstrate a dressing change. Provide advice on scar management, moisturizing, and sun protection. Suggest using water-based creams that penetrate the dermis (e.g., Vaseline Intensive Rescue) on healed areas to keep the skin supple and moisturized. This will decrease itching and flaking. Antihistamines taken at bedtime may help if itching persists.

Make sure they know when to contact the burn team (e.g., signs of infection, increased pain). Stress the need to keep outpatient visits. The need for further reconstructive surgery is reviewed during follow-up appointments. If needed, work with a social worker or discharge manager to arrange home care services to assist with care.

Assess pain management and nutrition needs during each visit. Encourage the patient to perform the PT and OT exercises. Reassure the patient to maintain morale, especially once the patient realizes that recovery can be slow.

Gerontologic Considerations: Burns

Older patients present many challenges for the burn team. They have thinner dermal layers, a loss of elastic fibers, a reduction in subcutaneous adipose tissue, and a decrease in vascularity. As a result, the thinner dermis, with reduced blood flow, sustains deeper burns with poorer rates of healing.

Once injured, the older adult has more complications in the emergent and acute phases of burn resuscitation because of preexisting comorbidities. Older patients with diabetes, heart failure, or COPD have morbidity and mortality rates exceeding those of healthy, younger patients. Burn wounds and donor sites take longer to heal. Recovery from surgical procedures can be more difficult. Weaning from a ventilator can be a challenge and pneumonia is a frequent complication. Although usually self-limiting, delirium, if it develops, maybe distressing. It usually takes longer for these patients to rehabilitate to the point at which they can safely return home. For some, returning home to independent living may not be possible. Working with communities to identify strategies to prevent burn injuries in older adults is a priority.

EMOTIONAL/PSYCHOLOGIC NEEDS OF PATIENTS AND CAREGIVERS

Patients and caregivers have many emotional and psychological needs during the often lengthy, unpredictable, and complex course of care. You have an important supportive and counseling role as patients struggle to get their lives back on track.[20]

To manage the enormous range of emotional responses that the burn patient may have, assess the circumstances of the burn (e.g., cause, people involved), family relationships, and previous ways of coping with stress. At any time, the patient may have a variety of emotions, such as fear, anxiety, anger, guilt, and depression (Table 26.10).

Burn survivors often have thoughts and feelings that are frightening and disturbing. There may be guilt about the incident, reliving the burn experience, fear of dying, concern about future therapy and surgery, frustrations with ongoing discomfort and treatment, and hopelessness about the future. During recovery, new fears may occur: "Can I do this?" "Am I a desirable person?" "How can I go outside looking like this?" These challenges confront patients throughout their recovery and often for years to come.

TABLE 26.10 Common Emotional Responses

Emotion	Possible Verbal Expression
Anger	• Why did this happen to me? • The nurses enjoy hurting me. • I hope the person who did this to me dies.
Anxiety	• I feel out of control. • What is going to happen to me? • When will I look normal again?
Depression	• It is no use going on like this. • I do not care what happens to me. • I wish people would leave me alone.
Fear	• Will I die? • What will happen next? • Will I be disfigured? • Will my family and friends still love me?
Guilt	• If only I had been more careful. • I am being punished because I did something wrong.
Hopefulness	• What do I need to do to survive this injury emotionally and return to my life/family/friends? • What am I meant to learn from this injury?

A burn injury may adversely affect a person's self-esteem. Some fear the loss of relationships because of perceived or actual physical disfigurement. In a society that values physical beauty, changes in body image can result in psychological distress.

Open and frequent communication among the patient, caregivers, close friends, and burn team members is essential. Because of the tremendous psychologic impact of a burn injury, be sensitive to the patient's emotions and concerns. Encourage the patient to discuss fears about loss of lifestyle, loss of function, temporary or permanent deformity and disfigurement, return to work and home life, and financial burdens resulting from a long and costly hospitalization and rehabilitation.

Encourage independence and an eventual return to pre-burn activities, such as school or work. Peer counseling and informal interactions with other burn survivors may bring comfort and help to restore confidence. Reassure patients that their feelings during this period of adjustment are a normal reaction to an extraordinary life event. Frustration and impatience are expected as they establish a new life. Help patients in adapting to a realistic, yet positive appraisal of their specific situation, emphasizing what they *can* do instead of what they *cannot* do.

Caregivers may share some or all these challenges and feelings. At times, they may feel helpless or too exhausted to help their loved ones. Continued support from trusted and familiar burn team members is essential. Helping caregivers assist with aspects of the patient's care helps them to reconnect with their loved one and eases the transition home. Many burn survivors and their caregivers remark on the powerful learning experience of the burn and a renewed appreciation of life, despite the ongoing challenges of a prolonged recovery. Acknowledge that their feelings are real and common. Most burn survivors speak of satisfaction with their post-burn life and are more empowered as time goes on.

It is important to address spiritual and cultural needs because both have a role in treatment decisions and recovery. Pastoral care may be a helpful resource for the patient and caregiver. The need for support, information, and family involvement may vary among cultures. Identify what is important to the patient and caregiver and communicate that information in the patient's plan of care. Encourage the burn care team to be culturally aware of and sensitive to the patient and caregiver's cultural needs.

The awkward issue of sexuality must be met with honesty. Acceptance of any changes in physical appearance is hard at first for the patient and their significant other. The nature of skin injury can cause modifications in processing sexual stimuli. Touch is an important part of sexuality. Immature scar tissue may make the sensation of touch unpleasant or may dull it. This may be only transient, but the patient and partner need to know that it is normal and receive anticipatory guidance from the burn team to avoid undue emotional strain.

Burn survivors may have preexisting mental health or substance use issues, which may have contributed to the burn incident. The stress of burn injury can precipitate a psychological crisis. Assessment by a psychiatrist who can prescribe appropriate drugs and offer counseling may be needed. Early psychiatric intervention is essential if the patient has a psychiatric illness or if the injury was a suicide attempt. Many burn patients have posttraumatic stress disorder. A history of mental health issues can influence the length of hospitalization and the time needed to prepare for discharge. However, distress and trauma symptoms can act as a catalyst for positive posttraumatic growth. Coping styles and social support assist in these positive changes postburn.

Psychological support begins in the hospital, but links to community resources are needed to ensure continuity of treatment. A referral to a psychiatrist, psychologist, psychiatric advanced practice nurse (APN), mental health counselor, or social worker is discussed if concerns are raised at burn clinic follow-up.

Caregiver and patient support groups may be beneficial in meeting the patient and caregiver's emotional needs at any phase of the recovery process. Speaking with others who have had burn trauma can be beneficial. Similar persons can confirm that the patient's feelings are normal and share helpful advice. The Phoenix Society (www.phoenix-society.org) is an international, highly respected burn survivors' support group. For many years, the society has offered valuable support and resources (e.g., the annual World Burn Congress conference) to burn survivors, caregivers, and burn team staff.

SPECIAL NEEDS OF NURSES

Warm, trusting, and mutually satisfying relationships often develop between burn patients and nursing staff during hospitalization and the long-term rehabilitation period. Sometimes the bond can be so strong that the patient has difficulty separating from the hospital and staff. The frequency and intensity of family contact can be rewarding as well as draining. It may be difficult to cope with the deformities caused by the burn injury, odors, unpleasant sight of wounds, and the reality of the pain that accompanies the burn and its treatment. Do not hesitate to seek help from coworkers, a manager, or the employee assistance program should you feel the need.[21]

In time, you will come to know that specialized burn care provides a critical difference in helping patients not only survive

but also cope and triumph over an intense and complex injury. Ongoing support services or critical incident stress debriefings led by a psychiatrist, psychologist, psychiatric APN, or social worker may be helpful. Peer support groups (e.g., ABA, International Society for Burn Injuries) can serve a similar purpose by helping you cope with difficult feelings from caring for burn patients. Attention to yourself is important to maintain a positive attitude and a healthy work-life balance. Time with family and friends and relaxation at home are essential parts of self-care and a balanced life with purpose and meaning.

Case Study

Burn Injury

(© Comstock/Thinkstock.)

Patient Profile

G.M., a 70-year-old man, arrives at the ED with burns to his face, neck, chest, right arm and hand, and right foot. He was burning brush on his farm when the fire went out of control.

Subjective Data

- Reports blurry vision and trouble swallowing
- States his burns are painful. Pain rated 8/10
- Says he is a "diabetic" and has "high blood pressure"
- Allergic to sulfa

Objective Data

Physical Assessment

- Is awake, alert, and oriented, but in some distress
- Eyes are red, irritated
- Voice is hoarse; nasal hair is singed. Frequent nonproductive cough
- Face is reddened with blisters noted on the nose and forehead
- Right arm, right hand, anterior chest, neck, and right foot have shiny, bright red, moist burns
- Shivering
- Vital signs: Temp 96.5, pulse 102/min, respiratory rate 26/min, BP 142/84 mm Hg, O_2 saturation 89% with O_2 nasal cannula 4 L/min
- Scattered wheezing throughout all lung fields

Discussion Questions

1. ***Recognize:*** What subjective and objective findings are you *most* concerned about?
2. ***Recognize:*** What metabolic disturbances would you expect to develop soon? Explain the physiologic basis for these changes.
3. ***Analyze:*** What complication is G.M. at risk for?
4. ***Plan:*** How will you involve other interprofessional team members?
5. ***Prioritize:*** What *priority* interventions do you need to implement in this situation?
6. ***Evaluate:*** What outcomes would indicate initial interprofessional care for the priority problem was effective?
7. ***Plan:*** What analgesics might be considered to relieve his pain?
8. ***Plan:*** Which criteria for burn center referral does G.M. meet for admission to the hospital burn unit?
9. ***Safety:*** What risk factors does G.M have for infection?
10. ***Act:*** What measures would be taken to support G.M.'s caregivers?
11. ***Act:*** What discharge teaching would you provide to G.M. and his family so they can successfully manage his care at home?
12. ***Act:*** What interventions are necessary before discharge to ensure G.M.'s safety at home?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The question number corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which instruction would the nurse provide to prevent burn injuries?
   - **a.** Set hot water temperature at 140°F.
   - **b.** Use only hardwired smoke detectors.
   - **c.** Encourage regular home fire exit drills.
   - **d.** Do not allow older adults to cook unattended.
2. Which wound description indicates a need for excision and grafting? *(select all that apply)*
   - **a.** Red, painful blisters
   - **b.** Leathery, brown, exposed tendon
   - **c.** Pearly white color, insensitive to pain, dry
   - **d.** Charred eschar, visible thrombosed blood vessels
   - **e.** Large, fluid-filled vesicles, moderate edema, moist, red
3. Estimate the total body surface area burn injury using the rule of 9's. Burns involve the entire right arm and upper back. _____%
4. A patient is hospitalized with burns to his head, neck, and anterior and posterior chest after an explosion in his garage. The respiratory therapist applied a non-rebreather mask. On assessment, the nurse auscultates wheezes throughout the lung fields. On reassessment, the wheezes are gone, and the breath sounds are greatly decreased. Respiratory rate is 6/min. Oxygen saturation decreases to 88%. The patient is unresponsive. What is the *priority* nursing intervention?
   - **a.** Notify the HCP and get ready for intubation.
   - **b.** Encourage the patient to cough and auscultate the lungs again.
   - **c.** Obtain vital signs, oxygen saturation, and a STAT arterial blood gas.
   - **d.** Document the findings and continue to monitor the patient's breathing.
5. Which lab result supports the need for additional IV fluid to treat burn shock?
   - **a.** Hematocrit 52%
   - **b.** Sodium 137 mEq/L
   - **c.** WBC 12.5×10^9/L
   - **d.** Potassium 3.4 mmol/L
6. What nutrition intervention may promote wound healing for a patient with a 10% burn injury?
   - **a.** Eat a high-protein, high-carbohydrate diet
   - **b.** Increase normal caloric intake by about 4 times
   - **c.** Eat at least 1500 calories/day in small, frequent meals
   - **d.** Eat a lactose-free diet to reduce the potential for diarrhea

7. A patient has 25% TBSA burn from a car fire. His wounds have been debrided and covered with a silver-impregnated dressing. What is the *most* important nursing intervention following surgery?
   a. Wash the wound with soap and water 3 times a day.
   b. Medicate for pain relief in between dressing changes.
   c. Reapply a new dressing without disturbing the wound bed.
   d. Assess the wound for signs of infection during dressing changes.
8. What nursing interventions can be used to manage burn pain? *(select all that apply)*
   a. Suggest pain management options.
   b. Use a pain-rating tool to monitor the patient's level of pain.
   c. Delay painful dressing changes until the patient's pain is completely relieved.
   d. Use a multimodal approach (e.g., sustained-release and short-acting opioids, NSAIDs, adjuvant analgesics).
   e. Provide nonpharmacologic therapies (e.g., music therapy, distraction) to replace opioids in the acute phase of a burn injury.
9. What intervention prevents hypertrophic scarring during the rehabilitation phase of burn recovery?
   a. Applying pressure garments
   b. Repositioning the patient every 2 hours
   c. Performing active ROM at least every 4 hours
   d. Applying a water-based moisturizer to healed skin
10. A patient is recovering from second- and third-degree burns over 30% of his body, and the burn care team is planning for discharge. The *first* action the nurse would take when meeting with the patient would be to
    a. arrange a return-to-clinic appointment and prescription for pain medications.
    b. give the patient written information and websites resources for burn survivors.
    c. teach the patient and the caregiver proper wound care to be performed at home.
    d. review the patient's current health care status and readiness for discharge to home.

1. c; 2. b, c, d; 3. 18% 4. a; 5. a; 6. a; 7. d. 8. a; b; d; 9. a; 10. d.

Case Study

Applying Clinical Judgment With Multiple Patients

You are working the day shift on a medical-surgical unit. The following 4 patients are among the 7 you are assigned to care for today. You have an AP who is assigned to work with you. There are 15 other patients on the unit being cared for by an additional 2 RNs and 2 APs.

(© Jack Hollingsworth/Photodisc/Thinkstock.)	J.K., a 68-year-old woman, had pneumatic retinopexy surgery yesterday to repair a partially detached retina. She has a history of type 2 diabetes, diabetic retinopathy, and hypertension. She is scheduled to be discharged today, but the night RN is concerned because her BP is 180/94.
(© Jack Hollingsworth/Photodisc/Thinkstock.)	R.S., a 57-year-old woman, is under observation with Ménière disease. She continues to have extreme dizziness, tinnitus, and nausea. The HCP plans to give an intratympanic injection of dexamethasone today. Vital signs: 100/64, 112, RR 20.
(© iStock.com/EyeMark.)	D.A., a 74-year-old woman, is admitted to the hospital with symptoms of chest tightness and shortness of breath. Her history is negative except for a recent diagnosis of basal cell carcinoma (BCC) on her face. She was scheduled to have the BCC surgically removed tomorrow. The HCP suspects D.A.'s symptoms are caused by anxiety but wants to rule out any coronary artery disease before surgery.
(© Comstock/Thinkstock.)	D.B., a 70-year-old man, was admitted 3 hr ago from the ED with partial-thickness burns on his chest and arms (estimated to be 6% TBSA). Vital signs: 142/84, 102, RR 22, O_2 saturation 94% with O_2 at 6 L/min vis nasal cannula. Scattered wheezing throughout all lung fields.

1. Highlight all the findings above that require your follow-up.
2. After receiving the report, which patient would you see first? Why?
3. Which tasks could you delegate to the AP? *(select all that apply)*
   a. Obtain vital signs on J.K.
   b. Take a BP reading on D.B.
   c. Perform a shift assessment on D.A.
   d. Explain planned diagnostic testing to D.A.
   e. Obtain a 12-lead electrocardiograph on J.K.
4. When you enter D.B.'s room, he tells you he is not feeling well. He says he has a headache, and his legs are "cramping up." He is unaware that he is in the hospital.

Use an X for the nursing actions listed below that are Indicated (appropriate or necessary), Contraindicated (could be harmful), or Nonessential (makes no difference or not necessary) for D.B. at this time.

Nursing Action	Indicated	Contraindicated	Nonessential
Perform a respiratory assessment.			
Direct the AP to stay with D.B. while you contact the HCP.			
Obtain a STAT blood glucose measurement.			
Administer as-needed acetaminophen for headache relief.			
Place the head of the bed flat.			
Have the AP obtain vital signs with O_2 saturation.			
Review recent laboratory results.			

Case Study Progression

D.B.'s vital signs are BP 114/48 mm Hg, heart rate is 112 beats/min, respirations are 18 breaths/min, and the temperature is 98°F (36.8°C). You receive notification that his laboratory results are available. They show the following:

Laboratory Results

Sodium	129 mmol/L
Potassium	5.0 mmol/L
HCO_3	26 mmol/L
BUN	37 mg/dL
Creatinine	2 mg/dL
Glucose	128 mg/dL
Calcium	9.1 mg/dL

5. Choose the most *likely* option for the information missing from statement below by selecting from the lists of options provided.

Based on the assessment findings and laboratory results, the nurse determines the patient is experiencing _____**1**_____. To manage this problem, you expect that the HCP will order _____**2**_____.

Options for 1	Options for 2
Hyperglycemia	Furosemide
Hyperkalemia	Insulin
Hyponatremia	IV fluids

6. You notify his HCP, who orders a normal saline IV to infuse at 100 mL/hr. Which nursing actions would you include in D.B.'s plan of care at this time?

Use an X to indicate which actions listed in the left column would be included in the plan of care for S.S.

Nursing Actions	Relevant Nursing Actions
Administer IV furosemide.	
Suggest a referral to the dietitian for parenteral nutrition.	
Monitor serum electrolyte values.	
Administer as ordered analgesia.	

Continued

Case Study—cont'd

Nursing Actions	Relevant Nursing Actions
Administer IV fluid replacement therapy as ordered.	
Initiate daily weights and intake and output.	

7. D.B. is thirsty and asks for something to drink. Which fluids would be appropriate to give him? *(select all that apply)*
   a. Gatorade
   b. Tap water
   c. Cola/soda
   d. Apple juice
   e. Orange juice
8. D.A. just returned to the unit following a transesophageal echocardiogram. Which action is the highest priority?
   a. Have the AP assist D.A. to lie flat on her back.
   b. Obtain vital signs and pulse oximetry every 4 hr.
   c. Maintain D.A. on NPO status until her gag reflex returns.
   d. Assess the lower extremities for signs of circulatory compromise.
9. In addition to teaching J.K. how to administer postoperative eye drops, you will also explain
   a. position and activity restrictions.
   b. how to change the dressing on her eye.
   c. the necessity for restricting fluid intake.
   d. that protective eyewear will no longer be needed.
10. Which interventions are appropriate for R.S. at this time?
    a. Inserting a nasogastric tube
    b. Keeping the room dark and quiet
    c. Placing an emesis basin at the bedside
    d. Elevating the head of the bed to the height desired
    e. Raising the side rails and having the bed in a low position

Assessment: Respiratory System

Samantha J. Bonaduce

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Functional Ability

Gas Exchange

LEARNING OUTCOMES

1. Distinguish the structures and functions of the upper respiratory tract, lower respiratory tract, and chest wall.
2. Describe the processes of inspiration and expiration.
3. Describe the process of oxygenation and ventilation.
4. Identify the respiratory defense mechanisms.
5. Discuss the significance of arterial blood gas values in relation to respiratory function.
6. Relate the signs and symptoms of inadequate oxygenation to physical assessment findings.
7. Link age-related changes of the respiratory system to key differences in assessment findings.
8. Obtain significant subjective and objective assessment data related to the respiratory system.
9. Perform a physical assessment of the respiratory system using the appropriate techniques.
10. Distinguish normal from common abnormal findings in a physical assessment of a patient's respiratory system.
11. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the respiratory system.

KEY TERMS

adventitious breath sounds
chemoreceptor
compliance
crackles, Table 27.6
dyspnea
fremitus
mechanical receptors
oximetry
oxygenation
resistance
surfactant
tidal volume (VT)
ventilation
wheezes, Table 27.6

The primary purpose of the respiratory system is gas exchange. This involves the transfer of oxygen (O_2) and carbon dioxide (CO_2) between the atmosphere and blood. While adequate perfusion is needed to distribute O_2 to the body tissues, adequate oxygenation depends on a healthy, functioning respiratory system.

STRUCTURES AND FUNCTIONS OF RESPIRATORY SYSTEM

The respiratory system is divided into 2 parts: the upper respiratory tract and the lower respiratory tract (Fig. 27.1).

Upper Respiratory Tract

The *upper respiratory tract* includes the nose, mouth, pharynx, epiglottis, larynx, and trachea. Air enters the respiratory tract through the nose. The nose is made of bone and cartilage. It is divided into 2 nares by the nasal septum. The inside of the nose is shaped into 3 passages by projections called *turbinates*. The turbinates increase the surface area of the nasal mucosa that warms and moistens the air as it enters the nose. The internal nose opens directly into the sinuses. The nasal cavity connects with the pharynx. It is a tubular passageway that is subdivided into 3 parts: *nasopharynx, oropharynx,* and *laryngopharynx*.

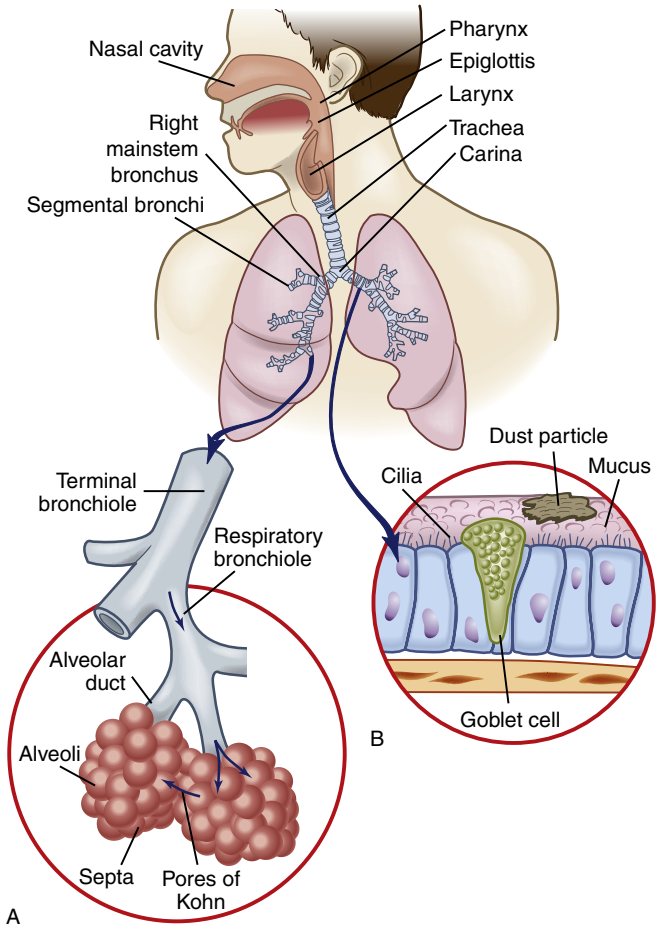

Fig. 27.1 Structures of the respiratory tract. (A) Pulmonary functional unit. (B) Ciliated mucous membrane. (Redrawn from Price SA, Wilson LM: *Pathophysiology: clinical concepts of disease processes,* ed 6, St Louis, 2003, Mosby.)

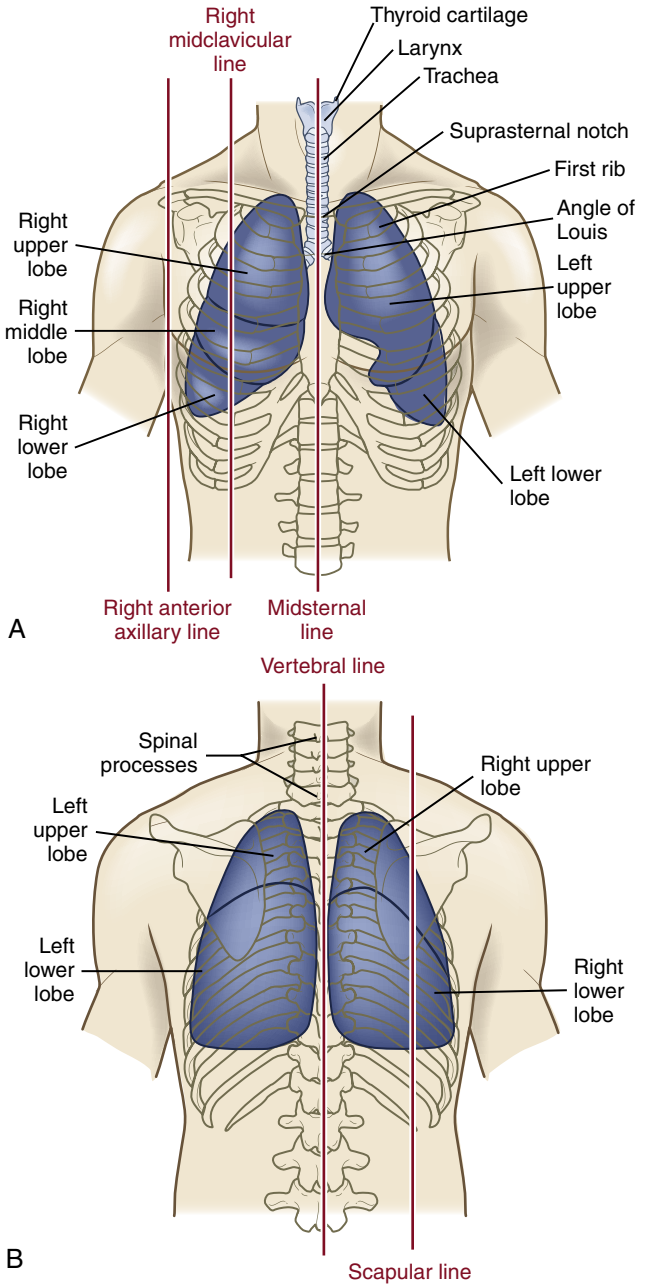

Fig. 27.2 Landmarks and structures of the chest wall. (A) Anterior view. (B) Posterior view. (Redrawn from Thompson JM, McFarland GK, Hirsch JE, et al: *Mosby's clinical nursing,* ed 5, St Louis, 2002, Mosby.)

The nose protects the lower airway by warming and humidifying air and filtering small particles before air enters the lungs. The olfactory nerve, found within the mucosa of the upper part of the nasal cavity, is responsible for the sense of smell.[1]

Air moves through the oropharynx to the laryngopharynx. It then travels through the epiglottis to the larynx before moving into the trachea. The *epiglottis* is a small flap behind the tongue that closes over the larynx during swallowing. This prevents solids and liquids from entering the lungs. The vocal cords are in the larynx. Air passes through the glottis (the opening between the vocal cords) and into the trachea.

The trachea is a cylindrical tube about 5 inches (10 to 12 cm) long and 1 inch (1.5 to 2.5 cm) in diameter. U-Shaped cartilages keep the trachea open but allow the adjacent esophagus to expand for swallowing. The trachea divides into the right and left mainstem bronchi at a point called the *carina.* The carina is located at the *angle of Louis,* which is at the level of the 4th and 5th thoracic vertebrae.[2] The carina is highly sensitive. Stimulation of this area during suctioning causes vigorous coughing.

Lower Respiratory Tract

Once air passes the carina, it is in the lower respiratory tract. The *lower respiratory tract* consists of the bronchi, bronchioles, alveolar ducts, and alveoli. Except for the right and left mainstem bronchi, all lower airway structures are found within the lungs. The right lung is divided into 3 lobes (upper, middle, and lower) and the left lung into 2 lobes (upper and lower) (Fig. 27.2).

The mainstem bronchi, pulmonary vessels, and nerves enter the lungs through a slit called the *hilus.* The right mainstem bronchus is shorter, wider, and straighter than the left mainstem bronchus. That is why aspiration is more likely to occur in the right lung than in the left lung.

The mainstem bronchi subdivide several times to form the lobar, segmental, and subsegmental bronchi. Further divisions form the bronchioles. The most distant bronchioles are

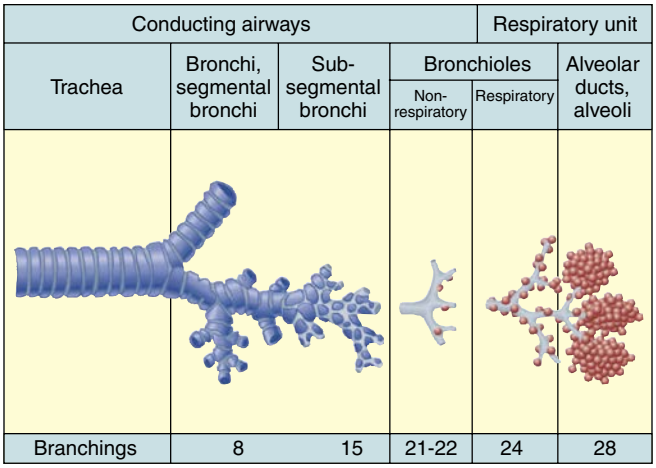

Fig. 27.3 Structures of lower airways. (Redrawn from Thompson JM, McFarland GK, Hirsch JE, et al.: *Mosby's clinical nursing,* ed 5, St Louis, 2002, Mosby.)

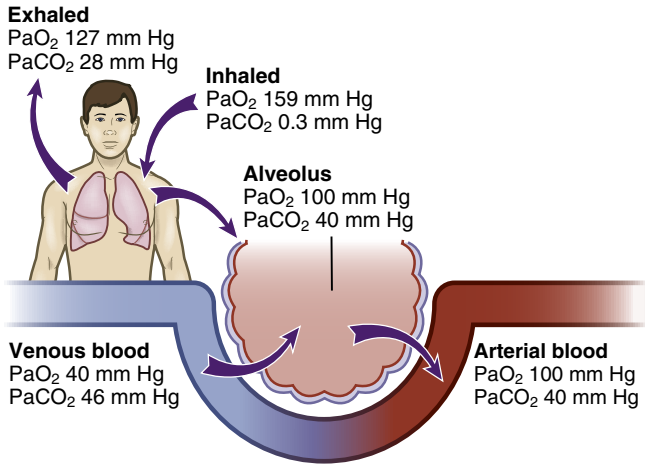

Fig. 27.4 Partial pressure of respiratory gases in normal respiration. The pressures are shown in inhaled and exhaled air from the lungs and at the level of the alveoli and pulmonary venous and arterial blood vessels.

the respiratory bronchioles. The bronchioles are encircled by smooth muscles that constrict and dilate in response to various stimuli. The terms *bronchoconstriction* and *bronchodilation* refer to a decrease or increase in the diameter of the airways caused by contraction or relaxation of these muscles. Beyond the bronchioles lie the alveolar ducts and alveoli (Fig. 27.3).

The trachea and bronchi act as a pathway to conduct gases to and from the alveoli. The volume of air in the trachea and bronchi is called the *anatomic dead space* (VD).[3] This air does not take part in gas exchange. In adults, a normal **tidal volume (V_T)**, or volume of air exchanged with each breath, is about 500 mL (in a 150-lb man). Of each 500 mL inhaled, about 150 mL is VD.

The alveoli are the final part of the respiratory tract (Fig. 27.3). *Alveoli* are small sacs in the lungs that are the primary site of gas exchange for O_2 and CO_2. The adult lung has over 300 million alveoli, each 0.3 mm in diameter. The alveoli are interconnected by pores of Kohn.[4] They allow movement of air from alveolus to alveolus (Fig. 27.1). Deep breathing promotes air movement through these pores and helps move mucus out of the respiratory bronchioles. Bacteria can also move through these pores, spreading infection to previously uninfected areas. Alveoli have a total volume of about 2500 mL, with a surface area for gas exchange that is about the size of a tennis court.

Gases are exchanged across the alveolar-capillary membrane, where the alveoli come in contact with pulmonary capillaries (Fig. 27.4). In conditions such as pulmonary edema, excess fluid fills the interstitial space and alveoli. This reduces gas exchange.

Surfactant

Because alveoli are unstable, they have a natural tendency to collapse. Alveolar cells secrete surfactant. **Surfactant** is a lipoprotein that lowers the surface tension in the alveoli.[5] It reduces the amount of pressure needed to inflate the alveoli and makes them less likely to collapse. Normally, each person takes a slightly larger breath, termed a *sigh,* after every 5 or 6 breaths. This sigh stretches the alveoli and promotes surfactant secretion.

When there is not enough surfactant, the alveoli collapse. The term *atelectasis* refers to collapsed, airless alveoli. The postoperative patient is at risk for atelectasis because of the effects of anesthesia, decreased mobility, and pain, which can alter breathing and lung expansion. In acute respiratory distress syndrome (ARDS), lack of surfactant contributes to widespread atelectasis and collapse of lung tissue (see Chapter 32).

Blood Supply

The lungs have 2 different types of circulation: pulmonary and bronchial. Pulmonary circulation provides the lungs with blood that takes part in gas exchange. The pulmonary artery receives deoxygenated blood from the right ventricle of the heart and delivers it to pulmonary capillaries that lie directly alongside the alveoli. O_2–CO_2 exchange occurs at this point. The pulmonary veins return oxygenated blood to the left atrium, which then delivers it to the left ventricle, and into systemic circulation. Venous blood is collected from capillary networks of the body and returned to the right atrium by way of the superior and inferior vena cava.

Bronchial circulation starts with the bronchial arteries, which arise from the thoracic aorta. Bronchial circulation does not take part in gas exchange but provides O_2 to the bronchi and other lung tissues. Deoxygenated blood returns from the bronchial circulation through the azygos vein into the superior vena cava.[1]

Chest Wall

The chest wall is shaped, supported, and protected by 24 ribs (12 on each side). The thoracic cage, which consists of the ribs and sternum, protect the lungs and the heart from injury. The *mediastinum* is the space in the middle of the thoracic cavity. It contains the major organs of the chest, including the heart, aorta, and esophagus. The mediastinum physically separates the right and left lungs into 2 separate compartments.

The chest cavity is lined with a membrane called the *parietal pleura.* The lungs are lined with a membrane called the *visceral pleura.* The parietal and visceral pleurae join to form one continuous membrane. The visceral pleura does not have any sensory (pain) fibers or nerve endings. The parietal pleura has

pain fibers. This is why irritation or inflammation of the parietal pleura can cause pain with each breath (pleuritic pain).

The *intrapleural space* is the space between the pleural layers. Normally this space contains 10 to 20 mL of fluid. This fluid serves 2 purposes: (1) it provides lubrication, allowing the pleural layers to slide over each other during breathing, and (2) it increases unity between the pleural layers. This promotes expansion of the pleurae and lungs during inspiration.

Fluid drains from the pleural space via lymphatic circulation. Several conditions may cause a pleural effusion, or excess fluid in the pleural space. Pleural fluid may accumulate because of blocked lymphatic drainage (e.g., from cancer) or an imbalance between intravascular and oncotic fluid pressures. This happens with heart failure. Purulent pleural fluid with bacterial infection is called *empyema*.

The *diaphragm* is the major muscle of respiration. During inspiration the diaphragm contracts, moves downward, and increases intrathoracic volume. At the same time, the internal intercostals relax and the external intercostal muscles contract. This increases the lateral and anteroposterior (AP) dimension of the chest.[6] The scalene muscles also contract on inspiration, raising the first and second ribs. This causes the size of the thoracic cavity to increase and intrathoracic pressure to decrease, pulling air into the lungs.

The diaphragm is made up of 2 hemidiaphragms, each innervated by the right and left phrenic nerves. The phrenic nerves arise from the spinal cord between C3 and C5, the 3rd and 5th cervical vertebrae. Injury to the phrenic nerve results in hemidiaphragm paralysis on the side of the injury. Complete spinal cord injuries above the level of C3 result in total diaphragm paralysis and dependence on a mechanical ventilator (see Chapter 65).

Physiology of Respiration

Oxygenation

Oxygenation refers to the process of obtaining O_2 from the atmospheric air and making it available to the organs and tissues of the body. The lungs' ability to oxygenate arterial blood adequately is evaluated by partial pressure of O_2 in arterial blood (PaO_2), arterial O_2 saturation (SaO_2), and patient assessment.

O_2 is carried in the blood in 2 forms: dissolved O_2 and hemoglobin-bound O_2. The PaO_2 represents the amount of O_2 dissolved in the plasma. It is expressed in millimeters of mercury (mm Hg). The SaO_2 is the amount of O_2 bound to hemoglobin in comparison with the amount of O_2 the hemoglobin can carry. The SaO_2 is expressed as a percent. For example, if the SaO_2 is 90%, this means that 90% of hemoglobin attachments for O_2 have O_2 bound to them.

O_2 and CO_2 move back and forth across the alveolar-capillary membrane by diffusion. The overall direction of movement is from the area of higher concentration to the area of lower concentration. Thus, O_2 moves from alveolar gas (atmospheric air) into the arterial blood and CO_2 from the arterial blood into the alveolar gas. Diffusion continues until equilibrium is reached.

Ventilation

Ventilation involves *inspiration,* or inhalation (movement of air into the lungs), and *expiration,* or exhalation (movement of air out of the lungs). Air moves in and out of the lungs because intrathoracic pressure changes in relation to pressure at the airway opening. Contraction of the diaphragm and external intercostal and scalene muscles increases chest dimensions. This decreases intrathoracic pressure. Gas flows from an area of higher pressure (atmospheric) to one of lower pressure (intrathoracic). When **dyspnea** (shortness of breath) occurs, neck and shoulder muscles, and other accessory muscles of respiration, can aid the effort. Some conditions (e.g., rib fractures, neuromuscular disease) may limit diaphragm or chest wall movement. This causes the patient to breathe with smaller tidal volumes. As a result, the lungs do not fully inflate, and gas exchange may be impaired.

In contrast to inspiration, expiration is passive. *Elastic recoil* is the tendency for the lungs to return to their original size after being stretched or expanded. The elasticity of lung tissue is due to the elastin fibers found in the alveolar walls and surrounding the bronchioles and capillaries. The elastic recoil of the chest wall and lungs allows the chest to passively decrease in size (volume). When intrathoracic pressure rises, air moves out of the lungs.

Exacerbations of asthma or chronic obstructive pulmonary disease (COPD) cause expiration to become an active, labored process (see Chapter 31). Intercostal, scalene, and accessory muscles (e.g., abdominal, trapezius) help expel air during labored breathing.

Compliance and Resistance

Changes in compliance and/or resistance can affect both oxygenation and ventilation. **Compliance** refers to the ability of the lungs to expand. This is a result of the elasticity of the lungs and elastic recoil of the chest wall.[6] With decreased compliance, it is harder for the lungs to inflate. This occurs with conditions that increase fluid in the lungs (e.g., pulmonary edema, ARDS, pneumonia), make lung tissue less elastic or distensible (e.g., pulmonary fibrosis, sarcoidosis), or restrict lung movement (e.g., pleural effusion). Compliance increases when there is destruction of alveolar walls and loss of tissue elasticity, as in COPD.

Resistance refers to any obstacle to airflow during inspiration and/or expiration. The main factor affecting airway resistance is changes in the diameter (size) of the airways. For example, a patient with an acute asthma attack has narrowed airways, resulting in increased resistance. Giving bronchodilators decreases resistance by increasing the diameter of the bronchi, promoting air entry. The presence of secretions in the bronchi also increases resistance. Secretions can partially occlude airways, making airways narrower. This makes it harder for patients to get air into their lungs. Moving secretions from the airway with mucolytics or expectorants helps decrease resistance.

Control of Respiration

Located in the brainstem, the respiratory center (the medulla) responds to chemical and mechanical signals. The medulla sends impulses to the respiratory muscles through the spinal cord and phrenic nerves.

Chemoreceptors

A **chemoreceptor** is a receptor that responds to a change in the chemical composition ($PaCO_2$ and pH) of the fluid around it. Central chemoreceptors are found in the medulla. They respond to changes in the hydrogen ion (H^+) concentration.[7] An increase in the H^+ concentration *(acidosis)* causes the medulla to increase the respiratory rate and VT. A decrease in H^+ concentration *(alkalosis)* has the opposite effect. Changes in $PaCO_2$ regulate ventilation primarily by their effect on the pH of cerebrospinal fluid. When the $PaCO_2$ level is increased, more CO_2 is available to combine with H_2O and form carbonic acid (H_2CO_3). This lowers the cerebrospinal fluid pH and stimulates an increase in respiratory rate. The opposite process occurs with a decrease in $PaCO_2$ level.

Peripheral chemoreceptors are found in the carotid bodies at the bifurcation of the common carotid arteries and in the aortic bodies above and below the aortic arch.[7] The peripheral chemoreceptors respond to decreases in PaO_2 and pH and increases in $PaCO_2$. These changes also stimulate the respiratory center.

In a healthy person, an increase in $PaCO_2$ or a decrease in pH causes an immediate increase in the respiratory rate. The $PaCO_2$ does not vary more than about 3 mm Hg if lung function is normal. Conditions such as COPD change lung function and may result in chronically elevated $PaCO_2$ levels. In these instances, the patient is not sensitive to further increases in $PaCO_2$ as a stimulus to breathe. They may be maintaining ventilation largely because of a hypoxic drive from the peripheral chemoreceptors (see Chapter 31).

Mechanical Receptors

Mechanical receptors are found in the conducting upper airways, chest wall, diaphragm, and capillaries of the alveoli. They are stimulated by a variety of physiologic factors, such as irritants, muscle stretching, and alveolar wall distortion. The 3 major types of mechanical receptors are irritant, stretch, and juxtacapillary (J) receptors.[5]

Irritant receptors are found in the conducting airways. These receptors are sensitive to inhaled particles and aerosols. When stimulated, they initiate the cough reflex. Signals from stretch receptors, in the smooth muscle of the airways, aid in the control of respiration. As the lungs inflate, stretch receptors activate the inspiratory center to inhibit further lung expansion. This is the *Hering-Breuer reflex*, which prevents overdistention of the lungs. Stimulation of J receptors, found in the capillaries of the alveoli, occurs with increased pulmonary capillary pressure. This causes rapid, shallow respiration (tachypnea) seen in pulmonary edema.

Respiratory Defense Mechanisms

Respiratory defense mechanisms are efficient in protecting the lungs from inhaled particles, microorganisms, and toxic gases. The defense mechanisms include air filtration, mucociliary clearance system, cough reflex, reflex bronchoconstriction, and alveolar macrophages.

Air Filtration

Nasal hairs filter inspired air. In addition, the abrupt changes in direction of airflow that occur as air moves through the nasopharynx and larynx increase air turbulence. This causes particles and bacteria to contact the mucosa lining these structures. Most large particles (greater than 5 μm) are less dangerous because they are removed in the nasopharynx or bronchi and do not reach the alveoli.

The velocity of airflow slows greatly after it passes the larynx, facilitating the deposition of smaller particles (1 to 5 μm). They settle the way that sand does in a river, a process termed *sedimentation*. Particles less than 1 μm in size are too small to settle in this manner and are deposited in the alveoli. An example of small particles that can build up is coal dust, which can lead to pneumoconiosis (see Chapter 30).

Mucociliary Clearance System

Below the larynx, the mucociliary clearance system, also called the *mucociliary escalator*, is responsible for the movement of mucus. Goblet cells and submucosal glands continually secrete mucus at a rate of about 100 mL/day. This mucus forms a blanket that contains the impacted particles and debris from distal lung areas (Fig. 27.1). Secretory immunoglobulin A (IgA) in the mucus helps protect against bacteria and viruses.

Cilia cover the airways from the level of the trachea to the respiratory bronchioles (Fig. 27.1). Each ciliated cell has about 200 cilia. They beat rhythmically about 1000 times per minute in the large airways, moving mucus toward the mouth. We normally swallow the mucus without noticing.

The ciliary beat is slower further down the tracheobronchial tree. As a result, we remove particles that penetrate more deeply into the airways less rapidly. Dehydration, smoking, inhaling high O_2 concentrations, infection, and drugs, such as atropine, anesthetics, alcohol, or cocaine, impair ciliary action. Patients with COPD and cystic fibrosis often have repeated lower respiratory tract infections. These conditions are associated with destroyed cilia, resulting in impaired secretion clearance, a chronic productive cough, and chronic colonization by bacteria. These lead to frequent respiratory tract infections.

Cough Reflex

The cough is a protective reflex that clears the airway by a high-pressure, high-velocity flow of air. It is a backup for mucociliary clearance, especially when this clearance mechanism is overwhelmed or ineffective. Coughing is effective in removing secretions only above the subsegmental level (large or main airways). Secretions below this level must be moved upward by the mucociliary mechanism before we can remove them by coughing.

Reflex Bronchoconstriction

Reflex bronchoconstriction is another defense mechanism. When we inhale large amounts of irritating substances (e.g., dusts, aerosols), the bronchi constrict to prevent entry of the irritants. A person with hyperreactive airways, such as a person with asthma, may have bronchoconstriction after inhalation of triggers, such as cold air, perfume, or other strong odors.

Alveolar Macrophages

Because there are no ciliated cells below the level of the respiratory bronchioles, the primary defense mechanism at the

TABLE 27.1 GERONTOLOGIC ASSESSMENT DIFFERENCES

Respiratory System

Changes	Differences in Assessment Findings
Structures	
↑ Anteroposterior diameter	Barrel chest appearance, kyphotic posture, ↓ chest wall movement, ↓ deep breathing, ↓ cough effectiveness
↓ Chest wall compliance	
Chest wall stiffening	
Costal cartilage calcification	↓ Vital capacity, ↑ residual volume, ↑ functional residual capacity
↓ Elastic recoil	
↓ Functioning alveoli	↓ Breath sounds, particularly at lung bases
↓ Respiratory muscle strength	↓ PaO_2 and SaO_2, normal pH and $PaCO_2$
Defense Mechanisms	
↓ Alveolar macrophage function	↓ Cough effectiveness, ↓ secretion clearance, thickened mucus
↓ Cell-mediated immunity	↑ Risk for upper respiratory aspiration, infection, influenza, pneumonia
↓ Cilia function	
↓ Cough force	Respiratory infections may be more severe and last longer
↓ Sensation in pharynx	
↓ Specific antibodies	
Respiratory Control	
↓ Response to hypercapnia	Slight ↓ PaO_2 and ↑ $PaCO_2$ before respiratory rate changes
↓ Response to hypoxemia	↓ Ability to maintain acid-base balance
	Significant hypoxemia or hypercapnia may develop from relatively small incidents
	Retained secretions, excessive sedation, or positioning that impairs chest expansion may change PaO_2 or SpO_2 values

alveolar level is alveolar macrophages. *Alveolar macrophages* rapidly phagocytize inhaled foreign particles, such as bacteria. The debris is moved to the level of the bronchioles for removal by the cilia or removed from the lungs by the lymphatic system. Particles (e.g., coal dust, silica) that cannot be adequately phagocytized tend to remain in the lungs for indefinite periods and can stimulate inflammatory responses. Because cigarette smoke impairs alveolar macrophage activity, the smoker who works in an occupation with heavy dust exposure (e.g., mining, foundries) has an especially high risk for lung disease.

Gerontologic Considerations: Effects of Aging on Respiratory System

We consider age-related changes in the respiratory system as alterations in structure, defense mechanisms, and respiratory control (Table 27.1). Structural changes include calcification of the costal cartilages, which can interfere with chest expansion. The outward curvature of the spine is marked, especially with osteoporosis, and the lumbar curve flattens. Therefore, the chest may appear barrel shaped, and the person may need to use accessory muscles to breathe. Respiratory muscle strength progressively declines after age 50. Overall, the lungs in the older adult are harder to inflate.

Within the lung, the number of functional alveoli decreases, and they become less elastic. Small airways in the lung bases close earlier in expiration. Therefore, more inspired air is distributed to the lung apices and ventilation is less well matched to perfusion, lowering the PaO_2. As a result, older adults have less tolerance for exertion, and dyspnea can occur if their activity exceeds their normal exercise.

In older adults, *respiratory defense mechanisms* are less effective because of a decline in immune function and the ability to produce antibodies. The alveolar macrophages are less effective at phagocytosis. An older patient has a less forceful cough and fewer and less functional cilia. Mucous membranes tend to be drier. Retained mucus predisposes the older adult to respiratory tract infections. Formation of secretory IgA, an important defense mechanism, is decreased. Swallowing is slower because of transit time in the pharyngeal area. There is reduced sensation in the pharynx. Consequently, the older adult is at greater risk for aspiration.

The aging process alters respiratory control, resulting in a more gradual response to changes in blood O_2 or CO_2 level. The PaO_2 may drop to a slightly lower than normal level and the $PaCO_2$ may rise to a level slightly higher than normal before the respiratory rate changes.

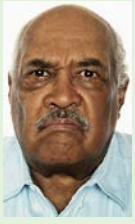
The extent of these changes in people of the same age varies greatly. For example, the older adult who has a significant smoking history, is obese, and has a chronic illness is at greater risk for adverse outcomes.

ASSESSMENT OF RESPIRATORY SYSTEM

Determining a patient's needs related to the respiratory system requires an accurate health history and a thorough physical assessment. A respiratory assessment can be part of a comprehensive or focused assessment. Use judgment in determining whether all or part of the history and physical assessment are needed, based on your evaluation of the patient's degree of respiratory distress. If respiratory distress is severe, only obtain pertinent information and defer a thorough assessment until the patient's condition stabilizes.

Case Study

Patient Introduction



(© Fuse/ Thinkstock.)

F.T. is a 70-year-old man who comes to the emergency department (ED) with nausea, fatigue, and increased shortness of breath, which started 3 days ago. He says that he started using his albuterol inhaler every 4 hours 2 days ago. While it worked at first, it is no longer helping. He can walk only a few feet in his apartment before he becomes short of breath. He sleeps in a recliner in the living room. He has noticed some swelling to his hands and feet and has been having trouble urinating.

Discussion Questions

1. What are the possible causes of F.T.'s shortness of breath?
2. Does F.T. need to be admitted to the hospital or is his condition stable?
3. What questions would be a priority during the subjective assessment?

You will learn more about F.T. and his condition as you read this assessment chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BOX 27.1 GENETIC RISK ALERT

- Respiratory problems with a strong genetic link include cystic fibrosis, COPD from α_1-antitrypsin deficiency, and asthma.
- If people have a family history of these respiratory problems, they have a greater risk for developing them.
- Although cigarette smoking is a major risk factor for COPD, only a minority of cigarette smokers develop symptomatic disease. The risk for COPD related to cigarette smoking is genetically related.

Subjective Data

Important Health Information

Health history. It is important to determine the frequency of upper respiratory problems (e.g., colds, sore throats, sinus problems, allergies). Do seasonal changes influence these problems? Ask about a history of lower respiratory problems, such as asthma, COPD, pneumonia, and tuberculosis (TB).

Ask the patient with allergies about possible precipitating factors or triggers, such as medications, pollen, smoke, mold, or pet exposure. Record the characteristics and severity of the allergic reaction, such as runny nose, wheezing, scratchy throat, or chest tightness. Determine the frequency of asthma exacerbations.

Ask about a history of other health problems (Box 27.1). Respiratory symptoms are often manifestations of problems that involve other body systems. For example, the patient with heart problems may have dyspnea (shortness of breath) because of heart failure. The patient with human immunodeficiency virus (HIV) infection may have frequent respiratory tract infections because of compromised immune function.

Medications. Take a thorough medication history, including the names of prescription and over-the-counter (OTC) medications. Ask about the dose (if known), frequency, length of time taken, side effects, and the reason for taking the medication. Assess for overuse of short-term bronchodilators as a key indicator of symptom control. Cough is a common side effect of angiotensin-converting enzyme (ACE) inhibitors. Encourage the patient to bring all medications and inhalers to each visit with an HCP.

If the patient is using O_2 for a breathing problem, record the fraction of inspired O_2 concentration (FIO_2), flow rate (liters per minute), method of administration, number of hours used per day, and effectiveness of the therapy. Assess safety practices. Include the patient's cognitive and physical ability related to using O_2 and any metered-dose inhalers.

Surgery or other treatments. Find out if the patient has been hospitalized for a respiratory problem. Note the dates, therapy (including surgery), and status of the problem. Determine if the patient has ever been intubated because of a respiratory problem. Ask about the use of and response to respiratory treatments, such as a nebulizer, humidifier, airway clearance modalities (see Chapter 28), high-frequency chest wall oscillation, postural drainage, and percussion.

Functional Health Patterns

Health history questions to ask a patient with a respiratory problem are outlined in Table 27.2.

Health perception–health management pattern. Ask the patient if there has been a perceived change in health status within the last several days, months, or years. In COPD, lung function declines slowly over many years. The patient may not notice this decline because they have been altering activity to accommodate reduced tolerance. If an upper respiratory tract infection is superimposed on a chronic problem, dyspnea and decreased exercise tolerance may occur very quickly. In asthma, symptoms may occur or worsen during exercise, in the presence of mold, or with changes in temperature or air pollution.

Explore common manifestations of respiratory problems (e.g., cough, dyspnea). Describe the course of the patient's illness, including when it began, type of symptoms, and factors that worsen or relieve these symptoms. Because of the chronic nature of respiratory problems, the patient may relate a change in symptoms (rather than the onset of new symptoms) when describing the present illness. For example, increased shortness of breath or increased purulence of sputum may suggest an acute COPD exacerbation.

If a cough is present, assess its quality. For example, a loose-sounding cough occurs with secretions. A dry, hacking cough may mean an airway irritation or obstruction. A harsh, barky cough suggests upper airway obstruction from inhibited vocal cord movement due to subglottic edema. Assess whether the cough is strong enough to clear secretions. Note whether it is productive or nonproductive of secretions. Determine if the cough is acute or chronic (longer than 3 weeks in duration) or if it first began with an upper respiratory tract infection. The pattern and cause of the cough are determined by asking questions such as: What has been the pattern of coughing? Has it been regular or paroxysmal (i.e., sudden, periodic onset) or related to a time of day, the weather, certain activities, talking, or deep breathing? Any change over time? Do you clear your throat a lot? What have you tried to relieve the coughing? Did you try any prescription or OTC drugs?

If the patient has a productive cough, evaluate the characteristics of sputum: amount, color, consistency, and odor. Quantify the amount of sputum per day. Note any recent increases or decreases in the amount. Sputum is normally clear or slightly whitish. If a patient is a cigarette smoker, the sputum is usually clear to gray with occasional specks of brown. The patient with COPD may have clear, whitish, or slightly yellow sputum, especially in the morning on rising. If the patient reports any change from baseline color, suspect pulmonary complications. Note any changes in consistency of sputum to thick, thin, or frothy and pink tinged. These changes may indicate dehydration, postnasal drip or sinus drainage, or possible pulmonary edema. Normally sputum should be odorless. A foul odor or exceptionally bad breath or taste in the mouth suggests an infectious process. Ask the patient if sputum production increases or decreases with changes in position (e.g., increased with lying down) or activity.

When assessing sputum, determine if the patient has a history of spitting or coughing up blood *(hemoptysis)*. Hemoptysis can range from a slight streaking of blood in the sputum to massive coughing up of blood. The patient may not be able to tell between hemoptysis and *hematemesis* (vomiting blood).

TABLE 27.2 HEALTH HISTORY

Respiratory System

Health Perception–Health Management

- Describe your daily activities. Have breathing problems prevented you from doing activities that you used to be able to do?[a] Are your breathing problems better, worse, or about the same compared with 6 months ago?
- How do your breathing problems affect your self-care abilities?
- Have you ever smoked? Do you smoke now? If so, what have you smoked? Cigarettes? Cigars? Pipes? Electronic cigarettes?
- If yes, how many cigarettes each day and for how long? Are you interested in stopping smoking? Are there aids we can tell you about that would assist your quitting? Would you be willing to come back for a visit so that we can explore your quitting? If you stopped smoking, did you do so because of your health?[a] How did you stop?
- Have you ever used chewing tobacco?
- Have you ever smoked street drugs?[a]
- Do you get the flu shot yearly? When was your last flu shot? Have you had a Pneumovax vaccination?
- What equipment helps you manage your respiratory problems? How often do you use it? Does it help? Cause problems?
- Do you feel that your respiratory problem is getting better or worse?

Nutritional-Metabolic

- Have you recently lost weight because of trouble eating related to your respiratory problem? How much weight have you lost? Have you lost this weight voluntarily?
- Do any foods affect your breathing?[a] Sputum production?[a]

Elimination

- Does your breathing problem make it hard for you to get to the toilet?[a]
- Are you inactive because of shortness of breath to the point that you have incontinence?[a] Constipation?[a]

Activity-Exercise

- Are you ever short of breath during exercise?a At rest?[a]
- Do you get too short of breath to do the things you want to do?[a]
- Is your home 1 story? 2 stories? How many steps from the street to your door?
- Can you walk up a flight of steps without stopping?
- Are you able to maintain your typical activities of daily living? If not, what are you able to do independently? What do you need help with? What have you had to give up?
- What do you do when you get short of breath? Does this help? How long does it take you to recover after you have been short of breath?

Sleep-Rest

- Do breathing problems cause you to wake up during the night?[a]
- Can you lie flat at night? If not, how many pillows do you use?
- Do you need to sleep upright in a chair?[a]
- Are you or your partner aware of any snoring?
- Do you awaken in the morning feeling rested?
- Do you ever wake up in the morning with a headache?[a]
- Do you fall asleep easily during the day?[a]

Cognitive-Perceptual

- Do you have any pain with breathing?[a] On a scale from 0 to 10, with 0 being "no pain" and 10 being "the worst pain you can imagine," where would you rate your pain? Does it hurt more on inspiration?[a] Expiration?[a] Or both?[a]
- If you are having pain with breathing, describe the pain.
- Has the pain gotten better, worse, or stayed about the same over the past 6 months?
- Do you ever feel restless, irritable, or confused without a reason?[a]
- Do you have difficulty remembering things?[a]

Self-Perception–Self-Concept

- Describe how your respiratory problems have changed your life.
- If you use O_2, do you ever go out without bringing it with you? How often does this occur? Why?

Role-Relationship

- Has your respiratory problem caused any problems in your work, family, or social relationships?[a]

Sexuality-Reproductive

- Has your respiratory problem caused a change in your sexual activity?[a]
- Have you and your partner talked about ways to minimize your breathing problems during sexual activity?

Coping–Stress Tolerance

- On a daily/weekly basis, how often do you leave your home?
- Do you feel under any stress right now?
- Does stress influence your breathing?[a]
- Do you notice if your emotions have any effect on your respiratory problems?
- Are you aware of any respiratory support groups in your area?

Value-Belief

- What do you think causes/has caused your respiratory problem(s)?
- How are you feeling right now?
- Do you think the things you have been told to do for your respiratory problems help? If not, why?
- What are you looking for/expecting from the HCP today, in terms of your breathing problem(s)?

[a] If answer is "yes" to any of these questions, ask the patient to describe.

Hemoptysis occurs with a variety of conditions such as pneumonia, TB, lung cancer, and severe bronchiectasis.

Assess for a history of any difficulty breathing. For example, *wheezes* are musical sounds that can be audible. Wheezing indicates some degree of airway obstruction, such as asthma, foreign body aspiration, and emphysema. Assess for any history of family exposure to *Mycobacterium tuberculosis.*

Smoking is the most important risk factor for COPD and lung cancer. Ask about cigarette use and find out about the use of any tobacco products. This includes cigars, pipes, chewing tobacco, electronic cigarettes (e-cigarettes), and hookah (instrument for vaporizing and smoking flavored tobacco). Find out about exposure to secondhand smoke. Determine if the patient has tried to quit using tobacco products, including using prescription, OTC, and herbal remedies.

Discuss current and past smoking habits. Quantify smoking habits in *pack-years.* Do this by multiplying the number of packs of cigarettes smoked per day by the number of years smoked. For example, a person who smoked 1 pack (20 cigarettes) per day for 15 years has a 15 pack-year history. If they smoked 2 packs for 15 years, then it would be a 30 pack-year history.

TABLE 27.3 Dyspnea Rating Scale

Modified Borg Rating Scale for Perceived Dyspnea

Rate	Description
0	Nothing at all
0.5	Very, very slight shortness of breath
1	Very mild shortness of breath
2	Mild shortness of breath
3	Mild shortness of breath or breathing difficulty
4	Somewhat severe
5	Strong or hard breathing
6	
7	Severe shortness of breath or very hard breathing
8	
9	Extremely severe
10	Shortness of breath so severe you need to stop

From Hillegass E: *Essentials of cardiopulmonary physical therapy,* ed 4, Philadelphia, 2017, Saunders.

Ask where the patient has lived and traveled. Risk factors for TB include immigrating from an area with high rates of TB or living in a group setting, such as a prison. Other risk factors include exposure to people with high rates of TB transmission, such as the homeless, IV drug users, and people with HIV infection. Risk factors for fungal lung infections include those exposed to bird and rodent feces or polluted water, those working closely with the soil, and immunocompromised patients.

Assess if the patient received immunizations for influenza (flu), COVID, and pneumococcal pneumonia. Ask the patient about the use of equipment to manage respiratory symptoms (e.g., home O_2 equipment, inhalers, devices for sleep apnea). Find out the type of equipment used, cleaning of the device, frequency of use, its effect, and any side effects. Have patients show you the use of their inhalers. Many patients do not use these devices correctly (see Chapter 28).

Nutritional-metabolic pattern. Weight loss can be a symptom of respiratory disease. Determine if weight loss was intentional. If not, was food intake changed by anorexia (from medications), fatigue (from hypoxemia, increased work of breathing), or feeling full quickly (from lung hyperinflation)? Anorexia, weight loss, and chronic malnutrition are common in patients with COPD, lung cancer, TB, and chronic severe infection (bronchiectasis). Assess fluid intake. Dehydration can cause sputum to thicken and obstruct the airway. Rapid weight gain from fluid retention may impair gas exchange.

Elimination pattern. Activity intolerance from dyspnea could result in incontinence, if unable to reach a toilet when needed. Dyspnea can be the cause of limited mobility, which can cause constipation. Ask the patient with dyspnea about frequency, urgency, and elimination patterns (e.g., day vs. night). People with a chronic cough, especially women, may have urinary incontinence during paroxysms of coughing.

Activity-exercise pattern. Determine if dyspnea limits activity. Assess whether the patient's residence (e.g., number of steps, levels) poses any problems. Ask the patient about the perceived degree of the dyspnea (Table 27.3). For example, can the patient walk up 1 flight of stairs without stopping because of dyspnea? Is dyspnea with activity better, worse, or about the same in the last few days or months? Determine if the patient has difficulty breathing in a certain position, or if dyspnea is relieved by assuming a different position (e.g., tripod position in COPD).

Discuss whether the patient can carry out activities of daily living without dyspnea or other respiratory symptoms. If unable, record the amount and type of care the patient needs. Immobility and sedentary habits are risk factors for hypoventilation leading to atelectasis or pneumonia.

Sleep-rest pattern. Determine if the patient wakes up at night because of lung problems. The patient with asthma or COPD may awaken with chest tightness, wheezing, or coughing. This suggests a need for adjunct therapy or other medication changes. The patient with heart disease (e.g., heart failure) may sleep with the head elevated on several pillows to avoid breathing problems brought on by lying flat *(orthopnea).* Excess weight interferes with normal ventilation and may cause sleep apnea (see Chapter 7). Extremely obese persons may hypoventilate while awake or asleep. Manifestations of sleep apnea include snoring, insomnia, abrupt awakenings, daytime drowsiness, and early morning headaches. Night sweats may be a sign of TB.

Cognitive-perceptual pattern. Because hypoxia can cause neurologic symptoms, ask the patient about apprehension, restlessness, irritability, and memory changes. These can indicate inadequate cerebral oxygenation. Assess the patient's cognitive ability to cooperate with treatment. Hypoxemia interferes with the ability to learn and retain information. Failure or inability to take part in needed therapy may result in worsening of respiratory problems. For this reason, teaching may be more effective if the caregiver is present during teaching sessions to provide reinforcement later.

Ask about any discomfort or pain with breathing. Explore reports of chest pain carefully to rule out heart involvement. Problems such as pleurisy, fractured ribs, and costochondritis cause chest pain. Assessment of the patient having pain with breathing, such as onset, exact location of the pain, and factors that make the pain better or worse, can help establish a diagnosis.

Self-perception–self-concept pattern. Dyspnea limits activity, impairs ability to fulfill normal roles, and often alters self-esteem. A patient may be reluctant to appear in public with a highly visible nasal cannula and O_2 equipment. A barrel chest, clubbed fingers, pursed-lip breathing, and frequent expectoration of sputum or throat clearing can be embarrassing and lead to social isolation. Explore with the patient any body image concerns. Referral to a support group or pulmonary rehabilitation program may be beneficial in developing a support system and coping strategies.

Role-relationship pattern. Acute and chronic respiratory problems can seriously affect performance in work or other activities. Discuss the impact of medications, O_2 therapy, and special routines (e.g., pulmonary hygiene for cystic fibrosis) on the patient's family, job, and social life.

Review the nature of the patient's work and frequency and intensity of exposure to fumes, toxins, asbestos, coal, fibers, or silica. Ask whether symptoms are worse in specific situations

(e.g., home vs. work environments). Hobbies, such as woodworking (sawdust) or pottery (silica), and animal exposure (allergies) can cause respiratory problems. Because of hyperreactive airways, exposure to fumes, smoke, and other chemicals may trigger an attack in the patient with asthma.

Sexuality-reproductive pattern. Most patients can continue to have satisfactory sexual relationships despite marked physical limitations. In a tactful manner, ask whether breathing difficulties have caused changes in sexual activity. If so, discuss positions that decrease dyspnea during sexual activity and alternative strategies for sexual fulfillment. For example, patients may need to perform good pulmonary hygiene (bronchodilators, coughing, deep breathing) before intimacy. They may need to use O_2 therapy equipment during intercourse just like they would with any strenuous physical activity.

Coping–stress tolerance pattern. Dyspnea causes anxiety, and anxiety worsens dyspnea. The result is a vicious cycle—the patient avoids activities that cause dyspnea, becoming more deconditioned and more dyspneic. The outcome is often physical and leads to social isolation. Assess how often the patient leaves home and interacts with others. Referral to a support group or pulmonary rehabilitation program may be helpful.

The chronic nature of many respiratory problems, such as COPD and asthma, can cause prolonged stress. Ask about the patient's coping strategies to manage this stress.

Value-belief pattern. Determine the patient's adherence to their treatment program. Explore possible reasons for lack of adherence, including conflict with cultural beliefs, financial constraints (e.g., costs of prescriptions), or failure to understand benefit. Correct misinformation and provide up-to-date information about respiratory conditions and medication management. Including the patient and caregiver in the planning of care can improve adherence.

Objective Data

Physical Assessment

Vital signs are important data to collect before examining the respiratory system (Table 27.4).

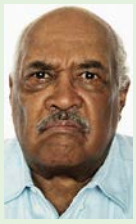
Nose. Inspect the nose for patency, inflammation, deformities, symmetry, and discharge. Check each nostril for air patency with respiration while briefly occluding the other nostril. Tilt the patient's head backward and push the tip of the nose upward gently. With a nasal speculum and a good light, inspect the interior of the nose. The mucous membrane should be pink and moist, with no evidence of edema (bogginess), exudate, or bleeding. Inspect the nasal septum for deviation, perforations, and bleeding. Some septal deviation is normal in an adult. Inspect the turbinates for polyps, which are abnormal, fingerlike projections of swollen nasal mucosa. Polyps may result from long-term irritation of the mucosa (e.g., from allergies). Assess any discharge for color and consistency. Purulent and malodorous discharge could occur with a foreign body. Watery discharge could be related to allergies or from cerebrospinal fluid. Bloody discharge could be from trauma or dryness. Thick mucosal discharge could mean an infection.

Mouth and pharynx. Using a good light source, inspect the interior of the mouth for color, lesions, masses, gum retraction, bleeding, and poor dentition. Inspect the tongue for symmetry and lesions. Observe the pharynx by pressing a tongue blade gently against the middle of the back of the tongue. If the oropharynx is tight, have the patient yawn. Yawning usually allows more structures to be visible. The pharynx should be smooth and moist, with no evidence of exudate, ulcerations, swelling, or postnasal drip. Note the color, symmetry, and any enlargement of the tonsils. Stimulate the gag reflex by placing a tongue blade along the side of the pharynx, at the back of the tongue. A normal response (gagging) means that cranial nerves IX (glossopharyngeal) and X (vagus) are intact and that the airway is protected.

Neck. Inspect the neck for symmetry and tender or swollen areas. Palpate the lymph nodes while the patient is sitting erect

Case Study

Subjective Data



(© Fuse/Thinkstock.)

A focused subjective assessment of F.T. revealed the following information:

- ***History:*** COPD, hypertension, heart failure, benign prostatic hyperplasia. No known allergies.
- ***Medications:*** Metoprolol (Toprol XL) 50 mg daily PO, furosemide 20 mg PO daily, finasteride 5 mg/day PO, Advair inhaler (fluticasone and salmeterol) 2 puffs twice daily, and albuterol inhaler 2 puffs every 4 hr PRN. Uses O_2 @ 3 L/min via nasal cannula at home for the past 10 years.
- ***Health Perception–Health Management:*** States he usually manages his COPD well with the Advair inhaler and occasional use of the albuterol inhaler. He thinks he caught a cold from his granddaughter last week. Increasing difficulty breathing, even with albuterol. Has a history of 30 pack-years of smoking, quitting 5 years ago.
- ***Nutritional-Metabolic Pattern:*** Eating and drinking very little over past 2–3 days.
- ***Elimination:*** Voiding small amounts of dark, concentrated urine (mostly at night).
- ***Activity-Exercise:*** At present, cannot walk 100 feet without feeling short of breath. Cannot walk up 1 flight of stairs (21 steps) to get in or out of his apartment without stopping to catch his breath.
- ***Sleep-Rest:*** Difficulty sleeping. Last night he slept upright in his recliner.
- ***Cognitive-Perceptual:*** Denies any pain with the shortness of breath. Feels slightly irritable because of lack of sleep.
- ***Coping–Stress Tolerance:*** Does not know how he will manage to get groceries or clean his apartment. His daughter lives an hour away and has 3 children in school.

Discussion Questions

1. Of the information provided, which subjective assessment findings concern you most?
2. From the information provided from F.T., what other information would you ask him about his condition (time permitting)?
3. What type of assessment would be most appropriate for F.T.: comprehensive, focused, or emergency?
4. F.T. cannot use his inhaler appropriately while he is talking with you. Is this a good time to teach him about the proper use of his inhaler?
5. What will you include in the physical assessment? What would you think will be priorities in your physical assessment?

You will learn about the physical assessment of the respiratory system in the next section.

with the neck slightly flexed. Progression of palpation is from the nodes around the ears, to the nodes at the base of the skull, and then to those under the angles of the mandible to the midline. The patient may have small, mobile, nontender nodes *(shotty nodes),* which are not a sign of a pathologic condition. Tender, hard, or fixed nodes may indicate disease. Describe the location and characteristics of any palpable nodes.

Thorax and lungs. Picture imaginary lines on the chest to help identify abnormalities (Fig. 27.2). Describe abnormalities in terms of their location relative to these lines (e.g., 2 cm lateral from the right midclavicular line).

Chest examination is best done in a well-lit, warm room. Take measures to ensure the patient's privacy. Expose the patient's chest. Perform all physical assessment maneuvers (inspection, palpation, percussion, auscultation) on either the anterior or the posterior chest first rather than moving from anterior to posterior or vice versa with each maneuver. It is best to begin on the posterior chest, particularly with female patients, since you can obtain more information without interference from breast tissue. If the patient tires or you are interrupted, you will obtain baseline data with the most information from examining the posterior chest.

When assessing the *posterior chest,* ask the patient to lean forward with arms folded. This position moves the scapulae away from the spine, exposing more of the area you need to examine. When assessing the *anterior chest,* have the patient sit upright or position the patient supine with the head of the bed elevated to 30 degrees (semi-Fowler's position). The patient may need to lean forward for support on the bedside table to facilitate breathing.

Inspection. First, observe the patient's appearance. Note any evidence of respiratory distress, such as tachypnea or use of accessory muscles. Next, determine the shape and symmetry of the chest. Chest movement should be equal on both sides. The AP diameter should be less than the side-to-side or transverse diameter. Normal AP ratio is 1:2. An increase in AP diameter (e.g., barrel chest) may be due to normal aging or result from lung hyperinflation. Look for abnormalities in the sternum (e.g., *pectus carinatum* [a prominent protrusion of the sternum]) and *pectus excavatum* (an indentation of the lower sternum above the xiphoid process). Note any spinal curvature. Spinal curvatures that affect breathing include kyphosis, scoliosis, and kyphoscoliosis.

Observe the respiratory rate, depth, and rhythm. The normal adult respiratory rate is 12 to 20 breaths/min. Inspiration (I) should take half as long as expiration (E) (I/E ratio = 1:2). Observe for abnormal breathing patterns. Note *Kussmaul* (rapid, deep breathing), *Cheyne-Stokes* (abnormal respirations characterized by alternating periods of apnea and deep, rapid breathing), or *Biot's* (irregular breathing with apnea every 4 to 5 cycles) respirations.

Skin color provides clues to respiratory status. Cyanosis, a late sign of hypoxemia, is best seen in light-skinned patients as a bluish tinge to the mucous membranes, lips, and palms of the hands. In dark-skinned persons, cyanosis may be seen as a gray or white discoloration in the conjunctivae or around the mouth. Causes of cyanosis include hypoxemia or decreased cardiac output. Inspect the fingers for evidence of long-standing hypoxemia, known as *clubbing.* It is an increase in the angle between the base of the nail and the fingernail to 180 degrees or more. Clubbing usually accompanied by an increase in the depth, bulk, and sponginess of the end of the finger.

Palpation. Determine tracheal position by gently placing the index fingers on either side of the trachea just above the suprasternal notch and gently pressing backward. Normal tracheal position is midline; deviation to the left or right is abnormal. Tracheal deviation occurs away from the side of a tension pneumothorax or a neck mass, but toward the side of a pneumonectomy or lobar atelectasis.

Symmetry of chest expansion and extent of movement are determined at the level of the diaphragm. Place your hands over the lower anterior chest wall along the costal margin and move them inward until the thumbs meet at midline. Ask the patient to breathe deeply. Observe the movement of the thumbs away from each other. Normal expansion is 1 inch (2.5 cm). Hand placement on the posterior side of the chest is at the level of the tenth rib. Move the thumbs until they meet over the spine (Fig. 27.5). You can check expansion anteriorly or posteriorly. It is not necessary to check both.

Normal chest movement is equal. Unequal expansion occurs when air entry is limited by conditions involving the lung (e.g., atelectasis, pneumothorax) or the chest wall (e.g., incisional

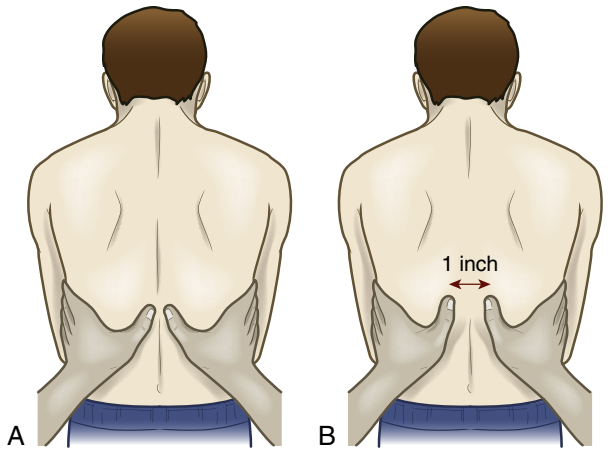

Fig. 27.5 Estimation of thoracic expansion. (A) Exhalation. (B) Maximal inhalation.

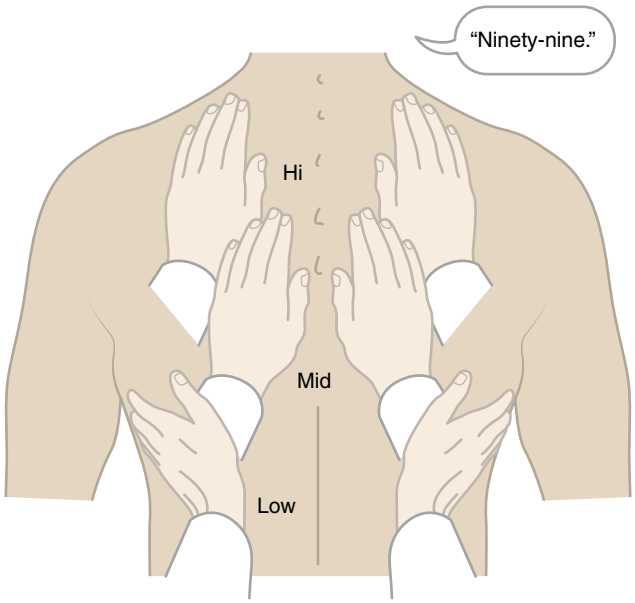

Fig. 27.6 Hand position for tactile fremitus. Place the palms of the hands in the position designated as "*low*" on the right and left sides of the chest. Compare the intensity of vibrations. Continue for all positions in each sequence.

pain). Equal but decreased expansion occurs in conditions that produce a hyperinflated or barrel chest or in neuromuscular diseases (e.g., amyotrophic lateral sclerosis, spinal cord lesions). Movement may be absent or unequal over a pleural effusion, an atelectasis, or a pneumothorax.

Fremitus is the vibration of the chest wall made by vocalization. You can feel tactile fremitus by placing the palmar surface of your hands against the patient's chest with the fingers hyperextended. Ask the patient to repeat a phrase, such as "boy-oh-boy," "toy boat," or "blue balloons," in a deeper, louder-than-normal voice. At the same time, move your hands from top to bottom on the patient's chest (Fig. 27.6). As you palpate, simultaneously compare vibrations (right side vs. left side, from top to bottom). Tactile fremitus is most intense by the sternum and between the scapulae because these areas are closest to the major bronchi. Fremitus is less intense farther away from these areas.

TABLE 27.5 Percussion Sounds

Sound	Description
Dull	Sound with medium-intensity pitch and duration heard over areas of "mixed" solid and lung tissue, such as top area of liver, partially consolidated lung tissue (pneumonia), or fluid-filled pleural space
Flat	Soft, high-pitched sound of short duration heard over very dense tissue where air is not present, such as posterior chest below level of diaphragm
Hyperresonance	Loud, lower pitched sound than normal resonance heard over hyperinflated lungs, such as in chronic obstructive pulmonary disease and acute asthma
Resonance	Low-pitched sound heard over normal lungs
Tympany	Drum-like, loud, empty quality sound heard over pneumothorax

Note any increase, decrease, or absence of fremitus. Increased fremitus occurs when the lung becomes filled with fluid or is denser. As the patient's voice moves through a dense tissue or fluid, you can feel that the vibration is increased. This happens with pneumonia, lung tumors, thick bronchial secretions, and above a pleural effusion (the lung is compressed upward). Fremitus is decreased if the hand is farther from the lung (e.g., pleural effusion) or the lung is hyperinflated (e.g., barrel chest). Absent fremitus may occur with pneumothorax or atelectasis. The anterior chest is harder to palpate for fremitus because of the large muscles and breast tissue.

Percussion. Percussion is used to assess the density or aeration of the lungs. Percussion sounds are described in Table 27.5.

The anterior chest is percussed with the patient in a semi-sitting or supine position. Starting above the clavicles, percuss downward, intercostal space by intercostal space. The area over lung tissue should be resonant, except for the area of cardiac dullness. To percuss the posterior chest, have the patient sit leaning forward with arms folded. The posterior chest should be resonant over lung tissue to the level of the diaphragm.

Auscultation. During chest auscultation, have the patient breathe slowly and a little more deeply than normal through the mouth. Auscultation should proceed from the lung apices to the bases, comparing opposite areas of the chest. If the patient is in mild respiratory distress or you think the patient will tire easily, start at the bases. Place the stethoscope over lung tissue, not over bony prominences. At each placement of the stethoscope, listen to at least 1 cycle of inspiration and expiration. Visualize the location of normal breath sounds (Fig. 27.7).

Lung sounds are heard anteriorly from a line drawn perpendicular from the sternum lateral to the midclavicular line. From the xiphoid process, palpate inferiorly (down) 2 ribs in the midaxillary line and around to the posterior chest. This gives you a fairly accurate and easy way to locate the lung fields. When recording the location of lung sounds, divide the anterior and posterior right lung into thirds (upper, middle, and lower) and the left lung into upper and lower areas. With practice, you will be able to identify which lobes of the lung has particular lung sounds.

The 3 normal breath sounds are bronchial, bronchovesicular, and vesicular (Fig. 27.8). *Bronchial sounds* are loud,

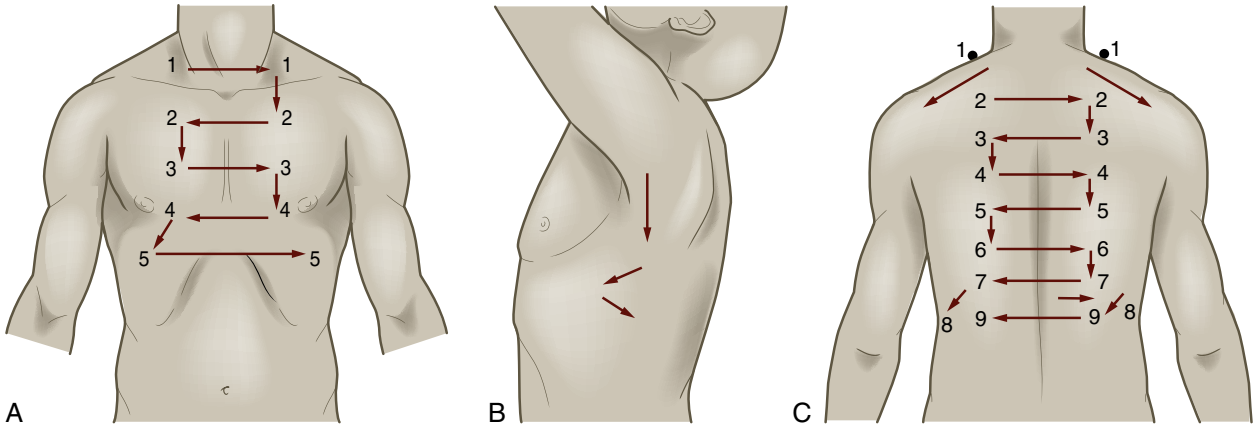

Fig. 27.7 Sequence for auscultation of the chest. (A) Anterior sequence. (B) Lateral sequence. (C) Posterior sequence. Place the stethoscope at each position and listen to at least 1 complete inspiratory and expiratory cycle. Keep in mind that with a female patient the breast tissue will influence the anterior examination.

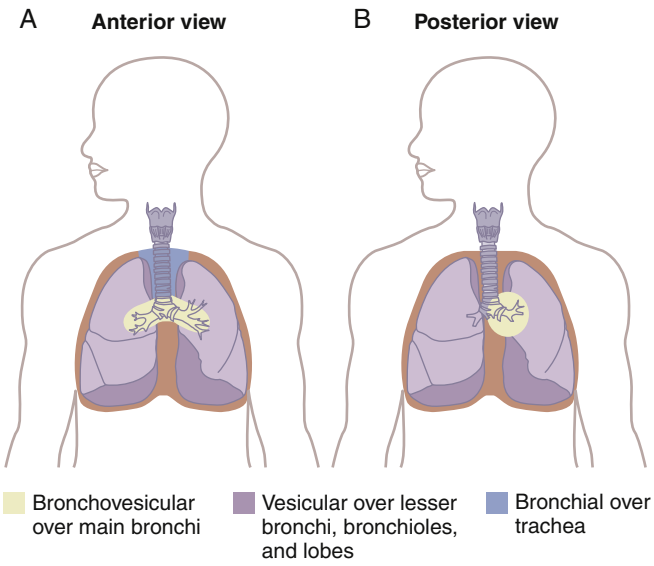

Fig. 27.8 Normal auscultatory sounds. (A) Anterior view. (B) Posterior view.

high-pitched sounds that resemble air blowing through a hollow pipe. Bronchial sounds have an inspiratory to expiratory (I/E) ratio of 2:3, with a gap between inspiration and expiration. To hear bronchial breath sounds, place the stethoscope next to the trachea in the neck. *Bronchovesicular sounds* have a medium pitch and intensity. They are best heard anteriorly between the first and second intercostal space and posteriorly between the scapulae. Bronchovesicular sounds have a 1:1 ratio, with inspiration equal to expiration. *Vesicular sounds* are relatively soft, low-pitched, gentle, rustling sounds. They are heard over all lung areas except the major bronchi. Vesicular sounds have a 3:1 ratio, with inspiration 3 times longer than expiration.

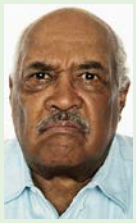
We classify breath sounds into 2 main categories: normal and abnormal (adventitious). There are a variety of terms that we have used inconsistently to describe abnormal breath sounds. **Adventitious breath sounds** include crackles (fine and coarse), wheezes, stridor, and pleural friction rub (Table 27.6). A *focused assessment* is used to evaluate the status of previously identified respiratory problems and to monitor for signs of new problems. Box 27.2 shows a focused assessment of the respiratory system.

As you begin your assessment of lung sounds, first note the air entry, which may be adequate, slightly decreased, or decreased. Absent air entry in any part of the lung is an assessment finding that you should report at once. Next, listen for the breath sounds and the presence of normal and adventitious sounds. Are the normal breath sounds where you would expect to hear them? Focus your assessment on the characteristics of any abnormal sound, including the location, pitch (e.g., high, low), duration of sound, and whether the sound is heard on inspiration, expiration, or both.

Assessment abnormalities of the thorax and lungs are outlined in Table 27.6. A record of the normal physical assessment of the respiratory system is shown in Table 27.7. Chest examination findings in common pulmonary problems are described in Table 27.8. Age-related changes in the respiratory system and assessment findings are outlined in Table 27.1.

Case Study

Objective Data: Physical Assessment



(© Fuse/ Thinkstock.)

Physical assessment findings of F.T. are as follows:

Temp: 38°C (100.4°F), apical pulse 110 (irregular), respiratory rate 30 (regular, shallow, slightly labored), BP 170/90 mm Hg. Sitting on edge of bed with arms resting on bedside table. Skin color normal for race with no signs of cyanosis. Using accessory muscles in neck and shoulders. Trachea midline. Barrel-shaped chest; chest expansion minimal but equal. Prolonged expiration. Slight clubbing noted. Edema: 3+ pitting edema of both lower legs and feet, bilaterally. Lungs: adequate air entry at apices bilaterally with fine crackles; decreased air entry to right middle lobe and both bases with coarse crackles. Slight expiratory wheeze heard throughout all lung fields. Cough: moist, productive, with yellow-tinged sputum.

You decide to check F.T.'s O_2 saturation (SpO_2). His SpO_2 is 87% on room air.

Discussion Questions

1. What physical assessment findings concern you most?
2. Identify 3 interventions that may be implemented immediately.
3. With F.T.'s physical assessment information, what diagnostic studies would you expect to be ordered?

You will learn about diagnostic studies of the respiratory system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

TABLE 27.6 ASSESSMENT ABNORMALITIES

Respiratory System

Finding	Description	Common Etiology and Significance
Inspection		
Abdominal paradox	Inward (rather than normal outward) movement of abdomen during inspiration	Inefficient and ineffective breathing pattern; nonspecific sign of severe respiratory distress
Accessory muscle use. Intercostal retractions	Neck and shoulder muscles used to assist breathing; muscles between ribs pull in during inspiration	COPD, asthma exacerbation, secretion retention Indicates severe respiratory distress/failure, hypoxemia
↑ AP diameter	AP chest diameter equal to lateral. Slope of ribs more horizontal (90 degrees) to spine	COPD, asthma, cystic fibrosis, lung hyperinflation, advanced age
Clubbing	↑ Depth, bulk, sponginess of distal part of finger	Chronic hypoxemia, cystic fibrosis, lung cancer, bronchiectasis
Cyanosis	Bluish color of skin best seen in lips and on the palpebral conjunctiva (inside the lower eyelid)	Reflects 5–6 g of hemoglobin not bound with O_2. ↓ O_2 transfer in lungs, ↓ cardiac output. Nonspecific, unreliable indicator
Kussmaul respirations	Regular, rapid, and deep respirations Fruity odor to breath	Metabolic acidosis. Increases CO_2 excretion
Pursed-lip breathing	Exhalation through mouth with lips pursed together to slow exhalation	COPD, asthma. Suggests ↑ breathlessness Strategy taught to slow expiration, ↓ dyspnea
Splinting	Voluntary ↓ in tidal volume to ↓ pain on chest expansion	Thoracic or abdominal incision, chest trauma, pleurisy
Tachypnea	Rate >20 breaths/min	Fever, anxiety, hypoxemia, restrictive lung disease Magnitude of ↑ above normal rate reflects ↑ work of breathing
Tripod position. Inability to lie flat	Leaning forward with arms and elbows supported on overbed table	COPD, asthma exacerbation, pulmonary edema Indicates moderate to severe respiratory distress
Palpation		
Altered chest movement	Unequal or equal but ↓ movement of 2 sides of chest with inspiration	Unequal movement caused by atelectasis, pneumothorax, pleural effusion, splinting Equal but ↓ movement caused by barrel chest, restrictive disease, neuromuscular disease
Altered tactile fremitus	↑ or ↓ in vibrations	↑ in pneumonia, pulmonary edema. ↓ in pleural effusion, lung hyperinflation. Absent in pneumothorax, atelectasis
Tracheal deviation	Leftward or rightward movement of trachea from normal midline position	Nonspecific sign of change in position of mediastinal structures. Medical emergency if caused by tension pneumothorax (trachea deviates to side opposite collapsed lung)
Percussion		
Dullness	Medium-pitched sound over areas that normally make a resonant sound	↑ Density (pneumonia, large atelectasis), ↑ fluid in pleural space (pleural effusion)
Hyperresonance	Loud, lower pitched sound over areas that normally make a resonant sound	Lung hyperinflation (COPD), lung collapse (pneumothorax), air trapping (asthma)
Auscultation		
Absent breath sounds	No sound heard over entire lung or area of lung	Pneumothorax, pleural effusion, mainstem bronchi obstruction, large atelectasis, pneumonectomy, lobectomy
Bronchophony, whispered pectoriloquy	Spoken or whispered syllable more distinct than normal on auscultation	Pneumonia
Coarse crackles	Louder, discontinuous, low-pitched sounds caused by air passing through airway intermittently occluded by mucus, unstable bronchial wall. May be heard on inspiration, expiration, or both. Similar sound to blowing through straw under water	Excess fluid within the lungs, heart failure, pulmonary edema, pneumonia with severe congestion, COPD
Egophony	Spoken "E" similar to "A" on auscultation because of altered transmission of voice sounds	Pneumonia, pleural effusion
Fine crackles	Short, discontinuous, high-pitched sounds heard just before the end of inspiration. Result of rapid equalization of gas pressure when collapsed alveoli or terminal bronchioles suddenly snap open. Similar sound to that made by rolling hair between fingers	Interstitial edema (early pulmonary edema), alveolar filling (pneumonia), loss of lung volume (atelectasis), early phase of heart failure, idiopathic pulmonary fibrosis
Pleural friction rub	Creaking or grating sound from roughened, inflamed pleural surfaces rubbing together. Evident during inspiration, expiration, or both. No change with coughing. Often uncomfortable, especially on deep inspiration	Pleurisy, pneumonia, pulmonary infarct
Stridor	Continuous musical or crowing sound of constant pitch. Result of partial obstruction of larynx or trachea	Croup, epiglottitis, vocal cord edema after extubation, foreign body
Wheezes	Continuous high-pitched squeaking or musical sound caused by rapid vibration of bronchial walls. First evident on expiration but possibly evident on inspiration as obstruction of airway increases. May be audible without stethoscope	Bronchospasm (caused by asthma), airway obstruction (caused by foreign body, tumor), COPD

BOX 27.2 FOCUSED ASSESSMENT

Respiratory System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Shortness of breath	Y	N
Pain with breathing	Y	N
Cough	Y	N
Sputum production (color, quantity)	Y	N
Wheezing	Y	N

Objective: Physical Assessment

Observe

Respirations: Rate, quality, and pattern
Accessory muscle use
Mouth or nose breathing

Inspect

Neck for position of trachea
Shape, symmetry, and movement of chest wall
Skin and nails for integrity and color

Palpate

Chest and back for abnormalities (i.e., masses)

Auscultate

Lung sounds (anterior and posterior)

Objective: Diagnostic

Check the following diagnostic tests for abnormal results.

Arterial blood gases
Chest x-ray
Hemoglobin
Hematocrit

DIAGNOSTIC STUDIES OF RESPIRATORY SYSTEM

Numerous diagnostic studies are available to assess the respiratory system. Select studies are described in more detail here.

Two methods are used to assess the effectiveness of gas transfer in the lung and tissue oxygenation: (1) oximetry and (2) analysis of *arterial blood gases* (ABGs) (Table 27.9). These are primarily used to assess for hypoxia. For the patient with normal or near-normal cardiac function, assessing SaO_2 or PaO_2 is usually enough to determine the level of oxygenation. With either one, we can also use CO_2 monitoring to assess for hypercapnia to determine patient's oxygenation and ventilatory status. The patient with impaired cardiac output or hemodynamic instability (e.g., altered level of consciousness, changes in heart rate and rhythm, low BP) may have inadequate tissue O_2 delivery and/or abnormal O_2 consumption. For these patients, we can evaluate venous O_2 saturation values.

TABLE 27.7 Normal Physical Assessment of the Respiratory System

Nose	• Symmetric with no deformities • Nasal mucosa pink, moist with no edema, exudate, blood, or polyps • Nasal septum straight (slight nasal deviation possible) • Nares patent bilaterally
Oral mucosa	• Light pink, moist, no exudate or ulcerations
Pharynx	• Smooth, moist, and pink
Neck	• Trachea midline
Chest	• AP diameter 1:2 • Respirations nonlabored at 12–20 breaths/min • Breath sounds vesicular without crackles or wheezes • Expansion equal bilaterally with no increase in tactile fremitus

TABLE 27.8 Chest Assessment Findings in Respiratory Problems

Problem	Inspection	Palpation	Percussion	Auscultation
Asthma exacerbation	Prolonged expiration, tripod position, pursed lips	↓ Movement	Hyperresonance	Wheezes, ↓ breath sounds ominous sign (severely decreased air movement)
Atelectasis	No change unless involves entire segment, lobe	If small, no change If large, ↓ movement, ↓ fremitus	Dull over affected area	Fine crackles (may disappear with deep breaths) Absent sounds if large
COPD	Barrel chest, cyanosis, tripod position, use of accessory muscles	↓ Movement	Hyperresonant or dull if consolidation	Crackles, wheezes, distant breath sounds
Pleural effusion	Tachypnea, use of accessory muscles	↑ Movement ↑ Fremitus above effusion Absent fremitus over effusion	Dull	↓ or absent over effusion, egophony above effusion
Pneumonia	Tachypnea, use of accessory muscles, duskiness or cyanosis	↑ Fremitus over affected area	Dull over affected areas	*Early:* Bronchial sounds *Later:* Fine and/or coarse crackles, egophony, whispered pectoriloquy
Pulmonary edema	Tachypnea, labored respirations, cyanosis, pink-tinged sputum	↓ Movement or normal movement	Dull or normal depending on amount of fluid	Fine or coarse crackles
Pulmonary fibrosis	Tachypnea	↓ Movement	Normal	Crackles or sounds like Velcro being pulled apart

TABLE 27.9 Diagnostic Studies

Oxygenation

Study	Description and Purpose	Nursing Responsibility
Arterial blood gases (ABGs)	Arterial blood is obtained through puncture of radial or femoral artery or through arterial catheter. Done to assess acid-base balance, oxygenation/ventilation status, need for and/or change in O_2 therapy, or change in ventilator settings. See Table 27.13 for reference values.	*Before:* Indicate whether patient is using O_2 (flow rate in L/min). Avoid change in O_2 therapy or interventions (e.g., suctioning, position change) for 15 min before obtaining sample. *During:* Assist with positioning (e.g., palm up, wrist slightly hyperextended if radial artery is used). Collect blood in heparinized syringe. To ensure accurate results, expel all air bubbles. *After:* Apply pressure to radial artery for at least 5 min after specimen is obtained to prevent hematoma at the arterial puncture site. Send sample to lab promptly for analysis.
O_2 Monitoring		
Noninvasive oximetry (SpO_2)	Monitors arterial O_2 saturation. Probe attaches to finger, toe, earlobe, bridge of the nose for SpO_2 monitoring. Used for intermittent or continuous monitoring and exercise testing. *Normal SpO2:* >95%	*During:* Apply probe. When interpreting SpO_2 values, first assess patient status and presence of factors that can alter accuracy of pulse oximeter reading. These include motion, low perfusion, cold extremities, bright lights, acrylic nails, dark skin color, carbon monoxide, and anemia.
Invasive oximetry ($ScvO_2/SvO_2$)	Monitors venous O_2 saturation intermittently by obtaining a blood sample from the PA catheter or continuously via a fiberoptic sensor as part of a specific central line and monitor. *Normal ScvO2/SvO2:* 60%–80%	*During:* Make sure the equipment is properly placed and prepped. Changes in these values provide an early warning of a change in cardiac output or tissue O_2 delivery. A decrease suggests that less O_2 is being delivered to the tissues or that more O_2 is being consumed.
CO_2 Monitoring		
End-tidal CO_2 ($PetCO_2$) (capnography) (see Fig. 27.9)	Assesses the level of CO_2 in exhaled air. Graphically displays partial pressure of CO_2. Expired gases are sampled from patient's airway and analyzed by a CO_2 sensor to measure exhaled CO_2. Sensor may be attached to an adaptor on endotracheal or tracheostomy tube. A nasal cannula with a side stream capnometer can be used in patients without an artificial airway. Can be a diagnostic measure to detect lung disease and for monitoring patients. *Normal difference between $PaCO_2$ and $PetCO_2$: 2–5 mm Hg ($PaCO_2$: 35–45 mm Hg; $PetCO_2$: 40–50 mm Hg).*	*Before:* Teach patient and caregiver about purpose of capnography monitoring, emphasizing the benefit of continuous monitoring. *During:* Make sure that sensor is properly attached. Record data per agency policy.

Oximetry

Oximetry is the measurement of the blood's O_2 saturation.[8] We can measure O_2 saturation in both arterial and venous blood. There are noninvasive and invasive means to measure these values.

Arterial

We monitor arterial O_2 saturation (SaO_2) noninvasively and continuously using *pulse oximetry*. We can place the probe on the finger, toe, ear, forehead, or bridge of the nose. The abbreviation SpO_2 is used to indicate the SaO_2. It represents how much O_2 hemoglobin is carrying compared to how much it could carry. SpO_2 and heart rate are displayed on the monitor as digital readings. Normal SpO_2 values are greater than 95% (Table 27.10).[9]

In many agencies, we assess SpO_2 with each routine vital sign check. SpO_2 values are used during exercise testing and when adjusting flow rates during O_2 therapy. Pulse oximetry is especially valuable in perioperative and critical care situations, in which anesthesia, sedation, or decreased consciousness may mask hypoxia. We can detect changes in SpO_2 and treat the patient quickly.

Pulse oximetry values are less accurate when the SpO_2 is less than 70%.[10] At this level, the oximeter may display a value that is ±4% of the actual value. For example, if the SpO_2 reading is 70%, the actual value can range from 66% to 74%. Pulse oximetry is inaccurate if hemoglobin variants (e.g., carboxyhemoglobin, methemoglobin) are present. Other factors that can alter the accuracy of pulse oximetry include motion, anemia, cold extremities, bright fluorescent lights, intravascular dyes, thick acrylic nails, and dark skin color. Accurate SpO_2 measurements may be hard to obtain on patients who are hypothermic, receiving IV vasopressor therapy (e.g., norepinephrine), or have hypoperfusion or vasoconstriction (e.g., shock).[11] If there is doubt about the accuracy of the SpO_2 reading, obtain an ABG analysis to verify the values.

Venous

Invasive O_2 saturation measurements include venous blood analysis (Table 27.11). Measuring the O_2 saturation of hemoglobin in venous blood helps to determine the adequacy of tissue oxygenation. The O_2 saturation of venous blood from a central venous catheter (CVC) is called *central venous O_2 saturation* ($ScvO_2$). The blood received and measured as $ScvO_2$ from

TABLE 27.10 Normal and Critical Values for PaO_2 and SpO_2

PaO_2 (mm Hg)	SpO_2 (%)	Significance	Manifestations	Management
80–100	≥95	Normal value	Asymptomatic	• Routine patient assessment
60–79	90	Mild hypoxemia	Restlessness, tachycardia, dysrhythmias, dyspnea, hypertension	• Assess patient as needed • Supplemental O_2 may be needed
40–59	88	Moderate hypoxemia	Confusion, lethargy, dysrhythmias, hypotension, respiratory distress, accessory muscle use	• O_2 required • Escalate level of care. Obtain critical care consult • Monitor frequently for sudden deterioration in condition
<40	75	Severe hypoxemia	Cyanosis, coma, respiratory and/or cardiac arrest possible	• High FIO_2, intubation, mechanical ventilation • Continuous patient assessment and evaluation

TABLE 27.11 Normal Mixed Venous Blood Gas Values

pH	7.31–7.41
PvO_2	38–42 mm Hg
SvO_2	60%–80%
$PvCO_2$	38–55 mm Hg
HCO_3–	22–26 mEq/L (mmol/L)

$PvCO_2$, Partial pressure of CO_2 in venous blood; *PvO_2*, partial pressure of O_2 in venous blood; *SvO_2*, mixed venous O_2 saturation.

a CVC is primarily from the superior vena cava (SVC), which supplies the upper body (e.g., brain). The O_2 saturation of blood from a pulmonary artery (PA) catheter is the *mixed venous O_2 saturation* (SvO_2). SvO_2 values measured from the PA catheter are a mixture of blood from the SVC, inferior vena cava (IVC), and coronary return.

$ScvO_2$ and SvO_2 reflect the balance among oxygenation of the arterial blood, tissue perfusion, and tissue O_2 consumption (Table 27.12).[12] This gives a global indicator of the balance between O_2 delivery and O_2 consumption. Normal $ScvO_2$ or SvO_2 at rest is 60% to 80%. Even though these values vary slightly, we use both effectively in the treatment of critically ill patients in the ICU. $ScvO_2$ and SvO_2 are useful in assessing hemodynamic status and response to treatments or activities when considered in conjunction with SaO_2.

Carefully review sustained decreases and increases in $ScvO_2$ or SvO_2. Decreased $ScvO_2$ or SvO_2 may indicate decreased arterial oxygenation, low CO, low hemoglobin level, or increased O_2 consumption or extraction, which is the ability of tissues to take O2 from the blood. If the $ScvO_2$ or SvO_2 falls below 60%, determine which factor has changed. Observe for changes in arterial oxygenation (e.g., monitor pulse oximetry, ABGs) and indirectly assess CO and tissue perfusion. This is done by noting any changes in mental status, strength and quality of peripheral pulses, capillary refill, urine output, and skin color and temperature. If arterial oxygenation, CO, and hemoglobin level are unchanged, a fall in $ScvO_2$ or SvO_2 indicates increased O_2 consumption or extraction. This could represent an increased metabolic rate, pain, movement, fever, or shivering. If O_2 consumption increases without a comparable increase in O_2 delivery, more O_2 is extracted from the blood. $ScvO_2$ and SvO_2 will continue to fall.[12]

Increased $ScvO_2$ or SvO_2 may indicate a clinical improvement (e.g., increased arterial O_2 saturation, improved perfusion, decreased metabolic rate) or problem (e.g., sepsis). In sepsis, O_2 is not extracted properly at the tissue level related to the immune response, leaking vessels, and increased fluid build-up, resulting in increased $ScvO_2$ or SvO_2.

Changes in $ScvO_2$ or SvO_2 guide your interventions. For example, you may note that the patient's HR increased slightly during repositioning but that the $ScvO_2$ remained stable. In this case, you would conclude that the patient tolerated the position change. If the $ScvO_2$ dropped, this would be a sign to stop the activity until the $ScvO_2$ returned to baseline.

In many cases, as activity or metabolism increases, HR and CO increase, and $ScvO_2$ or SvO_2 stays constant or varies slightly. However, critically ill patients often have conditions (e.g., HF, shock) that prevent substantial increases in CO. In these cases, $ScvO_2$ or SvO_2 can be a useful indicator of the balance between O_2 delivery and consumption.

Arterial Blood Gases

ABGs are obtained to determine oxygenation status and acid-base balance. ABG analysis includes measurement of the PaO_2, $PaCO_2$ (the partial pressure of CO_2 in arterial blood), acidity (pH), bicarbonate (HCO_3–), and SaO_2. Normal values for ABGs are shown in Table 27.13.

Blood for ABG analysis can be obtained by arterial puncture or from an arterial catheter, which is usually inserted into the radial or femoral artery. Both techniques allow for intermittent analysis. An arterial catheter permits ABG sampling without repeated arterial punctures. The normal PaO_2 decreases with advancing age. It varies in relation to the distance above sea level. At higher altitudes, the barometric pressure is lower, resulting in a lower inspired O_2 pressure and a lower PaO_2.

CO_2 Monitoring

CO_2 can be monitored using transcutaneous CO_2 ($PtCO_2$) and end-tidal CO_2 ($PetCO_2$) capnography. Transcutaneous measurement of CO_2 is a noninvasive method of estimating arterial pressure of CO_2 ($PaCO_2$) using an electrode placed on the skin.[13]

$PetCO_2$ is the noninvasive measurement of alveolar CO_2 during exhalation when CO_2 concentration is at its peak

TABLE 27.12 Interpreting $ScvO_2$ and SvO_2 Measurements

$ScvO_2$ and SvO_2 Measurement[a]	Physiologic Basis for Change in $ScvO_2$ or SvO_2	Clinical Diagnosis and Rationale
High $ScvO_2$ or SvO_2 (80%–95%)	↑ O_2 supply ↓ O_2 demand	• Patient receiving more O_2 than needed by clinical condition • Anesthesia, which causes sedation and ↓ muscle movement • Hypothermia, which ↓ metabolic demand (e.g., with cardiopulmonary bypass) • Sepsis caused by ↓ ability of tissues to use O_2 at the cellular level • False high positive because pulmonary artery catheter is wedged in a pulmonary capillary (SvO_2 only)
Normal $ScvO_2$ or SvO_2 (60%–80%)	Normal O_2 supply and metabolic demand	• Balanced O_2 supply and demand
Low $ScvO_2$ or SvO_2 (<60%)	↓ O_2 supply caused by low hemoglobin Low arterial saturation (SaO_2) Low cardiac output ↑ O_2 demand	• Anemia or bleeding with compromised cardiopulmonary system • Hypoxemia resulting from ↓ O_2 supply or lung disease • Cardiogenic shock caused by left ventricular pump failure • Metabolic demand exceeds O_2 supply in conditions that ↑ muscle movement and metabolic rate (e.g., seizures, fever)

[a]$ScvO_2$ values are generally slightly higher than SvO_2 values.

TABLE 27.13 Normal Arterial Blood Gas Values

Laboratory Value	Sea Level BP 760 mm Hg	1 Mile Above Sea Level BP 629 mm Hg
pH	7.35–7.45	7.35–7.45
PaO_2	80–100 mm Hg	65–75 mm Hg
SaO_2	>95%	>95%
$PaCO_2$	35–-45 mm Hg	35–45 mm Hg
HCO_3–	22–26 mEq/L (mmol/L)	22–26 mEq/L (mmol/L)

BP, Barometric pressure; *HCO_3–*, bicarbonate; *PaO_2*, partial pressure of O_2 in arterial blood; *$PaCO_2$*, partial pressure of arterial CO_2; *SaO_2*, arterial O_2 saturation.

(Fig. 27.9). It is used to monitor and assess trends in the patient's ventilatory status. Expired gases are sampled from the patient's airway and are analyzed by a CO_2 sensor that uses infrared light to measure exhaled CO_2. The sensor may be attached to an adaptor on the endotracheal tube or the tracheostomy tube. A nasal cannula with a sidestream capnometer can be used in patients without an artificial airway. Capnography is usually presented as a graph of expiratory CO_2 plotted against time.[14]

Fig. 27.9 End-tidal CO_2 detector.

Sputum Studies

Observe the patient's sputum for color, volume, viscosity, and presence or absence of blood. We can obtain a sputum sample by expectoration, tracheal suction, or bronchoscopy. When the patient is unable to expectorate spontaneously, sputum may be collected by inhaling an irritating aerosol, usually hypertonic saline. This is called *sputum induction*.

Specimens may be examined for culture and sensitivity to identify an infecting organism (e.g., *Mycobacterium*) or to confirm a diagnosis (e.g., cancer). Table 27.14 describes common sputum tests and our responsibilities when obtaining samples.

Skin Tests

Skin tests may be done to assess for allergies (see Chapter 14) or exposure to TB bacilli or fungi. Skin tests involve the intradermal injection of an antigen. Table 27.15 discusses how to interpret tuberculin skin testing. For example, a positive result on a TB skin test means that the patient has been exposed to the antigen. It does not mean that the patient has TB. A negative result means either no exposure or a depression of cell-mediated immunity, which occurs in HIV infection.

Our responsibilities are similar for all skin tests. First, to prevent a false-negative reaction, be sure that the injection is intradermal and not subcutaneous. After the injection, circle the site(s) and tell the patient not to remove the marks. When charting administration of the antigen, draw a diagram of the forearm and hand, and label the injection site. The diagram is especially helpful when the patient receives more than one test.

When reading test results, use a good light. If an induration is present, use a marking pen to indicate the periphery on all

TABLE 27.14 Sputum Studies

Study	Description and Purpose	Nursing Responsibility
Acid-fast bacteria (AFB) smear and culture	2 different tests used to assess sputum for acid-fast bacilli (e.g., *Mycobacterium tuberculosis*). In AFB smear (a rapid test), sputum sample spread thinly on glass slide, treated with a fluorochrome stain, and examined under a microscope for AFB. Culture for AFB may take up to 6 weeks.	*During:* Obtain specimen in early morning after mouth care because secretions collect during night. Have patient expectorate sputum into container after coughing deeply. If unsuccessful, try increasing oral fluid intake unless fluids are restricted. Can collect sputum in sterile container (sputum trap) during suctioning via endotracheal tube or by aspirating secretions from the trachea. If patient cannot produce specimen, they may need bronchoscopy (Fig. 27.10).
Culture and sensitivity	Diagnose bacterial infection, select antibiotic, and evaluate treatment. Sputum specimen collected in a sterile container. Takes 48–72 hr for results.	
Cytology	Determines presence of abnormal cells that may indicate cancer. Single sputum specimen collected in special container with fixative solution.	*After:* Send specimen to laboratory promptly for analysis.
Gram stain	Sputum staining allows for classification of bacteria into gram-negative and gram-positive types. Results guide therapy until culture and sensitivity results are complete.	

TABLE 27.15 Interpreting TB Skin Testing

Types of Responses	Consider Positive in the Following Groups
Positive Reactions	
≥5-mm induration	• HIV-infected people • People who had recent contact with a person with TB disease • People with fibrotic lesions on chest x-ray consistent with prior TB • Patients with organ transplants • Immunosuppressed persons (e.g., taking the equivalent of ≥15 mg/day of prednisone for ≥1 months)
≥10-mm induration	• Recent immigrants (<5 years) from high-prevalence countries • Injecting drug users • Residents and employees of high-risk congregate settings • Mycobacteriology laboratory personnel • People with clinical conditions (e.g., diabetes mellitus, end-stage kidney disease) that place them at high risk
≥15-mm induration	• Any person (including those with no known risk factors for TB)
False Reactions	**Possible Causes**
False-negative reactions (do not react even though infected)	• Anergy, immunosuppression • Recent TB infection (within 8–10 weeks of exposure) • Overwhelming TB infection • Very old TB infection (many years) • Recent live virus vaccination (e.g., measles, chickenpox)
False-positive reactions (react even though not infected)	• Nontuberculous mycobacteria (e.g., *Mycobacterium avium-intracellulare* [MAI] or *Mycobacterium avium* complex [MAC]) • Previous BCG vaccine

Source: Centers for Disease Control and Prevention: Tuberculosis (TB) fact sheet: tuberculin skin testing. Retrieved from www.cdc.gov/tb/publications/factsheets/testing/skintesting.htm.

4 sides of the induration. As the pen touches the raised area, make a mark. Then determine the diameter of the induration in millimeters. Do not measure reddened, flat areas.

Endoscopy

Bronchoscopy

Bronchoscopy is a procedure in which the bronchi are seen through a fiberoptic tube (Fig. 27.10). Bronchoscopy may be used for diagnostic purposes (obtain biopsy specimens) and for treatment (e.g., to remove mucous plugs, foreign bodies). Laser therapy, electrocautery, cryotherapy, and stents may be placed through a bronchoscope to achieve patency of an airway that has been partially or nearly fully obstructed by tumors (Table 27.16).

Bronchoscopy can be done in an outpatient procedure room, surgery, or at the bedside in the critical care or medical-surgical unit. The patient may be positioned supine, in low-Fowler's, or even be seated. The HCP inserts the bronchoscope through the nose or mouth. Depending on the approach, the nasopharynx or oropharynx is anesthetized with local anesthetic spray. The bronchoscope is coated with water-soluble lubricant and inserted down into the airways. Small amounts (30 mL) of sterile saline may be injected through the scope and withdrawn and examined for cells, a technique termed *bronchoalveolar lavage* (BAL). Bronchoscopy can be done through the endotracheal tube of a mechanically ventilated patient.

Lung Biopsy

Lung biopsy may be done (1) transbronchially, (2) percutaneously or via transthoracic needle aspiration (TTNA), (3) by video-assisted thoracic surgery (VATS), or (4) as an open lung biopsy (Table 27.16). The purpose of a lung biopsy is to obtain tissue, cells, and/or fluid for evaluation. Specimens can be cultured or examined for cancer cells.

Transbronchial biopsy involves passing a forceps or needle through the bronchoscope for a specimen. A combination of transbronchial lung biopsy and BAL is used to distinguish infection and rejection in lung transplant recipients. A percutaneous

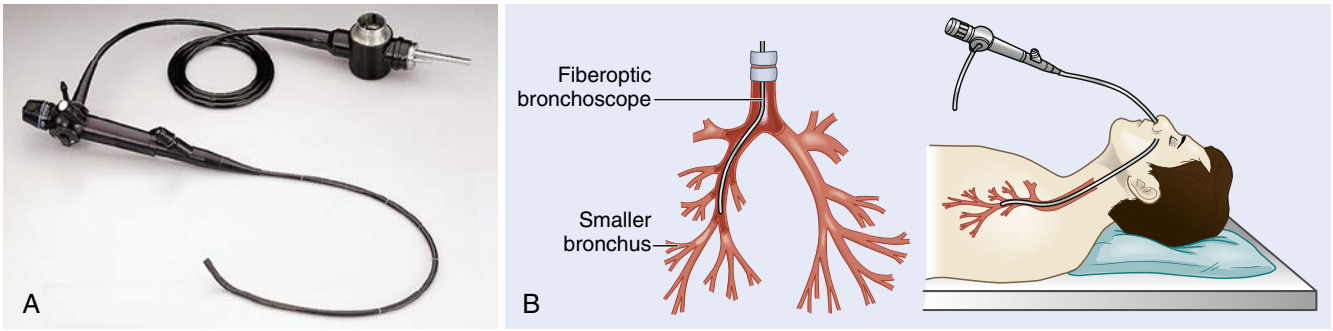

Fig. 27.10 Fiberoptic bronchoscope. (A) The transbronchoscopic balloon-tipped catheter and the flexible fiberoptic bronchoscope. (B) The catheter is introduced into a small airway and the balloon inflated with 1.5 to 2 mL of air to occlude the airway. Bronchoalveolar lavage is done by injecting and withdrawing 30-mL aliquots of sterile saline solution, gently aspirating after each instillation. Specimens are sent to the laboratory for analysis. (A, Courtesy Olympus America Inc, Melville, NY.)

TABLE 27.16 Diagnostic Studies

Respiratory System

Study	Description and Purpose	Nursing Responsibility
Endoscopy		
Bronchoscopy (Fig. 27.10)	Flexible fiberoptic scope used for diagnosis, biopsy, specimen collection, or assessment of changes. May be done to suction mucous plugs, lavage lungs, or remove foreign objects.	*Before:* Obtain signed consent. Have patient be NPO for 6–12 hr before the test. Give sedative as ordered. *After:* Keep patient NPO until gag reflex returns. Monitor for recovery from sedation. Blood-tinged mucus is not abnormal. If biopsy was done, monitor for hemorrhage and pneumothorax.
Lung biopsy	Specimens may be obtained by transbronchial or percutaneous biopsy or via transthoracic needle aspiration (TTNA), video-assisted thoracoscopic surgery (VATS), or open lung biopsy. Transbronchial biopsy and VATS can be done in the bronchoscopy suite. TTNA done under CT guidance in radiology department. Open lung and VATS done in the OR. Tests used to obtain specimens for laboratory analysis.	*Before:* Obtain signed consent. Same as bronchoscopy if procedure done with bronchoscope, and same as thoracotomy if open lung biopsy done. *After TTNA:* Check breath sounds q4hr for 24 hr and report any respiratory distress. Check incision site for bleeding. Chest x-ray should be done after TTNA or transbronchial biopsy to check for pneumothorax. *After VATS:* A chest tube may be placed postprocedure until lung has reexpanded. Monitor breath sounds to follow chest reexpansion. Encourage deep breathing for lung reinflation.
Mediastinoscopy	Scope inserted through a small incision in suprasternal notch and advanced into mediastinum to inspect and biopsy lymph nodes. Used to diagnose lung cancer, non-Hodgkin lymphoma, granulomatous infections, and sarcoidosis.	*Before:* Obtain signed consent. Prepare patient for surgery. Performed in OR using a general anesthetic. *After:* Monitor as for bronchoscopy.
Exercise Testing	Used to diagnose and determine exercise capacity. A *complete test* involves walking on a treadmill while monitoring expired O_2 and CO_2, respiratory rate, heart rate, and heart rhythm. In a *modified test* (desaturation test), only SpO_2 is monitored.	*Before:* Have patient wear comfortable shoes. *During:* Encourage patient to hold handlebars on treadmill and walk as quickly as possible.
Pulmonary Function Tests	Used to evaluate lung function. Involves use of spirometer to assess air movement as patient performs prescribed respiratory maneuvers (Tables 27.17 and 27.18).	*Before:* Avoid scheduling immediately after mealtime. Avoid administration of inhaled bronchodilator 6 hr before. Assess for respiratory distress. *During:* Assess for respiratory distress. *After:* Assess for respiratory distress. Provide rest after procedure.
Radiology		
Chest x-ray	Used to screen, diagnose, and evaluate changes in respiratory system. Most common views are anteroposterior (AP) and lateral.	*Before:* Have patient undress to waist, put on gown, and remove any metal between neck and waist.
Computed tomography (CT) scan	Diagnose suspicious lesions difficult to assess (e.g., mediastinum, hilum, pleura) by conventional x-ray. Common types are helical or spiral CT (contrast medium usually used) and high-resolution CT scan (contrast medium not used). Spiral CT used to diagnose a pulmonary embolism.	*Before:* Before contrast medium used, evaluate renal function. Assess if patient is allergic to shellfish, since the contrast is iodine based. Patient may need to be NPO 4 hr prior to study. *During:* Warn patient that contrast injection may cause a feeling of being warm and flushed. Patient must lie completely still during scan. *After:* Encourage patient to drink fluids to avoid renal problems with any contrast.

TABLE 27.16 Diagnostic Studies—cont'd

Respiratory System

Study	Description and Purpose	Nursing Responsibility
Magnetic resonance imaging (MRI)	Used for in-depth diagnosis of lesions difficult to assess by CT scan (e.g., lung apex) and for differentiating vascular from nonvascular structures. An IV contrast agent (gadolinium) may be given.	*Before:* Oral and/or IV contrast injection may be used. Check for pregnancy, allergies, and renal function before test. Have patient remove all metal objects. Remove metallic foil patches. Contraindicated for persons with implanted metallic devices or other metal fragments unless noted to be MRI safe. Ask about any history of surgical insertion of staples, plates, dental bridges, or other metal appliances. Patient may need to be fasting. Assess for claustrophobia and the need for antianxiety medication. *During*: Patient must lie completely still during scan.
Positron emission tomography (PET) scan	Glucose-containing nuclear tracer substance injected and taken up by metabolically active cells. Follow-up scan shows different-colored tissues based on metabolic rate. Because cancer cells have an increased uptake of glucose, "hot spots" reflecting increased glucose consumption indicate the presence of active cancer. Used to distinguish benign and cancerous lung nodules.	*Before:* Obtain IV access to inject the tracer substance. Patients should be NPO, except for water and medications, for at least 4 hr prior. Hold glucose-containing IV solutions and change to normal saline. Check blood glucose levels. The glucose level must be between 60–140 mg/dL (3.3–7.8 μmol/L) for accurate glucose metabolic activity. *During*: Patient must lie completely still during scan. *After:* Encourage fluids to excrete radioactive substance.
Pulmonary angiogram	Visualize pulmonary vasculature and locate obstruction or pathologic conditions (e.g., pulmonary embolus). Contrast medium injected through a catheter threaded into pulmonary artery or right side of heart. Series of x-rays taken after contrast medium is injected into pulmonary artery.	*Before*: Assess for allergies, especially to contrast dye. Have patient fast 6–12 hr before. Give sedative and other drugs, as ordered. *After:* Check pressure dressing site after procedure. Monitor BP, pulse, and circulation distal to injection site. Place compression device over site. Maintain IV and/or oral fluid intake.
Ventilation-perfusion (V/Q) scan	Assesses ventilation and perfusion of lungs. IV radioisotope given to assess perfusion. To assess ventilation, patient inhales a radioactive gas (xenon or krypton) that outlines alveoli. Normal scans show homogeneous radioactivity. ↓ or absent radioactivity suggests lack of perfusion or airflow. Ventilation without perfusion suggests a pulmonary embolus.	Same as for chest x-ray. *After:* No precautions needed afterward because the gas and isotope transmit radioactivity for only a brief interval.
6-Minute Walk Test	Used to measure functional capacity and response to treatment in patients with heart or lung disease. Pulse oximetry usually monitored during walk. Distance walked measured and used to monitor progression of disease or improvement after rehabilitation.	*During:* Patient walks as far as possible during 6 min, stopping when short of breath and continuing when able. Continually assess and observe patient tolerance to test.
Thoracentesis (Fig. 27.11)	Used to obtain specimen of pleural fluid for diagnosis, remove pleural fluid, or instill medication. Obtain chest x-ray after procedure to check for pneumothorax.	*Before:* Explain procedure and obtain signed consent. *During:* Usually done in patient's room. Position patient upright with elbows on an overbed table and feet supported. Tell patient not to talk or cough during procedure. *After:* Observe for signs of hypoxia and pneumothorax, and verify breath sounds in all fields. Encourage deep breaths to expand lungs. Send labeled specimens to laboratory promptly for analysis.

or TTNA biopsy involves inserting a needle through the chest wall, usually under bedside ultrasound or CT guidance. Because of the risk for a pneumothorax, a chest x-ray is done after TTNA.

In VATS, a rigid scope with a lens is passed through a trocar placed into the pleura via 1 or 2 small incisions in the thoracic cavity. The HCP views the lesions in the pleura or peripheral lung on a monitor directly via the scope and can obtain biopsy specimens. A chest tube is kept in place until the lung expands. VATS is much less invasive than open lung biopsy. It is associated with shorter hospital stays and reduced mortality.[15] It is ideal for pleural biopsy and resecting lung nodules.

An open lung biopsy is used when other procedures cannot diagnose pulmonary disease. With the patient under anesthesia, the chest is opened with a thoracotomy incision and a biopsy specimen is obtained. Post-procedure care is the same as after thoracotomy (see Chapter 28).

Thoracentesis

Thoracentesis is the insertion of a large-bore needle through the chest wall into the pleural space to obtain specimens for diagnostic evaluation, remove pleural fluid, or instill medication (see Fig. 27.11). The patient is positioned sitting upright, leaning on an overbed table with feet supported. The skin is cleansed and a local anesthetic (lidocaine) is injected subcutaneously. A percutaneous catheter may be left in to allow further drainage of fluid (Table 27.16).

Pulmonary Function Tests

Pulmonary function tests (PFTs) measure lung volumes and airflow. The results of PFTs can diagnose pulmonary disease, monitor disease progression, assess response to bronchodilators, and evaluate disability. Airflow measurement is obtained by trained personnel using a spirometer. The patient inserts a mouthpiece,

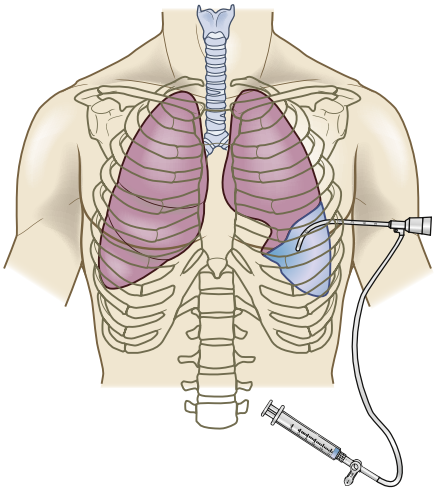

Fig. 27.11 Thoracentesis. A catheter is positioned in the pleural space to remove accumulated fluid.

takes as deep a breath as possible, and exhales as hard, as fast, and for as long as possible. Verbal coaching is given to ensure that the patient continues blowing out until exhalation is complete.

Computer software calculates the patient's percent of predicted values, that is, how well the performance compares with an average based on age, gender, race, and height.[16] Normal values are 80% to 120% of the predicted value. Normal values for PFTs are shown in Tables 27.17 and 27.18.

Spirometry may be done before and after giving a bronchodilator to determine the patient's response. This helps gauge the reversibility of airway obstruction (e.g., asthma). A positive bronchodilator response is an increase of greater than 200 mL or 12% in FEV_1 after administering a bronchodilator.

Home spirometry may be used to monitor lung function in people with asthma, cystic fibrosis, or COPD, as well as before and after lung transplantation or thoracic surgeries. A peak flow meter is the hand-held instrument used at home. The person blows through it forcefully and quickly after taking a deep breath. Spirometry changes can warn of early lung transplant rejection or infection. Data from a peak flow meter provide important feedback to patients with asthma so that they can learn to change activities and medications in response to changes in peak expiratory flow rates.

TABLE 27.17 Lung Volumes and Capacities

Parameter	Definitions	Normal Value (L)[a]
Volumes		
Expiratory reserve volume (ERV)	Additional air that can be forcefully exhaled after normal exhalation is complete	1.0
Inspiratory reserve volume (IRV)	Maximum volume of air that can be inhaled forcefully after normal inhalation	3.0
Residual volume (RV)	Amount of air remaining in lungs after forced expiration. Air available in lungs for gas exchange between breaths	1.5
Tidal volume (V_T)	Volume of air inhaled and exhaled with each breath. Only a small proportion of total capacity of lungs	0.5
Capacities		
Functional residual capacity (FRC)	Volume of air remaining in lungs at end of normal exhalation (FRC = ERV + RV). Increase or decrease possible with lung disease	2.5
Inspiratory capacity (IC)	Maximum volume of air that can be inhaled after normal expiration (IC = V_T + IRV)	3.5
Total lung capacity (TLC)	Maximum volume of air that lungs can contain (TLC = IRV + V_T + ERV + RV)	6.0
Vital capacity (VC)	Maximum volume of air that can be exhaled after maximum inspiration (VC = IRV + V_T + ERV). Higher VC for men (generally)	4.5

[a]Normal values vary with patient's height, weight, age, race, and gender.

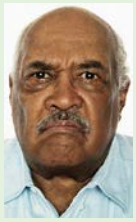
TABLE 27.18 Pulmonary Function Airflow

Measure	Description	Normal Value[a]
Forced vital capacity (FVC)	Amount of air that can be quickly and forcefully exhaled after maximum inspiration	>80% of predicted
Forced expiratory volume in first second of expiration (FEV_1)	Amount of air exhaled in first second of FVC. Grades severity of airway obstruction	>80% of predicted
FEV_1/FVC ratio	Dividing value for FEV_1 by value for FVC. Useful in differentiating obstructive and restrictive pulmonary dysfunction	*Age <50:* ≥75% of predicted *Age ≥50:* ≥70% of predicted
Forced midexpiratory flow rate ($FEF_{25\%–75\%}$)	Measurement of airflow rate in middle half of forced expiration. Early indicator of disease of small airways	*Age <50:* ≥75% of predicted *Age ≥50:* ≥70% of predicted
Peak expiratory flow rate (PEFR)	Maximum airflow rate during forced expiration. Aids in monitoring bronchoconstriction in asthma. Can be measured with peak flow meter	Up to 600 L/min
Maximal voluntary ventilation (MVV)	Deep breathing as rapidly as possible for specified period. Fairly nonspecific test that gives information about exercise capacity. Used in conjunction with exercise stress test	About 170 L/min

[a]Normal values vary with patient's height, age, race, and gender.

Case Study

Objective Data: Diagnostic Studies



(© Fuse/ Thinkstock.)

The HCP orders the following diagnostic studies for F.T.:

- Pulse oximetry
- Chest x-ray
- 12-lead electrocardiogram (ECG)
- CBC, basic metabolic panel (electrolytes, BUN, creatinine)
- ABGs
- Sputum for culture and sensitivity

F.T.'s SpO_2 is 87% on O_2 @ 3/L min via nasal cannula. The chest x-ray shows a slightly enlarged heart and bilateral consolidation to both lower lobes. The 12-lead ECG reveals sinus tachycardia, rate 110, with no ST segment elevation or depression and no T-wave inversion. The ABGs show compensated respiratory alkalosis with hypoxemia. The WBC is 17,350/μL and potassium 2.9 mEq/L. Sputum results are pending. F.T. is admitted to the medical nursing unit.

Discussion Questions

1. Which diagnostic test results concern you most?
2. What do you think is the cause of F.T.'s problems?
3. What patient teaching can you do with F.T. as he is waiting to be admitted to the hospital unit?
4. What is the interprofessional team's top priority for F.T. at this time?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered learning outcome identified at the beginning of this chapter.

1. The key anatomic landmark that separates the upper respiratory tract from the lower respiratory tract is the
   a. carina.
   b. larynx.
   c. trachea.
   d. epiglottis.
2. A patient asks, "How does air get into my lungs?" The nurse bases their answer on knowledge that air moves into the lungs because of
   a. positive intrathoracic pressure.
   b. contraction of the accessory abdominal muscles.
   c. stimulation of the respiratory muscles by the chemoreceptors.
   d. a decrease in intrathoracic pressure from an increase in thoracic cavity size.
3. The nurse can *best* determine adequate arterial oxygenation of the blood by assessing
   a. heart rate.
   b. hemoglobin level.
   c. arterial oxygen partial pressure.
   d. arterial carbon dioxide partial pressure.
4. Defense mechanisms that help protect the lung from inhaled particles and microorganisms include the *(select all that apply)*
   a. cough reflex.
   b. mucociliary escalator.
   c. alveolar macrophages.
   d. reflex bronchoconstriction.
   e. alveolar capillary membrane.
5. A student nurse asks the RN what can be measured by arterial blood gas (ABG). The RN tells the student that the ABG can measure *(select all that apply)*
   a. acid-base balance.
   b. bicarbonate (HCO_3–).
   c. mixed venous O_2 (SvO_2).
   d. compliance and resistance.
   e. partial pressure of O_2 (PaO_2).
6. To detect early signs or symptoms of inadequate oxygenation, the nurse would examine the patient for
   a. dyspnea and hypotension.
   b. apprehension and restlessness.
   c. cyanosis and cool, clammy skin.
   d. increased urine output and diaphoresis.
7. During the respiratory assessment of an older adult, the nurse would expect to find *(select all that apply)*
   a. a vigorous reflex cough.
   b. increased chest expansion.
   c. increased residual volume.
   d. decreased lung sounds at base of lungs.
   e. increased anteroposterior (AP) chest diameter.
8. When assessing subjective data related to the respiratory health of a patient with emphysema, the nurse would ask about *(select all that apply)*
   a. date of last chest x-ray.
   b. dyspnea during rest or exercise.
   c. pulmonary function test results.
   d. ability to sleep through the entire night.
   e. prescription and over-the-counter medication.
9. When auscultating the chest of an older patient in mild respiratory distress, it is *best* to
   a. begin listening at the apices.
   b. begin listening at the lung bases.
   c. begin listening on the anterior chest.
   d. ask the patient to breathe through the nose with the mouth closed.
10. Which respiratory assessment finding does the nurse interpret as abnormal?
    a. Inspiratory chest expansion of 1 inch
    b. Symmetric chest expansion and contraction
    c. Resonance (to percussion) over the lung bases
    d. Bronchial breath sounds in the lower lung fields
11. The nurse is preparing the patient for a diagnostic procedure to remove pleural fluid for analysis. The nurse would prepare the patient for which test?
    a. Thoracentesis
    b. Bronchoscopy

c. Pulmonary angiography
d. Sputum culture and sensitivity

1.a; 2.d; 3.c; 4.a, b, c, d; 5.a, b, e; 6.b; 7.c, d, e; 8.b, d, e; 9.b; 10.d; 11.a.

Supporting Ventilation

Eugene E. Mondor

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Acid-Base Balance
Functional Ability
Gas Exchange
Nutrition
Sleep

LEARNING OUTCOMES

1. Identify airway clearance techniques that promote gas exchange.
2. Describe the indications for O_2 therapy, including delivery methods and complications.
3. Explain the purpose, function, and nursing responsibilities related to chest tubes and chest drainage systems.
4. Identify the types of chest surgery and appropriate perioperative care.
5. Relate the important aspects of care for the patient receiving noninvasive ventilation.
6. Distinguish the indications for and modes of mechanical ventilation.
7. Select appropriate nursing interventions related to the care of an intubated patient.
8. Identify the steps involved in suctioning a patient with an oral endotracheal tube or tracheostomy.
9. Describe complications of mechanical ventilation and corrective actions to ensure optimal ventilation and safe patient care.
10. Describe the process of weaning from mechanical ventilation.
11. Select appropriate nursing interventions related to care of the patient with a new tracheostomy.
12. Outline the essential teaching needed for the patient with a permanent tracheostomy.

KEY TERMS

assist-control (AC) ventilation
chest physical therapy (CPT)
continuous positive airway pressure (CPAP)
decannulation
endotracheal (ET) tube
extubation
intubation
mechanical ventilation
negative pressure ventilation
noninvasive ventilation (NIV)
positive end-expiratory pressure (PEEP)
positive pressure ventilation (PPV)
pressure control (PC) ventilation
pressure support ventilation (PSV)
pressure ventilation
pursed-lip breathing (PLB)
synchronized intermittent mandatory ventilation (SIMV)
thoracotomy
tracheostomy
volume ventilation
weaning

The exchange of O_2 and carbon dioxide (CO_2) is vital for life. The purpose of this chapter is to provide an overview of various strategies we use to promote optimal ventilation and oxygenation. Promoting respiratory function is important for best patient outcomes. Without an optimal route for ventilation, O_2 therapy will not benefit the patient. While providing optimal ventilation is no guarantee that oxygenation will improve, without a patent airway, the patient will die.

RESPIRATORY PHYSIOTHERAPY

Breathing Exercises

Two main types of breathing exercises are diaphragmatic breathing and pursed-lip breathing. *Diaphragmatic (abdominal) breathing* focuses on using the diaphragm instead of the accessory muscles of the chest to achieve maximum inhalation and slow the respiratory rate. Ideal candidates for diaphragmatic breathing instruction are

TABLE 28.1 PATIENT & CAREGIVER TEACHING

Pursed-Lip Breathing

Teach the patient to use PLB before, during, and after any activity that may cause them to be short of breath.

1. Inhale slowly and deeply through the nose.
2. Exhale slowly through pursed lips, as if whistling.
3. Be sure to relax your facial muscles without puffing your cheeks—like whistling—while you are exhaling slowly.
4. Make breathing out (exhalation) 3 times as long as breathing in (inhalation).
5. The following activities can help you get the "feel" of PLB:
   - Blow through a straw in a glass of water, forming small bubbles.
   - Blow a lit candle enough to bend the flame without blowing it out.
   - Steadily blow a table-tennis ball across a table.
   - Blow a tissue held in the hand until it gently flaps.
6. Practice 8–10 repetitions of PLB 3 or 4 times a day.

PLB, Pursed-lip breathing.

TABLE 28.2 PATIENT & CAREGIVER TEACHING

Effective Huff Coughing

Help the patient assume a sitting position with head slightly flexed, shoulders relaxed, knees flexed, forearms supported by pillow, and, if possible, feet on the floor.

Then teach the patient to:

1. Inhale slowly through the mouth while breathing deeply from the diaphragm.
2. Hold the breath for 2–3 sec.
3. Forcefully exhale quickly as if they are fogging up a mirror with their breath (thus creating a "huff"). This helps moves secretions into larger airways.
4. Repeat the "huff" 1 or 2 more times while refraining from a "regular" cough.
5. Cough when mucus is felt in the airways (breathing tubes).
6. Rest for 5–10 regular breaths.
7. Repeat the huffs (3–5 cycles) until you feel you have cleared mucus, or you become tired.

thoracic and abdominal surgery patients. Diaphragmatic breathing in patients with chronic obstructive pulmonary disease (COPD) may increase the work of breathing (WOB) and dyspnea. People with moderate to severe COPD with marked hyperinflation may not tolerate diaphragmatic breathing.

The purpose of **pursed-lip breathing (PLB)** is to prolong exhalation, which prevents bronchiolar collapse and air trapping.[1] PLB is simple, easy to teach, and easy to learn (Table 28.1). It gives the patient more control over breathing, especially during exercise and periods of dyspnea. PLB slows the respiratory rate and is easier than diaphragmatic breathing. Teach the patients to use "just enough" positive pressure with PLB because excessive resistance may increase the WOB. In the patient with extreme acute dyspnea, focus on helping the patient slow the respiratory rate by using PLB.

Airway Clearance Techniques

Many patients with COPD or other respiratory conditions who retain secretions, such as cystic fibrosis (CF) and bronchiectasis, need help to adequately clear their airways. Airway clearance techniques (ACTs) loosen mucus and secretions so they can be cleared by coughing. This helps maintain a patent airway. Techniques include huff coughing, chest physiotherapy, postural drainage, airway clearance devices, and high-frequency chest ventilation. ACTs are often used with other treatments. For example, the patient may receive bronchodilator therapy before ACT. Then the ACT is used, followed by effective coughing (e.g., huff coughing). Respiratory therapists (RTs), physical therapists, and nurses can teach patients and caregivers ACTs.

Huff Coughing

Huff coughing, or *huffing,* is a forced expiratory technique that consists of a series of smaller coughs. You can easily teach the patient huff coughing. Position the patient and ensure they are breathing deeply from the diaphragm. After holding the breath for a few seconds, the patient exhales with several small coughs, then rests for several breaths, and repeats the cycle.[2] Persons with COPD and emphysema benefit from huff coughing. Table 28.2 outlines teaching about huff coughing.

Chest Physical Therapy

Chest physical therapy (CPT) consists of postural drainage, percussion, and vibration. It can be done on spontaneously breathing patients as well as those who are intubated and mechanically ventilated. CPT is used for patients with excessive bronchial secretions who have difficulty clearing them.

CPT should be done by a physiotherapist or other trained person. Complications from improperly performed CPT include fractured ribs, bruising of the chest wall, hypoxemia, and discomfort. CPT may be stressful for some patients. Teaching can help ease fear and anxiety and gain trust and cooperation.

Postural Drainage

Postural drainage is the use of positioning techniques that drain secretions from specific segments of the lungs and bronchi into the trachea. The postural drainage position used depends on the areas of lung that are involved. This is determined by patient assessment, chest x-rays, chest auscultation, and, when possible, patient preference. For example, a patient with left lower lobe involvement needs postural drainage of only the affected region. On the other hand, a person with CF may need postural drainage of all segments.

The purpose of various positions in postural drainage is to drain each segment toward the larger airways. The patient who cannot tolerate a head-down position may use a side-lying position. We usually give aerosolized bronchodilators and hydration therapy before postural drainage. The patient stays in the chosen position for about 5 minutes during percussion and vibration. A common order is to perform postural drainage 2 to 4 times a day. In acute situations, we may do postural drainage as often as every 4 hours.[3] Schedule the procedure at least 1 hour before meals or 3 hours after meals.

Postural drainage is best for patients with atelectasis, CF, COPD, and pneumonia. Some commercially available specialty beds can rotate and percuss the patient in various postural drainage positions. Patients with traumatic brain injury, neck injury, chest trauma, hemoptysis, heart disease, or pulmonary embolus should not receive postural drainage. It is contraindicated in hemorrhage and when the patient is not stable.

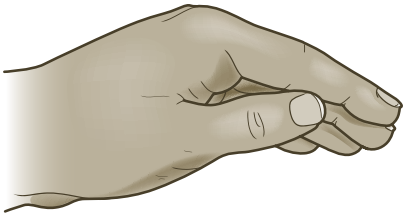

Fig. 28.1 Cupped-hand position for percussion. Cup the hand as though scooping up water.

Percussion

Percussion is done in the appropriate postural drainage position. Place the hands in a cuplike position with the fingers and thumbs closed (Fig. 28.1). The cupped hand should create an air pocket between the patient's chest and the hand. Both hands alternate in a rhythmic fashion. You will hear a hollow sound if done correctly. The air-cushion impact promotes the movement of thick mucus. For patient comfort, place a thin towel over the area you will percuss. The patient may choose to wear a T-shirt or hospital gown.

Vibration

Vibration promotes movement of secretions to the larger airways. We perform vibration by tensing the hand and arm muscles repeatedly and pressing mildly with the flat of the hand on the affected area while the patient slowly exhales a deep breath. Commercially available mechanical chest vibrators are available for hospital and home use.

Airway clearance devices. Airway clearance devices are available to help mobilize secretions. They are sometimes easier to tolerate than CPT and often take less time than CPT sessions. Popular devices include the Flutter, Acapella, and TheraPEP Therapy System.

The Flutter mucus clearance device is a hand-held device. It is shaped like a small, fat pipe. The Flutter has a mouthpiece, a high-density stainless-steel ball, and a cone that holds the ball. To use the Flutter, the patient takes a slightly bigger than normal breath and exhales through the mouth and into the Flutter. As a result, the steel ball moves, which causes vibrations in the airways. The vibration helps loosen mucus in the airways to allow improved expectoration. Flutter use should be followed by huffing and coughing. Clean a Flutter daily in warm, soapy water.

The Acapella is another small hand-held device. It combines positive expired pressure (PEP) and airway vibrations to mobilize secretions. It can be used in any setting. Patients are free to sit, stand, or recline. Prior to use, the resistance dial on the device needs to be set (1=minimal exhalation resistance, 5=high exhalation resistance). The patient takes in a deep breath through the nose or mouth, then seals their lips around the mouthpiece, and exhales through the device. You should hear the gentle noise of the rocker inside the device on exhalation. The Acapella can help deliver aerosolized drugs.

The TheraPEP Therapy System is similar to the Acapella. It uses PEP and can assist with airway clearance and deliver aerosolized drugs. TheraPEP can have either a mouthpiece or mask that is attached to tubing that is connected to a small adjustable resistor and a pressure indicator. The patient inhales through the nose or mouth, holds the breath for a few seconds, then exhales through the resistor. The pressure indicator gives visual feedback about the pressure that the patient needs to hold during exhalation to receive maximal benefit of PEP.

High-frequency chest wall oscillation. High-frequency chest wall oscillation uses an inflatable vest (e.g., Vest System, Smart Vest) with hoses connected to a high-frequency pulse generator. The pulse generator delivers air to the vest, which vibrates the chest. The high-frequency airwaves dislodge mucus from the airways, mobilize the mucus, and move it toward larger airways. The vest is easy to apply. It can be used without the aid of another person. The unit weighs 23 to 30 lbs. (10 to 13 kg), are quiet, come in a suitcase, and are portable.

O_2 THERAPY

O_2 therapy is a common treatment for hypoxemia and hypoxia. O_2 is a colorless, odorless, tasteless gas that constitutes 21% of the atmosphere. Giving supplemental O_2 increases the partial pressure of O_2 (PO_2) in inspired air. O_2 therapy requires an HCP order. The dose of O_2 administered to patients is the *fraction of inspired oxygen (FIO_2)*.

We give O_2 to treat hypoxemia caused by many problems, such as shock, pneumonia, and pulmonary emboli. O_2 therapy is tailored to meet each patient's unique circumstances and physiologic needs. For most patients, the goal of O_2 therapy is to keep the SaO_2 greater than 92% during rest, sleep, and activity, or the PaO_2 greater than 60 mm Hg. We may modify these goals depending on the patient's clinical situation. For example, the HCP may accept an SpO_2 an PaO_2 greater than 88% for the patient with longstanding COPD.

DRUG ALERT

O_2

- O_2 is considered a drug.
- Administering high levels of O_2 (FIO_2 greater than 60% for more than 24 hr) to mechanically ventilated patients can lead to O_2 toxicity.
- Target FIO_2 levels are to maintain SpO_2 >92% and PaO_2 between 60 and 100 mm Hg.
- Assess PaO_2 and SpO_2 as needed.
- Monitor for manifestations of O_2 toxicity: blurred vision, coughing, chest pain, dyspnea, seizures.

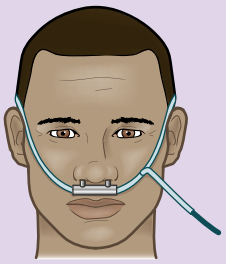
Methods of O_2 Administration

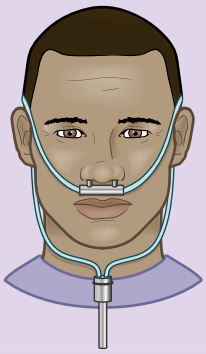
There are various ways to administer O_2 (Table 28.3). The device used depends on the patient's underlying condition, the FIO_2 the patient needs, advantages and disadvantages of each device, comfort, cost, and financial resources.

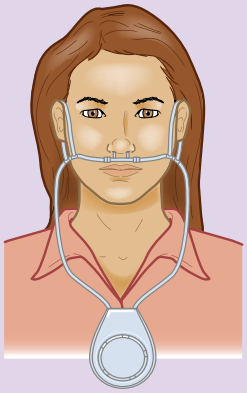
We classify O_2 delivery systems as low-flow or high-flow systems. Low-flow O_2 delivery devices are appropriate for patients who are awake, alert, and spontaneously breathing with a stable, intact respiratory drive. These devices provide O_2 in concentrations that do not meet all the patient's inspiratory demands.[4] Low-flow devices pull in a proportion of room air, which makes the exact FIO_2 unknown. We do know the range of FIO_2

TABLE 28.3 Methods of O_2 Administration

Description	Nursing Interventions
Low-Flow Delivery Devices	
Nasal Cannula	
• Most commonly used. • O_2 delivered through plastic tubing (prongs) that fits in the nares. • Used for a patient requiring low O_2 concentrations. • Achieves O_2 concentrations of 24% (at 1 L/min) to 44% (at 6 L/min). • Safe • Easy to set-up and use • Patient can eat, talk, or cough while wearing device. • Allows some freedom of movement.	• Stabilize nasal cannula when caring for a restless patient. • Amount of O_2 inhaled depends on room air and patient's breathing pattern. • Most patients with COPD can tolerate 2–4 L/min through a cannula. • Assess the nares and ears for skin breakdown. May need to pad tubing where it sits on ears. • If flow rates are >5 L/min, nasal membranes may dry and place patient at risk for nose bleeds.
O_2-Conserving Cannula	
• Generally indicated for longer-term O_2 therapy at home (e.g., CF, pulmonary hypertension). • Looks like a "moustache" (Oxymizer) or "pendant" type. • Cannula has a built-in reservoir that ↑ O_2 concentration and allows patient to use lower flow, usually 30%–50%, which increases comfort, lowers cost, and can be increased with activities. • Can deliver O_2 flow rates up to 15 L/min.	• More expensive than standard nasal cannula. • Cannula is highly visible. • Assess the nares and ears for skin breakdown. May need to pad tubing where it sits behind ears. • Cannot clean cannula. Change cannula every week. • May need ABGs and oximetry to determine correct flow rate.
Partial and Non-Rebreather Masks	
• Used for short-term therapy for patients with higher O_2 needs • Achieves O_2 concentrations of 60%–90% (with flow rates of 10–15 L/min). • O_2 flows into reservoir bag and mask during inhalation. • Bag allows patient to rebreathe about first third of exhaled air (rich in O_2) in conjunction with flowing O_2. • Vents stay open on partial mask. Some agencies prefer this over non-rebreather as a safety issue.	• O_2 flow rate must be sufficient to keep bag from deflating during inspiration to avoid CO_2 buildup and rebreathing of CO_2. • If deflation occurs, increase flowrate on flowmeter on wall to keep bag inflated. • Mask should fit snugly. • With non-rebreather masks, make sure valves open during expiration and close during inhalation to prevent decrease in FIO_2 or build-up in CO_2. • Monitor patient closely, since more advanced interventions such as CPAP, Bi-PAP, or intubation with mechanical ventilation may be needed.
Simple Face Mask	
• Covers the nose and mouth. • Achieves O_2 concentrations of 35%–50% with flow rates of 6–12 L/min. • Mask provides adequate humidification of inspired air. • Safe • Easy to set up and use • Typically used only for short periods.	• Wash and dry under mask q4hr and PRN. • Mask must fit snugly. • Must have flow rates of at least 6 L/min to wash exhaled gases out of mask (if O_2 flow rate not high enough, CO_2 rebreathing is possible) • May change to nasal cannula while patient is eating. • Watch for pressure necrosis at top of ears from elastic straps if patient wears for a longer time. Gauze or other padding may alleviate this problem.

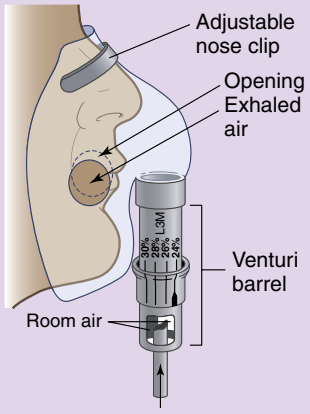






Pendant-type O_2-conserving cannula.

TABLE 28.3 Methods of O_2 Administration—cont'd

Description	Nursing Interventions
High-Flow Delivery Devices	
High-Flow Nasal Cannula	
• Blends O_2 with compressed air to generate high FIO_2 • Achieves O_2 concentration up to 100% (at flow rate of up to 60 L/min). • Heated humidifier capable of providing 100% humidity. • Soft and flexible nasal prongs. • More comfortable than mask.	• Nasal cannula must be smaller than 50% of nares to allow flow during exhalation and flush out end-expiratory CO_2. • Well tolerated. • Patients can eat and drink with device in place. • Patient may describe feeling of always having to blow nose ("rainout") due to humidification.
Tracheostomy Collar	
• Collar attaches to neck with elastic strap and can deliver humidity and O_2 through the tracheostomy. • Some O_2 concentration is lost into atmosphere because collar does not fit tightly. • Venturi device can be attached to flowmeter and can deliver exact amounts of O_2 through the collar.	• Secretions collect inside collar and around tracheostomy. • Remove collar and clean at least q4hr and PRN to prevent aspiration of fluid and infection. • Because condensation occurs in tubing, periodically drain tubing distal to tracheostomy.
	Tracheostomy T-Piece	
• Almost identical to tracheostomy collar, but it has a T-connector attached to an O_2 blender. • Tight fit allows better O_2 and humidity delivery than tracheostomy collar. • T-piece allows an inline catheter to be connected for suctioning.	• Because T-piece connector can disconnect easily, monitor closely. • T-piece connector may pull on the tracheostomy tube, causing irritation and potential tissue damage. Monitor closely.
Venturi Mask	
• Mask can deliver precise, high-flow rates of O_2. • Lightweight plastic, cone-shaped mask. Masks are available for delivery of 24%, 28%, 31%, 35%, 40%, and 50% O_2. • Method is especially helpful for giving low, constant O_2 concentrations to patients with COPD. • Adaptors can increase humidification.	• Entrainment device on mask must be changed to deliver higher concentrations of O_2. • Air entrainment ports must not be occluded. • Uncomfortable. • Must be removed for eating. • Patient can talk but voice may be muffled.
	


Bi-PAP, Bi-level positive airway pressure; *CF,* cystic fibrosis; *COPD,* chronic obstructive pulmonary disease; *CPAP,* continuous positive airway pressure; *FIO2,* fraction of inspired oxygen.

delivered by each device. Examples include nasal prongs, simple masks, and non-rebreather masks.

High-flow O_2 delivery devices deliver fixed O_2 concentrations (e.g., 28%, 35%) independent of the patient's respiratory rate or pattern. High flow systems provide O_2 in concentrations that meet or exceed the patient's inspiratory demand. These patients are also awake, alert, and spontaneously breathing, but have higher O_2 requirements that low flow devices cannot meet.[4] High flow devices help meet achieving specific PaO_2 or SpO_2 targets. Examples include the Venturi mask and high-flow nasal cannula.

Humidification

O_2 obtained from O_2 cylinders or wall systems is a dry gas. Dry O_2 has an irritating effect on mucous membranes and dries secretions. Humidification involves adding sterile water attached to the O_2 delivery device to prevent breathing dry air. A common device used for humidification when the patient has a cannula or mask is a small plastic jar filled with sterile water called a *bubble-through humidifier.* It is attached to the O_2 source by a flowmeter.

Many agencies have moved away from providing humidification for low flow O_2 delivery devices. Humidification with high flow O_2 devices (e.g., Vapotherm) is important. Follow agency policy about O_2 therapy and humidification.

Complications

Combustion

O_2 supports combustion and increases the rate of burning. Smoking must be prohibited in any patient care area where O_2 is being used. Display a "No Smoking" sign on the patient's door and in any area where O_2 is in use. Caution the patient against smoking with an O_2 cannula in place as it can easily ignite and cause significant burns and life-threatening airway issues.

O_2 Toxicity

O2 toxicity may result from prolonged exposure to a high level of O_2 (FIO_2). High O_2 concentrations can result in a severe inflammatory response because O_2 free radicals damage the alveolar-capillary membrane.[5] This can cause severe pulmonary edema, shunting of blood, hypoxemia, and pulmonary edema.

Preventing O_2 toxicity is essential. The amount of O_2 administered should be enough to maintain the PaO_2 within a normal or acceptable range for that patient. The most important rule you can follow is to provide FIO_2 at the lowest possible level while still maintaining acceptable SpO_2 and PaO_2 values for that specific patient. Monitoring ABGs often helps evaluate the effectiveness of therapy and guide the tapering of supplemental O_2.

Absorption Atelectasis

The alveoli contain many different gases, including O_2, CO_2, and nitrogen. Nitrogen helps maintain the size, shape, and structure of the alveolus. If the bronchial tubes become obstructed (e.g., with mucous), the exchange of O_2 and CO_2 cannot occur. Nitrogen will eventually move out of the alveolus and into the bloodstream. This is a "nitrogen washout." As a result, the alveolus collapses, and absorption atelectasis occurs. This can worsen hypoxemia.

Frequent chest x-rays for patients requiring higher levels of O_2 therapy, monitoring ABGs, suctioning the airway as needed, and giving O_2 at the lowest level possible help avoid this condition.

CO_2 Narcosis

Chemoreceptors control the drive to breathe. They respond to CO_2 and O_2 concentrations in the blood. Normally, an increase in CO_2 in the blood is a major stimulant of the respiratory center. However, some patients (e.g., COPD) develop a tolerance for high CO_2 levels. As a result, the respiratory center loses its sensitivity to high CO_2 levels. For these patients, a major "drive" to breathe is hypoxemia. As a result, there is concern about the dangers of giving O_2 to COPD patients and reducing their drive (stimulus) to breathe.

However, the hypoxic drive is complex and involves many other factors. Not all patients with COPD retain CO_2. Therefore, it is good practice to administer O_2 to any patient who will likely benefit from O_2 therapy, whether they need it or not. The danger of not giving O_2 to a patient far outweighs the risk of administering O_2 when it is not needed.

Infection

Infection is a rare complication of O_2 use. It is often related to the device used and how often the device must be cleaned or changed. Heated nebulizers present the highest risk. The constant use of humidity supports bacterial growth. Whenever possible, use disposable and single patient use equipment. Follow agency policy about the frequency of equipment changes.

❖ NURSING MANAGEMENT: O_2 THERAPY

We use pulse oximetry and/or ABGs to determine the FIO_2 each patient needs. The goal is an O_2 saturation (SpO_2) of at least 92% or a PaO_2 of at least 60 mm Hg. Titrate the O_2 concentration with close monitoring of the PaO_2 and $PaCO_2$. Assess mental status and vital signs before starting O_2 therapy and frequently thereafter. Nursing management of the patient receiving O_2 therapy is outlined in Table 28.4.

TABLE 28.4 NURSING MANAGEMENT

O_2 Administration

- Assess need for adjustments in O_2 flow rate.
- Evaluate response to O_2 therapy, especially when changes are made.
- Provide patient and caregiver teaching about O_2 therapy (see Table 28.5).
- Monitor patient for adverse effects of O_2 therapy.
- Supervise AP:
  - Use pulse oximetry to measure O_2 saturation and report level to RN.
  - Assist patient with adjustment of O_2 delivery devices (e.g., nasal cannula, simple face mask).
  - Report to RN any change in patient condition.

Collaborate With Respiratory Therapist

- Assist with choosing optimal O_2 delivery device.
- Make sure equipment is clean and replaced as needed.
- Check accuracy of O_2 delivery.
- Frequently assess need for adjustments in O_2 flow rate.

O_2 Therapy at Home

Some patients need O_2 therapy at home to treat hypoxemia associated with chronic conditions. The patient with mild to moderate hypoxemia that persists after discharge from the hospital may need short-term therapy. For example, a patient who had COVID pneumonia may need continued O_2 therapy to treat hypoxemia for a few weeks after discharge. Home health personnel can assess the patient's oxygenation status after an acute episode to determine if they still need O_2.

Patients usually rent home O_2 systems. The company then sends a RT to the home. The therapist teaches the patient and caregiver how to use the O_2 system, maintain it, troubleshoot, recognize when the supply is low, and reorder O_2. Table 28.5 shows patient and caregiver teaching guide for using O_2 at home.

Nasal cannulas, including O_2 conservation systems, deliver O_2 from a central source in the home. Sources include a liquid O_2 storage system, compressed O_2 in tanks or cylinders, or an O_2 concentrator or extractor. The one chosen depends on the patient's activity level, environment, insurance coverage, and proximity to an O_2 supply company. To increase mobility in the home, the patient can use extension tubing with some devices without lowering the O_2 flow delivery. The patient who is active outside the home can use a small, portable system, such as liquid O_2.

Patients may need O_2 only during exercise and/or sleep. Evaluate the need for O_2 during these periods with a 6-minute walk test or overnight oximetry. The patient on long-term therapy needs assessed at regular intervals (e.g., every 30 to 90 days during the first year, then each year if they are stable).

Encourage the patient who uses home O_2 to remain active and travel normally. If travel is by car, they can make arrangements for O_2 to be available at their destination. O_2 supply companies can help with these arrangements. If a patient plans to travel by bus, train, or airplane, the patient should inform these agencies when making reservations that they need O_2. O_2 needs for flying can be determined by a pulmonary function test, a 6-minute walk test, hypoxic challenge test, or predictive formula. Portable O_2 concentrators are a ready source of renewable O_2. They can be available by recharging at home or with a direct current (DC) (e.g., auto) power supply. Several are approved by airlines for in-flight use. The patient should contact the airline to determine accommodations and policies for in-flight O_2.

TABLE 28.5 PATIENT & CAREGIVER TEACHING

Home O_2 Use

The company that provides the O_2 and equipment will teach the patient about O_2 delivery and equipment care. The following are some general instructions that you may include when teaching the patient and caregiver about the use of home O_2.

Patient Care

- Set the O_2 flowrate at the rate your HCP told you to set it at. Do not change the rate without first talking to your HCP.
- If you have any shortness of breath, are lightheaded or dizzy, or develop wheezing, call the HCP right away
- Check to make sure you have enough O_2 on hand for weekends and holidays. The company will tell you how to check the O_2 level and when / how you re-order more O_2.

Decreasing Risk for Infection

- Wash hands before and after using your O_2 therapy.
- Wash nasal cannula (prongs) with a liquid soap and thoroughly rinse once or twice a week.
- Brush teeth or use mouthwash several times a day.
- Ask the company providing the equipment how often to change the tubing and filter.
- Replace cannula every 2–4 weeks.
- If you have a cold, replace the cannula after your symptoms pass.

Safety Issues

- Keep O_2 tanks at least 5 feet (1.5 m) away from any source of heat (e.g., gas stoves, fireplaces)
- Post "No Smoking—Oxygen in Use" warning signs on the front and back doors of your home.
- Do not allow smoking in the home, and do not smoke yourself while wearing O_2. Nasal cannulas and masks can catch fire and cause serious burns to face and airways.
- Store O_2 tanks upright.
- Do not use blankets or fabrics that carry a static charge, such as wool or synthetics.
- Do not use flammable liquids such as paint thinners, cleaning fluids, gasoline, kerosene, oil-based paints, or aerosol sprays while using O_2.
- Inform the staff at your electric company if you are using a concentrator. In case of a power failure, they will know the medical urgency of restoring your power.

ARTIFICIAL AIRWAYS

Patients sometimes need help to maintain a patent airway. Inserting a small, plastic tube into the nose, mouth, or trachea, thereby bypassing upper airway and laryngeal structures, creates a route for ventilation to occur. There are 5 artificial airways we commonly use in practice.

Nasopharyngeal Airway

A nasopharyngeal airway (NPA) is a small, flexible plastic tube inserted into the nostril to help maintain a route for ventilation (Fig. 28.2). The NPA can be placed in a conscious or unconscious patient. To measure the length of the tube needed, hold an NPA up to the side of the patient's face. Choose an NPA that correctly measures from the tip of the nose to the tip of the ear. To select the right internal diameter, choose a tube with a slightly smaller diameter than the patent's nostrils.

Choose the nostril of greatest airflow. Lubricate the tube, and gently insert while rotating the tube toward the patient's ear. Stop if you encounter any obstruction or difficulty. When correctly positioned, the flange should rest comfortably against the nostril.

Oropharyngeal Airway

The oropharyngeal airway (OPA) is a smaller, shorter tube of firm, hard plastic. The tube is curved, with a flange on 1 end and blunt opening on the other. Do not insert an OPA in a conscious patient as this will induce vomiting and risk of aspiration. Only insert the OPA into an unconscious patient.

To measure the length of the OPA needed, hold the OPA up to the side of the patient's face. Measure the tube against the corner of the mouth to the angle of the jaw or earlobe. If the tube

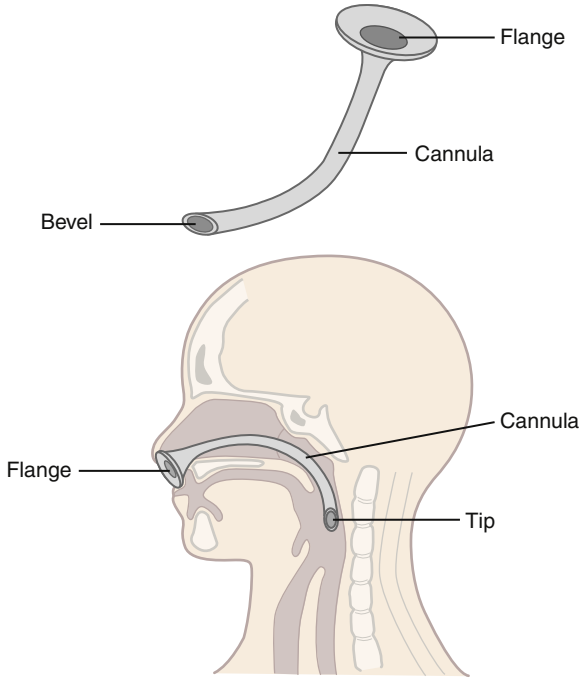


Fig. 28.2 Nasopharyngeal airway.

is too short, you may push the tongue into the oropharynx and occlude the airway. If the tube is too long, you may damage the posterior oropharynx.

To insert the OPA, lubricate the tube with water soluble lubricant. Insert the tube with the bevel pointed towards the roof of the mouth. As the flange reaches the lips, rotate the OPA 90 degrees so that the curvature of the OPA fits the natural curvature of the upper airway. Correctly inserted, the flange will fit comfortably against the lips.

Endotracheal Tube

The **endotracheal (ET) tube** is a long, flexible, plastic tube that secures a patient's airway when they need mechanical ventilation. An ET consists of a standard adaptor (used to attach the bag-valve-mask [BVM] or ventilator), cuff, pilot balloon, and radiopaque markings along the length of the tube. The markings help gauge the distance the tube is inserted. The parts of the oral ET tube are shown in Fig. 28.3.

The most common sizes are 7F and 8F tubes. The size refers to the internal diameter of the tube. Often, females need a 7F tube, and males need an 8F tube. A larger diameter tube can also be used. A larger tube reduces the WOB because of less airway resistance. It is also easier to suction and remove secretions and, if needed, perform bronchoscopy.

In *oral intubation,* the ET tube is passed into the mouth, through the vocal cords, and into the trachea with the aid of a laryngoscope or a bronchoscope. Oral ET intubation is preferred for intubations because the airway can be secured rapidly.

Indications for intubation include (1) acute respiratory distress, (2) apnea, (3) upper airway obstruction (e.g., burns, tumor, bleeding), (4) ineffective clearance of secretions, and (5) high risk for aspiration. ET intubation is done quickly and safely at the bedside by an HCP or RT. ET intubation is common in

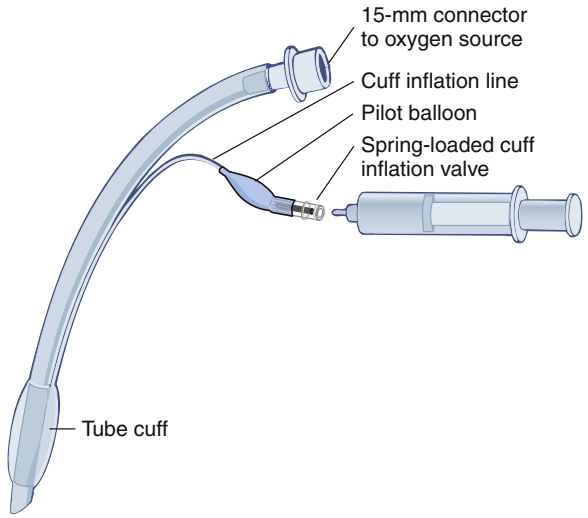

Fig. 28.3 Parts of an endotracheal tube. (From Beare PG, Myers JL: *Adult health nursing,* ed 3, St. Louis, 1998, Mosby.)

ICU patients requiring mechanical ventilation for short periods of time (e.g., less than 2 weeks).

Nasotracheal Tube

When oral intubation through the mouth is not possible (e.g., unstable cervical spine injury, dental abscess, epiglottitis), a nasotracheal (NT) tube can help provide an airway. The NT tube is slightly longer than the oral ET tube. It is inserted through the nostril and placed blindly (without seeing the larynx). We attach the patient to the ventilator via the standard adaptor at the end of the NT tube.

Tracheostomy

The **tracheostomy** is a special type of artificial airway. It is a small, plastic tube that consists of a flange, pilot balloon, balloon inflation port, and a cuff. The tube is placed into the trachea through a surgical incision that is created on the anterior surface of the neck. The tracheostomy may be inserted urgently (when oral and/or nasal intubation is not possible). Tracheostomies and their care are discussed later in this chapter.

PROCEDURES TO SUPPORT VENTILATION

A variety of diagnostic, therapeutic, and surgical strategies are available to assist patients with improving oxygenation and promoting more effective ventilation. Bronchoscopy may be used for diagnostic purposes and treatment (e.g., remove mucous plugs, foreign bodies). It can help achieve patency of an airway that has been partially or nearly obstructed by tumors. A **thoracentesis** can relieve symptoms by draining air or excess fluid from the pleural space. Usually, we remove no more than 1000 to 1200 mL of fluid at one time. Rapid removal of a large volume of pleural fluid can result in hypotension, hypoxemia, or re-expansion pulmonary edema. These procedures are discussed in Chapter 27.

Chest Tubes and Pleural Drainage

If enough fluid or air accumulates in the pleural space, the normally negative subatmospheric pressure becomes positive and 1 or both lungs collapse. Inserting a chest tube into the pleural

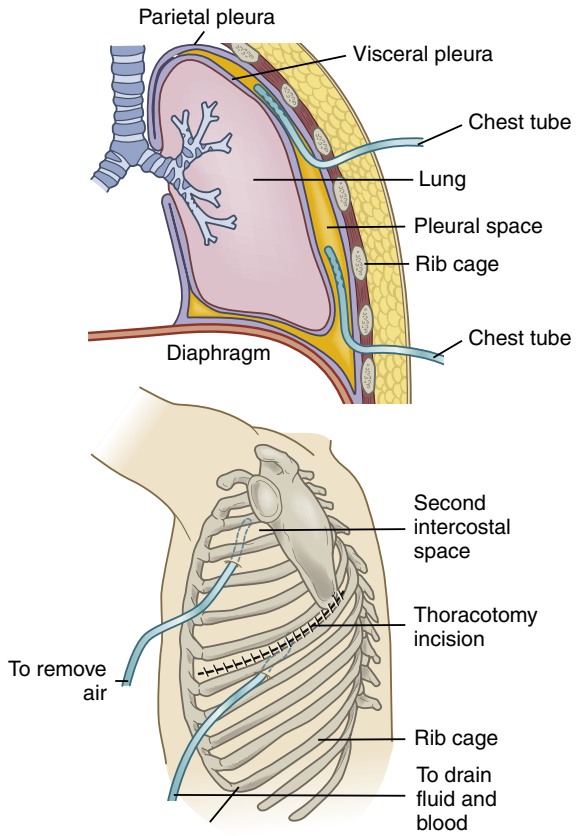

Fig. 28.4 Placement of chest tubes.

space can re-establish negative pressure, drain the pleural space, and allow for lung expansion.[6]

Chest tubes are about 20 in (51 cm) long and vary in size from 12F to 40F. The size inserted depends on the reason for the chest tube insertion. Large (36F to 40F) tubes are used to drain blood. Medium (24F to 36F) tubes are used to drain fluid. Small (12F to 24F) tubes are used to drain air. Pigtail catheters are very small (10F to 14F) tubes with a curly end designed to keep them in place.[7] Sometimes, they are a safe and effective alternative to larger-bore chest tubes for treatment of pneumothorax.

Chest Tube Insertion

Insertion of a chest tube can take place in the ED, surgery, or at the bedside. Time permitting, a chest x-ray is done to confirm the affected side. The patient is positioned with the arm raised above the head on the affected side to expose the midaxillary area, the standard site for insertion. Elevate the head (up to 45 degrees when possible) to lower the diaphragm and reduce the risk for injury.

The area is cleansed with an antiseptic solution. The HCP injects a local anesthetic and makes a small incision over a rib. The chest tube is advanced up and over the top of the rib to avoid the intercostal nerves and blood vessels that are behind the rib inferiorly (Fig. 28.4). Once inserted, the HCP sutures the tube in place and closes the incision with sutures. The tube is connected to a pleural drainage system. The wound is covered with an occlusive dressing. Most HCPs prefer to seal the wound

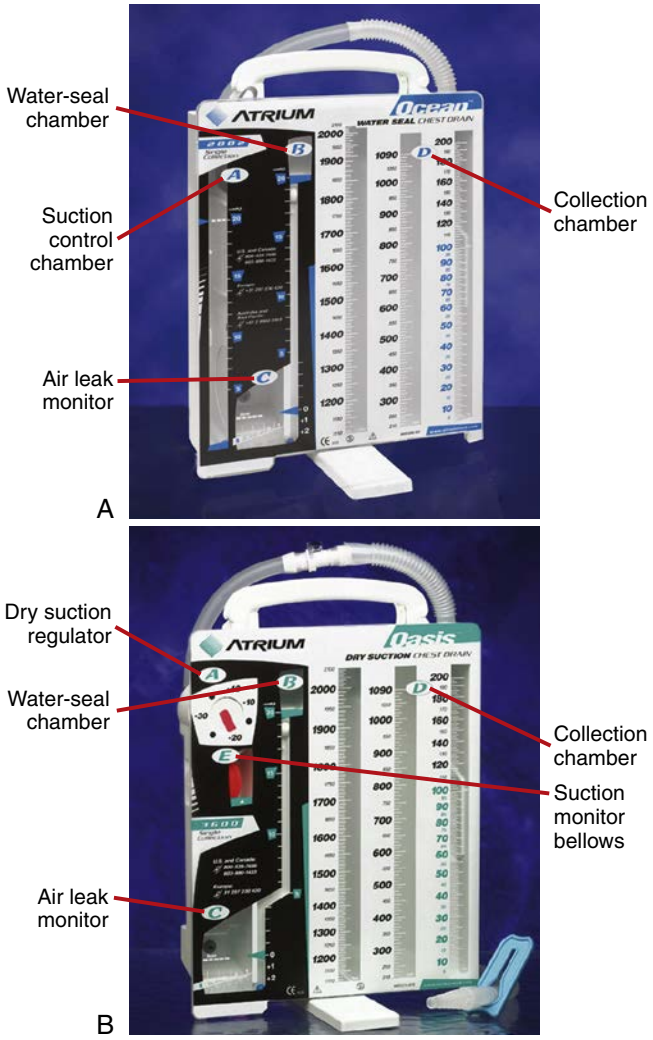

Fig. 28.5 Chest drainage unit. Both units have 3 chambers: (1) collection chamber; (2) water-seal chamber; and (3) suction control chamber. Suction control chamber requires connection to a wall suction source for the suction to work. (A) Water suction. This unit uses water in the suction control chamber to control the suction pressure. (B) Dry suction. This unit controls suction by using a regulator control dial. (From Atrium Medical Corporation, Hudson, NH.)

around the chest tube with petroleum (airtight) gauze. Tube placement is confirmed by chest x-ray.

Inserting a chest tube is painful. Monitor the patient's comfort frequently and use appropriate pain-relieving interventions.

Pleural Drainage System

A chest tube is usually attached to a drainage device or chamber to collect fluid, air, and/or blood from the chest cavity. Many disposable, plastic chest drainage systems are available. Manufacturers include directions for set-up and use with each unit. Most units have a 2000 mL capacity.

All drainage units have 3 basic compartments (Fig. 28.5). The first compartment, or collection chamber, receives fluid and air from the pleural space. The drained fluid stays in this chamber while expelled air vents to the second compartment.

The second compartment is the water-seal chamber. It contains about 2 cm of water, which acts as a 1-way valve. Incoming air enters from the collection chamber and bubbles up through the water. The water prevents backflow of air into the patient. Brisk bubbling of air often occurs in this chamber when a pneumothorax is first evacuated. Intermittent bubbling during exhalation, coughing, or sneezing (when intrathoracic pressure is increased) may occur as long as there is air in the pleural space. Eventually, as the air leak resolves and the lung becomes more fully expanded, bubbling ceases.

Normal water fluctuation within the water-seal chamber is called *tidaling*. This up and down movement of water with the patient's breathing reflects intrapleural pressure changes during inspiration and expiration. This is normal. If tidaling stops suddenly, assess the chest tube immediately. It may mean the tube is occluded. As the lung re-expands, tidaling gradually slows then eventually stops.

The third compartment, the suction control chamber, applies suction to the chest drainage unit. There are 2 main types of suction control: water and dry. For wet suction systems, the suction control chamber uses a column of water to control the amount of suction from the wall regulator. The chamber is filled with a specific amount of water. This amount of water determines the amount of suction applied to the chest drainage unit. You may need to add more water to the suction control chamber as water evaporates. Problems can arise with this chamber if the chest tube unit is tipped or knocked over.

A dry suction chest tube system does not contain water. The amount of suction is determined by turning a dial on the chest tube drainage device to the ordered amount. Suction pressure is usually −20 cm H_2O. A visual alert shows you if the suction is working. Higher pressures (−40 cm H_2O) are sometimes needed to evacuate the pleural space. Lower pressure (−10 cm H_2O) may be used for frail and older patients at risk for tissue damage.

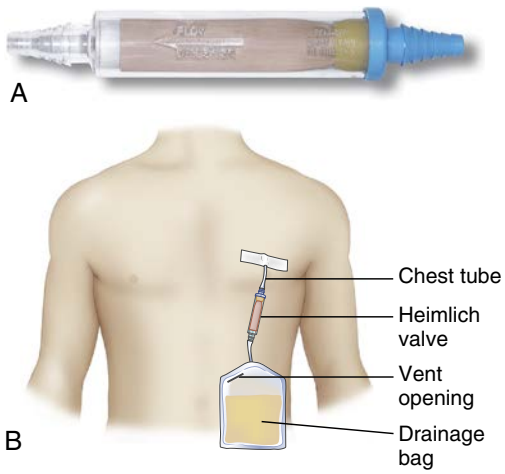

Fig. 28.6 (A) Heimlich chest drain valve is a specially designed valve that is used in place of a chest drainage unit for small uncomplicated pneumothorax. The valve allows for escape of air but prevents the reentry of air into the pleural space. (B) Placement of valve between chest tube and vented drainage bag, which can be worn under a gown or clothes. (A, Courtesy and © Becton, Dickinson and Company.)

A flutter valve (also called the *Heimlich valve*) is used to remove air from the pleural space (Fig. 28.6). This device consists of a 1-way rubber valve within a rigid plastic tube. It is attached to the external end of the chest tube. It has 2 nozzles. The inlet nozzle allows the air to pass into the valve through the chest tube attached to it. The outlet nozzle allows the air to pass to the environment or a collecting device during expiration. During inspiration, when pressure in the chest decreases, the valve closes. This prevents air from going back into the patient's chest. During expiration, when intrathoracic pressure increases, the valve opens.

The flutter valve can be used for a small to moderate-sized pneumothorax. It allows for patient mobility. The patient can hide the smaller drainage bag under clothes when they ambulate. Drainage bags attached to the flutter valve must have a vent to the atmosphere to prevent a tension pneumothorax. This is done by simply cutting a small slit in the top of any drainage bag that does not have a built-in vent. Patients may go home with a flutter valve in place.

❖ NURSING MANAGEMENT: CHEST DRAINAGE

General guidelines for nursing care of the patient with chest tubes and chest tube drainage systems are shown in Table 28.6.

Immediately after chest tube insertion, closely monitor the patient for complications from the chest tube placement and drainage. Monitor vital signs, including respiratory rate and rhythm. If volumes from 1 to 1.5 L of fluid and/or blood are removed rapidly, re-expansion pulmonary edema or severe, symptomatic hypotension may occur. Ask the HCP how much drainage to expect. Notify the HCP if excess drainage occurs.

Inspect the integrity of the system. Monitor the color and amount of drainage hourly in the first few hours after chest tube insertion. Report drainage greater than 200 mL in the first hour, development of subcutaneous emphysema, or any signs and symptoms of respiratory distress to the HCP at once.

Subcutaneous emphysema can occur from air leaking into the tissue surrounding the chest tube insertion site. If present, you will feel a "crackling" sensation when palpating the skin. A small amount of subcutaneous air is harmless and will be reabsorbed. However, severe subcutaneous emphysema around the head and neck can cause swelling with airway compromise.

Sterile technique during dressing changes can reduce infection of the insertion site. Implement measures to reduce the risk for atelectasis and shoulder stiffness. Encourage coughing, deep breathing, incentive spirometer use, and range-of-motion (ROM) exercises.

If a chest tube suddenly becomes disconnected, the immediate priority is to reestablish the water-seal system. In some agencies, when disconnection occurs, the exposed end of the chest tube is immersed in sterile water to act as a water seal until a new system can be set up and chest drainage reestablished. Do not clamp the tube. The danger of rapid accumulation of air in the pleural space, causing tension pneumothorax, is far greater than that of a small amount of atmospheric air that enters the pleural space. We no long "milk" or "strip"

chest tubes. Doing so generates large changes in intrathoracic pressure.[8]

You can momentarily clamp a chest tube to change the drainage apparatus or check for air leaks. Appearance of a new air leak warrants assessment of the drainage system to identify whether the air leak is coming from the patient or from the system. Follow your agency policy about specific clinical situations when you may clamp a chest tube.

TABLE 28.6 Chest Tubes and Chest Tube Drainage Units

Set-Up and Insertion

1. Explain procedure to the patient and family/significant others.
2. Gather equipment:
   - Thoracotomy or chest tube insertion tray
   - Disposable chest drainage unit (CDU)
   - Chest tube
   - Bottle of sterile water
   - 1% lidocaine
   - Suction tubing and collection container
   - Occlusive dressing
3. Prepare CDU:
   - *Wet suction:* Add sterile water to 2-cm mark in water-seal chamber and to 20-cm mark (or as ordered) in suction control chamber.
   - *Dry suction:* Add sterile water to the fill line of the air leak meter. Attach suction tubing to wall suction and increase suction until the bellows-like float moves across the display window.
4. Position and support the patient to minimize movement during procedure.

Clinical Status

- Monitor the patient. Assess vital signs, lung sounds, pain and need for analgesia.
- Evaluate for subcutaneous emphysema at insertion site.
- Have the patient breathe deeply periodically to promote lung expansion. Encourage ROM exercises to the shoulder on the affected side. Encourage use of incentive spirometry every hour while awake to prevent atelectasis or pneumonia.
- Assess for complications. Auscultate the lungs (↓ or absent breath sounds may indicate air and/or fluid reaccumulating in chest); observe color and characteristics of chest tube drainage (significant bleeding >100 mL/hr); observe chest tube insertion site daily (infection may be identified by change in color or amount of drainage, erythema at site, patient fever, ↑ WBCs).

Chest Tube Dressings

- Change dressing according to policy and HCP preference.
- Remove old dressing carefully. Assess the site for inflammation or infection and culture site as needed.
- Cleanse the site according to policy, maintaining strict sterile asepsis.
- Redress with occlusive dressing. Some HCPs prefer a petroleum gauze dressing around the tube to prevent air leak. Date the dressing and document dressing change.

General Chest Tube Management

- Keep all connections between chest tubes, drainage tubing, and the drainage collector tight. Tape all connections.
- Keep all tubing loosely coiled below chest level. Position tubing so that drainage flows freely. Never raise the drainage system to the level of the patient's chest because fluid can drain back into the lungs.
- Observe for air fluctuations (tidaling) and bubbling in the water-seal chamber.
- Mark the time of measurement and the fluid level on the drainage unit according to policy. Report any change in the quantity or characteristics of drainage (e.g., clear yellow to bloody) to the HCP. Notify HCP if >100 mL/hr drainage.
- Change the unit if the collection chamber is full. Do not try to empty it.
- Never compress, milk, or strip chest tube tubing.

Wet Suction System (see manufacturer's directions for use)

- Keep the suction control chamber at the right water level by adding sterile water as needed to replace water lost to evaporation.
- After filling the suction control chamber to the ordered suction amount (generally 20 cm H_2O suction), connect the suction tubing to the wall suction.
- Dial the wall suction regulator until there is continuous, gentle bubbling in the suction control chamber (no more than 120 mm Hg). Vigorous bubbling is not necessary and will increase the rate of evaporation.
- If there is no bubbling in the suction control chamber, (1) there is no suction, (2) suction is not high enough, or (3) the pleural air leak is so large that suction is not high enough to evacuate it.

Dry Suction System (see manufacturer's directions for use)

- After connecting patient to system, turn the dial on the chest drainage system to amount ordered (generally –20 cm H_2O), connect suction tubing to wall suction source. Increase the suction until the float appears in the window of the CDU.
- If ordered to decrease suction, turn the dial down and depress the high-negativity vent. Assess for a rise in the water level of the water-seal chamber.

TABLE 28.6 Chest Tubes and Chest Tube Drainage Units—cont'd

Chest Tube Complications

1. Tidaling
   - In the spontaneously breathing patient, if fluid does not rise with inspiration or fall with expiration, the drainage system may be blocked, the lungs have re-expanded, or the system is attached to suction.
   - If the chest tube is connected to suction, disconnect momentarily from wall suction to check for tidaling.
2. Bubbling
   - If bubbling increases, there may be an air leak in the drainage system or a leak from the patient.
   - Suspect a system leak when bubbling is continuous.
   - Retape tubing connections
   - Ensure chest tube dressing is air occlusive
   - If leak persists, briefly clamp the chest tube at the patient's chest. If the leak stops, the air is coming from the patient.
   - If the air leak persists, briefly and methodically move the clamps down the tubing away from the patient until the air leak stops. The leak will then be present between the last 2 clamp points. If the air leak persists all the way to the drainage unit, replace the unit.
3. Drainage System Overturned
   - If the drainage system is overturned and the water seal is disrupted, return it to an upright position and encourage the patient to take a few deep breaths.
4. Inadvertent Disconnection from Patient
   - If the drainage system breaks, place the distal end of the chest tubing (patient-side) in a container of sterile water as an emergency water seal.

CHECK YOUR PRACTICE

You are caring for a 37-year-old male patient who has chest injuries from a motorcycle accident. He has 2 chest tubes in place that are each attached to a chest drainage system. While assisting him to turn in bed, you accidentally disconnect 1 of the chest tubes from the drainage system.

- What is your most immediate priority?

Chest Tube Removal

Chest tubes are removed when the lungs are re-expanded, and fluid drainage has ceased or is minimal. Sometimes, we discontinue the suction and allow the chest tube to drain by gravity for 24 hours before removing the tube.

Give pain medication about 30 to 60 minutes before chest tube removal. Gather dressing supplies, including petroleum gauze and dry gauze dressing. Explain the procedure to the patient. In most settings, the HCP or an advanced practice nurse removes the tube. They cut the suture holding the chest tube in place. With the patient holding their breath or bearing down (Valsalva maneuver), the tube is removed. The site is immediately covered with the airtight, occlusive dressing to prevent air from entering the pleural space. A dry gauze dressing is placed over top. The pleura will seal off, and the wound usually heals in a few days. A chest x-ray is done 30 to 60 minutes after chest tube removal to check for pneumothorax or fluid accumulation.

Observe the wound for drainage and reinforce the dressing if needed. Monitor and record vital signs. Assess the patient for respiratory distress. This may signify a recurrence of the original problem. If respiratory distress occurs, notify the HCP at once.

Chest Surgery

Chest surgery is done for various reasons, including lung, heart, vascular, and esophageal problems. The most common chest surgeries are described in Table 28.7.

Thoracotomy

A **thoracotomy** is a surgical incision into the chest to gain access to the heart, lungs, esophagus, thoracic aorta, or anterior spine. Two common approaches to a thoracotomy are the median sternotomy and lateral thoracotomy.

The median sternotomy involves splitting the sternum. It is mainly used for surgery involving the heart. A lateral thoracotomy can be done using a posterolateral or anterolateral incision. A *posterolateral incision* is used for most surgeries involving the lung. The incision is made from front to back at the level of the 4th, 5th, or 6th intercostal space. Strong mechanical retractors are used to separate the ribs and gain access to the lung. An *anterolateral incision* is made in the 4th or 5th intercostal space from the sternal border to the midaxillary line. This procedure is often done for surgery or trauma victims, mediastinal operations, and wedge resections of the upper and middle lobes of the lung.

Video-Assisted Thoracic Surgery

Video-assisted thoracoscopic surgery (VATS) is a widely used, minimally invasive surgical approach for thoracic procedures. It provides a real-time 2-dimensional video image of the inside of the chest cavity. VATS is used for diagnosis and treatment of pleural disease, masses and nodules, and interstitial lung disease. Through incisions just large enough to insert the instruments, the HCP can inspect the chest cavity, biopsy suspicious areas, obtain fluid samples for analysis, and remove tissue.

VATS is increasingly being used for patients with chest trauma. The HCP can examine, diagnose, and manage injuries in both blunt and penetrating trauma, including injuries to the diaphragm. A chest tube is placed in the pleural space through 1 or more of the incisions at the end of the procedure, secured with sutures, and connected to a drainage unit in the usual manner.

The advantages of VATS include less pain, faster return to normal activity, reduced length of hospital stay, lower postoperative morbidity, and fewer complications. Patients who have low respiratory reserve or are too debilitated to tolerate an open thoracotomy approach may benefit from the VATS procedure.

❖ NURSING MANAGEMENT: CHEST SURGERY

◆ Preoperative Care

Assess cardiopulmonary status to determine their ability to tolerate the surgery and provide a baseline reference for

TABLE 28.7 Chest Surgeries

Type	Description	Indications
Decortication		
Removal or stripping of thick, fibrous membrane from visceral pleura Allows for improved lung expansion	Need chest tubes postoperatively	Empyema or other inflammatory process unresponsive to conservative management
Exploratory Thoracotomy		
Incision into thoracic cavity to look for injured or bleeding tissues	Need chest tubes postoperatively	Chest trauma
Lobectomy		
Removal of 1 lobe of lung	Lung tissue expands to fill up space left by resected lobe Need chest tubes postoperatively	Lung cancer, bronchiectasis, TB, advanced emphysema, benign lung tumors, fungal infections
Lung Volume Reduction Surgery		
Bronchoscopy procedure	Used to place one-way valves in airways leading to the diseased parts of the lung Valves let air out, but not in, thus collapsing a certain segment of lungs	Advanced emphysema, α_1-antitrypsin emphysema
Open surgical procedure	Involves reducing lung volume by multiple wedge excisions or VATS Removes most diseased lung tissue	Emphysema, lung cancer
Pneumonectomy		
Removal of entire lung	When lobectomy or segmental resection will not remove all diseased lung Fluid will gradually fill space where lung was removed May have chest tube postoperatively Position patient on operative side to promote expansion of remaining lung	Lung cancer (most common)
Segmental Resection		
Removal of 1 or more lung segments	Indicated for a patient unable to handle more extensive surgery Remaining lung tissue expands to fill space Need chest tubes postoperatively	Lung cancer, bronchiectasis
Thoracotomy (Not Involving Lungs)		
Incision into thorax for surgery on other organs	Postoperative care related to thoracotomy and reason for surgical procedure Need chest tubes after surgery	Hiatal hernia repair, open heart surgery, esophageal surgery, tracheal resection, thoracic aorta repair
Video-Assisted Thoracic Surgery (VATS)		
Video-assisted technique with a rigid scope with a distal lens inserted into pleura and image shown on a monitor screen	Allows HCP to manipulate instruments passed into pleural space through separate small intercostal incisions Done under general anesthesia in operating room May need chest tube after surgery	Lung biopsy, lobectomy, resection of nodules, fistula repair
Wedge Resection		
Removal of small, localized lesion that occupies only part of a lung segment	Most conservative approach Done to remove small peripheral nodules or for patients unable to handle more extensive surgery Need chest tubes after surgery	Lung biopsy, excision of small nodules

postoperative care. Preoperative evaluation may include chest x-ray, electrocardiogram (ECG), ABGs, pulmonary function studies, CT or MRI. Laboratory studies may include CBC, blood glucose, serum electrolytes, blood urea nitrogen (BUN), serum creatinine, prothrombin time/international normalized ratio (PT/INR), and activated partial thromboplastin time (aPTT).

The patient should be in the best possible health and, if applicable, stop smoking before elective surgery. Anxiety associated with anticipated surgery makes smoking cessation difficult. Provide encouragement, support, and teaching about ways to help stop smoking before surgery (see Chapter 11).

Teach the patient what to expect after surgery. Include the use of O_2, IV fluids, the chance of intubation, blood administration, and the purpose and function of chest tubes. Reassure the patient that they will receive adequate analgesia to reduce pain. Explain how to use patient-controlled analgesia (PCA), if planned.

Preoperative teaching should always include exercises for effective deep breathing and incentive spirometry use. If the patient practices these techniques before surgery, they will be easier to perform after surgery. Teach the patient how to splint

the incision with a pillow to promote deep breathing. Have them teach-back ROM exercises on the affected surgical side.

The thought of losing part of a vital organ is often frightening. Reassure the patient that the lungs have a large degree of functional reserve. Even after the removal of 1 lung, there is enough lung tissue left to maintain adequate oxygenation. Answer the patient and caregiver's questions openly and honestly.

◆ Postoperative Care

The thoracotomy incision is the most painful surgical incision for patients and a difficult one for nurses to manage. Pain after a thoracotomy is typically intense because respiratory muscles are cut during surgery. For most chest surgeries, chest tubes are placed in the pleural space to allow for lung re-expansion. In a pneumonectomy, chest tubes may be placed in the space where the lung was removed.

Pain management is a priority to prevent respiratory compromise. A multimodal management approach is best after thoracic surgery. This may include the use of oral, subcutaneous, and/or IV opioids, PCA, epidural infusions, and/or intercostal nerve blocks. Effective pain management allows patients to breathe deeply, cough, move the arm and shoulder on the operative side, and mobilize.

Nursing care priorities include assessing respiratory function, including observing respiratory rate and effort, breath sounds, and sputum volume and color. Monitor chest tube function. Note amount and type of drainage. Daily chest x-rays are often done. Assess pain, monitor temperature, and observe the surgical site as you would for other postoperative patients (see Chapter 20). Care after thoracotomy is described in eNursing Care Plan 27.1 (available on the website for this chapter).

NONINVASIVE VENTILATION

Noninvasive ventilation (NIV) uses a mask instead of an ET tube to help oxygenate and ventilate a patient. The mask can be nasal or full face. NIV is ideal for those who need a higher level of ventilatory support, but their condition is not bad enough to need mechanical ventilation. Good candidates for using NIV are patients with COPD exacerbations and heart failure (HF).[9] The patient with an acute myocardial infarction or gastrointestinal (GI) bleed is not a candidate for NIV. Two common modes are continuous positive airway pressure (CPAP) and bi-level positive airway pressure (Bi-PAP).

Continuous Positive Airway Pressure

Continuous positive airway pressure (CPAP) helps restore functional residual capacity (FRC). It provides 1 level of pressure. That pressure is delivered continuously during both inspiration and expiration. CPAP is a common treatment for obstructive sleep apnea.

CPAP is delivered through a tight-fitting face mask, nasal mask, or nasal pillows. It increases WOB because the patient must forcibly exhale against the CPAP. Therefore, it is used with caution in patients with heart problems. Monitor the patient closely. Report any decline in their condition to the HCP at once.

Fig. 28.7 Bi-PAP delivered through a face mask. (Courtesy Respironics Inc., Murrysville, PA.)

Bilevel Positive Airway Pressure

Bilevel positive airway pressure (Bi-PAP) provides 2 levels of positive pressure support: inspiratory positive airway pressure (IPAP) and expiratory positive airway pressure (EPAP) (Fig. 28.7). IPAP is a higher level of pressure than EPAP. It helps with CO_2 removal. EPAP is a lower level of pressure. It helps keep the alveoli open at end expiration, assisting with oxygenation.

The patient must be awake, alert, able to breathe spontaneously, and tolerate the face piece. Bi-PAP is used for COPD patients with acute conditions (e.g., pneumonia) or exacerbation of chronic conditions (e.g., HF, acute respiratory failure [ARF]). Its use after extubation from mechanical ventilation can help prevent reintubation. Patients with shock, altered mental status, or increased airway secretions cannot use Bi-PAP because of the risk for aspiration and the inability to remove the mask.

❖ NURSING MANAGEMENT: NONINVASIVE VENTILATION

Patients with NIV need constant assessment. Assess level of consciousness (LOC), hemodynamic stability, and WOB. Patients who develop a decreased LOC may not be able to maintain a patent airway because they cannot protect their airway or clear secretions. In this situation, they may need intubation and mechanical ventilation. Any degree of hemodynamic instability (e.g., tachycardia, hypotension) warrants immediate re-evaluation of NIV.

Provide mouth, nare, and eye care. Provide measures to protect the skin from breakdown and ulceration. Any degree of redness constitutes a Stage I pressure injury. Attempts to alleviate pressure from the tightfitting mask, including alternating the length of time the mask is on, is important. Using masks of different sizes and styles can help. Collaborate with the RT.

The patient must be able to remove the mask independently due to the risk of vomiting. Elevate the head of the bed 30 to 45 degrees.

MECHANICAL VENTILATION

Mechanical ventilation is the process by which a ventilator is used to deliver O_2 to the lungs. It is a means of supporting patients until they recover the ability to breathe independently. It can serve as a bridge to long-term mechanical ventilation or until a decision is made to stop ventilatory support. Mechanical ventilation is not curative.

Indications for mechanical ventilation include (1) ARF, (2) apnea, (3) inability to breathe or protect the airway, (3) acute respiratory distress, (4) severe hypoxemia and/or hypercarbia, and (5) respiratory muscle fatigue.[10] Other patients who receive mechanical ventilation include those with hemorrhage, trauma, neuromuscular problems, drug overdose, burns, and shock.

Patients with chronic lung disease and their caregivers should discuss mechanical ventilation before a health crisis occurs. Encourage all patients, especially those with chronic illnesses, to discuss the subject of life-sustaining measures, including mechanical ventilation, with their families and HCPs. The patient's wishes about end-of-life treatment should be recorded in an advance directive.

The decision to use, withhold, or stop mechanical ventilation must be made carefully. We must respect the wishes of the patient. When the health care team, patient, and/or caregiver disagree over the treatment that the patient wishes, conferences are essential to keep the lines of communication open and discuss options. Sometimes, you may need to consult the agency's ethics committee for assistance.

Types of Ventilators

Negative Pressure Ventilation

Negative pressure ventilation involves the use of chambers that encase the chest or body and surround it with intermittent subatmospheric (or negative) pressure. It is a form of NIV, as it does not require an artificial invasive airway.

The "iron lung" was the first form of negative pressure ventilation. It was developed in the 1950s during the polio epidemic. Intermittent negative pressure around the chest pulls the chest wall outwards, reducing intrathoracic pressure. Air rushes into the upper airway, which is outside the sealed chamber. Expiration is passive. The machine cycles off, allowing chest retraction. This type of ventilation is like normal ventilation in that decreased intrathoracic pressures produce inspiration, and expiration is passive.

A few portable negative pressure ventilators are available for home use. They are mainly for patients with chronic neuromuscular diseases and central nervous system problems. Some of these patients will have used negative pressure ventilators for years. They are rarely used for acutely ill patients.

Positive Pressure Ventilation

Positive pressure ventilation (PPV) is the main method of mechanical ventilation used with acutely ill patients (Fig. 28.8). During inspiration, the ventilator pushes air into the lungs under positive pressure. Unlike spontaneous ventilation, intrathoracic pressure is increased during lung inflation, not decreased. Expiration is passive, as occurs in normal expiration. Ventilators can deliver positive pressure breaths to the patient by either volume or pressure ventilation.

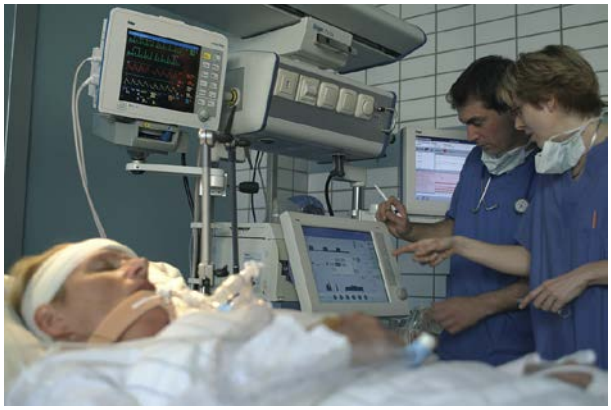

Fig. 28.8 Patient receiving mechanical ventilation. (Courtesy Draeger Medical, Houston, TX.)

Volume ventilation. With **volume ventilation**, a predetermined tidal volume (V_T) is delivered with each inspiration.[11] The amount of pressure needed to deliver the breath varies based on the compliance and resistance of the lungs. The V_T is consistent from breath to breath, but the airway pressures needed to deliver the V_T will vary.

Pressure ventilation. With pressure ventilation, the peak inspiratory pressure (PIP) is predetermined.[11] The VT delivered to the patient will vary, based on the pressure selected and compliance and resistance factors of the lungs. Careful attention must be given to monitoring the exhaled V_T to prevent hypoventilation and hypoxemia.

Endotracheal Intubation Procedure

Intubation is the process of securing the airway with an oral or nasal ET tube, providing an effective route for ventilation. Unless ET intubation is emergent, consent for the procedure is obtained. Tell the patient and caregiver the reason for ET intubation and steps in the procedure. Explain that the patient will not be able to speak while intubated, but that you will provide other means of communication. Tell them that the patient's hands may have removable mitts or wrists may have soft restraints applied to remind them not to touch the ET tube.

Have a self-inflating BVM attached to O_2 and suctioning equipment ready at the bedside. The BVM has a reservoir that is filled with O_2 so that it delivers concentrations of up to 100%. A patent IV is needed to give pre-intubation drugs. Assemble and check the equipment. Remove any dentures or partial plates (for oral intubation) and give drugs as ordered. Premedication varies depending on the patient's LOC (e.g., awake, obtunded), urgency (e.g., emergent, nonemergent), and the HCP's preferences.

For oral intubation, place the patient supine with the head slightly extended and the neck flexed ("sniff position"). This position allows the HCP to see the vocal cords more easily. For nasal intubation, spray the nasal passages with a local anesthetic and vasoconstrictor (e.g., lidocaine with epinephrine) to reduce trauma and bleeding. Before starting intubation, preoxygenate

the patient using the BVM and 100% O_2 for at least 2 minutes. Each intubation attempt is limited to less than 30 seconds. Ventilate the patient between successive attempts using the BVM and 100% O_2.

Rapid sequence induction (RSI) is the rapid, concurrent administration of both a sedative and a paralytic drug during emergency airway management to induce unconsciousness for intubation. It decreases the risks for aspiration and injury. RSI is not indicated in patients who are in cardiac arrest or have a known difficult airway. The patient receives a sedative-hypnotic-amnesic (e.g., propofol, etomidate) to induce unconsciousness and a rapid-onset opioid (e.g., fentanyl) to blunt the pain of the procedure. This is followed with a drug (e.g., rocuronium) to produce skeletal muscle paralysis.

During intubation, monitor vital signs, including heart rate and rhythm, signs of visible chest movement, BP, and mean arterial pressure (MAP). Monitor O_2 status with pulse oximetry. Immediately inform the team if the SpO_2 is less than 92%. Monitor the patient's tolerance to the procedure. Follow agency policy about RSI drug administration.

Immediately after intubation, inflate the cuff on the ET tube. Help confirm placement of the ET tube while continuing to manually ventilate the patient using the BVM with 100% O_2. Auscultate the lungs for bilateral breath sounds and the epigastrium for the absence of air sounds. Observe for symmetric chest wall movement. SpO_2 should be stable or improve.

Use an $EtCO_2$ detector to help confirm placement by noting the presence of exhaled CO_2 from the lungs. A portable $EtCO_2$ monitor can help confirm correct placement of the tube (Fig. 28.9). A steadily rising CO_2 value and the presence of a waveform confirms correct placement. Or place a colorimetric CO_2 detector between the BVM and ET tube and look for a color change (indicating the presence of CO_2) or a number. At least 5 or 6 exhalations with a consistent CO_2 level must occur to confirm tube placement in the trachea.

If the findings support ET tube placement, help secure the ET per agency policy. Connect the ET tube to a ventilator and closed suctioning system (Fig. 28.10). Assess the need to suction the ET tube and pharynx. Insert a bite block, if needed. Secure it separately from the ET tube to the patient's face. This will help prevent the patient from biting the ET and preventing O_2 delivery.

Obtain a chest x-ray to confirm tube location (2 to 3 cm above the carina in the adult). This position allows the patient to move the neck without moving the tube or causing it to enter the right mainstem bronchus. Once positioning is confirmed with x-ray, record and mark the position of the oral ET tube at the lip or teeth. For a nasotracheal tube, mark the exit of the tube at the nare.

Obtain ABGs 15 to 30 minutes after intubation to determine baseline oxygenation and ventilation status. ABG values assess oxygenation and ventilation and assist in our determining changes to ventilator settings. Continuous pulse oximetry gives data about arterial oxygenation. $EtCO_2$ monitoring provides data about ventilation.

There are risks with oral ET intubation. It is hard to place the tube with limited head and neck mobility (e.g., spinal cord injury). Teeth can be chipped or accidentally removed during the procedure. Patients can obstruct the ET tube by biting down on the tube. Salivation increases, and swallowing is difficult. Sedation, along with a bite block or oropharyngeal airway, can help prevent obstruction. Mouth care is a challenge because of limited space in the oral cavity.

Ventilator Settings

Ventilator settings include the respiratory rate, V_T, O_2 concentration (FIO_2), positive end expiratory pressure (PEEP), inspiratory:expiratory ratio, and sensitivity (Table 28.8). Settings are based on the patient's condition, LOC, respiratory muscle strength, chest x-ray, and ABGs. Manipulating ventilator settings (Fig. 28.11) can help correct hypoxemia and hypercarbia. As the patient's condition improves, we can adjust the settings to allow them to take more control over their own WOB. Know your responsibility regarding changing ventilator settings. In most settings, this task is the responsibility of the HCP or RT. Always assess the patient's response to any setting changes.

Fig. 28.9 End-tidal CO_2 detector. Used to help confirm placement of an endotracheal tube post-intubation. (From Thomsen TW, Setnik GS: Orotracheal intubation, *Procedures Consult,* 2017.)

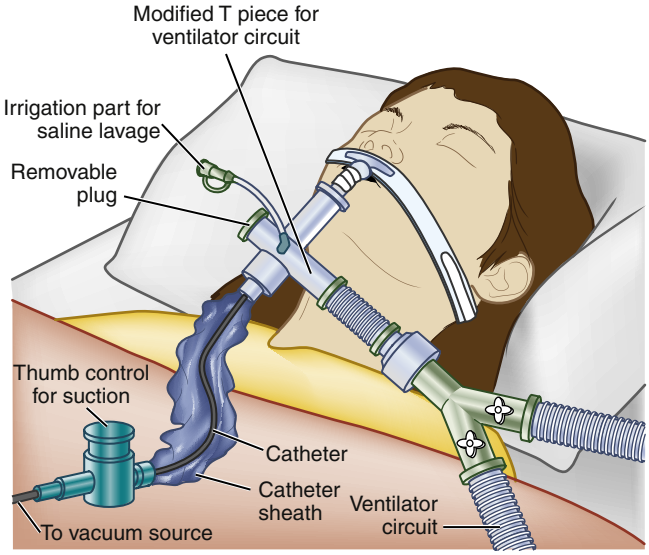

Fig. 28.10 Oral ET tube connected to ventilator circuit and closed tracheal suction system.

TABLE 28.8 Adjustable Ventilator Settings

Parameter	Mode	Description
Respiratory rate	Full support	Number of breaths the ventilator delivers per minute. *Example:* 12–20 breaths/min
Tidal volume (V_T)	Full support	Volume of gas delivered to patient during each ventilator breath. *Example:* 4–8 mL/kg
O_2 concentration (FIO_2)	All modes	Fraction of inspired O_2 (FIO_2) delivered to patient. May be set between 30% and 100%. You would never intubate a patient and place on room air (21%). *Usually adjusted* to maintain PaO_2 level >60 mm Hg or SpO_2 level >92%
Positive end-expiratory pressure (PEEP)	All modes	Positive pressure applied at the end of expiration of ventilator breaths. *Example:* 5 cm H_2O
Pressure support	Spontaneous Breathing Mode	Positive pressure used to augment patient's inspiratory pressure during spontaneous breathing. *Usual setting:* 5–10 cm H_2O
I/E ratio		Duration of inspiration (I) to duration of expiration (E). *Example:* 1:2 (exhalation is twice as long as inspiration)
Inspiratory flow rate and time	Full, partial support	Speed with which the V_T is delivered. *Example:* 40–80 L/min and time is 0.8–1.2 s
Sensitivity	Full, partial support	Determines the amount of effort the patient must generate to initiate a breath from the ventilator. The "trigger" to initiate the breath can be set on the ventilator for either pressure or flow triggering. *Example:* A pressure trigger is set 0.5–1.5 cm H_2O below baseline pressure; a flow trigger is set 1–3 L/min below baseline flow
Peak inspiratory pressure (PIP)	Full support	The maximal pressure the ventilator can generate to deliver the V_T. When the PIP limit is reached, the ventilator ends the breath and spills the undelivered volume into the atmosphere. *Example:* 30 cm H_2O

Positive End-Expiratory Pressure

Positive end-expiratory pressure (PEEP) is a ventilator setting in which positive pressure is applied to the airway during exhalation.[12] During exhalation, airway pressure normally drops to near 0. Exhalation occurs passively. With PEEP, exhalation remains passive, but pressure falls to the preset PEEP level, often set between 5 to 10 cm H_2O. PEEP increases FRC and often improves oxygenation by restoring the lung volume that normally remains at the end of passive exhalation. The mechanisms by which PEEP increases FRC and oxygenation include splinting open of previously collapsed alveoli (increasing the opportunity for O_2 and CO_2 to diffuse across the alveolar capillary membrane) and preventing alveolar collapse throughout the respiratory cycle.

Fig. 28.11 Ventilator control panel. (From Roberts JR: *Roberts and Hedges' clinical procedures in emergency medicine and acute care*, ed 7, St Louis, 2019, Elsevier.)

PEEP is indicated in all patients who are mechanically ventilated. An intubated patient would never be placed on zero PEEP. PEEP is titrated to the point that oxygenation improves without compromising hemodynamics. We call this *optimal PEEP.* Often 5 cm H_2O PEEP (referred to as *physiologic PEEP*) is used to replace the glottic mechanism, which is bypassed when the patient has an oral ET tube.[12] We can often reduce FIO_2 when PEEP is used.

The classic indication for PEEP therapy is ARDS. PEEP is used with caution in patients with traumatic brain injury, increased ICP, low CO, and hypovolemia. In these cases, the adverse effects of high PEEP may outweigh the benefits. During weaning PEEP improves gas exchange, vital capacity, and inspiratory force.

Modes of Volume Ventilation

The way by which the ventilator delivers effective ventilation is called the *ventilator mode.* The selected ventilator mode is based on how much WOB the patient can perform. WOB is the inspiratory effort needed to overcome the elasticity and viscosity of the lungs along with the airway resistance. The ventilator mode is mainly determined by the patient's LOC, respiratory drive, WOB, and ABGs.

Modes of mechanical ventilation can be complex. This is because there are many different manufacturers of ventilators. Similarly, terminology among manufacturers differs as many companies trademark a mode of ventilation with a particular name. To begin to understand mechanical ventilation, focus on 2 key components: (1) how much work the ventilator is doing

for the patient (full or partial support or spontaneous breathing) and (2) how the breath is being delivered to the patient (volume or pressure).

In *full support* mechanical ventilation, the ventilator does most of the WOB for the patient. There is often a set respiratory rate, set V_T, and PIP limit. In a *partial support* mode, there is shared responsibility between the patient and ventilator. There may be a set respiratory rate or V_T, but the patient assumes more responsibility for breathing. In a *spontaneous mode* of mechanical ventilation, the patient is intubated or has a tracheostomy. The patient assumes responsibility for almost all breathing. Spontaneous modes are often used just before the patient is extubated from the ventilator.

Let us look at the 5 most common modes of mechanical ventilation in North America. These modes include (1) assist control, (2) pressure control, (3) synchronous intermittent mandatory ventilation, (4) pressure support, and (5) CPAP (Table 28.9).

TABLE 28.9 Modes of Mechanical Ventilation

Mode of Ventilation	Ventilator Settings	Nursing Implications
Full Support		
Assist-control (AC)	• Set respiratory rate, V_T, inspiratory time, and PEEP • Ventilator delivers a pre-set number of breaths with designated V_T • If the patient initiates a spontaneous breath, a full breath with designated V_T is delivered	• V_T is consistent; trend pressure (PIP) • Hyperventilation can occur if patient increases respiratory rate above set rate • To limit spontaneous breaths, sedation may be needed • Example: New surgical patients
Pressure-control (PC)	• Set respiratory rate, peak inspiratory pressure (PIP), inspiratory time, and PEEP • Ventilator delivers a pre-set number of breaths up to a specific PIP (set by HCP) • If the patient initiates a spontaneous breath, a full breath delivered up to the set PIP is delivered	• PIP is never exceeded; trend V_T as will be variable • To limit spontaneous breaths, sedation may be needed • Example: ARDS (decreased compliance, increased resistance)
Pressure regulated volume control (PRVC)	• Set respiratory rate, V_T, PIP, PEEP, and sensitivity • Ventilator attempts to deliver the desired V_T with the least amount of PIP • Ventilator software analyzes resistance and compliance of each breath and continuously makes adjustment	• Trend V_T and PIP • Monitor for increased WOB
Partial Support Modes		
Synchronized intermittent mandatory ventilation (SIMV)	• Set respiratory rate and V_T for all ventilator-delivered breaths (can also be set up with a PIP, but V_T more common) • Inspiratory time, sensitivity, and PEEP also set • Ventilator delivers the pre-set number of breaths with designated V_T in "synchrony" with the patient's own inspirations • Between "ventilator-delivered breaths," patient breathes at their own rate and V_T	• Muscle fatigue may occur due to ↑ WOB
Spontaneous Modes		
Pressure support ventilation (PSV)	• Set inspiratory pressure level, PEEP, and sensitivity • When the patient initiates a breath, a high flow of gas is delivered to the preselected pressure level, and pressure is maintained throughout inspiration • Patient determines V_T, respiratory rate, and inspiratory time • Provides an augmented inspiration to a spontaneously breathing patient	• Patient must be awake and alert and be able to initiate a breath • Observe respiratory rate and V_T • Reduces WOB • Increased ventilator synchrony • Monitor for increased WOB • Monitor for apnea
Proportional assist ventilation (PAV)	• Will increase or decrease airway pressure in response to the patient's own respiratory effort • Provides a level of support at a percentage of patient effort (e.g., 80%); if patient working hard to initiate a breath, ventilator offers more support • Patient determines own inspiratory volume and inspiratory flow rate	• Monitor WOB • PAV is of no use in the patient who is not spontaneously breathing (will give no support)
Continuous positive airway pressure (CPAP)	• One set level of pressure (on inspiration and expiration), PEEP • Patient is spontaneously breathing through the ventilator circuit • There is no set respiratory rate, V_T, or inspiratory time	• Patient must be awake and alert and breathing spontaneously • Observe respiratory rate and V_T • Monitor for increased WOB • Monitor for apnea
Other		
Airway pressure release ventilation (APRV)	• Can be used as a full support or spontaneous mode of ventilation • Set pressure (P-high, P-low) and time (T-high, t-low) • Most of ventilator-delivered breath is spent at P-high and T-high (V_T is not a set variable) • Quick timed release (P-low, T-low) allows for CO_2 elimination • Permits spontaneous breathing at P-high, T-high	• Trend ABGs and acid-base balance • APRV increases venous return to the heart • Hemodynamics improvement may occur

Full support modes

Assist control. In **assist-control (AC) ventilation (or volume control)**, the ventilator delivers a preset V_T at a preset respiratory rate.[12] When the patient initiates a spontaneous breath, the ventilator senses a change in the airflow in the ventilator circuit and then delivers the preset V_T. The patient's respiratory rate on AC ventilation will never be below the set respiratory rate. On AC ventilation, the patient can take a breath whenever they want. If the patient breathes over and above the set respiratory rate, the ventilator will deliver the additional breath with the designated V_T.

AC ventilation is the most common mode of full support mechanical ventilation when the patient is first intubated. It is used in patients with a variety of problems. This includes new postoperative patients and those with neuromuscular disorders and ARF.

With AC, the potential for hyperventilation exists. For example, a patient waking up after anesthesia may begin to take more spontaneous breaths above the set respiratory rate. As a result, the patient will receive all additional breaths with the full V_T. This can easily lead to respiratory alkalosis.

Pressure control. **Pressure-control (PC)** ventilation provides the patient with a pressure-limited breath.[11] In other words, besides a set respiratory rate, there is a set PIP. When the patient initiates the breath, the ventilator will deliver a volume of gas up to the PIP limit. In PC mode, the PIP limit will never be exceeded but there is no set V_T.

Like AC, PC ventilation permits the patient to take a breath over and above the set rate anytime they like. When the patient takes a breath above the set rate, the ventilator will deliver the breath based on the current ventilator settings.

PC ventilation is good for patients with decreased compliance and increased resistance ("stiff lungs"). This allows us to have control over the amount of pressure going into the patient, thereby decreasing risk of volutrauma and barotrauma.

Partial support modes

Synchronized intermittent mandatory ventilation. In **synchronized intermittent mandatory ventilation (SIMV)**, both the patient and the ventilator do the WOB. The ventilator delivers a preset V_T at a preset respiratory rate, in synchrony with the patient's spontaneous breathing.[11] In between the ventilator-delivered breaths, the patient can breathe spontaneously and achieve whatever V_T they can achieve. In other words, the patient receives the designated V_T for the machine delivered breaths, but during the spontaneous breaths, the patient can breathe at whatever respiratory rate they wish. Their V_T is variable.

SIMV is used when the patient's condition is too good for a full support mode of mechanical ventilation, but they are not yet ready for a spontaneous mode. Sometimes, we combine SIMV with pressure support. Benefits of SIMV include improved patient-ventilator synchrony, lower mean airway pressures, and prevention of respiratory muscle atrophy as the patient takes on more responsibility for the WOB.

Spontaneous breathing modes

Pressure support. With **pressure support ventilation (PSV)**, positive pressure is applied to the airway only during inspiration. The patient must be able to initiate a breath in this mode. The level of positive airway pressure is preset so that the inspiratory flow rate of the gas is greater than the patient's inspiratory flow rate. As the patient starts a breath, the ventilator senses the spontaneous respiratory effort and supplies a rapid flow of gas at the initiation of the breath and then a tapering flow towards the end of inhalation.[11] With PSV, the patient determines their own inspiratory length, V_T, and respiratory rate.

PSV is the most common mode of spontaneous mechanical ventilation in North America. Its purpose is to help facilitate weaning. It may be combined with SIMV during weaning when patients have a less than stable respiratory drive. PSV is not used during ARF because of the risk for hypoventilation and apnea. Advantages include increased patient comfort, decreased WOB (because inspiratory efforts are augmented), decreased O_2 consumption (because inspiratory work is reduced), and increased endurance conditioning (because the patient is exercising respiratory muscles).

Continuous positive airway pressure. CPAP refers to a mode of spontaneous ventilation where the ventilated patient controls almost all aspects of the breath.[11] Do not confuse this with noninvasive CPAP that is used for sleep apnea. With this CPAP, all that is set is the FIO_2 and PEEP. There is one level of pressure on both inspiration and expiration. There is no set respiratory rate, no set V_T, and no set PIP. The patient determines their respiratory rate and V_T.

CPAP is used to assess the patient's respiratory rate and rhythm, WOB, and hemodynamic status after a period of intubation. In most circumstances, this mode will be used for a short period of time, around 30 to 120 minutes. If the patient is stable, respiratory assessment parameters stay with normal limits, and there is no increased WOB or desaturation, the patient is often extubated.

Newer Modes of Mechanical Ventilation

Advances in technology have led to the development of many other modes of mechanical ventilation. These include (1) pressure-regulated volume control (PRVC), (2) airway pressure release ventilation (APRV), and (3) proportional assist ventilation (PAV; Table 28.9).

Pressure-regulated volume control. Pressure-regulated volume control (PRVC) is a full support mode of mechanical ventilation. It combines features of both volume and pressure delivery of the mechanical breath. In this mode, there is a set VT to be achieved and a PIP limit. The ventilator attempts to deliver the targeted VT with the least amount of pressure.11 The ventilator constantly analyzes, breath by breath, resistance and compliance of the lungs, the exhaled VT and PIP. It adjusts the delivery of each breath based on feedback received.

Airway pressure release ventilation. *Airway pressure release ventilation (APRV)* can be used in full support or spontaneous mode, depending on the patient. There are 2 levels of pressure in APRV: pressure-high (p-high) and pressure-low (p-low). There are also 2 time values: time-high (t-high) and time-low (t-low). For most of the ventilator breath (inhalation), the patient is at

p-high and t-high (e.g., pressure of 30 cm H_2O for around 6 to 8 seconds).[13] During exhalation, pressure drops to near zero (p-low) for a very short period (t-low, about 0.8 second) to promote CO_2 elimination.

APRV permits spontaneous breathing at any point during the inspiratory respiratory cycle (p-high, t-high). We adjust the pressure levels in APRV to meet oxygenation goals. The timed releases are increased or decreased to meet ventilation goals. V_T is not set. It varies depending on the pressure levels, lung compliance and resistance, and degree of spontaneous breathing effort.

APRV is best for patients who need high pressure levels to open collapsed alveoli. It allows for spontaneous respirations. This may reduce the need for deep sedation or paralysis.

Proportional assist ventilation. *Proportional assist ventilation (PAV)* is a partial support mode of mechanical ventilation. In this mode, the ventilator generates and adjusts inspiratory pressures in proportion to the patient's own respiratory efforts.[11] The patient determines their own inspiratory flow rate and volume. The support that the ventilator provides the patient is a proportion of the patient's effort (e.g., 80%). The ventilator continually monitors compliance and resistance and calculates the degree of support it needs to offer. The patient is an active participant in breathing while receiving PAV. Decreased WOB and less dyssynchrony occur.

❖ NURSING MANAGEMENT: MECHANICALLY VENTILATED PATIENT

Care of the mechanically ventilated patient requires an interprofessional approach (Table 28.10). Nurses and other team members must constantly synthesize large amounts of data about the patient's status, communicate even the smallest changes with one another, and collaborate on needed changes. This section reviews important aspects to be consider when caring for a patient who needs mechanical ventilation.

◆ Artificial Airway Management

Managing an artificial airway is often a shared responsibility between you and the RT. Agency policy dictates which providers perform which task. Nursing responsibilities include (1) maintaining correct tube placement, (2) maintaining proper cuff inflation, (3) maintaining tube patency, and (4) maintaining alarm systems.

◆ Maintaining Correct Tube Placement

Continuously monitor the patient with an ET tube for placement. Note the exit point from the mouth or nare. Assess the integrity of the tape or securement device. Observe for symmetric chest wall movement. Auscultate to confirm bilateral breath sounds.

If the tube moves or is dislodged, it could easily migrate upwards in the pharynx or enter the right or left mainstem bronchus (thus ventilating only 1 lung). This is an airway emergency. Stay with the patient and try to maintain the airway. Support ventilation with a BVM and 100% O_2. Call for the appropriate help to assess or reposition the tube. If a dislodged tube is not repositioned, minimal or no O_2 is delivered to the lungs, or the entire V_T is being delivered to 1 lung. This places the patient at risk for hypoxemia, pneumothorax, and respiratory and/or cardiac arrest.

TABLE 28.10 NURSING MANAGEMENT

Care for the Patient Requiring Mechanical Ventilation

- Monitor LOC, hemodynamic stability, patient-ventilator interaction, patient tolerance to ET or tracheostomy.
- Auscultate breath sounds and respiratory effort, assessing for decreased ventilation or adventitious sounds.
- Monitor ventilator settings and alarms.
- Monitor tube placement and cuff pressure.
- Determine need for ET tube suctioning and suction patients as needed.
- Give sedatives, analgesics, and NMBA drugs as ordered.
- Reposition and re-secure ET tube (per agency policy).
- Provide ordered VTE and GI prophylaxis.
- Develop plan for communication with the patient.
- Monitor oxygenation level and signs of respiratory fatigue during weaning.
- Teach patient and caregiver about mechanical ventilation and weaning.
- Supervise AP:
  - Obtain vital signs and report to RN.
  - Provide personal hygiene, skin care, and oral care.
  - Assist with frequent position changes, including early mobility,
  - Help to perform passive or active ROM exercises.

Collaborate With Respiratory Therapist
- Maintain ventilator system.
- Change ventilator settings as needed or ordered by HCP.
- Maintain correct cuff inflation on ET tube.
- Auscultate breath sounds and respiratory effort, assessing for decreased ventilation or adventitious sounds.
- Determine need for ET tube suctioning and suction patients as needed.
- Reposition and re-secure ET tube (based on agency policy).

Collaborate With Dietitian
- Assess and monitor nutrition status.
- Recommend EN formulas and optimal diet.

Collaborate With Physical and Occupational Therapist
- Perform ROM exercises.
- Assist with early and progressive ambulation.

Collaborate With Speech Language Therapist
- Perform swallowing studies.
- Assess cognitive function and assist with communication.
- Provide teaching for patient with a long-term tracheostomy.

Collaborate With Social Worker
- Work with the patient and caregiver to identify care needs.
- Help the patient with transitions through the health care system.

! SAFETY ALERT

Endotracheal Tube Placement

- Maintain proper ET tube position by recording and marking the position of the tube at the lip or teeth (e.g., 21 cm at the teeth; 23 cm at the lips).
- Assess ET tube position at least once per shift and with changes in patient position, early mobility, and before and after patient transport.

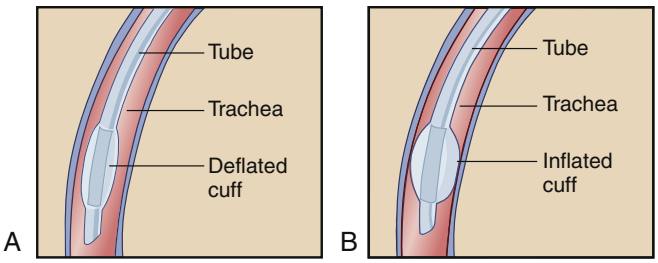

Fig. 28.12 Endotracheal tube cuff. (A) Tube in place with cuff deflated. (B) Tube in place with cuff inflated.

Maintaining Proper Cuff Inflation

The cuff is an inflatable, pliable, plastic sleeve encircling the lower, outer wall of the ET tube (Fig. 28.12). The cuff stabilizes and "seals" the ET tube within the trachea, prevents escape of ventilating gases. It also helps maintain correct tube position and "seals off" the lower airways, thus protecting against aspiration.

Excess volume in the cuff can damage the tracheal mucosa. To prevent this, inflate the cuff with air and measure and monitor the cuff pressure. To ensure adequate tracheal perfusion, maintain cuff pressure at 20 to 30 cm H_2O.[14] Measure and record cuff pressure after intubation and on a routine basis (e.g., every 8 hours) using the *minimal occluding volume* (MOV) *technique.* To perform the MOV technique in the mechanically ventilated patient, place a stethoscope over the trachea and inflate the cuff to MOV by adding air until you hear no air at PIP (end of ventilator inspiration). For the spontaneously breathing intubated patient, you inflate until you hear no sound after a deep breath or after inhalation with a BVM. Second, use a manometer to confirm that cuff pressure is between 20 and 30 cm H_2O. Record cuff pressure in the chart. If adequate cuff pressure cannot be maintained or larger volumes of air are needed to keep the cuff inflated, there could be a leak in the cuff or tracheal dilation at the cuff site. In these situations, notify the HCP.

Maintaining Tube Patency

Suctioning is needed to clear secretions and to maintain airway patency Indications for suctioning include (1) visible secretions in the ET tube, (2) increase in respiratory rate or frequent coughing, (3) sudden decrease in SpO_2, (4) suspected aspiration of secretions. Other signs that indicate the patient needs suctioning include an increase in peak airway pressure and auscultating adventitious breath sounds over the trachea or bronchi.

Assess the need for suctioning hourly. Indications include visible coughing, coarse crackles or wheezes over large airways, moist cough, increase in PIP, and restlessness or agitation. Neurologic patients may not show any signs of the need to be suctioned, so suctioning once per shift (at minimum) is recommended. Do not suction routinely. Suction the patient when needed. Note the color, character, consistency, and amount of sputum suctioned.

Two common ways we suction are the *closed-suction technique* (CST) and the *open-suction technique* (OST). The CST uses a suction catheter that is enclosed in a plastic sleeve connected directly to the patient-ventilator circuit (Fig. 28.10). With CST, exposure to the patient's secretions and infection is reduced for the patient and HCP's safety. The CST is the way we suction most intubated patients (Table 28.11).[15]

TABLE 28.11 Closed Suctioning Technique

The suction technique described here is appropriate for those patients with an oral ET tube or tracheostomy, who are receiving invasive mechanical ventilation. Maintaining a closed circuit at all times is best to reduce the risk for infection and for staff safety.

Before You Begin

1. Gather all equipment.
2. Wash hands and don personal protective equipment and gloves.
3. Explain procedure and patient's role in assisting with secretion removal by coughing.
4. Monitor neurologic and cardiopulmonary status (e.g., LOC, vital signs, ECG, SpO_2) before, during, and after suctioning.
5. Check suction source and regulator. Adjust suction pressure to no greater than 120 mm Hg pressure with tubing occluded.
6. Press [Silence] on the ventilator (to pause the alarms while suctioning).

How to Perform the Closed Suction Technique

7. Connect the suction tubing to the end of the in-line suction catheter.
8. Hyperoxygenate the patient by pressing the [100% FIO_2] button on the ventilator. This is the safest way to hyperoxygenate the patient.
   - Another option is to manually increase the FIO_2 to 100%. NOTE: Remember to return FIO_2 to baseline level when done suctioning, if not done automatically after preset time by ventilator.
   - Least preferred method is to disconnect the ventilator tubing and provide manual ventilation with 100% O_2 using a BVM device. Attach a PEEP valve to the BVM for patients on >5 cm H_2O PEEP. Have a second person give 5 or 6 breaths over 30 sec.
9. Gently but quickly insert the in-line suction catheter into the oral ET tube/tracheostomy, pausing momentarily to pull back on the plastic sleeve containing the catheter. When the patient begins to cough more forcefully, STOP catheter insertion. NOTE: Do NOT insert the catheter until you meet resistance. This means that the end of the suction catheter is hitting the carina (fragile, vascular tissue that separates right and left mainstem bronchus).
10. Apply continuous suction on withdrawal of the catheter over around 10 sec.
11. Observe patient tolerance to procedure.
12. Disconnect the suction tubing from the end of the in-line suction catheter and attach the Yankauer. Gently suction the patient's oral cavity.
13. Ask the patient if they need another suction pass.
14. If the patient does need more suctioning, ensure the ventilator is still providing FIO_2 100%. If not, press the [100% FIO_2] button again.
15. Repeat steps 9 through 13.
16. When the patient does not need more suctioning, ensure the suction tubing is attached to the end of the in-line suction catheter.
17. Rinse the catheter and connecting tubing with the sterile saline solution. Always rinse the tubing away from the patient.
18. Ensure the FIO_2 has returned to its previous setting, or manually return the FIO_2 to the desired value.
19. Reassess the patient for hemodynamic stability and that suctioning was effective. Auscultate to assess changes in lung sounds.
20. Record time, amount, character of secretions and patient's response to suctioning.

We perform OST when we need sterile sputum samples or CST is not available. OST is best performed with 2 persons. One removes the patient from the ventilator and uses the BVM while the second person suctions the patient. Table 28.12 describes the OST method.

TABLE 28.12 Open Suctioning Technique

The suction technique described here is appropriate for those patients with an oral ET tube or tracheostomy, who are receiving invasive mechanical ventilation. Please note that this is best done with 2 people.

Before You Begin

Follow the same steps (steps 1–6) as identified in Closed Suctioning Technique (Table 28.11).

How to Perform the Open Suction Technique

1. Use sterile technique to open catheter package, using the inside of the package as a sterile field.
2. Fill the sterile solution container with sterile normal saline or water.
3. Don sterile gloves. Designate 1 hand as contaminated for connecting and disconnecting the tubing at the suction catheter and operating the suction control.
4. Pick up the sterile suction catheter with dominant hand. Check function of equipment by suctioning a small volume of sterile saline solution from the container.
5. Have the second person hyperoxygenate the patient with 100% FIO_2. Disconnect the ventilator tubing from the ET tube/tracheostomy and provide manual ventilation to the patient with 100% O_2 using a BVM device. Attach a PEEP valve to the BVM for patients on >5 cm H_2O PEEP. Have the second person give 5 or 6 breaths over 30 sec.
6. Once hyperoxygenated, have the second person remove the bagger from the end of the oral ET tube or tracheostomy, and gently but quickly insert the in-line suction catheter *without suction* into the airway. When the patient begins to cough more forcefully, STOP catheter insertion. Do not insert the catheter until you meet resistance. This means that the end of the suction catheter is hitting the carina (fragile, vascular tissue that separates right and left mainstem bronchus).
7. Apply continuous suction on withdrawal of the catheter over around 10 sec.
8. Once the catheter is removed, immediately have the second person reattach the BVM to the oral ET tube/tracheostomy and hyperoxygenate the patient.
9. Observe patient tolerance to procedure. Immediately stop suctioning the patient and remove the in-line suction catheter from the patient if they become bradycardic or hypotensive. A vagal response may have occurred.
10. Ask the patient if they need another suction pass. Wait at least 30 sec (ventilator) or 5–6 breaths (BVM) in between each suctioning pass.
11. Rinse the sterile suction catheter (with sterile saline solution) between suctioning passes.
12. If the patient needs more suctioning, have the second person remove the BVM from the oral ET tube or tracheostomy and repeat steps 8 through 12.
13. When the patient does not need more suctioning, the second person will reattach the patient to the ventilator. Discard all used suctioning supplies. Dispose of the catheter by wrapping it around the fingers of gloved hand and pulling glove over catheter.
14. Reassess the patient for hemodynamic stability and that suctioning was effective. Auscultate to assess changes in lung sounds.
15. Record time, amount, character of secretions, and patient's response to suctioning.

Potential complications from suctioning include hypoxemia, bronchospasm, increased intracranial pressure (ICP), dysrhythmias, hypertension, hypotension, airway trauma (mucosal damage), pulmonary bleeding, pain, and infection.[16] Closely assess the patient, including ECG and SpO_2, before, during, and after suctioning. If the patient does not tolerate suctioning (e.g., decreased SpO_2, increased or decreased BP, sustained coughing, dysrhythmias), stop at once. Continue to reassess the patient until they achieve hemodynamic stability, recover, and/or the situation resolves before trying to suction again. Prevent hypoxemia by always hyperoxygenating the patient before and after each suctioning pass and limiting each pass to 10 seconds or less.

Causes of dysrhythmias during suctioning include (1) hypoxemia resulting in myocardial ischemia; (2) vagal stimulation caused by tracheal irritation; and (3) sympathetic nervous system stimulation caused by anxiety, discomfort, or pain. Dysrhythmias include tachydysrhythmias and bradydysrhythmias, premature beats, and asystole. Stop suctioning if any new dysrhythmias develop. Avoid excess suctioning in patients with severe hypoxemia or bradycardia.

Tracheal mucosal damage may occur due to suction pressures greater than 120 mm Hg, overly vigorous catheter insertion, and the suction catheter itself. Blood streaks or tissue shreds in aspirated secretions may indicate mucosal damage. This increases the risk for infection and bleeding, especially if the patient is receiving anticoagulants.

Secretions may be thick and hard to suction because of inadequate hydration or humidification, or infection. Maintain adequate hydration when indicated (e.g., IV fluids). Provide supplemental humidification of inspired gases through the ventilator to help thin secretions. Turning (e.g., every 2 hours) and early mobilization help move secretions into larger airways. If infection is the cause of thick secretions, give antibiotics as ordered.

◆ Maintaining Alarm Systems

You need to assure that all ventilator alarms are always on. Alarms alert us to potentially dangerous situations, such as patient-ventilator dyssynchrony, ventilator disconnection or malfunction, or unplanned extubation (Table 28.13). On many ventilators, we can temporarily suspend or silence alarms for up to 2 minutes for suctioning. After that time, the alarm system automatically turns back on.

! SAFETY ALERT

Alarm Fatigue

- Alarm fatigue can develop in those who hear an excess number of alarms, resulting in sensory overload.
- This can cause a delayed response to alarms or dismissing them altogether and can lead to serious adverse events (e.g., patient death).
- One way to reduce alarm fatigue includes customizing alarm parameters based on patient specific needs.

TABLE 28.13 NURSING MANAGEMENT

Ventilator Alarms

Alarm	Possible Causes	Interventions
Apnea	• Change in patient condition • Increased WOB • Inappropriate mode of ventilation • Loss of airway • Oversedation • Respiratory arrest	• ↑ Analgesia • ↑ Sedation • Change mode of ventilation • Disconnect patient from ventilator, attach BVM, call for help
High-pressure limit	• ↑ Compliance (e.g., pulmonary edema, ARDS, tension pneumothorax, atelectasis, pneumonia) • Condensate (water) in tubing • Coughing, secretions • Improper alarm setting • Kinked or compressed tubing (e.g., patient biting on ET tube) • Patient fighting ventilator (ventilator dyssynchrony) • ↑ Resistance (e.g., bronchospasm)	• Suction the patient • Reassure patient • Administer analgesia and/or sedation • Unkink tubing • Insert bite block • Give bronchodilator • Remove water from ventilator tubing • Assess breath sounds, obtain chest x-ray
High V_T, minute ventilation, or respiratory rate	• Anxiety, pain • Change in patient condition (e.g., ↑ metabolic demand, fever, hypoxia, hypercapnia, septic shock, patient condition improving) • Excess condensate or secretions in tubing (e.g., false reading)	• Reassure patient • Administer analgesia and/or sedation • Assess and reassess patient for change in condition • Change mode of ventilation • Remove water or secretions from tubing
Low-pressure limit	• Disconnect from ventilator disconnect • ET tube or tracheotomy cuff leak (e.g., patient speaking, grunting) • Loss of airway (e.g., partial or total extubation)	• Check all connections • Confirm adequate V_T • Reinflate cuff PRN • Time permitting, confirm ET tube/tracheostomy position with chest x-ray
Low V_T, minute ventilation, or respiratory rate	• ET tube or tracheotomy cuff leak (e.g., air leak) • Inappropriate mode of ventilation • Insufficient gas flow • Oversedation • Disconnection, loose connection, or leak in circuit	• Reduce sedation • Assess ventilator circuit for leaks • Measure cuff pressure to ensure cuff is adequately inflated • Change mode of ventilation • Based on respiratory rate and patient condition, disconnect patient from ventilator, attach BVM, call for help
Ventilator inoperative	• Internal battery not charged • Malfunction • Power failure	• Plug ventilator into correct power source at all times • Disconnect patient from ventilator, attach BVM, call for help

◆ Analgesia and Sedation

Patients receiving PPV may need analgesia (e.g., fentanyl, hydromorphone) and/or sedation (e.g., propofol) to help with ventilation. Before giving analgesia or sedation, try to identify the cause of distress. Common problems that can result in patient pain, agitation or anxiety include PPV itself, hypoxemia, hypercapnia, drugs, environmental stressors (e.g., fear, sleep deprivation), and the discomfort from intubation.

Assess the effectiveness in achieving an acceptable level of patient comfort by using a valid pain scale, sedation scale (e.g., Richmond Agitation and Sedation Scale [RASS], Sedation Agitation Scale [SAS]), and/or delirium scale. Consider using relaxation techniques (e.g., music therapy) to complement drug therapy. The goal is to have the patient awake, interacting with their environment, and breathing comfortably and in synchrony with the ventilator.

At times, we decide to paralyze the patient with a neuromuscular blocking agent (NMBA). NMBAs paralyze skeletal muscles, including the diaphragm. The purpose is to decrease WOB and provide more effective synchrony with the ventilator, thus improving both oxygenation and ventilation. Remember that the paralyzed patient can hear, see, and feel. It is essential to give IV sedation and analgesia concurrently when the patient is paralyzed. The patient may or may not be aware of their surroundings. Always address them as if they were awake and alert.

Monitoring patients receiving NMBAs is challenging. The nurse giving these drugs often receives additional training. We can assess the depth of paralysis by using the train-of-four (TOF) peripheral nerve stimulation and observing for signs of pain or anxiety (e.g., changes in HR and BP), and ventilator dyssynchrony. The TOF assessment involves using a peripheral nerve stimulator to deliver 4 successive stimulating currents to elicit muscle twitches (Fig. 28.13). The number of twitches varies with the depth of neuromuscular blockade. The usual goal is 1 or 2 twitches out of 4 currents.

Noninvasive electroencephalogram technology (e.g., bispectral index monitoring [BIS]) can also help guide analgesic, sedative, and NMBA therapy.[17] A NMBA should never be given to a patient with a cholinesterase deficiency. Excess administration of NMBAs may predispose the patient to prolonged paralysis and muscle weakness even after the drugs are stopped.

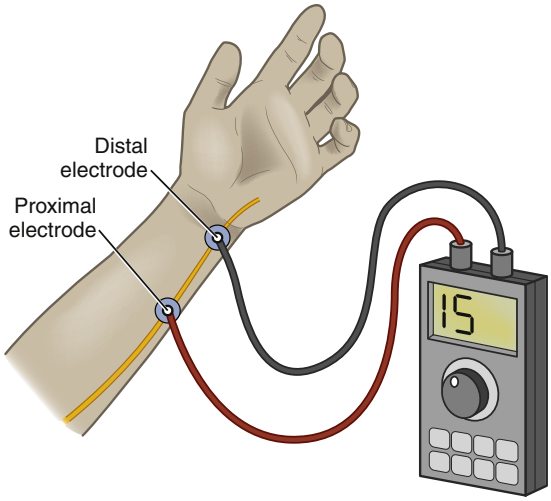

Fig. 28.13 Peripheral nerve stimulator. Placement of electrodes along ulnar nerve.

Hemodynamic Monitoring

The patient receiving invasive mechanical ventilation is hemodynamically monitored. Continuous assessment of the ECG, respiratory rate, synchrony with the ventilator, BP and MAP, and SpO_2 provides vital information. Promptly treat ventilator dyssynchrony, hypertension, hypotension, and decreased O_2 saturations. The patient who cannot maintain heart rate, CO, and BP targets may need IV fluids and drug therapy, such as vasopressors and inotropes.

Oxygenation and Ventilation

Monitoring the respiratory rate and rhythm is important. Is the patient using accessory muscles? Auscultate breath sounds. Assess air entry and breath sound for each lobe, both anteriorly and posteriorly. Is the patient "riding" the ventilator (not taking any breaths over and above the set rate)? Are they initiating some spontaneous breaths? Is there an increase in the WOB? Ensure ordered changes to mechanical ventilation (e.g., respiratory rate, FIO_2, PEEP, V_T, minute ventilation) are made.

Assess for signs of hypoxemia, such as a change in mental status (e.g., confusion), dusky skin, and dysrhythmias. Periodic ABGs and continuous SpO_2 provide objective data about oxygenation. CVP or PA catheters with $ScvO_2$ or SvO_2 capability provide an indirect measure of the tissue oxygenation status.

Indicators of ventilation include $PaCO_2$ and end-tidal carbon dioxide ($EtCO_2$, $PETCO_2$). Changes in $PaCO_2$ reflect alveolar hyperventilation (decreased $PaCO_2$) or hypoventilation (increased $PaCO_2$). $EtCO_2$ monitoring *(capnography)* is done by analyzing exhaled gas directly at the patient-ventilator circuit *(mainstream sampling)* or by transporting a sample of gas through a small-bore tubing to a bedside monitor *(sidestream sampling)*. Continuous $EtCO_2$ monitoring can assess the patency of the airway and presence of breathing. Gradual changes in $EtCO_2$ values may accompany an increase in CO_2 production (e.g., sepsis, hypoventilation), or a decrease in CO_2 production (e.g., hypothermia, decreased CO, metabolic acidosis). $EtCO_2$ is normally 35 to 45 mm Hg.[18]

TABLE 28.14 Oral Care for Patient on a Ventilator

General Measures

1. Gather all equipment.
2. Wash hands and don personal protective equipment and gloves.
3. Explain procedure to the patient and caregiver (if present).
4. Perform oral care every 2–4 hr using toothettes or a suction toothbrush, a Yankauer suction device, and toothpaste or mouthwash (use 0.12% Chlorhexidine oral rinse twice daily).
5. Provide oral care for 1–2 min, suctioning often.
6. Apply a mouth moisturizer to oral mucosa and lips with each cleaning.
7. Suction oral cavity and pharynx only when needed.
8. Dispose of trash and clean equipment. Rinse non-disposable oral suction apparatus with sterile normal saline and place on a dry paper towel.
9. Change all oral suction equipment and suction tubing every 24 hr.

Oral Care

When an oral ET tube is in place, the patient's mouth is always open. Moisten the lips, tongue, and gums with saline or water swabs to prevent mucosal drying. Oral care provides comfort and prevents injury to the gums and plaque formation (Table 28.14). Using Chlorhexidine, either as a mouthwash or toothpaste, at least 3 times per day, can help decrease oral contamination and ventilator-associated pneumonia (VAP). If space is limited in the oral cavity, use smaller or pediatric-sized oral products for providing oral care.

Skin Integrity

Frequent assessment and good care are needed to prevent skin breakdown on the face, lips, tongue, and nares because of pressure from the ET tube or the method used to secure the ET tube. Ongoing assessment is a shared responsibility between the RN and RT. Reposition and re-tape the ET tube (per agency policy) as needed to prevent skin breakdown. Two staff members should always perform repositioning to maintain correct position of the tube and to prevent accidental ET tube dislodgment. Monitor the patient for any signs of respiratory distress throughout the procedure.

For the orally intubated patient, remove the bite block (if present) and the old tape. Provide oral hygiene; then reposition the ET tube to the opposite side of the mouth. Replace the bite block (if used) and reconfirm proper cuff inflation and tube placement. Secure the ET tube again (per agency policy).

We can use a commercial device to secure the ET tube. Some may increase the risk for skin breakdown compared to tape. If you use a commercial device, follow the manufacturer's directions for maintaining tube position, providing skin care, and preventing skin breakdown. Always assess the skin under the ET tube, including upper and lower lips and chin, and underneath any securement devices for redness and skin breakdown.

Nutrition Therapy

Nutrition problems make the patient prone to poor O_2 transport from anemia. They can delay weaning from mechanical ventilation, decrease resistance to infection, and slow extubation and recovery. The presence of an ET tube eliminates the

normal route for eating. A nasogastric (NG) or an orogastric (OG) tube is inserted and connected to low, intermittent suction when a patient is intubated.

The main goal of nutrition support is to prevent or correct nutrition problems. This goal is achieved through early enteral (EN), or if not possible, parenteral nutrition. EN preserves the structure and function of the gut mucosa and stops the movement of gut bacteria across the intestinal wall and into the bloodstream.[19] Patients likely to remain intubated for 3 to 5 days should have a nutrition assessment completed on admission and EN started within 24 hours. Consult the dietitian to determine the patient's caloric and nutrient needs.

Venous Thromboembolism and GI Prophylaxis

The intubated patient is often confined to bed, with brief changes of position. As a result of the decreased mobility, stasis of blood in the lower extremities and the risk of venous thromboembolism (VTE) is of real concern. Start VTE prophylaxis as ordered (see Chapter 41). We might assist them to a sitting position in a chair at the bedside.

Patients may be stressed because of the serious illness, immobility, or discomfort from the ventilator. This places them at risk for developing stress ulcers and GI bleeding. Patients with a pre-existing ulcer or those receiving corticosteroids have a higher risk. Any circulatory compromise, including reduced CO caused by PPV, may contribute to ischemia of the gastric and intestinal mucosa and increase the risk for translocation of bacteria from the GI tract. Stress ulcer prophylaxis includes giving histamine (H_2)-receptor blockers (e.g., ranitidine), proton pump inhibitors (PPIs) (e.g., esomeprazole), or EN.

Early Mobility

Maintaining muscle strength and preventing complications from immobility are important. With few exceptions (hemodynamically unstable patient, those receiving NMBA, unstable cervical or thoracic spine fractures medically contraindicated condition), we encourage most patients receiving invasive mechanical ventilation to exercise and mobilize as soon as possible.

Plan for early and progressive mobility (Box 28.1).[20] Collaborate with physical and occupational therapy. Help the patient perform passive and then active exercises to maintain muscle tone. Simple maneuvers, such as leg lifts or arm circles, are appropriate. Prevent contractures and pressure injures by proper positioning and using specialized mattresses or beds. Use a portable ventilator or provide manual ventilation with a BVM and 100% O_2 when ambulating patients who are mechanically ventilated.

Communication

Intubated patients have stress from not being able to talk and communicate their needs. Inability to communicate may be because of analgesia, sedation, the ET tube, or neurologic impairment. This lack of communication can be frustrating for the patient, caregiver, and health care team. To communicate more effectively, use a variety of methods.

Provide the patient with a paper and pencil, a white board, or cellphone for texting. A communication board with pictures of common needs is convenient for patients who may speak other languages. A visual alphabet for spelling words is useful for patients who are weak or have difficulty writing.

As part of every procedure, explain what will happen or is happening to the patient. When the patient cannot speak, use picture boards, notepads, magic slates, or computers. When speaking with the patient, look directly at the patient and use hand gestures as appropriate.

Nonverbal communication is important. High levels of procedure-related touch and lower levels of comfort-related touch often characterize the ICU environment. Patients have different levels of tolerance for touch, usually related to culture and personal history. If appropriate, use comforting touch with ongoing evaluation of the patient's response. Encourage the caregiver to talk to the patient, even if the patient is intubated, is sedated, or appears comatose. Hearing is often the last sense to decrease. Even if the patient cannot respond, they may still be able to hear.

Psychosocial Concerns

The patient receiving mechanical ventilation often has physical and emotional stress. The patient supported by a ventilator cannot speak, move, or breathe normally. Tubes and machines cause pain and fear. Anxiety is common. There is a loss of independence. They may have feelings of helplessness and

BOX 28.1 EVIDENCE-BASED PRACTICE

The Mechanically Ventilated Patient and Early Mobilization

W.R. is a 72-year-old female patient who has been in the ICU for 3 days. She failed extubation in the PACU after a cholecystectomy, was reintubated, and admitted to the adult ICU. Weaning trials are planned for today. Yesterday, you started passive exercises and dangling with W.R. Today, you and the physical therapist discuss early mobilization with her and her husband.

Making Clinical Decisions

Best Available Evidence

Implementing an early exercise and mobilization protocol for stable, mechanically ventilated patients is safe and well tolerated. Early mobilization improves patient outcomes. Involving patients and caregivers in decision-making around care (e.g., early mobilization) is a priority among this group.

Clinician Expertise

Your unit has successfully implemented an early mobilization protocol for intubated and mechanically ventilated patients in your ICU (part of the ABCDEF bundle). You are aware that patients and their families often worry about ambulating with complex equipment attached to them.

Patient Preferences and Values

W.R. writes on the computer that she does not want to get out of bed until her "breathing tube is out and she has no more IV lines." Her husband tells you she is "afraid of falling."

Implications for Nursing Practice

1. What will you tell W.R. and her husband about the benefits of early mobilization?
2. How will you help reduce W.R.'s concerns about being "afraid of falling"?
3. How will you involve W.R. and her husband in the decision to take part in the early mobilization program?

Reference for Evidence

Schallom M, Tymkew H, Vyers K, et al.: Implementation of an interdisciplinary AACN early mobility protocol, *Crit Care Nurse* 40:e7, 2020.

hopelessness. Usual activities, such as eating and elimination, are complicated. Many patients and caregivers feel uncomfortable in the ICU with its complex equipment, high noise and light levels, and intense pace of activity. Sleeplessness and loss of control enhance anxiety.

Feeling safe is an overpowering need. Work to strengthen the factors that affect feeling safe. Encourage hope, as appropriate. Build trusting relationships with both the patient and caregiver. Involve them in decision-making as much as possible.

To help reduce anxiety, include patients and caregivers in all conversations. Explain the purpose of equipment and procedures. Encourage them to express concerns, ask questions, and state their needs. Structure the environment in a way that decreases anxiety. For example, encourage caregivers to bring in photographs and personal items. Relaxation techniques (e.g., music therapy) and antianxiety drugs (e.g., lorazepam) may reduce the stress response that anxiety can trigger.

Preventing Delirium

The ABCDEF Bundle is evidence-based practice of providing care that strives to attain an environment in which all patients receiving mechanical ventilation are calm, delirium free, and able to express their needs for pain control, positioning, and reassurance. The ABCDEF Bundle ensures (1) **A**ssessment, (2) **B**reathing trials are done daily, (3) correct **C**hoice of analgesia and sedation, (4) **D**elirium prevention and management, (5) **E**arly mobility, and (6) **F**amily engagement (see Chapter 64).[21]

"Rescue" Therapies

Rescue therapies alleviate hypoxemia in patients who are not able to maintain reasonable oxygenation despite appropriate mechanical ventilation, high FIO_2, and PEEP. Rescue therapies are tailored to each patient's requirements. Three therapies, inhaled pulmonary vasodilators, proning, and extracorporeal membrane oxygenation (ECMO), are briefly discussed here.

Inhaled Pulmonary Vasodilators

Inhaled pulmonary vasodilators, such as nitric oxide (NO) and epoprostenol (Flolan), are gas molecules that take part in the regulation of pulmonary vascular tone. For example, inhibiting NO production results in pulmonary vasoconstriction. Continuous inhaled NO results in pulmonary vasodilation. Giving pulmonary vasodilators by inhalation helps increase pulmonary arterial blood flow and decrease pulmonary pressures. As a result, there may be an improvement in gas exchange and arterial oxygenation.

Prone Positioning

Prone positioning is the repositioning of a patient from a supine or lateral position to a prone (on the stomach, face down) position. Proning improves lung recruitment through various mechanisms (see Fig. 32.11). Gravity reverses the effects of fluid in the dependent parts of the lungs. The heart rests on the sternum, away from the lungs, contributing to an overall uniformity of pleural pressures. The prone position requires increased sedation and is nurse intensive. It is an effective supportive therapy used in critically ill patients with severe ARDS to improve oxygenation. Patients with refractory hypoxemia and ARDS should remain prone for at least 12 hours per day.[22]

Extracorporeal Membrane Oxygenation

Extracorporeal membrane oxygenation is an alternative form of pulmonary support for the patient with severe respiratory failure (Fig. 28.14). Think of ECMO as a modification of cardiac bypass or kidney dialysis. ECMO involves removing blood from a patient through large-bore vascular access catheters. When the blood goes through the ECMO unit, it is infused with O_2. CO_2 is removed at the same time. The newly oxygenated blood is then returned to the patient.

ECMO is very labor intensive. It most often occurs in an ICU, with a skilled team of specialists, including a perfusionist and specially trained nurses. There are specific criteria the patient must meet to receive ECMO. It requires systemic anticoagulation. The risk of bleeding is considered before starting therapy.

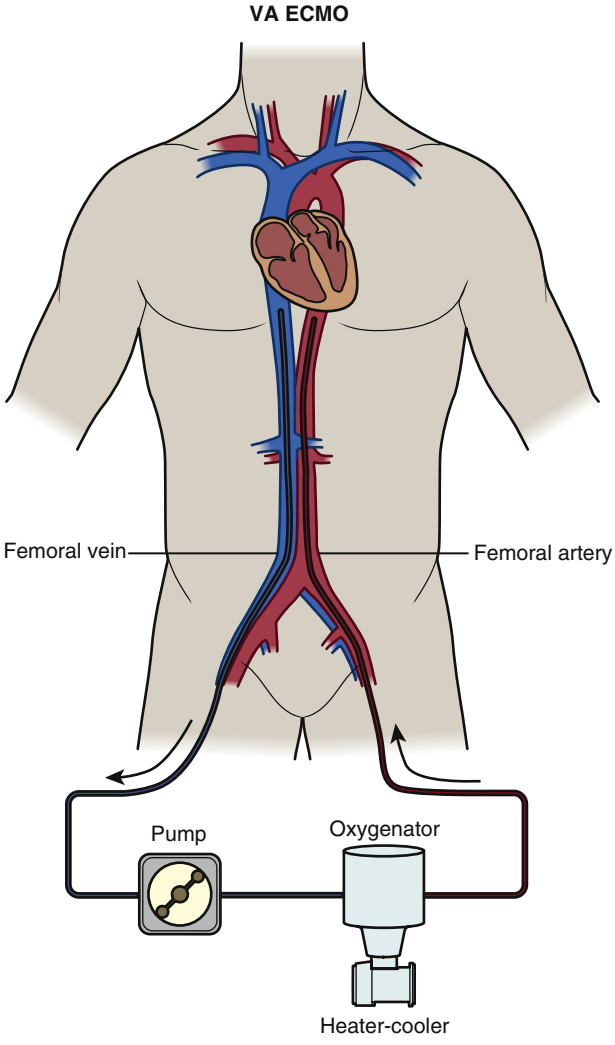

Fig. 28.14 ECMO circuit. The circuit consists of a blood pump, oxygenator, and heating-cooling element. Circulatory access is typically obtained through the femoral vein and artery. Blood is removed from the patient, O_2 is added by the oxygenator, CO_2 is removed, and the blood re-infused back into the patient. (From Mann DL, Zipes DP, Libby P, et al.: *Braunwald's heart disease: a textbook of cardiovascular medicine,* ed 11, St Louis, 2019, Saunders.)

Complications of Mechanical Ventilation

Aspiration

Aspiration is a potential hazard for the patient with an oral ET tube. The ET tube passes through the epiglottis, keeping it in an open position. As a result, the patient cannot protect the airway from aspiration. The high-volume, low-pressure ET cuff cannot totally prevent the trickle of oral or gastric secretions into the trachea. Further, secretions collect above the cuff. When the cuff is deflated, those secretions can move into the lungs.

Oral intubation increases salivation and swallowing is difficult. Suction the patient's mouth often. Use a Yankauer (tonsil-tip) suction catheter or a sterile single-use catheter. Other factors contributing to aspiration include improper cuff inflation, patient positioning, and decreased gastric mobility and bowel function if receiving EN. Even when the cuff is properly inflated, take precautions to prevent vomiting, which can lead to aspiration. Some newer oral ET tubes provide continuous suctioning of secretions above the cuff (Fig. 28.15). Unless contraindicated, keep the head of the bed elevated at least 30 degrees in all intubated patients who are receiving EN.

Sodium and Water Imbalance

Progressive fluid retention can occur 48 to 72 hours after starting PPV, especially with PEEP. Fluid retention is associated with decreased urine output and increased sodium retention. Fluid balance changes may be due to decreased CO, which causes decreased renal perfusion. This stimulates the release of renin with the subsequent production of angiotensin and aldosterone. This results in sodium and water retention.

As a part of the stress response, release of antidiuretic hormone (ADH) and cortisol contributes to sodium and water retention. Less insensible water loss occurs with an artificial airway because ventilated gases delivered to the patient are humidified. Pressure changes in the thorax decrease release of atrial natriuretic peptide, which contributes to sodium and water retention.

Fig. 28.15 The Hi-Lo Evac Tube. A specialized endotracheal tube with separate side port for aspiration of subglottic secretions. Sideport exits above the cuff. Sideport is attached to continuous low suction (20 mmHg), which allows for suctioning of secretions from the subglottic area. (Reprinted by permission of Nellcor Puritan Bennett Inc, Pleasanton, CA.)

Adverse Hemodynamic Effects

PPV affects circulation because of the transmission of increased mean airway pressure to various structures in the thorax. Increased intrathoracic pressure compresses the thoracic vessels. This compression decreases venous return to the heart, preload, systolic BP, MAP, and CO. Mean airway pressure increases further when more than 5 cm H_2O of PEEP is being used.

Alveolar Ventilation Changes

Alveolar hypoventilation can be caused by inappropriate ventilator settings, air leaking from the ventilator tubing or around the ET tube or tracheostomy cuff, lung secretions or obstruction, and administering too much analgesia or sedation. A low V_T or respiratory rate decreases minute ventilation. This results in hypoventilation, atelectasis, and respiratory acidosis.

Alveolar hyperventilation can occur if the respiratory rate or V_T is too high (mechanical overventilation) or if the patient receiving assisted ventilation is hyperventilating. Hyperventilation leads to respiratory alkalosis. If hyperventilation is spontaneous, it is important to determine the cause and treat it. Common causes include hypoxemia, pain, anxiety, or compensation for metabolic acidosis. Patients who fight the ventilator or breathe out of synchrony may be anxious or in pain. If the patient is anxious and fearful, sitting with them and coaching them to breathe with the ventilator or weaning the ventilator to a more appropriate setting may help.

Barotrauma

Barotrauma results when increased airway pressure distends the lungs and possibly ruptures fragile alveoli or blebs. The risk for barotrauma increases as lung inflation pressures increase. Patients with noncompliant (stiff) lungs are at greatest risk. This includes those with ARDS.

Increasing inflation pressure also places the patient at risk for a pneumothorax. With PPV, a simple pneumothorax can become a life-threatening tension pneumothorax. The mediastinum and contralateral lung are compressed, reducing CO. Immediate treatment is needed.

Volutrauma

Volutrauma can occur if too large a volume of air (V_T) is used to ventilate noncompliant lungs. Volutrauma causes alveolar rupture and movement of fluids and proteins into the alveolar spaces. To minimize volutrauma, we use low-volume ventilation in patients with stiff, noncompliant lungs (e.g., ARDS).

Auto-Positive End-Expiratory Pressure

Auto-PEEP is a result of inadequate exhalation time. Auto-PEEP is PEEP over and above what has been set by the HCP.[11] This added PEEP may result in increased WOB, barotrauma, and hemodynamic instability. Interventions to limit auto-PEEP include sedation and analgesia, large-diameter ET tube, bronchodilators, short inspiratory times, and decreased respiratory rates. Reducing water accumulation in the ventilator circuit by frequent emptying or use of heated circuits limits auto-PEEP.

Alterations in Gastric Motility

Immobility, sedation, impaired circulation, decreased oral intake, opioid use, and stress contribute to decreased peristalsis. The patient's inability to exhale against a closed glottis may make defecation difficult. As a result, the ventilated patient is at risk for constipation. Start a bowel regimen to help with motility.

Ventilator Disconnection and Malfunction

Ventilators may become disconnected from the patient. Most disconnections are discovered by low-pressure alarms. The most frequent site for disconnection is between the tracheal tube and the adapter. Push connections together to secure tightly. Teach the patient the importance of not touching the ET tube. Be certain that alarms are always set and activated. You can pause alarms (not turn off) during suctioning. Make sure you reactivate all alarms before leaving the patient.

Ventilator malfunction has been known to occur. Although most agencies have emergency generators in case of a power failure, and newer ventilators may have battery backup, power failure is always a possibility. Have a plan for manually ventilating all patients who depend on a ventilator. If, at any time, you decide the ventilator is malfunctioning (e.g., failure of O_2 supply), or, if you cannot determine the cause of an alarm and the patient is in respiratory distress, disconnect the patient from the machine and manually ventilate with a BVM and 100% O_2 until help arrives and the ventilator is fixed or replaced.

CHECK YOUR PRACTICE

You are caring for a 75-year-old woman who was orally intubated yesterday for respiratory distress due to pneumonia. She is on AC (full support) ventilation. Her ventilator settings are RR 14 (set), FIO_2 40%, PEEP 5 cm H_20, V_T 400 mL. You respond to the ventilator alarm. You hear audible air escaping from around her mouth as you suction her. The alarm panel shows "low exhaled tidal volume." She appears anxious. Vital signs: HR 112, RR 26, and SpO_2 89%.

- What would be your next steps?

Ventilator-Associated Pneumonia

Ventilator-associated pneumonia is pneumonia that occurs 48 hours or more after ET intubation. It occurs in as many as 40% of all intubated patients.[23] Patients who develop VAP have significantly longer days mechanically ventilated, longer hospital stays, and higher mortality rates.[23] Most patients develop VAP early, often within 96 hours of starting mechanical ventilation.

The most common organisms that cause VAP are gram-negative bacteria (e.g., *Escherichia coli, Klebsiella, Streptococcus pneumoniae, Haemophilus influenzae*).[23] Others include antibiotic-resistant organisms, such as *Pseudomonas aeruginosa* and oxacillin-resistant *Staphylococcus aureus.*[23] These organisms are abundant in the hospital environment and the patient's GI tract. They can spread in several ways, Examples include contaminated respiratory equipment, inadequate hand washing, adverse environment (e.g., poor room ventilation, high traffic flow), and decreased patient ability to cough and clear secretions. Colonization of the oropharynx tract by gram-negative organisms predisposes the patient to gram-negative pneumonia. Poor nutrition, immobility, and the underlying disease process (e.g., immunosuppression, organ failure) increase risk.

Signs that suggest VAP include a fever, high white blood cell count, change in color and/or amount of sputum, crackles or wheezes on auscultation, and new lung infiltrates observed on chest x-ray. We obtain sputum cultures and start broad-spectrum antibiotics

Guidelines for VAP prevention include (1) minimizing sedation, including daily spontaneous awakening trials (SATs) or daily spontaneous breathing trials (SBTs), (2) early mobilization, (3) use of ET tubes with subglottic secretion drainage ports, (4) elevating the head of the bed a minimum of 30 to 45 degrees unless contraindicated, (5) oral care with chlorhexidine, and (6) no routine changes of the ventilator circuit tubing.[23]

Other preventive measures include strict hand washing before and after suctioning whenever ventilator equipment is touched and after contact with any respiratory secretions. Always wear gloves when in contact with the patient and change gloves between activities (e.g., emptying urinary catheter drainage, hanging an IV drug). As it collects, always drain the water that collects in the ventilator tubing away from the patient.

SAFETY ALERT

VAP Prevention

- Practice good hand hygiene techniques before and after suctioning and between patient care tasks.
- Keep the head of the bed elevated 30 to 45 degrees.
- Turn patient according to agency policy.
- Begin early mobilization.
- Follow agency policy for limiting sedation with SAT.
- Perform daily SBT unless contraindicated.
- Wear gloves when providing oral hygiene.
- Suction patients as needed for comfort.

Unplanned Extubation

Unplanned extubation can be due to patient self-removal of the ET tube or accidental removal during movement or a procedure. Sometimes the unplanned extubation is obvious (e.g., the patient is holding the ET tube). Other times, the tip of the ET tube is in the hypopharynx or esophagus, and the extubation is not obvious. Signs of unplanned extubation include sounding of the low-pressure ventilator alarm, decreased or absent breath sounds, respiratory distress, or an audible cuff leak. The patient may be talking to you. Sometimes, an unplanned extubation can be an immediate life-threatening event.

Help prevent unplanned extubation by ensuring that the ET tube is secured and supporting the ET tube during repositioning, procedures, and patient transfers. Giving adequate sedation and analgesia and following weaning protocols decrease the incidence of self-extubation.

Using restraints to immobilize the patient's hands is a deterrent to self-extubation. Explain to the patient and caregiver when you use short-term restraints for patient safety and discuss the use of alternatives. Reassess for the continued need of restraints and limit restraint use when possible.

! SAFETY ALERT

Unplanned Extubation

What to do during an unplanned extubation:

- Stay with the patient and call for help.
- Support oxygenation as needed by applying an adjunct therapy, such as a nasal cannula or manually ventilating the patient with a BVM and 100% O_2.
- Immediately notify the HCP and RT.
- Assess for respiratory distress.
- Assess the need for reintubation.
- If the patient cannot protect their airway or is in respiratory distress, prepare for immediate reintubation.
- Provide emotional support and reassure the patient.

Weaning From Positive Pressure Ventilation

Weaning is the process of gradually reducing ventilator support and allowing the patient to assume greater responsibility for breathing spontaneously. The weaning process typically differs for patients on short-term ventilation (3 to 5 days) versus long-term ventilation (longer than 5 days). Those with short-term ventilation (e.g., after heart surgery) have a very straightforward weaning process. Patients with prolonged PPV (e.g., patients with COPD who develop respiratory failure, ARF patients) often have a weaning process that consists of alternating gains and losses. Preparation for weaning begins almost as soon as the patient is intubated and involves a team approach.

Weaning is a complex process. It consists of an assessment of both respiratory and nonrespiratory factors (Table 28.15). First, the primary problem that prompted intubation and mechanical ventilation should be resolving. Second, the lungs should be reasonably clear on auscultation and chest x-ray. Third, the patient needs to be able to breathe spontaneously. The patient who transitions from a full support to a spontaneous mode of mechanical ventilation, is hemodynamically stable, and has acceptable ABGs and SpO_2 shows tolerance of the weaning process.

Nonrespiratory factors include neurologic status, hemodynamic stability, acid-base balance, nutrition status, fluid and electrolyte balance, and hemoglobin. It is important to have an alert, well-rested, and well-informed patient relatively free from pain and anxiety who can cooperate with the weaning plan. This does not mean complete withdrawal from sedatives or analgesics. Instead, drugs should be titrated to achieve comfort without causing excessive drowsiness.

A *spontaneous awakening trial* and a *spontaneous breathing trial* help assess the ability of the patient to maintain a stable respiratory drive and adequate O_2 saturation. An SAT should be done by stopping all sedatives and, in patients without active pain, all opioids. Sedation should be restarted at 50% of the previous dose in patients who "fail" the SAT (increased respiratory

TABLE 28.15 Indicators of Weaning Readiness

Patients receiving mechanical ventilation should have a formal assessment of "readiness for weaning" if the following are satisfied:

1. Awake, alert, easily rousable
2. Reversal of the underlying cause/condition of respiratory failure
3. Hemodynamically stable
   - Absence of dysrhythmias, myocardial ischemia
   - Absence of clinical hypotension (low dose or no vasopressor therapy)
4. Adequate oxygenation
   - PaO_2/FIO_2 >300
   - SpO_2 ≥92%
   - PEEP ≤5–8 cm H_2O
   - FIO_2 ≤40%
   - pH ≥7.35
5. Stable, intact respiratory drive with ability to initiate spontaneous respirations
6. Other Weaning Criteria[a]
   - Hemoglobin ≥7 g/dL
   - Core temperature ≤ 101.3°F (38.5°C)

Weaning Assessment

Measurement	What It Means	Normal Value	Usual Criteria for Extubation
Spontaneous respiratory rate (RR)	Respiratory rate (number of breaths) over 1 min	12–20 breaths/min	>8–10 breaths/min <30 breaths/min
Spontaneous tidal volume (V_T)	Amount of air moved in and out of the lungs during a single breath (at rest)	>5–7 mL/kg	≥5 mL/kg
Minute ventilation (V_E)	Volume of air moved in and out of the lungs during 1 min (at rest) V_T multiplied by respiratory rate over 1 min. *For example:* 0.350 (V_T) × 28 (f) = 9.8 L/min.	3–10 L/min	<15 L/min
Negative inspiratory force or pressure (NIF, NIP)	Amount of negative pressure that a patient can generate Measure of expiratory muscle strength and ability to cough. *Measured by clinician:* A pressure manometer (Nifometer) is attached to airway or mouth and the patient is asked to take a big deep breath. Clinician observes the values on the Nifometer.	<– 20 to –30 cm H_2O	<–20 cm H_2O The more negative the number, the better indication for extubation.
Rapid shallow breathing index, RSBI (f/V_T)	Tobin number Is the spontaneous respiratory rate (over 1 min) divided by V_T (in liters). *For example:* 30 (f)/0.400 (V_T) = 75	<105	<105
Spontaneous breathing trial (SBT)	If patient passes daily weaning screen, assess patient during SBT with little or no ventilator assistance. Trial should be at least 30 min to a maximum of 120 min.		Successful completion of trial is based on assessment (e.g., LOC, vital signs, ABG, chest x-ray, patient WOB).

[a]The decision to use these criteria is made by the HCP and based on agency policy and HCP preference.

rate, decreasing O_2 saturations, low V_T) and remain off in patients who "pass."

An SBT should last at least 30 minutes but no more than 120 minutes. It may be completed with low levels of FIO_2, PEEP, or low levels of PSV.[24] Tolerating the SBT may lead to extubation. Failure to tolerate an SBT should prompt a search for reversible or complicating factors and a return to the previous mode of mechanical ventilation. Unless contraindicated, all patients should have an SBT daily.

There is no "right" way to wean the patient from mechanical ventilation. Most HCPs will attempt weaning early in the morning after the patient had a good night's rest. The patient should be hemodynamically stable and comfortable. Obtain baseline vital signs and respiratory parameters. Place the patient in bed in a semi-recumbent position or sitting in a chair at the bedside.

All health care team members should be familiar with the weaning plan. Weaning approaches include decreasing the number of ventilator-delivered breaths in SIMV. Or we gradually decrease the degree of pressure support daily as ventilatory status permits. PSV provides gentle, slow respiratory muscle conditioning. It may be beneficial for patients who are deconditioned or have heart problems.

During the weaning trial, closely monitor the patient for signs and symptoms that may signal a need to end the trial. These include tachypnea, dyspnea, tachycardia, dysrhythmias, sustained desaturation (SpO_2 less than 92%), hypertension or hypotension, agitation, diaphoresis, anxiety, and changes in mental status. Should the patient not tolerate the weaning trial, allow the patient's respiratory muscles to rest between trials. Once the respiratory muscles become fatigued, they may need 12 to 24 hours to recover.

The patient and caregiver need ongoing emotional support. Explain the weaning process to the patient and family to keep them informed of progress. Record the patient's tolerance throughout the weaning process. Include statements about the patient's and the caregiver's feelings.

Extubation

Extubation is the physical removal of the oral or nasal ET tube. Extubation assessments should include muscle strength (negative inspiratory force) and endurance (spontaneous V_T, vital capacity, minute ventilation, rapid shallow breathing index) (Table 28.15). There should be minimal secretions and the ability to cough and gag.

Before extubation, hyperoxygenate and suction the patient. Have an alternative O_2 delivery device (e.g., nasal prongs) set up. Loosen the ET tapes or commercial holder. Have the patient take a deep breath, and at the peak of inspiration, deflate the ET tube cuff and slowly remove the tube in one smooth motion.

After removal, encourage the patient to deep breath and cough. Suction the oropharynx as needed. Assess their ability to speak. Give supplemental O_2 and provide oral care. Carefully monitor vital signs, respiratory status, and oxygenation immediately after extubation and for the first 2 to 3 hours (per agency policy). If the patient does not tolerate extubation (e.g., decreased SpO_2 levels, tachypnea or bradypnea, tachycardia, decreased LOC, decrease in PaO_2, increase in $PaCO_2$), immediate reintubation or a trial of noninvasive ventilation may be needed.

TRACHEOSTOMY

A **tracheostomy** is a surgically created stoma (opening) in the anterior part of the trachea (Fig. 28.16A). A tracheostomy may be done to (1) establish a patent airway, (2) bypass an upper airway obstruction, (3) simplify removal of secretions, (4) permit long-term mechanical ventilation, and (5) facilitate weaning. When the need for an artificial airway is expected to be prolonged, early tracheotomy (done within 10 to 14 days) appears to have advantages over delayed tracheotomy. These include fewer ventilator dependent days, reduced length of stay, decreased pain, and improved communication.

The tracheostomy tube is shorter in length and slightly wider in diameter than an ET tube. This makes it easier to keep the tube clean and promotes better oral and bronchial hygiene. A tracheostomy (compared to an ET tube) may increase patient comfort because no tube is present in the mouth. There is also less risk of long-term damage to vocal cords.

A variety of tracheostomy tubes are available to meet patient needs (Table 28.16). All tracheostomy tubes have a faceplate, or flange, which rests against the neck and an *obturator.* It is used to help insert the tube. Many tracheostomy tubes have an *outer cannula* (which keeps the airway patent) and an *inner cannula* (which can be disposable or non-disposable and removed for cleaning) (Fig. 28.16B).

Cuffed and *uncuffed* tracheostomy tubes are available. A tracheostomy tube with an inflated cuff is used the most, especially if the patient needs mechanical ventilation. The cuff is inflated through the balloon inflation port on the tracheostomy tube. Cuffs ensure the patient receives the volume of air delivered by the ventilator and decrease the risk of aspiration. Cuffless tubes are often used for patients with longer-term tracheostomies, when mechanical ventilation is not needed, and the risk of aspiration has decreased. With some tracheostomies, talking and eating is possible.

The outer and/or inner cannula may be *fenestrated* or *non-fenestrated*. A *fenestrated tube* has an opening (a hole) on the dorsal surface of the tube. This helps promote spontaneous breathing. With a cuffed, fenestrated tracheostomy tube, when the cuff is deflated and the inner cannula removed, air can pass from the lungs up through the opening in the tracheostomy tube and through the vocal cords (including larynx) and into the upper airway (including the mouth and nose). This allows the patient to breathe spontaneously and speak with the tracheostomy tube in place. When the cuff is reinflated and the inner cannula reinserted, air cannot pass from the lungs through the vocal cords.

Most patients who need mechanical ventilation have an oral ET tube first. The oral ET tube can be quickly inserted in an emergency. When swelling, trauma, or upper airway

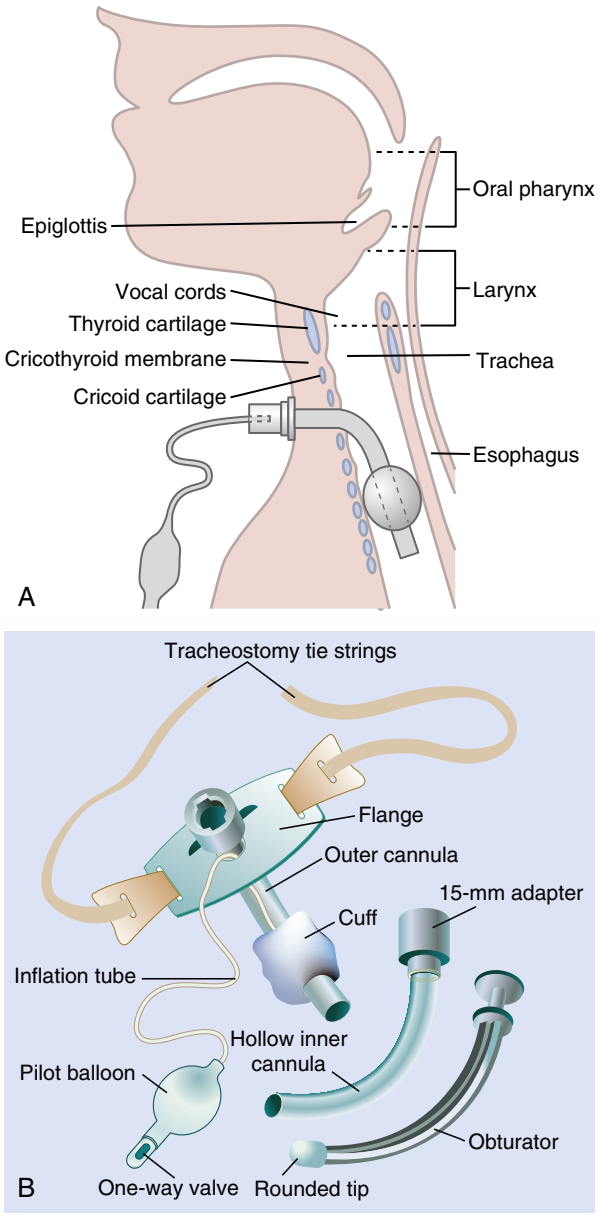

Fig. 28.16 Tracheostomy tube. (A) Placement of a tracheostomy tube. (B) Parts of a tracheostomy tube.

obstruction prevents oral ET intubation, an emergent *surgical cricothyroidotomy* (or cricothyrotomy) is needed. This procedure, which can be completed in minutes, involves making an incision through the skin and cricothyroid membrane on the anterior surface of the neck.

Most surgical tracheostomies are done in the operating room using general anesthesia. They may be done electively on intubated patients who need prolonged mechanical ventilation. A horizontal incision is made on the anterior part of the trachea. The tracheostomy tube is inserted, the incision is sutured, and a sterile dressing applied.

A newer surgical technique is the *percutaneous tracheostomy.* Using local anesthesia, sedation, and under video-assisted guidance, the ET tube is withdrawn up to the level of the glottis. A needle is placed between the second and third tracheal rings, into the middle of the trachea. A dilator is then placed over the top of the needle. The opening is progressively made larger (with increasingly larger dilators) until the hole is big enough for insertion of the tracheostomy tube. Percutaneous tracheostomy approaches have less risk of bleeding and fewer postoperative complications. Surgical and percutaneous tracheostomies may be done at the bedside in the emergency department or ICU.

Preparing the Patient for a Tracheostomy

Preprocedure Care

Before the tracheostomy procedure (and time permitting), explain the purpose of the procedure to both the patient and caregiver. If the patient is having the tracheostomy in the operating room, follow all policies for preparing the patient for surgery (see Chapter 18).

If the procedure is being done at the bedside, ensure all appropriate personnel, including RT, are present. A BVM, suction, and emergency resuscitation equipment should be readily available, functional, and at the bedside.

Record baseline vital signs. Ensure an existing IV line is patent. Help assemble and set up all the equipment. Position the patient supine. Give analgesia and sedation as ordered by the HCP.

During the Procedure

Monitor hemodynamic status. Observe the patient's response to analgesia and/or sedatives. Note the patient's tolerance to the procedure. Observe the SpO_2 and immediately notify the HCP if the SpO_2 is less than 92%.

Postprocedure Care

The tracheostomy cuff is inflated immediately. We use several methods to confirm correct tracheostomy tube placement: (1) auscultation of the patient's chest for air entry, (2) $EtCO_2$ capnography, (3) video-assisted confirmation for percutaneous tracheostomy, and (4) passage of a suction catheter through the tracheostomy tube. After placement is confirmed, the ET tube is removed. The tracheostomy tube is sutured and secured in place with cotton tracheostomy ties, tracheostomy tapes, or Velcro straps.

Monitor vital signs. SpO_2 readings should remain stable. Obtain a chest x-ray. Note and record the ventilator settings, including mode, FIO_2, and PEEP. Complications of a tracheostomy include airway obstruction, bleeding, infection, and potential tube dislodgement (Table 28.17). Observe the amount of blood on the dressing at the insertion site. Notify the HCP if bleeding persists.

❖ NURSING MANAGEMENT: PATIENT WITH A TRACHEOSTOMY

This section highlights general guidelines when caring for a patient with a tracheostomy during the first few days after the procedure (Table 28.18). Considerable variation exists regarding which health care team member is responsible for care activities. In some places, it is the nurse who is responsible. In others, it is a shared responsibility between nursing and RT. Follow your agency policy.

TABLE 28.16 NURSING MANAGEMENT

Specific Types of Tracheostomies

Tube and Characteristics	Nursing Management
Tracheostomy tube with cuff and pilot balloon When properly inflated, low-pressure, high-volume cuff distributes cuff pressure over large area, minimizing pressure on tracheal wall.	**Procedure for cuff inflation:** • Mechanically ventilated patient: • *Minimal occlusion volume (MOV) technique* recommended. Place stethoscope over lateral neck (beside trachea). Inflate cuff by slowly injecting air into the cuff until no leak (sound) is heard at peak inspiratory pressure (end of ventilator inspiration). • *Spontaneously breathing patient:* Inflate cuff by slowly injecting air into the cuff until no sound is heard after deep breath or during inhalation with bag-valve-mask. • *Immediately after cuff inflation:* Confirm pressure is within accepted range 20–30 cm H_2O (15–22 mm Hg) with a manometer. Record cuff pressure and volume of air used for cuff inflation in chart. **Care of patient with an inflated cuff:** • Monitor and record cuff pressure q8hr and PRN. Cuff pressure should be 20–30 cm H_2O (15–22 mm Hg) to allow adequate tracheal capillary perfusion. If needed, remove or add air to the pilot tubing using a syringe and stopcock. Afterward, confirm cuff pressure is within accepted range with manometer. • Report inability to keep the cuff inflated or need to use progressively larger volumes of air to keep cuff inflated. Potential causes include tracheal dilation at the cuff site or a crack or slow leak in the 1-way inflation valve. If the leak is due to tracheal dilation, the HCP may cannulate the patient with a larger tube.
Fenestrated tracheostomy tube (Shiley, Portex) with cuff, inner cannula, and decannulation plug When non-fenestrated inner cannula is removed, cuff deflated, and decannulation plug inserted, air flows around tube, through fenestration in outer cannula, and up over vocal cords. Patient can then speak. A fenestrated inner cannula can be used to facilitate cleaning and weaning from mechanical ventilation.	• If possible, assess risk of aspiration before removing inner cannula. A speech pathologist may be able to assist if available. Deflate cuff. Note coughing. • *Never* insert decannulation plug in tracheostomy tube until cuff is deflated and non-fenestrated inner cannula removed. Otherwise, patient will not be able to breathe (no air inflow). This will precipitate a respiratory arrest. • Assess for dyspnea and/or respiratory distress when a fenestrated cannula is first used. If this occurs, remove the cap, insert a non-fenestrated inner cannula, reinflate the cuff, and notify the HCP. • A non-fenestrated inner cannula must be used to suction patient to prevent tracheal damage from suction catheter passing through fenestrated openings. • Cuff management as described above.
Talking tracheostomy tube (Portex with cuff, 2 external tubings) Has 2 tubings, 1 leading to cuff and 1 to opening above the cuff. When port is connected to air source, air flows out of opening and up over the vocal cords, allowing the patient to speak.	• Patient must be awake, alert, and hemodynamically stable. • Must be able to tolerate cuff deflation. Can exhale around the tracheostomy tube. • When patient wants to speak, deflate cuff, and connect port to compressed air (or O_2). Be certain to identify correct tubing. If gas enters the cuff, it will overinflate and rupture, requiring an emergency tube change. • Use lowest flow (typically 4–6 L/min) that results in speech. Patient may not tolerate high flows. • Give O_2 through tracheal collar or adaptor on speaking valve. • Observe for dyspnea and/or respiratory distress. • Cuff management as described above.
Tracheostomy tube (Bivona, Fome-Cuf) with foam-filled cuff Cuff filled with plastic foam. Before insertion, cuff is deflated. After insertion, cuff self-inflates. Pilot tubing not capped. No cuff pressure monitoring needed. Patient cannot speak with this tube.	• Before insertion, withdraw all air from the cuff using a 20-mL syringe. Cap pilot balloon tubing to prevent reentry of air. • After tracheostomy is inserted, remove cap from pilot tubing, allowing cuff to passively reinflate. Cuff is always inflated on this tube. • Do not inject air into tubing or cap pilot balloon tubing while it is in patient. Air will flow in and out in response to pressure changes (head turning). Place tag on tubing to alert staff not to cap or inflate cuff. • Tube tends to collect moisture and secretions while patient is on the ventilator. • Deflate cuff daily to assess integrity of cuff. Assess ability to easily deflate cuff. Difficulty deflating cuff indicates a need for tube change. If aspirate returns with air, cuff is no longer intact. • Tube can be used for up to 1 month in patients on home mechanical ventilation. • Good choice for patients who need inflated cuff at home since teaching about cuff pressure is simplified.

Much of the management of the patient receiving mechanical ventilation through a tracheostomy is the same as that of the patient with an ET tube. There are some slight differences. At a minimum, you must assess the tracheostomy site and confirm patency of the tracheostomy tube every shift, or more often based on your assessment. Observe the site for any redness, inflammation, edema, ulceration, or signs of infection. Perform sterile dressing changes every 12 to 24 hours. You may need another person to help you with tracheostomy care. Clean around the stoma with normal saline and apply a sterile precut dressing around the tracheostomy tube site. You can complete dressing changes more often if needed. Care of the stoma and cannula for the patient with a tracheostomy is described in Table 28.19.

Because an inflated tracheostomy cuff exerts pressure on the tracheal mucosa, inflate the cuff with the least amount of air needed to obtain an airway seal. Measure cuff inflation pressure with a cuff manometer at least every 8 hours. Cuff inflation

TABLE 28.17 Complications of Tracheostomy

Closely monitor patients with a tracheostomy for the following potential complications:

- Air leak
- Airway obstruction
- Altered body image
- Aspiration
- Bleeding
- Fistula formation
- Impaired cough
- Infection
- Subcutaneous emphysema
- Tracheal necrosis
- Tracheal stenosis
- Tube displacement

TABLE 28.18 NURSING MANAGEMENT

Caring for the Patient With a Tracheostomy

Nursing management of the patient with a tracheostomy includes most of the care provided to the patient who is intubated and mechanically ventilated with an oral ET tube.

- Assess tracheostomy site at least once per shift for any signs of inflammation or infection.
- Suction the tracheostomy as needed.
- Provide tracheostomy care per agency guidelines.
- Maintain appropriate cuff inflation pressure at 20–30 cm H_2O (15–22 mm Hg).
- Teach patient and caregiver about tracheostomy care.

Collaborate With the Respiratory Therapist

- Ensure equipment is available for suctioning and tracheotomy care.
- Measure tracheal cuff pressures.
- Maintain appropriate cuff inflation pressure at 20–30 cm H_2O (15–22 mm Hg).
- Provide tracheostomy care per agency guidelines.
- Replace the tracheostomy tube or ventilate the patient with a BVM device if accidental dislodgment occurs.
- Assist with decannulation.

Supervise the LPN/VN

- Determine the need for suctioning.
- Suction the tracheostomy.
- Assess patient status after suctioning.
- Provide tracheostomy care using sterile technique.
- Notify the RN of any changes in respiratory status.

Collaborate With the Dietitian

- Assess risk for aspiration.
- Recommend a diet to promote nutrition and decrease aspiration risk.

Collaborate With Physical and Occupational Therapy

- Develop a plan for active range of motion and early mobility.
- Help facilitate any adaptation for patients going home with a tracheostomy.

Collaborate With Speech Language Pathology

- Assess swallowing ability and risk for aspiration.
- Develop plan to avoid aspiration.

TABLE 28.19 NURSING MANAGEMENT

Stoma and Cannula Care for a Tracheostomy

The following are general guidelines for basic tracheostomy care. Follow the specific policies in your agency.

Before You Begin

1. Explain procedure to patient.
2. Use tracheostomy care kit or collect sterile equipment (e.g., suction catheter, 1 pair sterile gloves, 1 pair non-sterile gloves, water basin, tracheostomy ties, tube brush or pipe cleaners, 4- × 4-inch gauze pads, sterile water or normal saline, tracheostomy dressing [optional]).
   - Note: Clean technique is used for the patient with a tracheostomy at home.
3. Position patient in semi-Fowler's position.
4. Assemble supplies on bedside table.
5. Wash hands. Put on PPE.

Providing Tracheostomy Care

6. Open sterile equipment. Pour sterile H_2O or normal saline into 2 compartments of sterile container or 2 basins, then apply sterile gloves.
7. If present, unlock and remove inner cannula. Many tracheostomy tubes do not have inner cannulas. Care for these tubes includes all steps listed below, except for inner cannula care.
8. Inner cannula care
   - Disposable: If using a disposable inner cannula, replace with new cannula.
   - Non-disposable:
     - Immerse inner cannula in sterile solution and clean inside and outside of cannula using tube brush or pipe cleaners.
     - Rinse cannula in sterile solution. Remove from solution and shake to dry. Insert inner cannula into outer cannula with the curved part downward, and lock in place.
9. Stoma care:
   - Remove dried secretions from stoma using 4 × 4-inch gauze pad soaked in sterile water or saline. Gently pat area around the stoma dry. Be sure to clean under the tracheostomy flange (faceplate), using cotton swabs to reach this area.

pressure should not exceed 20 to 30 cm H_2O (15 to 22 mm Hg). Higher pressures may compress tracheal capillaries, limit blood flow, and predispose the patient to tracheal necrosis. The minimal occlusion volume (MOV) is one technique used to inflate the tracheostomy cuff (Table 28.16).

Suctioning and tracheostomy care are complex nursing activities. Every nurse who performs suctioning and tracheostomy care must know the scope of practice and policies of the agency for all health care personnel. Collaborate with the RT, who will play a key role in the patient's care.

Suction the tracheostomy tube as needed. Try to avoid suctioning through the newly created tracheostomy in the first few hours after the procedure. This may worsen discomfort and promote bleeding. Suctioning may be done using sterile glove and catheter technique, or an existing in-line suction catheter (Fig. 28.17). Each time you suction the patient, observe the amount, color, and clarity of secretions. Note patient tolerance.

At first, patients should receive humidified air to compensate for the loss of the upper airway to warm and moisturize secretions.[25] Humidification helps keep secretions thin, decrease formation of mucous plugs, and promote comfort.

Fig. 28.17 Suctioning a tracheostomy tube with a closed system suction catheter. (From Potter PA, Perry AG: *Basic nursing: essentials for practice,* ed 7, St. Louis, 2011, Mosby.)

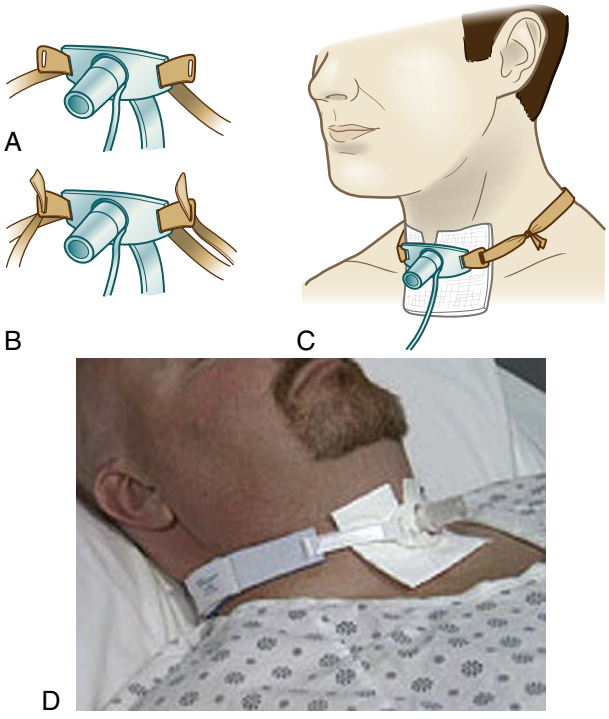

Fig. 28.18 Changing tracheostomy tapes. (A) Cut a small slit about 1 inch (2.5 cm) from the end. Put the slit end into the opening of the cannula. (B) Make a loop with the other end of the tape. (C) Tie the tapes together with a double knot on the side of the neck. (D) A Velcro tracheostomy tube holder. (D, Courtesy Dale Medical Products.)

If the inner cannula is disposable, replace per manufacturer and agency guidelines. If non-disposable, clean the inner cannula at least every shift. Cleaning removes mucus from the inside of the tube to prevent airway obstruction.

Change the tracheostomy tapes after the first 24 hours and then as needed (Fig. 28.18). Using a 2-person technique, 1 person stabilizes the tracheostomy while the other person changes the tapes. During the procedure, apply gentle pressure to the flange. Tie the tracheostomy tapes (or Velcro straps) securely with room for 2 fingers between the tapes and the skin. These steps are considered best practice to ensure that the tracheostomy does not become accidentally dislodged during the procedure. In some centers, the HCP or RT may complete this task.

When turning and repositioning the patient, take care not to dislodge the tracheostomy tube. Because tube may be difficult to reinsert in the immediate postoperative period, several precautions are needed. Keep a replacement tube of equal or smaller size at the bedside, readily available for emergency reinsertion. Do not change tracheostomy tapes for at least 24 hours afterwards. The HCP often performs the first tube change. This happens usually no sooner than 7 days after the tracheotomy.

◆ Accidental Decannulation

If the tracheostomy tube is accidentally dislodged, immediately call for help. While waiting for the HCP or RT to arrive, you have several options. These depend on agency policy.

Quickly assess the patient's LOC, their ability to breathe, and the presence of any respiratory distress. If respiratory distress is present, and it is within your scope of practice, one option is to quickly use a hemostat to spread the opening where the tube was. Insert the obturator in the replacement tube, lubricate with saline, and insert the tube into the stoma. Once the tube is inserted, remove the obturator at once so that air can flow through the tube. Another option is to insert a suction catheter to allow air passage and serve as a guide for insertion. Thread the tracheostomy tube over the catheter and remove the catheter. Trying to reinsert is easier if the stoma tract is mature or more than 1 week old.

If the tube cannot be replaced because of tract immaturity (less than 1 week old) or other circumstances, immediately place the patient in semi-Fowler's position to decrease dyspnea. Cover the stoma with a sterile dressing and ventilate the patient with the BVM over the nose and mouth. If a patient has had a total laryngectomy, there will be complete separation between the upper airway and trachea. Ventilate this patient through the tracheostomy stoma. Severe dyspnea and hypoxemia may progress to respiratory and cardiac arrest.

CHECK YOUR PRACTICE

You are caring for a patient who had a surgically created tracheostomy 6 hours ago. While suctioning the patient, he coughs, dislodging the tracheostomy tube.

- What should you do?

◆ Decannulation

Removal of the tracheostomy from the trachea is called **decannulation**. Removal is possible when the primary condition for which the patient received a tracheostomy has been resolved. The patient also needs to (1) be hemodynamically stable, (2) have a stable, intact respiratory drive, (3) be able to adequately exchange air, and (4) independently expectorate secretions.

Immediately prior to decannulation, explain to the patient what will occur. Monitor vital signs. Suction the patient through the tracheostomy. Clear the mouth of any oral secretions. Loosen and/or cut the tracheostomy tapes. Remove any visible sutures holding the tracheostomy in place. Deflate the

tracheostomy cuff. Pull the tracheostomy tube outwards in one smooth motion. Stop if you meet any resistance and notify the HCP immediately.

After removing the tube, apply a sterile occlusive dressing and monitor for bleeding. Change the dressing if it gets soiled or wet. If needed, close the stoma with tape strips. Monitor respiratory status and O_2 saturation for airway compromise or difficulty breathing. Apply an alternate method of O_2 delivery (e.g., nasal prongs) if needed. Teach the patient to splint the stoma with the fingers when coughing, swallowing, or speaking. Epithelial tissue begins to form in 24 to 48 hours, and the opening closes within 4 or 5 days. Surgery to close the tracheostomy is usually not needed.

❖ NURSING MANAGEMENT: CARE OF THE PATIENT WITH A LONG-TERM TRACHEOSTOMY

Some patients have a tracheostomy for life. They may be receiving mechanical ventilation or have a tracheal or laryngeal problem. Care of the patient with a long-term tracheostomy includes all the same care as patients with a new tracheostomy. This includes observing the tracheostomy site, cleaning the inner cannula, suctioning, and changing tracheostomy tapes.

The tracheostomy tube should be changed around 1 month after the first tube change and every 1 to 3 months thereafter. When a tracheostomy has been in place for several months, the healed tract should be well formed. Changing the tracheostomy tube is important as it permits assessment of the stoma and cleaning of the tube. Teach the patient signs and symptoms of infection and how to change the tube at home using a clean technique. Engaging patients to take part in their care helps decrease complications and infection and promotes their feeling of well-being.

◆ Swallowing Problems

An inflated tracheostomy tube cuff may result in swallowing problems by interfering with the normal function of muscles used to swallow. Therefore for long-term tracheostomy patients, we need to evaluate the patient's swallowing ability and risk for aspiration.

A speech language therapist (SLT) should assess the patient's ability to swallow. To assess for aspiration, the patient receives thickened fluids of different consistencies. If the patient can swallow without aspiration when the cuff is deflated, the cuff may be left deflated or a cuffless tube may be inserted. At this time, patients may have varying levels of thickened fluids and soft foods.

◆ Speech With a Tracheostomy Tube

The spontaneously breathing patient may be able to talk with a tracheostomy. Several options are available depending upon the type of tracheostomy (Fig. 28.19). For example, if the patient is at low risk of aspiration, (1) remove the inner cannula (if non-fenestrated), (2) deflate the cuff, and (3) place the cap on the tube. When the tracheostomy cuff is deflated, exhaled air can flow upward over the vocal cords. When a fenestrated cannula is first used, frequently assess the patient for respiratory distress. If the patient cannot tolerate the procedure, remove

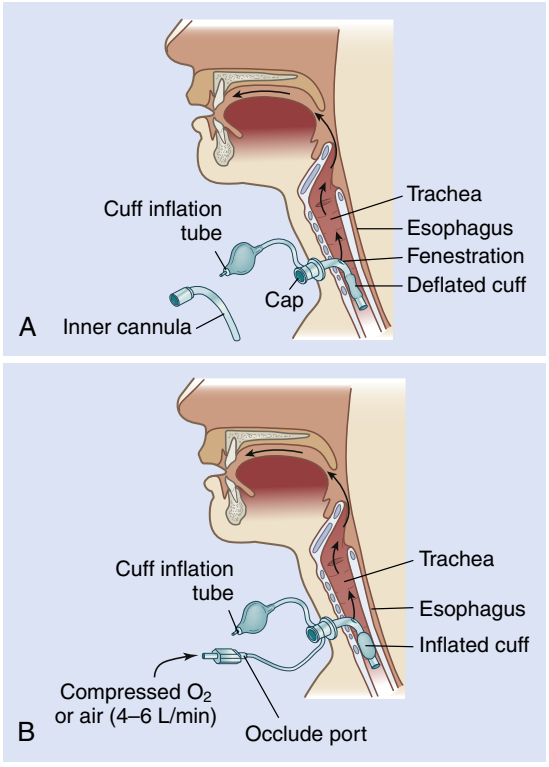

Fig. 28.19 Tracheostomy tubes. (A) Fenestrated tracheostomy tube with cuff deflated, inner cannula removed, and tracheostomy tube capped to allow air to pass over the vocal cords. (B) Speaking tracheostomy tube. One tube is used for cuff inflation. The second tube is connected to a source of compressed air or O_2. When the port on the second tube is occluded, air flows up over the vocal cords, allowing speech with an inflated cuff.

Fig. 28.20 Passy-Muir tracheostomy speaking valve. The valve is placed over the hub of the tracheostomy tube after the cuff is deflated. Multiple options are available for ventilated and nonventilated patients. The 1-way valve allows air to enter the lungs during inspiration and redirects air upward over the vocal cords into the mouth during expiration. (Courtesy Passy-Muir, Inc, Irvine, CA.)

the cap, insert a non-fenestrated cannula, and reinflate the cuff. Monitor for improvement in patient condition.

The Passy-Muir valve is a simple device that attaches to the hub of the tracheostomy tube (Fig. 28.20). With the cuff deflated, the valve redirects air flow through the vocal cords. On inspiration, the valve on the device opens, allowing the patient

to inhale. When the patient exhales, the valve closes, air flows upward around the tracheostomy, and through the vocal cords. The patient exhales through the nose and mouth instead of through the tracheostomy, allowing speech. At first, the patient may only tolerate short periods of use until they are used to exhaling through the mouth. Remove the valve immediately if there are any signs of respiratory distress. Speaking devices may help improve self-care and increase self-esteem for the patient with a long-term tracheostomy.

Tracheostomy and Chronic Mechanical Ventilation in the Home

Ventilators and tracheostomies are a part of home care. Sometimes, chronically ill, ventilated patients who meet specific criteria (e.g., tracheostomy, stabile ventilator settings) are discharged home. The success of home mechanical ventilation depends, in part, on careful predischarge assessment and planning for the patient and caregivers.[26]

Negative pressure and positive pressure ventilators can be used. Negative pressure ventilators do not need an artificial airway. They are less complicated to use. Several types of small, portable, battery-powered positive pressure ventilators are available. They can be attached to a wheelchair or placed on a bedside table. Settings and alarms on these ventilators are simpler to use than standard ventilators.

Home mechanical ventilation has advantages and disadvantages. Having the patient in the home eliminates the strain that the hospital setting imposes on family dynamics. Caregivers may experience many feelings when they first hear about the need for long-term mechanical ventilation.[27] These feelings are often balanced by the chance to care for the patient. At home, the patient may be more mobile and able to take part in more activities of daily living on a personalized schedule.

Disadvantages include problems related to equipment, reimbursement, and caregiver stress and fatigue. Ventilated patients are often dependent and require extensive nursing care, at least at first. Disposable products may not be reimbursable.

Carefully assess financial resources when arranging home ventilation. Hold a care conference before starting a discharge teaching plan. Caregivers may seem enthusiastic about providing care but may not understand the sacrifices they may have to make financially and in personal time and commitment. Encourage caregivers to consider respite care to periodically relieve their stress and fatigue.

Case Study

Mechanical Ventilation

(© Thinkstock.)

Patient Profile

R.K. is a 72-year-old male who collapsed in his home. He was found by the police during a wellness check when his nephew became concerned that he had not heard from him for 2 days. Police activated the emergency response system. On arrival of the paramedics, he was semi-alert, was breathing at 32 beaths/min, and incontinent of a large amount of foul-smelling urine. He was placed on O_2 @ 15 L/min with non-breather mask. A large bore #18G IV was placed in his right lower arm. On admission to the emergency department, R.K. had weak, non-purposeful movement of all 4 limbs. Vital signs became unstable, with BP 84/49 and SpO_2 84%. Suddenly he made no spontaneous respiratory effort. R.K. was immediately intubated. A chest x-ray and ABG were done. He received a 500 mL IV fluid bolus. An indwelling urinary catheter and OG tube were inserted. R.K. was admitted to the ICU.

Objective Data

Physical Assessment

- Weight: 168 lb. (76 kg)
- GCS: Motor: 5; Verbal: Not scored (patient intubated); Eyes: 2.
- BP 85/64 mm Hg (cuff); HR 128; temperature 102° F (39.3° C); SpO_2 is 94%
- ECG shows atrial fibrillation with a rapid ventricular response.
- Breath sounds: coarse crackles bilaterally, decreased breath sounds to the right middle and both lower lobes
- Thick, purulent secretions suctioned from ET tube
- Appears dehydrated (dry mucous membranes, cracked lips)

Diagnostic Studies

- Chest x-ray shows right middle and bilateral lower lung lobe consolidation
- ABGs: pH 7.27; PaO_2 75 mm Hg; $PaCO_2$ 54 mm Hg; HCO_3 25 mEq/L

Interprofessional Care

- Full support positive pressure ventilation: AC. Settings: FIO_2 100%, V_T 500 mL, respiratory rate 14 breaths/min (patient is making no spontaneous respiratory effort), PEEP 5 cm H_2O
- HOB elevated at 30 degrees
- IV 0.9% at 75mL/hr
- EN at 25 mL/hr, increase by 20 mL/hr every 4 hr with a goal of 75 mL/hr
- 12 lead ECG in AM
- Daily chest x-ray for next 3 days
- Chest physiotherapy and mobilize tomorrow
- Urine for culture and sensitivity
- Drug Therapy:
  - Famotidine 10 mg IV q12hr
  - Enoxaparin 40 mg subcutaneous daily
  - Ceftriaxone 1gram IV q24hr
  - Azithromycin 500 mg IV q24hr
  - Fentanyl 50 mcg IV q1hr PRN

Discussion Questions

1. ***Recognize***: Why do you think R.K. collapsed?
2. ***Analyze***: From a respiratory perspective, what findings from the physical assessment and diagnostic studies concern you most? Which need would be addressed first?
3. ***Plan***: Identify 2 reasons for intubating and providing mechanical ventilation for R.K.
4. ***Prioritize*** Based on R.K.'s ABGs, should any ventilator setting(s) be changed? If so, what changes would you suggest?
5. ***Plan***: R.K.'s condition deteriorates. PaO_2 drops to 58 mm Hg, and SpO_2 is 85%. What can be done to help improve oxygenation?
6. ***Act***: R.K.'s caregivers want to know why he is receiving tube feedings. What would you tell them?
7. ***Safety:*** What safety precautions would be implemented for R.K. while he is a patient in the adult ICU?
8. ***Evaluate***: What implications would increasing PEEP have for R.K.'s hemodynamic status?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which technique would be most appropriate for a patient with mild COPD to promote airway clearance?
   a. Huff coughing
   b. Postural drainage
   c. Pursed lip breathing
   d. High-frequency chest wall oscillation
2. The major advantage of a Venturi mask is that it can
   a. deliver up to 80% O_2.
   b. provide continuous 100% humidity.
   c. deliver a precise concentration of O_2.
   d. be used while a patient eats and sleeps.
3. In a spontaneously breathing patient, the nurse notes tidaling of the water level in the water-seal chamber of the chest tube drainage system. The nurse would
   a. continue to monitor the patient.
   b. check all connections for a leak in the system.
   c. raise the collection unit above the level of the heart.
   d. clamp the tubing at a distal point away from the patient.
4. After a left lower lobe lobectomy, an appropriate nursing measure is to
   a. position the patient prone every 2 hours.
   b. monitor the chest tube drainage and functioning.
   c. auscultate lung sounds frequently in the lower left lobe.
   d. administer IV fluid boluses to maintain blood pressure.
5. Which assessment finding concerns you *most* in a patient with pneumonia who is receiving noninvasive ventilation (Bi-PAP)?
   a. New onset of confusion to time and place
   b. Fine crackles on auscultation of affected lobe
   c. Patient asks to remove the mask for oral care
   d. HR: 98, RR: 16 bpm, BP: 110/60, SpO_2: 93%
6. A patient with multiple gunshot wounds returns to the ICU from surgery. Vital signs are stable. They are making no spontaneous respiratory effort. Which mode of ventilation would be most appropriate?
   a. Assist control (AC)
   b. Pressure support (PS)
   c. Bi-level positive airway pressure (Bi-PAP)
   d. Synchronized intermittent mandatory ventilation (SIMV)
7. Nursing management of a patient with an oral ET tube would include
   a. maintaining ET tube cuff pressure at 35 to 40 cm H_2O.
   b. routine suctioning of the ET tube at least every 2 hours.
   c. observing the patient for spontaneous respiratory effort and work of breathing.
   d. preventing ET tube dislodgment by limiting mouth care to lubrication of the lips.
8. Which nursing action would be the *highest priority* when suctioning a patient with an oral ET tube or tracheostomy?
   a. Hyperoxygenate with 100% FIO_2 before suctioning.
   b. Auscultate lung sounds after suctioning is completed.
   c. Instill 5 mL of normal saline into the tube before suctioning.
   d. Give antianxiety medications 30 minutes before suctioning.
9. The nurse monitors the patient with positive pressure mechanical ventilation for
   a. paralytic ileus because pressure on the abdominal contents affects bowel motility.
   b. diuresis and sodium depletion because of increased release of atrial natriuretic peptide.
   c. signs of cardiovascular insufficiency because pressure in the chest impedes venous return.
   d. respiratory acidosis in a patient with COPD because of alveolar hyperventilation and increased PaO_2 levels.
10. Which findings indicate the patient is ready for weaning from mechanical ventilation? *(select all that apply)*
    a. Serum hemoglobin of 15 g/dL
    b. Respirations of 18 breaths/min
    c. Patient is alert and follow commands
    d. Chest x-ray shows large pleural effusion
    e. Mean arterial pressure (MAP) of 55 mm Hg
    f. ABGS: pH 7.38, $PaCO_2$ 37 mm Hg, HCO_3^- 24 mEq/L, PaO_2 94
11. Immediate care priorities in the first few hours for a patient with a new tracheostomy include
    a. encouraging early mobility.
    b. changing the tracheostomy ties.
    c. suctioning the tracheostomy hourly.
    d. observing for bleeding at the insertion site.
12. Appropriate discharge teaching for the patient with a permanent tracheostomy after a total laryngectomy would include (*select all that apply*)
    a. encouraging regular exercise such as swimming.
    b. washing around the stoma daily with a moist washcloth.
    c. emphasizing the importance of regular follow-up appointments
    d. providing pictures and "hands-on" instruction for tracheostomy care.
    e. having a list of emergency contact numbers and where to obtain supplies.

1. a; 2. c; 3. a; 4. b; 5. a; 6. a; 7. c; 8. a; 9. c; 10. a. b, c; f; 11. d; 12. b, c, d, e.

CONCEPTUAL FOCUS

Cellular Regulation
Functional Ability
Gas Exchange
Infection
Sensory Perception

LEARNING OUTCOMES

1. Describe the clinical manifestations and nursing and interprofessional management of problems of the nose.
2. Discuss the clinical manifestations and nursing and interprofessional management of problems of the paranasal sinuses.
3. Describe the clinical manifestations, nursing, and interprofessional management of an upper respiratory infection.
4. Describe the clinical manifestations and nursing and interprofessional management of problems of the pharynx and larynx.
5. Outline the risk factors for and clinical manifestations of head and neck cancer.
6. Discuss the nursing and interprofessional management of patients undergoing surgery for head and neck cancer.
7. Explain essential components of discharge teaching for the patient going home with a permanent tracheostomy after total laryngectomy for cancer.

KEY TERMS

acute laryngitis
airway obstruction
allergic rhinitis
epistaxis
influenza
laryngectomy, Table 29.7
pharyngitis
rhinoplasty
sinusitis
upper respiratory infections

This chapter discusses problems of the upper respiratory system, which includes the nose, sinuses, pharynx, and larynx, and the care of those undergoing surgery for head and neck cancers. The primary concern with upper respiratory problems is the impact on ventilation and oxygen (O_2) availability. They can negatively affect sleep and impair the ability to obtain and maintain nutrition. Sinus and upper respiratory tract infections, allergies, and oral problems can change the senses of both smell and taste. The patient with head and neck cancer often has depression, changes in body image, and impaired sexuality.

NASAL AND PARANASAL SINUS PROBLEMS

DEVIATED SEPTUM

Deviated septum is a deflection of the normally straight nasal septum. The cause is usually from trauma or is genetic. Up to 80% of adults may have septa that are slightly off-center. The diagnosis of a deviated septum is generally reserved for those whose septa are severely shifted.[1] A deviated septum can interfere with both airflow and sinus drainage due to the narrowed passageway.

Symptoms vary depending on the degree of deviation. Minor septal deviations can range from asymptomatic to nasal congestion and frequent sinus infections. Manifestations of severe septal deviation include facial pain, nosebleeds *(epistaxis),* and obstruction to nasal breathing.

The diagnosis is made during examination with a nasal speculum. The medical management of minor septal deviation focuses on symptom control. For nasal inflammation and congestion, use saline rinses and decongestants to clear nasal passages and analgesics for pain relief. For severe septal deviation, a nasal septoplasty reconstructs and properly aligns the deviated septum.

NASAL FRACTURE

Nasal fracture is the most common facial fracture and the third most common fracture of any bone.[2] They often occur from blunt trauma, including fights, automobile accidents, falls, and sports injuries. Using protective sports equipment and safeguarding against falls can prevent many nasal fractures.

There is no universally accepted classification system for nasal fractures. We can classify nasal fractures by their fracture pattern (e.g., impacted, comminuted) or the direction of injury (e.g., lateral, frontal). *Simple fractures* may be unilateral or bilateral. They typically have little or no displacement. Powerful frontal blows can cause *complex fractures,* which may involve damage to adjacent facial structures, such as the teeth or eyes. Patients with nasal fractures from blunt force trauma should be evaluated for injury to the cervical spine, orbital sockets, and mandible. Complications include airway obstruction, nosebleeds, meningeal tears causing cerebrospinal fluid (CSF) leakage, septal hematoma, and cosmetic deformity.

Diagnosis of a nasal fracture is based on health history and physical assessment. Although facial deformity with a nasal fracture is common, a nosebleed may be the only manifestation. Other manifestations include localized pain, crepitus on palpation, swelling, difficulty breathing out of the nostrils, and bruising.

Assess the patient's ability to breathe through each side of the nose. Note the presence of edema, bleeding, or hematoma. Periorbital bruising involving both eyes is called *raccoon eyes*. It suggests a basilar skull fracture. It increases the chance of CSF leaking into the nasal cavities. Inspect the nose internally for evidence of septal deviation, clear drainage, edema, or bleeding. Clear or pink-tinged persistent drainage after control of bleeding suggests a possible CSF leak. If needed, send a specimen to the laboratory to determine the fluid type.

Goals of nursing care are to maintain a patent airway, reduce edema and pain, prevent complications, and provide emotional support. The best way to maintain the airway is to keep the patient sitting upright. Apply ice to the face and nose in 10- to 20-minute intervals to help reduce edema and bleeding. Tell the patient not to blow their nose once bleeding has stopped so they do not disrupt the clot or cause further trauma. Give analgesia as ordered to control pain. Acetaminophen is preferred over nonsteroidal antiinflammatory drugs (NSAIDs) or aspirin for the first 48 hours to avoid prolonging clotting time and increasing the risk for bleeding. Nasal stuffiness may be relieved with nasal decongestants, saline nasal sprays, and a humidifier. The patient should avoid hot showers and alcohol for the first 48 hours to prevent an increase in swelling. Encourage the patient to quit or decrease smoking to help tissue healing.

When a fracture is confirmed, the goals are to realign the fractured bones using either manual manipulation or surgery.[3] Simple fractures are often reduced with manual manipulation. With complex nasal fractures, considerable swelling of soft tissues occurs. It may be necessary to wait to repair the fracture until after the edema subsides. This may be 5 to 10 days. Antibiotics should be considered for any nasal fracture with disruption to the mucosa.

Surgical options include septoplasty and rhinoplasty. Septoplasty is done to correct a deviated septum. Patients have rhinoplasty for several reasons. Both procedures help maintain a patent airway, restore function of the nose, and help reestablish the patient's cosmetic appearance. The presence of septal hematoma increases the patient's risk for deformity and infection, which may require drainage and antibiotic therapy.

RHINOPLASTY

Rhinoplasty is the surgical reconstruction of the nose. It is done for cosmetic reasons or to improve airway function when trauma or developmental deformities result in nasal obstruction.

Most rhinoplasty is an outpatient procedure using regional or general anesthesia. Nasal tissue is added or removed, and the nose may be lengthened or shortened. Plastic implants are sometimes used to reshape the nose. Incisions are typically inside the nose and hidden. Sonic rhinoplasty employs an ultrasonic device to gently aspirate bone, enabling a refined cosmetic result.[4]

Before surgery, assess the patient's expectations of the surgery. Actual or perceived changes in body image (e.g., deformed or enlarged nose) can affect self-esteem and interactions with others. The HCP can use digital photographs to show patients their projected appearance after surgery. These images can help patients decide whether to undergo rhinoplasty.

Obtain a medication history. Aspirin-containing drugs and NSAIDs may need to be stopped for 5 days to 2 weeks before surgery to reduce the risk of bleeding. Encourage smoking cessation to promote postoperative wound healing.

During the immediate postoperative period, nursing interventions include (1) ensuring patency of the airway, (2) continuous assessment of respiratory status, (3) monitoring for airway obstruction, (4) pain management, and (5) observation of the surgical site for edema, bleeding, and infection.

After surgery, nasal packing may be inserted to apply pressure and prevent bleeding or septal hematoma formation. An external plastic splint protects and supports the new shape of the nose during the healing process. If present, nasal packing is usually removed 1 or 2 days after surgery. The splint may be left in place for 1 to 2 weeks.

Teaching is important because the patient must be able to detect complications at home. The patient typically has temporary nasal and/or facial edema and bruising. Cold compresses and elevating the head can help minimize swelling and discomfort. Teach about activity restrictions aimed at preventing bleeding and injury (no nose blowing, swimming, heavy lifting, strenuous exercise). Sometimes swelling may be slow to resolve, delaying the achievement of a full cosmetic result for up to 1 year.

EPISTAXIS

Epistaxis (nosebleed) most often occurs in adults over age 50. Nosebleeds can be caused by trauma, low humidity, upper respiratory tract infections, allergies, sinusitis, foreign bodies, chemical irritants (e.g., street drugs), overuse of decongestant nasal

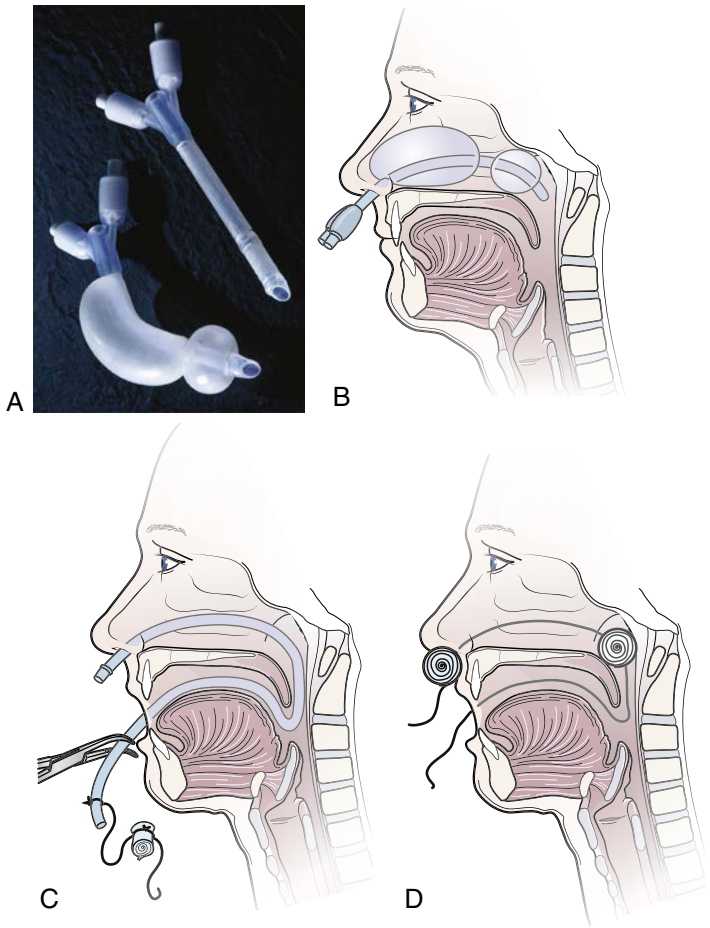

Fig. 29.1 (A) Epistaxis balloon. The balloon is inflated after insertion. (B) Epistaxis balloon properly position in nares. (C) Method for placing posterior nasal pack. A catheter is passed through the bleeding side of the nose and pulled out through the mouth with a hemostat. Strings are tied to the catheter. The pack is pulled up behind the soft palate and into the nasopharynx. (D) Nasal pack in position in the posterior nasopharynx. Dental roll at the nose helps maintain the correct position. (A, Courtesy Boston Medical, Westborough, MA. B, From Roberts JR, Hedges JR: *Clinical procedures in emergency medicine,* ed 5, Philadelphia, 2009, Saunders.)

sprays, facial or nasal surgery, anatomic malformation, and tumors. Conditions that prolong bleeding time or change platelet counts may predispose a patient to nosebleeds.[5] Bleeding time may be prolonged if the patient takes aspirin, NSAIDs, warfarin, or other anticoagulant drugs.

We describe nosebleeds as anterior or posterior. About 90% of nosebleeds occur in the anterior part of the nasal cavity. They are easy to visualize. Anterior bleeding can be self-treated and usually stops spontaneously. Posterior bleeding occurs more often with older adults with other health problems. Since posterior nosebleeds are closer to the throat, it is often hard to determine how much blood loss has occurred. Posterior bleeding may need medical treatment.

❖ Nursing and Interprofessional Management: Epistaxis

Use simple first aid measures to control nosebleeds:

1. Place the patient in a sitting position, leaning slightly forward with head tilted forward.
2. Apply direct pressure by squeezing the entire soft lower part of the nose (nostrils) together for 5 to 15 minutes.
3. If bleeding does not stop within 15 minutes, seek medical assistance.

An anterior bleed may be treated medically by placing a pledget (nasal tampon) impregnated with anesthetic solution (lidocaine) and/or vasoconstrictive agents (epinephrine) into the nasal cavity. Absorbable materials, such as oxidized cellulose (surgical), gelatin foam (Gelfoam), or a gelatin-thrombin combination (Floseal), are another option. Packing for anterior bleeds can stay in place for 48 to 72 hours. Silver nitrate may be used to chemically cauterize a specific bleeding point. Thermal cauterization is reserved for more severe bleeding. It may require the use of local or general anesthesia.[6]

It may be harder to find the location of a posterior bleed. Posterior bleeds often need packing. Packing with compressed nasal sponges (e.g., Merocel) or epistaxis balloons (e.g., Rapid Rhino) is best because of the ease of placement. Packing is inserted into the nares and advanced along the floor of the nasal cavity. The sponge expands with moisture to fill the nasal cavity and tamponade bleeding. An epistaxis balloon inflated with air achieves the same pressure effect (Fig. 29.1). In the absence of a specific nasal device, we may use a size 10F, 12F, or 14F Foley

catheter with a 30-mL balloon. A nasal sling (folded 2 × 2–inch gauze pad) may be gently taped under the nares to absorb drainage. If packing does not stop the bleeding, the patient may need arterial embolization.

Nasal sponges, packing, and balloons can impair respiratory status. Closely monitor the level of consciousness, heart rate and rhythm, respiratory rate, and O_2 saturation (SpO_2) using pulse oximetry. Observe for any signs of difficulty breathing or swallowing. Because of the increased risk for complications due to the location of the injury, all patients with posterior packing should be on a monitored unit for close observation.

Nasal packing is painful because sufficient pressure must be applied to stop the bleeding. The patient should receive appropriate analgesia. Nasal packing predisposes patients to infection from bacteria (e.g., *Staphylococcus aureus*) present in the nasal cavity. Antibiotics effective against staphylococci may be prescribed. Nasal packing for posterior bleeds may be left in place for 2 to 3 days. Before removal, pre-medicate the patient for pain as this procedure is uncomfortable. After packing removal, cleanse the nares gently and lubricate them with water-soluble jelly.

Before discharge, teach the patient and caregiver about follow-up care. Review how to use saline nasal spray and/or a humidifier. Have the patient sneeze with the mouth open and avoid the use of aspirin-containing products or NSAIDs. Teach the patient to avoid vigorous nose blowing, engaging in strenuous activity, and lifting and straining for 4 to 6 weeks.

ALLERGIC RHINITIS

Allergic rhinitis is inflammation of the nasal mucosa, often in response to a specific allergen. We usually describe allergic rhinitis by the causative allergen (seasonal or perennial) and the frequency of symptoms (episodic, intermittent, or persistent). *Episodic* refers to symptoms related to sporadic exposure to allergens not typically encountered in the patient's normal environment. An example is exposure to animal dander when visiting another person's home. *Intermittent* means that the symptoms are present less than 4 days a week or less than 4 weeks per year. *Persistent* means that symptoms are present more than 4 days a week and for more than 4 weeks per year.

Seasonal rhinitis usually occurs in the spring and fall. It is caused by an allergy to pollens from trees, flowers, grasses, or weeds. Attacks may last for several weeks during times when pollen counts are high. Then it disappears and often recurs at the same time the next year. *Perennial rhinitis* occurs year-round from exposure to environmental allergens, such as animal dander, dust mites, cockroaches, fungi, and molds. Both seasonal and perennial rhinitis can be classified as episodic, intermittent, or persistent, depending on the duration and frequency of symptoms.

Sensitization to an allergen occurs with initial allergen exposure, which results in the production of antigen-specific immunoglobulin E (IgE) (see Fig. 14.6). After exposure, mast cells and basophils release histamine, cytokines, prostaglandins, and leukotrienes. These cause the early symptoms of sneezing, itching, rhinorrhea (runny nose), and congestion (stuffy nose).[7] Within 4 to 8 hours after exposure, inflammatory cells infiltrate the nasal tissues, causing and maintaining the inflammatory response. Because symptoms of rhinitis are like those of the common cold, the patient may think the condition is a continuous or repeated cold.

Clinical Manifestations

Manifestations of allergic rhinitis are sneezing; watery, itchy eyes and nose; decreased sense of smell; and thin, watery nasal discharge that can lead to more sustained mucus production and congestion. Nasal turbinates appear pale, boggy, and swollen. The turbinates may fill the air space and press against the nasal septum. The posterior ends of the turbinates can become so enlarged that they obstruct sinus aeration or drainage and result in sinusitis. With chronic exposure to allergens, the patient may develop a headache, stuffy nose, nasal congestion, and sinus pressure. Nasal polyps, soft, painless growths in the sinus cavity, may form. Postnasal drip occurs when mucous runs down the back of the throat. Both nasal polyps and postnasal drip are the most common causes of cough for people with allergies. The patient may report hoarseness and the need to frequently clear the throat to remove the mucous.

❖ Nursing and Interprofessional Management: Allergic Rhinitis

The key step to managing allergic rhinitis is identifying and avoiding triggers of allergic reactions (Table 29.1). Teach the patient to take note when allergic reactions occur and keep a diary of activities that precipitate the reaction. Patients are often more aware of intermittent exposure to an allergen, such as pets, than they are of more persistent exposure to allergens, such as dust mites, cockroaches, or mold. Identifying triggers is the first step toward avoiding them.

The goal of drug therapy is to reduce inflammation from allergic rhinitis, reduce nasal symptoms, minimize complications, and maximize quality of life. Appropriate oral medication options include H_1-antihistamines, decongestants, and leukotriene receptor antagonists (LTRAs). Intranasal medications include antihistamines, anticholinergics, corticosteroids, mast-cell stabilizers, and decongestants (Table 29.2).[8,9]

Second-generation antihistamines are used before first-generation antihistamines because of their non-sedating effects. Teach patients taking antihistamines to have adequate fluid intake to reduce adverse symptoms and keep secretions thin. Nasal corticosteroid sprays decrease inflammation with little absorption in the systemic circulation. This makes systemic side effects are rare. If monotherapy does not relieve symptoms, a 2-drug combination, such as an oral H_1-antihistamine and an intranasal corticosteroid, may be helpful.

DRUG ALERT

Antihistamines

- First-generation antihistamines (e.g., diphenhydramine) can cause drowsiness and sedation.
- Warn patients that operating machinery and driving may be dangerous because of the sedative effect.

TABLE 29.1 PATIENT & CAREGIVER TEACHING

Avoiding Allergens in Allergic Rhinitis

Include the following instructions when teaching a patient or caregiver about allergic rhinitis:

What to Avoid	Specific Approaches
House dust	• Focus on the bedroom. Remove carpeting. Limit furniture. • Put the pillows and mattress in airtight vinyl bags. • Limit clothing in the bedroom to items worn often. Place clothing in airtight, zipper-sealed vinyl clothes bags. • Install a high-efficiency particulate air (HEPA) filter. • Close the air-conditioning vent into room. • Use blinds rather than draperies.
House dust mites	• Wash bedding in hot water (140°F [60°C]). • Wear a mask when vacuuming. • Install a filter on the outlet port of vacuum cleaner. • Avoid sleeping or lying on upholstered furniture. • Keep house temperature and conditions cool and dry.
Mold spores	• The 3 *D*s that promote growth of mold spores are darkness, dampness, and drafts. • Ventilate closed rooms and open doors. Consider adding windows to dark rooms and keeping a small light on in closets. • Basement light with a timer that provides light several hours a day may decrease mold growth. • Avoid places with high humidity (e.g., basements, clothes hampers, greenhouses, barns).
Pet allergens	• Remove pets from interior of home. • Clean living area thoroughly. • Do not expect instant relief. Symptoms usually do not improve for 1–2 months after pet removal.
Pollens	• Stay inside with doors and windows closed during high-pollen season. • Install an air conditioner with an air filter. Wash filters weekly during high-pollen season. • Use your car's air conditioner "recirculation" feature (circulates air inside the car while shutting off air coming into the vehicle from the outside). • Avoid having plants, especially in the bedroom.
Smoke	• Encourage family and friends to refrain from smoking (if possible) or to go outdoors to smoke. • Presence of a smoker will sabotage any symptom reduction program.

DRUG ALERT

Pseudoephedrine (Sudafed)

- Large doses may cause tachycardia and palpitations, especially in patients with heart disease.
- Overdose in those over 60 years of age may result in central nervous system depression, seizures, and hallucinations.

Immunotherapy (allergy shots) may be used when a specific, unavoidable allergen is identified, and drugs are not tolerated or are ineffective in controlling symptoms. Immunotherapy involves controlled exposure to small amounts of the known allergen through frequent (at least weekly) injections with the goal of decreasing sensitivity. Sublingual or intranasal administration of allergen immunotherapy may be an option for select patients. Immunotherapy is discussed in Chapter 14.

UPPER RESPIRATORY INFECTIONS

ACUTE VIRAL RHINOPHARYNGITIS

An **upper respiratory infection** (URI) is an infection of the nose, sinuses, and/or throat. Viruses cause most URI. However, bacterial agents may cause a URI as well. *Acute viral rhinopharyngitis* (nasopharyngitis, common cold) is one type of URI. Sinusitis and influenza are examples of other types of URI.[10] There are over 200 viruses that may cause a URI. The most typical viruses are the rhinovirus, coronavirus, influenza, parainfluenza, respiratory syncytial virus (RSV), and enterovirus. The most common bacterium is *Streptococcus pyogenes*. It is a group A streptococcus that causes strep throat.[11] Adults may have an average of 2 to 3 colds per year.

Viruses are contagious. They spread by airborne droplets emitted by the infected person while breathing, talking, sneezing, or coughing. Because the pathogens can survive on inanimate objects for up to 3 days, transmission may occur by directly touching the surface and then touching your eyes, nose, or mouth with contaminated hands. Frequency of infections increases in winter months when people stay indoors, and overcrowding is more common. Other factors that increase susceptibility include fatigue, physical and emotional stress, allergies affecting the nose and throat, and a compromised immune status. Exercise, managing stress, sleeping adequately, and eating a well-balanced diet may reduce the number and or severity of URIs.[12]

Clinical Manifestations

Symptoms typically begin 2 or 3 days after infection. They may include runny nose, watery eyes, nasal congestion, sneezing, cough, sore throat, fever, headache, and fatigue. Patients are contagious 1 to 2 days before symptom onset and remain contagious until symptoms have subsided. Symptoms may last 2 to 14 days, with typical recovery in 7 to 10 days.

❖ Nursing and Interprofessional Management: URI

Interventions are directed at relieving symptoms. Care includes rest, oral fluids, antipyretics, and analgesics. Warm saltwater gargles, ice chips, lozenges, or sprays may help ease a sore throat. Saline nasal spray reduces nasal congestion. Antihistamine and decongestant therapy reduce postnasal drip and decreases the severity of cough, nasal obstruction, and nasal discharge. Caution patients to use intranasal decongestant sprays for no more than 5 days to prevent rebound congestion from occurring. Cough suppressants for irritating, bothersome coughs can be used but may not be effective. Patients may ask about vitamin C, echinacea, and zinc products. There is inconclusive evidence to support treatment with these therapies.

Complications include acute bronchitis, sinusitis, otitis media, tonsillitis, and pneumonia. Antibiotics have no effect on

TABLE 29.2 Drug Therapy

Rhinitis and Sinusitis

Drug	Mechanism of Action	Side Effects	Nursing Actions
Anticholinergic Nasal Spray			
ipratropium bromide	Blocks nasal cholinergic receptors, reducing nasal secretions in the common cold and nonallergic rhinitis.	Nasal dryness and irritation, nosebleeds may occur. Does not cause systemic side effects.	• May reduce the need for other rhinitis medications.
Antihistamines			
First-Generation Oral Agents			
brompheniramine diphenhydramine	Bind with H_1 receptors on target cells, blocking histamine release. Relieve acute symptoms of allergic response (itching, sneezing, rhinorrhea).	Cross blood-brain barrier, often causing sedation and somnolence. Can cause paradoxic stimulation (restlessness, nervousness, insomnia). Anticholinergic side effects (palpitations, dry mouth, constipation, urinary hesitancy).	• Warn patient that operating machinery and driving may be dangerous because of sedative effect. • Teach patient to report palpitations, change in heart rate, change in bowel or bladder habits. • Teach patient not to use alcohol because of additive depressant effect. • Rapid onset of action, no drug tolerance with prolonged use.
Second-Generation Oral Agents			
cetirizine (Zyrtec) desloratadine (Clarinex) fexofenadine (Allegra) levocetirizine (Xyzal) loratadine (Claritin)	Same as above.	Limited affinity for brain H_1 receptors. Cause minimal sedation, few effects on psychomotor activities or bladder function.	• Teach patient to expect few, if any, side effects. • More expensive than traditional antihistamines. • Rapid onset of action, no drug tolerance with prolonged use.
Second-Generation Nasal Sprays			
azelastine (Astelin) olopatadine (Patanase)	Blocks histamine release and reduces nasal congestion.	Headache, bitter taste, somnolence, nasal irritation.	• Longer use increases risk for rebound vasodilation, which can increase congestion.
Corticosteroid Nasal Sprays			
budesonide (Rhinocort) ciclesonide (Omnaris) flunisolide fluticasone (Flonase) fluticasone mometasone (Nasonex) triamcinolone	Inhibits inflammatory response of allergic rhinitis. Decreases mucosal inflammation and facilitates drainage of sinuses. Systemic effects may occur with higher than recommended doses.	At recommended dose, systemic side effects unlikely due to low systemic absorption. Mild transient nasal irritation, mucosal drying, nosebleeds. In rare instances, localized fungal infection with *Candida albicans*.	• Adherence important. Teach patient to use on regular basis and not PRN. • Have patient clear nasal passages before use. • Reinforce that spray acts to decrease inflammation and it may take several days or 1–2 wks to achieve maximum effects. • Stop use if nasal infection develops.
Decongestants			
Oral			
pseudoephedrine (Sudafed)	Stimulates adrenergic receptors and promotes vasoconstriction of superficial vessels in the nose and reduces nasal congestion.	CNS stimulation, causing insomnia, excitation, headache, irritability, increased blood and ocular pressure, dysuria, palpitations, tachycardia.	• Tolerance variable. • Advise patient of adverse reactions. • Patient to inform HCP if preexisting cardiovascular disease, hypertension, diabetes, glaucoma, benign prostatic hyperplasia, liver or kidney disease present before starting therapy. • Rebound nasal congestion may occur with chronic overuse.
Nasal Spray			
oxymetazoline phenylephrine	Same as above.	Same as above.	• Teach not to use for >5 days or >3 or 4 times/day. • Rebound nasal congestion may occur. • Addiction possible.
Leukotriene Receptor Antagonists (LTRAs) and Inhibitors			
Antagonists			
montelukast (Singulair) zafirlukast (Accolate)	Suppress leukotriene activity, thereby inhibiting airway edema, mucus production, bronchoconstriction, and inflammation.	Well tolerated. May cause headaches, dizziness, rash, altered liver function, GI changes.	• Monitor liver function tests periodically while on therapy. Stop if elevated. • Give on empty stomach. • Do not stop therapy without consulting HCP.
Inhibitors		*Zafirlukast and zileuton:* Monitor PT levels if patient is taking warfarin.	• Do not use for acute attacks.
zileuton (Zyflo)			

TABLE 29.2 Drug Therapy—cont'd

Rhinitis and Sinusitis

Drug	Mechanism of Action	Side Effects	Nursing Actions
Mast Cell Stabilizer Nasal Spray			
cromolyn spray	Suppresses release of histamine and other inflammatory mediators from mast cells.	Minimal side effects. Occasional nasal irritation.	• Reinforce that spray prevents symptoms. • Begin 1 week before pollen season starts and use throughout pollen season. • For isolated allergy, use prophylactically before exposure to allergen. • When used to treat chronic rhinitis, may use antihistamine and/or nasal decongestant at the same time.

viruses. They are an option only if complications are present. Refer to an HCP if there is no improvement in symptoms within 10 to 14 days.

Teach patients to recognize the manifestations of a secondary bacterial infection. These include a temperature higher than 103°F (39.4°C); tender, swollen glands; severe sinus or ear pain; or significantly worsening symptoms. Green, purulent nasal drainage during the later stages of a cold is not uncommon and not always indicative of bacterial infection. In a patient with lung disease, signs of infection include a change in consistency, color, or volume of the sputum. Because infection can progress rapidly, teach the patient with chronic respiratory disease to immediately report sputum changes, increased shortness of breath, and chest tightness.

During the cold season, teach patients with a chronic illness or a compromised immune system to avoid crowded situations and those with obvious cold symptoms. Frequent hand washing and avoiding hand-to-face contact can help prevent direct spread.

INFLUENZA

Influenza (flu) is a highly contagious respiratory illness that causes significant morbidity and mortality. The flu season begins in September and continues through April of each year, peaking between December to February. Millions of people are infected yearly, causing an increased burden to the community and health care system. Although we do not know the exact number of flu-related deaths, it is thought that it is responsible for up to 49,000 deaths annually, depending on the strain.[13] Vaccination of high-risk groups may help prevent many of these deaths.

Etiology and Pathophysiology

We classify influenza viruses into 4 serotypes (A, B, C, D). Only A and B cause significant illness in humans. Influenza A is subtyped based on the presence of 2 surface proteins: hemagglutinin (H) and neuraminidase (N). The H antigens enable the virus to enter the cell, and the N antigens facilitate cell-to-cell transmission. As a result, we name influenza A viruses by their H and N-type (e.g., H3N2).

Influenza A is the most common and most virulent flu virus. It can infect a variety of animals and humans. More than 100 types of influenza A can occur in birds (avian flu), pigs (swine flu), horses, seals, and dogs. When the virus mutates (changes), this allows it to infect different species. When a new viral strain reaches humans, people do not have immunity. The virus can spread quickly around the globe, causing a *pandemic*. For example, type A H1N1 influenza (swine flu) emerged in 2009. It had never been seen in humans before, resulting in a worldwide pandemic. The reemergence of a strain that has not circulated for many years can also trigger a pandemic. *Epidemics* are more localized outbreaks, often occurring yearly, caused by variants of already circulating strains of the influenza virus.

Influenza B and C viruses only infect humans. We do not divide them into subtypes. Outbreaks of influenza B can cause regional epidemics. The disease it produces is milder than that caused by influenza A. Influenza C causes mild illness and does not cause epidemics or pandemics. Influenza D only occurs in animals.

The flu is communicable between humans mainly through infected droplets, inhalation of aerosolized particles, and, to a lesser extent, through direct contact with contaminated surfaces. The virus has an incubation period of 1 to 4 days, with peak transmission risk starting 1 day before the onset of symptoms and continuing for 5 to 7 days after a person first becomes sick.[14]

Clinical Manifestations

For some patients, it may be hard to tell between the common cold and flu (Table 29.3). The onset of flu is abrupt. There may be chills, fever, and generalized myalgia, often accompanied by a headache, cough, sore throat, and fatigue. Assessment findings are usually minimal, with normal breath sounds on chest auscultation. In uncomplicated cases, symptoms often subside within 7 days.

Common complications include pneumonia, which can be either primary influenza [viral] pneumonia or secondary bacterial pneumonia, and ear or sinus infections. Dyspnea and diffuse crackles are signs of pulmonary complications. Some patients, especially older adults, have weakness or lethargy that may last for weeks. The patient who develops secondary bacterial pneumonia usually has a gradual improvement of flu symptoms, then worsening cough and purulent sputum. Treatment with antibiotics is usually effective if started early.

Diagnostic Studies

The flu is often diagnosed based on the patient's health history, physical assessment, and knowledge of other cases of

TABLE 29.3 Comparison of Common Cold and Influenza

Manifestations and Treatment	Common Cold (Viral Rhinitis)	Influenza
Symptom onset	Appear gradually	Abrupt onset. Within 3–6 hr
Fever	Rare	Characteristically high 102–104°F (38.9–40°C]). Lasts 3–4 days
Headache	Uncommon, but may occur	Common (can be severe)
General aches and pains	Slight	Often severe myalgia
Fatigue and weakness	Sometimes. Usually mild	Usual. Starts early and can last up to 2–3 weeks
Exhaustion	Uncommon	Usual at beginning of illness
Stuffy nose	Common	Sometimes
Sneezing	Common	Sometimes
Sore throat	Common	Sometimes
Chest discomfort, cough	Common. Mild to moderate hacking cough	Common
Complications	Sinus congestion. Earache	Bronchitis, pneumonia, acute respiratory failure, and acute respiratory distress syndrome (ARDS). Can be life-threatening
Prevention	Hand washing. Avoid close contact with anyone who has a cold	Hand washing. Annual vaccination. Antiviral drugs. Avoid close contact with anyone who has the flu
Treatment	Temporary relief of symptoms: rest, hydration, decongestants, acetaminophen or ibuprofen for headache, aches, and pains	Antiviral drugs if given within 24–48 hr of onset. Rest, hydration, acetaminophen, or ibuprofen for headache, aches, and pains

Adapted from Centers for Disease Control and Prevention. Retrieved from www.cdc.gov/flu/about/qa/coldflu.htm.

influenza in the community. Testing can help distinguish the flu from other viral and bacterial infections with similar manifestations that may be serious but are treated differently. Cultures are often done via the nose or throat and may help identify the causative agent. The preferable method of culture collection is from the nasopharyngeal area via a mid-turbinate nasal swab. This should occur within 4 days of symptom onset. Guidelines for testing include those who are high-risk (e.g., immunocompromised) or patients with acute onset respiratory symptoms. In the hospital, we often test those with cardiopulmonary disease whose condition is worsening.[15]

Rapid influenza diagnostic tests (RIDTs) can help detect the virus in secretions from the respiratory tract. Depending on the method, the test may be completed in the HCP's office, with results available in as little as 15 minutes. RIDTs are best used within the first 48 hours of the onset of symptoms. The main disadvantages of RIDTs are that the patient may have a false-negative result, and the test is more sensitive to Influenza A than B.[16]

❖ Nursing and Interprofessional Management: Influenza

The most effective strategy is prevention. Two types of flu vaccines are available: inactivated and live attenuated (Table 29.4). Receiving a flu vaccine results in the production of antibodies against the viruses in the vaccine.

The flu vaccine is changed on a yearly basis. The content depends on the virus strains the Centers for Disease Control and Prevention (CDC) determines as being most likely to cause illness in the upcoming flu season. The best time to receive the vaccine is in September or October (before flu exposure) because it takes 2 weeks for antibodies to form and provide full protection from the flu. However, the vaccine can be given at any time during the flu season.

! SAFETY ALERT

Influenza Vaccination

- Advocate for vaccination of all people older than 6 months of age, especially those at high risk (e.g., health care workers, residents of long-term care facilities).
- Give high priority to groups, such as health care workers, who can transmit the flu to high-risk persons.

Vaccinating healthy people decreases the incidence and risk for transmitting influenza to those who have less ability to cope with the effects of this illness. Current vaccines are highly purified, and reactions are very rare. Soreness at the injection site is the most reported adverse effect. Contraindications are a history of severe allergic reactions to a previous flu vaccine. Patients with anaphylactic hypersensitivity to eggs should discuss the vaccine with their HCP, as alternatives for vaccinating patients with egg allergies are now available.

The primary nursing goals for those with the flu are symptom relief and preventing secondary infection. Unless the patient is at high risk or complications develop, supportive therapy is often all the patient needs. Rest, hydration, analgesics, and antipyretics can provide symptom relief. Older adults and those with a chronic illness may need hospitalized.

There are several antiviral medications we can use that shorten the duration of flu symptoms and reduce the risk for complications. Zanamivir (Relenza), oseltamivir (Tamiflu), and peramivir (Rapivab) are neuraminidase inhibitors that prevent the virus from being released and spreading to other cells.[17] Zanamivir is given using an inhaler. Oseltamivir is available as an oral capsule. Peramivir is given IV. The newest drug is baloxavir marboxil (Xofluza). It is a PA endonuclease inhibitor that works by inhibiting viral replication. Patients receive 1 oral dose. Do not give Xofluza with dairy products or calcium-fortified drinks.

TABLE 29.4 Types of Influenza Immunization

Trivalent (TIV) or Quadrivalent (QIV) Inactivated Influenza Vaccine	Live Attenuated Influenza Vaccine (LSIV)
Trivalent: Protects against 3 different types of influenza virus (2-type A; 1-type B) *Quadrivalent:* Protects against 4 different types of influenza virus (2-type A; 2-type B)	Made from weakened influenza virus
Given by injection	Given as an intranasal spray into both nostrils
Approved for use in people ≥6 months of age	Approved for healthy people ages 2–49 years • Children 2–8 years and have not had influenza vaccine before need 2 doses (second dose 4 weeks after first dose) • Children >9 years need 1 dose
Should NOT be used in: • Infants <6 months in age • Serious allergy/reaction to previous influenza vaccine • Guillain-Barré syndrome diagnosed within previous 6 weeks	Should NOT be used in: • Children <2 years or adults >50 years • Pregnant women or women who plan to become pregnant
Can be used in people at increased risk: • People of any age with chronic medical conditions • Residents of nursing homes and long-term care facilities • People who are immunocompromised • Pregnant women	Prior to receiving the vaccination, please inform the HCP if you or the person you are caring for have any of the following: • Immunodeficiency • Children or adolescents receiving aspirin or other salicylates • Medical conditions that increase the risk for complications from influenza (chronic heart, lung, liver, kidney, or CNS problems, diabetes; hemoglobinopathies) • HCPs of high-risk patients because of risk for viral transmission from vaccine (should not care for high-risk patients for 7 days after vaccination)
Most common side effects are injection site reactions, such as pain, redness, and swelling	Adverse effects are rare. When effects do occur, may resemble mild flu with runny nose, nasal congestion, cough, and headache

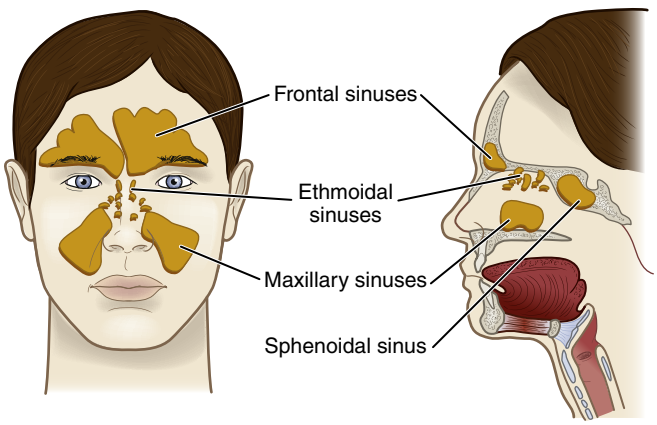

Fig. 29.2 Location of the sinuses.

Treatment with antiviral medication should be started as soon as possible in hospitalized patients with influenza, those with severe or complicated illness, or those at high risk for complications. For maximum benefit in treating the flu, therapy should begin within 2 days of the onset of symptoms. It can be started later based on clinical judgment.

SINUSITIS

Sinusitis affects 1 in every 7 adults. It develops when inflammation or swelling of the mucosa blocks the openings (ostia) in the sinuses, through which mucus drains into the nose (Fig. 29.2). *Rhinosinusitis,* which may accompany sinusitis, is concurrent inflammation or infection of the nasal mucosa. Nasal polyps, foreign bodies, deviated septa, or tumors can cause obstruction of mucus drainage. Secretions that accumulate behind the blocked ostia provide a rich medium for growth of bacteria, viruses, and fungi, all of which may cause infection.

Viral sinusitis may follow a URI in which the virus penetrates the mucous membrane and decreases ciliary function. Viral infections usually resolve without treatment in less than 14 days. If symptoms worsen after 3 to 5 days or last for longer than 10 days, a secondary bacterial infection may be present. Only 5% to 10% of patients with viral sinusitis develop a bacterial infection and need antibiotic therapy.

Sinusitis can be classified as acute, subacute, recurrent acute, or chronic.[18] *Acute sinusitis* typically begins within 1 week of a URI and lasts less than 4 weeks. *Subacute sinusitis* is present when symptoms progress over 4 to 12 weeks. Recurrent acute rhinosinusitis is defined as having 4 or more sinus infections per year, lasting 7 to 10 days, without having continual symptoms. *Chronic sinusitis* (lasting longer than 12 weeks) is a persistent infection usually related to allergies or nasal polyps. It generally results from repeated episodes of acute sinusitis that result in irreversible loss of the normal ciliated epithelium lining the sinus cavity.

Clinical Manifestations

Acute sinusitis causes significant pain over the affected sinus, purulent nasal drainage, nasal obstruction, congestion, fever, and malaise. The patient may appear acutely ill. Inspect the nasal mucosa and palpate the paranasal sinuses for pain. Findings that indicate acute sinusitis include edematous mucosa, discolored purulent nasal drainage, enlarged turbinates, tenderness over the involved frontal and/or maxillary sinuses, and *halitosis* (bad

breath). Recurrent headaches are common. They may change in intensity with position changes or when secretions drain.

The symptoms of chronic sinusitis are often nonspecific. The patient is rarely febrile. They may have facial or dental pain, nasal congestion, and increased drainage. Severe pain and purulent drainage are often absent. Some symptoms mimic those seen with allergies. X-rays or CT scans of the sinuses may help confirm the diagnosis. CT scans may show sinuses filled with fluid or a thickened mucous membrane. Nasal endoscopy with a flexible scope may be used to examine the sinuses, obtain a specimen for culture, and restore normal drainage.

As many as 50% of patients with moderate to severe asthma have chronic sinusitis. The exact link between these diseases is unclear. Postnasal drip from sinusitis may trigger asthma by stimulating bronchoconstriction. Gastroesophageal reflux disease (GERD) and smoking may increase the risk for a person with asthma developing sinusitis. Appropriate treatment of sinusitis often causes a reduction in asthma symptoms.

❖ Nursing and Interprofessional Management: Sinusitis

If allergies are the precipitating cause of sinusitis, teach the patient ways to reduce sinus inflammation and infection, including environmental control of allergens and appropriate drug therapy.

Initial treatment for acute sinusitis focuses on symptom relief. Medications include oral or topical decongestants to promote drainage, intranasal corticosteroids to decrease inflammation, analgesics to relieve pain, and saline nasal spray to relieve congestion. Teach patients using topical decongestants to use the medication for no longer than 5 days to prevent rebound congestion caused by vasodilation. Saline irrigation of the nasal cavity can rinse nasal passages, promote drainage, and decrease inflammation. Saline nasal spray is available over the counter.

If symptoms worsen or last longer than 1 week, antibiotic therapy may be prescribed.

With chronic sinusitis, mixed bacterial flora is often present, and infections are hard to eliminate. Broad-spectrum antibiotics may be used for 4 to 6 weeks. Patient and caregiver teaching for acute and chronic sinusitis is shown in Table 29.5.

Medical therapy may not relieve the symptoms of some patients with persistent, recurrent, or chronic sinus illnesses. These patients may need nasal endoscopic surgery to relieve blockage caused by hypertrophy or septal deviation. This is usually an outpatient procedure under local anesthesia. Propel, a self-expanding implant, can be placed directly in the sinus during surgery. Propel helps maintain patency to the sinus cavity after surgery and provides local corticosteroid delivery directly to the sinus lining before dissolving after 30 days.

TABLE 29.5 PATIENT & CAREGIVER TEACHING

Acute or Chronic Sinusitis

Include the following instructions when teaching the patient and caregiver about managing sinusitis:

1. Get plenty of rest to help the body fight infection and promote recovery.
2. Keep well hydrated by drinking 6–8 glasses of water per day to loosen secretions.
3. Take hot showers. Use a steam inhaler (15-min vaporization of boiled water), bedside humidifier, or nasal saline spray to promote secretion drainage.
4. Apply warm, damp towels around nose, cheeks, and eyes to ease facial pain.
5. Sleep with head elevated to help sinuses drain and reduce congestion.
6. Report a temperature of 100.4°F (38°C) or higher, which indicates infection.
7. Follow prescribed medication plan:
   - Take analgesics to relieve pain.
   - Take decongestants/expectorants to relieve swelling.
   - Take antibiotics (as prescribed) for infection. Take the entire prescription and report continued symptoms or a change in symptoms.
   - Use nasal sprays to relieve congestion.
8. Perform nasal saline washes once or twice a day to wash sinuses.
9. Do not smoke and avoid exposure to smoke. It will irritate and worsen symptoms.
10. If allergies predispose to sinusitis, follow instructions about environmental control, drug therapy, and immunotherapy to reduce the inflammation and prevent sinus infection.

NASAL AND SINUS OBSTRUCTION

Nasal Polyps

Nasal polyps are soft, painless, benign (non-cancerous) growths that form slowly in response to repeated inflammation of the sinus or nasal mucosa. They are most common in adults over age 40 and are twice as likely to occur in men.[19] Polyps, which appear as chronic yellow, gray, or pink semitransparent projections in the naris, can exceed the size of a grape.

Small polyps are typically asymptomatic. Manifestations of larger polyps include nasal obstruction, nasal discharge (usually clear mucus), and speech distortion. Topical and systemic corticosteroids are primary therapies used to shrink nasal polyps. Endoscopic or laser surgery can remove nasal polyps, but recurrence is common.

Foreign Bodies

A variety of foreign bodies may potentially lodge in an adult's upper respiratory tract, but it is a rare occurrence. Foreign bodies, such as food, may cause a local inflammatory reaction and nasal discharge. The discharge may become purulent and foul-smelling if the object stays in the nasal cavity for an extended time. Foreign bodies can cause pain, difficulty breathing, and nasal bleeding.

We usually remove foreign bodies from the nose through the route of entry. Sneezing or blowing the nose with the opposite nostril closed may be effective in removing the foreign object. Avoid irrigating the nose or pushing the object backward since these could cause aspiration and airway obstruction. If sneezing or blowing the nose does not remove the object, consult an HCP.

PHARYNGEAL PROBLEMS

ACUTE PHARYNGITIS

Acute **pharyngitis** is an acute inflammation of the pharyngeal walls. It may include the tonsils, palate, and uvula. It can be

caused by a viral, bacterial, or fungal infection. Viral pharyngitis accounts for about 90% of cases. Bacterial pharyngitis ("strep throat") usually results from group A β-hemolytic streptococci and accounts for 5% to 10% of cases.

Fungal pharyngitis, such as candidiasis, can develop with the prolonged use of antibiotics or inhaled corticosteroids. It can also occur in immunosuppressed patients, especially those with human immunodeficiency virus (HIV) infection. Other causes of pharyngitis include dry air, smoking, GERD, allergy, postnasal drip, ET intubation, chemical fumes, and cancer.

Clinical Manifestations

Symptoms of acute pharyngitis range in severity from a "scratchy" throat to pain so severe that swallowing is difficult. Because both viral and streptococcal infections appear as a red and edematous pharynx (with or without patchy exudates), it may be hard to tell between them.

Four classic manifestations present in bacterial pharyngitis include (1) fever greater than 100.4°F (38°C); (2) anterior cervical lymph node enlargement; (3) tonsillar or pharyngeal exudate; and (4) absence of cough.[20] However, appearance is not always diagnostic. When 2 or 3 of these criteria are present, a rapid antigen detection test and/or a throat culture can help with the diagnosis. White, irregular patches on the oropharynx suggest fungal infection with *Candida albicans*.

❖ Nursing and Interprofessional Management: Acute Pharyngitis

The goals of treatment are infection control, symptom relief, and prevention of secondary complications.

For viral pharyngitis, antibiotics are not recommended. For bacterial pharyngitis caused by group A β-hemolytic streptococci, penicillin is the drug of choice. This antibiotic must be taken several times a day for a full 10 days to prevent complications, such as rheumatic fever. For patients allergic to penicillin, erythromycin and clindamycin are substitutes.[21] Other antibiotics, such as azithromycin (Zithromax) or a 1st generation cephalosporin, are options. Most people with streptococcal infections are contagious until they have been on antibiotics for 24 to 48 hours. Repeat throat cultures after antibiotic therapy are not needed.

Candida infections are treated with nystatin, an antifungal antibiotic. Teach patients to swish the preparation in their mouths for as long as possible before swallowing it. Treatment should continue until symptoms are gone. Patients taking inhaled corticosteroids are at risk for infection with *Candida* organisms. Thoroughly rinsing the mouth with water after using corticosteroids can prevent this infection.

Teach patients to use ibuprofen or acetaminophen for pain relief. Encourage the patient to increase fluid intake. For symptom relief, have patients gargle with warm salt water (½ tsp of salt in 8 oz of water); drink warm or cold liquids; and suck on popsicles, hard candies, or throat lozenges. Cool, bland liquids and gelatin will not irritate the pharynx. Citrus juices are often irritating. Encourage the patient to use a cool-mist vaporizer or humidifier.

PERITONSILLAR ABSCESS

Peritonsillar abscess is a complication of tonsillitis. It is most often caused by group A β-hemolytic streptococci. The abscess causes pain, swelling, and blockage of the throat (when severe), threatening airway patency. The patient may have a high fever, chills, leukocytosis, difficulty swallowing, and a muffled voice. Treatment consists of IV antibiotic therapy and needle aspiration or incision and drainage of the abscess. In some cases, an emergency tonsillectomy is done. An elective tonsillectomy is scheduled after the infection has subsided.

LARYNGEAL AND TRACHEAL PROBLEMS

LARYNGEAL POLYPS

Laryngeal polyps develop on the vocal cords from vocal abuse (e.g., excessive talking, singing) or irritation (e.g., intubation, cigarette smoking). The most common sign is hoarseness. Conservative treatment involves voice rest and adequate hydration. Large polyps may cause dysphagia, dyspnea, and stridor. They may need surgically removed. Polyps are usually benign but may be removed because they can become cancerous.

ACUTE LARYNGITIS

Acute laryngitis is swelling and inflammation of the voice box (larynx). A virus (e.g., flu, common cold) is the most common cause. Other causes include inflammatory or infectious conditions of the upper respiratory tract (e.g., tonsillitis, acute bronchitis), overuse of one's voice (e.g., yelling loudly at a concert or a sporting event), exposure to smoke, or chemical inhalation.

The classic hallmark signs include a tingling or burning sensation at the back of the throat, a persistent need to clear the throat, and hoarseness, which may be accompanied by complete loss of voice. The patient may have a low-grade fever, persistent cough, or feeling of fullness in the throat. Symptoms will appear suddenly, increase in severity over 2 to 3 days, then gradually subside over the next 7 to 10 days as the condition improves. It usually resolves within 21 days.

Diagnosis of acute laryngitis is made based on the history, physical assessment, and changes in voice. Treatment for acute laryngitis is supportive. The patient is strongly encouraged to limit use of the larynx. This includes no talking or singing, which, realistically, is almost impossible to do. Patients will want to whisper when communicating but whispering places increased strain on the vocal cords that may worsen the pain. Acetaminophen, cough suppressants, throat lozenges, and using a humidifier are helpful for throat discomfort.

Have the patient increase fluid intake. They should avoid caffeine and alcohol, which may worsen a sore throat. Encourage smoking cessation. If a bacterial cause is known, such as acute bronchitis or tonsillitis, antibiotics should help resolve the condition. If symptoms last longer than 3 weeks, patients should return to their HCP for further investigation and treatment.

AIRWAY OBSTRUCTION

Acute **airway obstruction** is a medical emergency. Airway obstruction can be caused by aspiration of food or a foreign body, allergic reactions, edema and inflammation caused by infections or burns, peritonsillar or retropharyngeal abscesses, cancer, laryngeal or tracheal stenosis, and trauma.

Airway obstruction may be partial or complete. The presentation of an airway obstruction often depends on the cause of the obstruction and/or location of the blockage. For example, objects lodged within the larynx may cause voice hoarseness or complete airway obstruction. Tracheal obstruction may cause wheezing. Objects lodged within the lower respiratory system (e.g., bronchus) may cause a cough or decreased air entry on the affected side.

Manifestations include choking, stridor, flaring nostrils, wheezing, restlessness, tachycardia, cyanosis, and changes in level of consciousness.[22] Prompt assessment and treatment are essential because partial obstruction may quickly progress to complete obstruction. Complete airway obstruction can result in permanent brain damage or death if not corrected within 3 to 5 minutes.

Your immediate priority is to ensure the patient has a patent airway. Interventions to reestablish a patent airway include the obstructed airway (Heimlich) maneuver (see Appendix A), cricothyroidotomy, ET intubation, or tracheostomy. Unexplained partial airway obstruction or recurrent symptoms indicate the need for more tests, including a chest x-ray, laryngoscopy, and rigid bronchoscopy.

HEAD AND NECK CANCER

Head and neck cancer is classified according to the area where it occurs. These cancers may involve the nasal cavity and paranasal sinuses, nasopharynx, oropharynx, larynx, oral cavity, and/or salivary gland. Cancer of the oral cavity is discussed in Chapter 46. Most head and neck cancers arise from squamous cells that line the mucosal surfaces of the head and neck.

More than 53,000 new cases of head and neck cancer are diagnosed each year in the United States.[23] Tobacco use causes 85% of head and neck cancers. Excess alcohol use is another major risk factor. Head and neck cancer most often occurs in people over age 50 and twice as often in men. Head and neck cancers in those younger than 50 years are often related to human papillomavirus (HPV) infection. Other risk factors include exposure to the sun, asbestos, industrial carcinogens, marijuana use, radiation therapy to the head and neck, and poor oral hygiene.[24]

Unfortunately, most patients have locally advanced disease at the time of diagnosis. Disability from both the disease and its treatment is significant because of the potential loss of voice, adverse effects from chemotherapy and/or radiation, disfigurement, and social concerns.

Clinical Manifestations

The early manifestations vary with the location of the tumor. For example, patients with pharyngeal cancer may have what feels like a lump in the throat or a sore throat that does not get better with treatment. Some have white or red patches in the mouth or a change in the quality of the voice. Hoarseness that lasts more than 2 weeks may be a symptom of early laryngeal cancer.

Other manifestations may include ear pain or ringing in the ears, swelling or lumps in the neck, constant coughing, and coughing up blood. Swelling of the jaw can cause dentures to fit poorly or become uncomfortable. Unintentional weight loss and difficulty with chewing, swallowing, moving the tongue or jaw, and breathing are typically late symptoms. A partially or fully obstructed airway is often a late manifestation of head and neck cancer.

TABLE 29.6 Interprofessional Care

Head and Neck Cancer

Management
- Surgery (Table 29.7)
- Radiation therapy
- Chemotherapy
- Targeted therapy
- Respiratory therapy
- Physical therapy
- Occupational therapy
- Speech therapy

Diagnostic Studies

Early detection is key to patient survival. Physical assessment involves a focused assessment of the ears, nose, throat, mouth, and neck. Thoroughly examine the mouth, including the area under the tongue and dentures, with a flashlight. There may be thickening of the normally soft and pliable oral mucosa. Inspect the floor of the mouth and tongue. *Leukoplakia* (white patch) or *erythroplakia* (fiery red patch) may be present. Both leukoplakia and carcinoma in situ (localized to a defined area) may precede invasive carcinoma by many years. Palpate the lymph nodes in the neck.

If lesions are suspected, the HCP may examine upper airways using indirect pharyngoscopy and laryngoscopy (which involves using a laryngeal mirror). The larynx and vocal cords are visually inspected for lesions and tissue mobility. Typically, multiple biopsy specimens are obtained to help determine the extent of the disease. A CT scan or MRI may be done to detect local and regional spread. Positron emission tomography (PET) scanning is also used in diagnosis. The interprofessional care of head and neck cancer is outlined in Table 29.6.

Staging of Head and Neck Cancer

Head and neck cancer is staged based on the size of the tumor (T), number and location of involved lymph nodes (N), and

extent of metastasis (M). This is referred to as *TNM staging*.[25] Staging is slightly different for each type of cancer. Generally, stage 0 is in situ, or confined to where it began, through stage 4, with more advanced disease. Oral cancer staging considers a patient's HPV status. TNM staging is discussed in Chapter 16.

Interprofessional Care

The choice of treatment for head and neck cancer is based on many factors. These include the tumor location, TNM stage, age and overall general health, urgency of treatment, cosmetic and functional considerations (e.g., ability to talk, swallow, chew), and patient choice. Treatment options include surgery, radiation therapy, chemotherapy, targeted therapy, or any combination of these therapies.

Surgical Therapy

Surgery is often the first-line treatment option for head and neck cancers. Some patients may be treated with surgery alone. For other patients, combining surgery with radiation therapy and/or chemotherapy may be appropriate. Surgical options depend on the location and stage of cancer (Table 29.7). After extensive surgery to remove head and neck cancer, reconstructive operations can help restore both the structure and function of the affected areas.

Radiation Therapy

Radiation therapy can be delivered by either external-beam therapy or internal implants (brachytherapy). Brachytherapy is a concentrated and localized method of delivering radiation that involves placing a radioactive source near or into the tumor. The goal is to deliver high doses of radiation to the target area while limiting the exposure of surrounding tissues. Thin, hollow, plastic needles are inserted into the tumor area, and radioactive seeds are placed in the needles. The seeds emit continuous radiation. Radiation therapy and brachytherapy are discussed in Chapter 16.

Radiation therapy is often preferred for patients with early head and neck cancer because it offers the patient good results with voice preservation. Some patients refuse surgery for advanced lesions because of the extent of the procedure and potential risks involved. In this situation, radiation therapy is used as the sole treatment or in combination with chemotherapy. Other patients may opt for surgery and a combination of either radiation and/or chemotherapy treatments.

Chemotherapy and Targeted Therapy

Chemotherapy is used in combination with radiation therapy for patients with stage 3 or 4 head and neck cancers. Chemotherapy agents currently recommended include cisplatin, 5-fluorouracil, carboplatin, docetaxel (Taxotere), paclitaxel, methotrexate, and bleomycin.[26]

Cetuximab (Erbitux), a targeted therapy, is used with chemotherapy to treat patients with late-stage head and neck cancer. The drug targets epidermal growth factor receptor (EGFR), a specific protein within cancer cells, and stops the cells from growing. Targeted therapy is discussed in Chapter 16 and Table 16.13.

TABLE 29.7 Surgical Procedures for Head and Neck Cancer

Cordectomy	Removal of part or all the vocal cords May be changes in tone of voice Removing part of a vocal cord may lead to a hoarse voice If both vocal cords are removed, speech will no longer be possible
Laser surgery	An endoscope with a laser is inserted down the throat, and the tumor can be vaporized or removed
Laryngectomy	Removal of part (partial) or all (total) the larynx Total laryngectomy changes airflow in and out of the lungs, and normal voice production will not be possible (Fig. 29.3)
Lymph node removal	Amount of tissue and number of lymph nodes removed depend on how far cancer has spread
Pharyngectomy	Removal of part or all the throat
Tracheostomy	Creates an alternate pathway for breathing by creating a stoma in the trachea
Vocal cord stripping	Removal of outer layers of tissue on the vocal cords May be used for a biopsy or to treat some stage 0 cancers confined to the vocal cords Rarely affects speech
Neck Dissection Surgery	
Modified radical neck dissection	Most common type of neck dissection Removal of all lymph nodes Less neck tissue removed than with radical dissection May spare the nerves in the neck and, sometimes, the blood vessels or muscle
Radical neck dissection	Removal of all the tissue on the side of the neck from the mandible to the clavicle Removes the muscle, nerve, salivary gland, major blood vessels
Selective neck dissection	If cancer has not spread far, fewer lymph nodes are removed May save muscle, nerve, blood vessels in the neck

Nutrition Therapy

Many patients with head and neck cancer are malnourished even before treatment begins. Treatment modalities increase the risk for malnutrition. For example, after radical neck surgery, the patient may be unable to consume nutrients orally because of swelling, the location of sutures, or difficulty with swallowing. Side effects from chemotherapy and radiation therapy can impair the patient's ability to maintain adequate nutrition. Painful oral mucositis often leads to breaks in treatment if the patient is relying solely on oral intake for nutrition.

A thorough nutrition assessment and prophylactic placement of a gastrostomy tube in high-risk patients are vital to maintaining adequate nutrition.[27] Enteral nutrition (EN) may be started before treatment to obtain and maintain optimal nutrition needed for tissue repair (see Chapter 44.) Elevate the head of the bed while the patient is eating. Observe for feeding intolerance. Adjust the amount, time, and/or formula if nausea, vomiting, diarrhea, or distention occurs. Teach the patient and caregiver about EN.

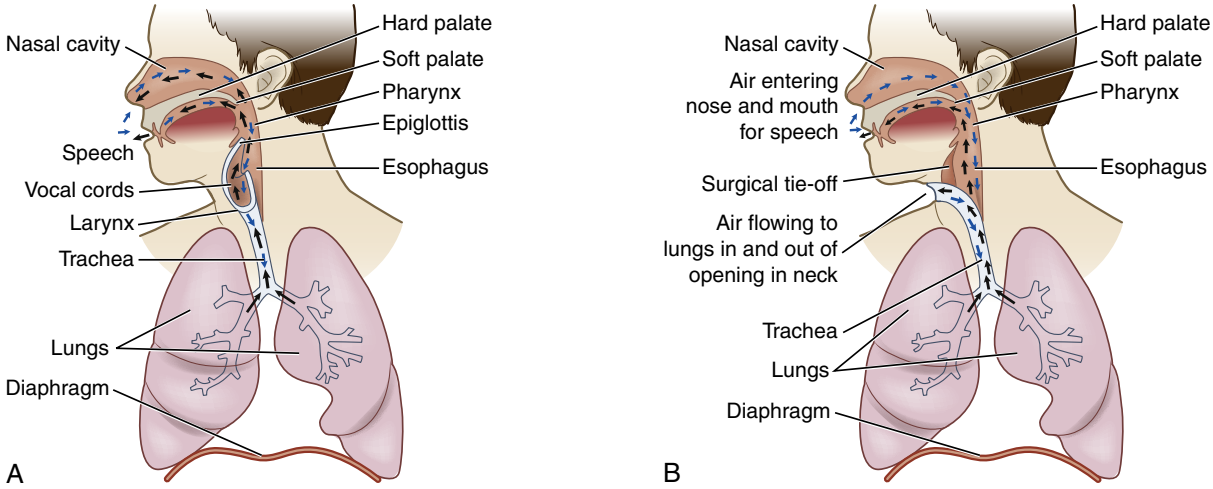

Fig. 29.3 Airflow in and out of the lungs (A) before and (B) after total laryngectomy. There is no anatomic connection between the nose, mouth, and throat. Inhaled and exhaled air enters the lungs through a surgically created stoma (hole) in the neck.

Patients who are not candidates for or who refuse EN need to be monitored closely for weight loss.[27] Antiemetics or analgesics given before meals can reduce nausea and mouth pain. Bland foods are easier for patients to tolerate. Patients can increase caloric intake by adding dry milk to foods during preparation, eating foods high in calories, and using oral supplements. It is helpful to add mild sauces and gravy to food. This adds calories and moistens food so that it is easier to swallow

Expect swallowing problems when the patient resumes eating after surgery. The type and degree of difficulty varies depending on the surgery. A video-fluoroscopic swallowing study may evaluate the safety of swallowing after surgery. When the patient can successfully swallow with low or no risk for aspiration, they may have small amounts of thickened liquids or pureed foods while in high-Fowler's position. Avoid thin, watery fluids because they are hard to swallow and increase the risk for aspiration. Closely monitor and observe for any signs or symptoms of respiratory distress and/or choking when eating resumes. Oral suctioning can help prevent aspiration.

Physical Therapy

After surgery for head and neck cancer, the physical therapist will help teach the patient how to use the upper extremities to assist with support and movement of the head. In the immediate postoperative period, the patient should begin an exercise program to maintain strength and movement in the shoulders and neck. Without exercise, the patient may develop a "frozen" shoulder and limited range of neck motion. The patient should continue the exercise program after discharge to prevent future functional disabilities.

Speech Therapy

Before surgery, a speech therapist should meet with the patient and caregiver to discuss any effect that surgery will have on the voice and potential adaptations or voice restoration options. The International Association of Laryngectomees, a group for laryngectomy patients, focuses on helping patients reestablish speech. Local groups, such as "Lost Chord" or "New Voice," often have volunteers to visit patients before surgery.

We use 3 major approaches to restore oral communication: (1) electrolarynx, (2) tracheoesophageal puncture (TEP) voice restoration, and (3) esophageal speech. An *electrolarynx* is a hand-held, battery-powered device that creates speech with the use of sound waves (Fig. 29.4A). This option allows for speech immediately after surgery. It needs little maintenance and is easy to learn. The primary disadvantage is the mechanical sound quality, which many patients find unacceptable.

In TEP, a fistula is created in the tracheoesophageal wall. It diverts pulmonary air across the pharyngoesophageal mucosa for phonation when the tracheostoma is occluded. A one-way prosthetic valve is placed in the tract. The valve prevents aspiration of food or saliva from the esophagus into the tracheostomy. To speak, the patient manually blocks the stoma with the finger. Air moves from the lungs, through the prosthesis, into the esophagus, and out the mouth. Speech is made by the air vibrating against the esophagus and is formed into words by moving the tongue and lips. A common voice prosthesis is the Blom-Singer prosthesis (Fig. 29.4B). TEP offers the best speech quality with the highest degree of patient satisfaction.

Esophageal speech depends upon air entering the esophagus and then being expelled past the pharyngoesophageal segment, the vibratory source for sound production. The primary disadvantages of developing esophageal speech are the length of time needed to learn the technique and the reduction in voice quality.

❖ NURSING MANAGEMENT: HEAD AND NECK CANCER

◆ Assessment

Table 29.8 presents subjective and objective data to obtain from a person with head and neck cancer.

◆ Clinical Problems

Clinical problems for the patient with head and neck cancer include:

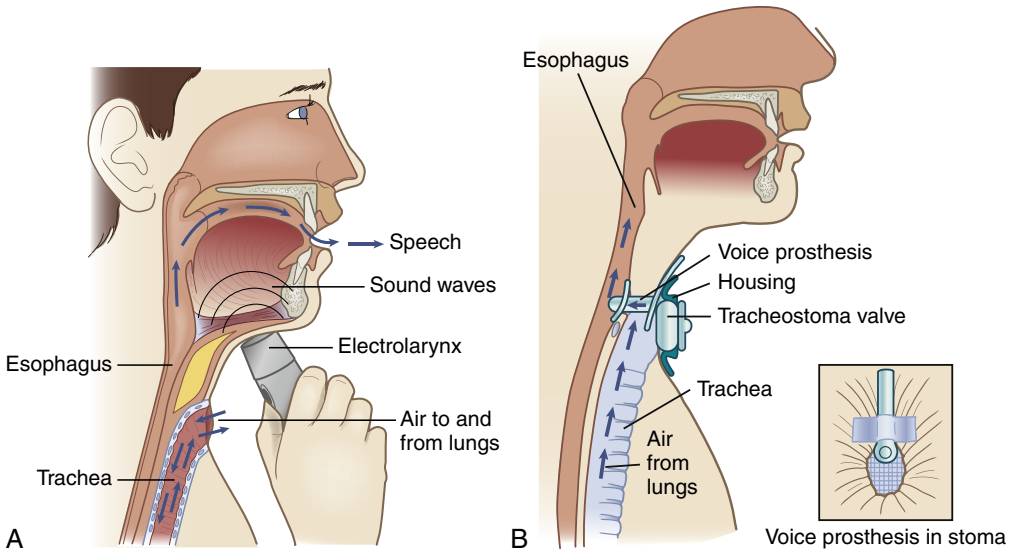

Fig. 29.4 (A) The sound waves created by the electrolarynx allow the person to speak. (B) The Blom-Singer voice prosthesis and valve.

TABLE 29.8 NURSING ASSESSMENT

Head and Neck Cancer

Subjective Data

Important Health Information

Health history: Positive family history; prolonged tobacco use (cigarettes, pipes, cigars, chewing tobacco, smokeless tobacco); prolonged, heavy alcohol use; poor intake of fruits and vegetables

Medications: Prolonged use of over-the-counter medication for sore throat, decongestants

Functional Health Patterns

Health perception–health management: Does not take part in preventive health measures, long history of alcohol and tobacco use

Nutritional-metabolic: Mouth ulcer that does not heal, change in fit of dentures, change in appetite, sudden or unexplained weight loss, swallowing difficulty (e.g., sensation of a lump in throat, pain with swallowing, aspiration when swallowing)

Activity-exercise: Fatigue with minimal exertion

Cognitive-perceptual: Sore throat, pain on swallowing, referred ear pain

Objective Data

Respiratory

Hoarseness, change in voice quality, chronic laryngitis, nasal voice, palpable neck mass and lymph nodes (tender, hard, fixed), tracheal deviation; dyspnea, stridor (late sign)

Gastrointestinal

White (leukoplakia) or red (erythroplakia) patches inside mouth, ulceration of mucosa, asymmetric tongue, exudate in mouth or pharynx, mass or thickening of mucosa

Possible Diagnostic Findings

Mass on direct or indirect laryngoscopy; tumor on soft tissue x-ray, CT scan, or MRI; positive biopsy

- Impaired respiratory function
- Risk for aspiration
- Difficulty coping
- Impaired communication

More information on clinical problems and the care of the patient with head and neck cancer is presented in eNursing Care Plan 26.2 on the website for this chapter.

◆ Planning

The overall goals are that the patient will have (1) a patent airway, (2) an acceptable body image, (3) no complications related to therapy, (4) adequate nutrition intake, (5) minimal to no pain, and (6) the ability to communicate.

◆ Implementation

◆ Health Promotion

Many head and neck cancers can be prevented. Their development is closely related to personal habits, mainly tobacco use and excess alcohol use. Poor oral hygiene and HPV infection are also risk factors for head and neck cancer.

Include information about risk factors in health teaching. Encourage good oral hygiene. Teach patients about safe sex practices to prevent HPV infection (e.g., use condoms, encourage monogamous relationships, choose a partner who has had no or few previous partners). When cancer has been diagnosed, tobacco and alcohol cessation are still important. The chance of a cure, by any treatment modality, for a patient with head and neck cancer who continues to smoke and use alcohol is decreased. Also, the risk for a second primary cancer is significantly increased. Give patients information about smoking cessation and techniques for success. If needed, refer to an alcohol treatment program. Smoking cessation and treatment of alcohol use are discussed in Chapter 11.

◆ Acute Care

Teach the patient and caregiver about the type of treatment, care needed, and reason for treatment and care. Help prepare them to deal with the psychological impact of the diagnosis of cancer, change in physical appearance, possible need for EN, and use of other communication methods because of loss of voice.

Assess the patient's support system. The patient may not have someone to help after discharge or may have a job that cannot be continued, leaving the patient unemployed.

Surgical therapy. Before surgery, assess the patient's physical and psychosocial needs. Physical preparation is the same as for any major surgery, with an emphasis on oral hygiene. Assess understanding of the planned surgery and clarify information as needed. When possible, include the caregiver in preoperative teaching.

Tailor teaching to the planned surgical procedure. For example, include information about expected changes in speech after a laryngectomy. Alphabet boards, writing materials, pictorial guides, laptops, and hand signals are useful methods for communicating. Programmable speech-generating devices allow the use of recorded messages that are matched with a graphic representing each message. Integration of newer technology into patient care enhances the patient's ability to communicate basic needs after surgery.

Immediately after surgery, nursing care priorities include airway management, wound care, nutrition, communication, and psychosocial issues related to body image changes. Maintaining a patent airway is essential. Inflammation in the surgical area may compress the trachea. Keep the patient in a semi-Fowler's position to decrease edema and limit tension on suture lines.

Give analgesic drugs as needed for pain control. Because patients may not be able to speak, have them nonverbally rate their pain (e.g., visual pain scale) to help assess the effectiveness of the medication. Pain management is discussed in Chapter 9. Monitor vital signs frequently. Be alert for hemorrhage, as many of the structures in the head and neck area are very vascular. Pay attention to heart rate, BP, SpO_2, and hemoglobin values.

The patient with a laryngectomy needs frequent suctioning via the tracheostomy tube. Secretions typically change in amount and consistency over time. The patient may initially have a large amount of blood-tinged secretions that gradually diminish and thicken. Maintain adequate fluid intake (IV, enteral) and humidification of inspired gases to keep secretions liquid and mucous membranes moist. Encourage deep breathing and coughing.

Pressure dressings, packing, or drainage tubes may be present, depending on the surgery. Do not change any dressing unless you have a specific order from the HCP. Dressings are typically not present with skin flaps. This allows better visualization of the flap and avoids excess pressure on tissue. Initially, check skin flaps hourly for color and any change in size or edema. We may use doppler ultrasound to determine the presence of a pulse, depending upon the location of the skin flap.

Care for any Hemovac, Jackson-Pratt, and Penrose drains that are in use. Drainage may be bloody at first, then serosanguineous. It should gradually decrease in volume over 24 to 48 hours. Monitor patency of drainage tubes every hour in the first few hours after surgery, then every 4 hours to ensure proper functioning. If tubing becomes obstructed, fluid will accumulate under the skin flap. This predisposes the patient to hematomas or seromas, impaired wound healing, and increased risk for infection. After removal of the drainage tubes, closely monitor the area to detect any swelling. Closely monitor incision sites for signs of infection.

The patient may have a nasogastric (NG) tube inserted during surgery to remove gastric contents via intermittent suction for the first 24 to 48 hours until peristalsis returns. Because the NG tube lies close to internal incision lines, do not manipulate or move the tube. When bowel sounds return, start EN slowly and advance to meet nutrition needs.

Radiation therapy. Dry mouth *(xerostomia),* a frequent and annoying problem, typically occurs within a few weeks of treatment. The patient's saliva decreases in volume and becomes thick. This change may be temporary or permanent. Pilocarpine hydrochloride (Salagen) is often effective in increasing saliva production.

CHECK YOUR PRACTICE

Your 64-years-old male patient with oral cancer has been receiving radiation therapy for 3 weeks. He has developed xerostomia and oral mucositis. He asks if you have any suggestions to help relieve his symptoms.

- How would you respond?

Once patients can have foods or fluids by mouth, they can get symptom relief by increasing fluid intake, chewing sugarless gum or sugarless candy, using nonalcoholic mouth rinses (baking soda, glycerin solutions), and using artificial saliva. Teach patients to always carry a water bottle with them. Fluoride gels or treatments can help prevent dental deterioration caused by xerostomia.

Oral mucositis can cause irritation, ulceration, and pain. Teach the patient oral care basics, including the use of a soft toothbrush and regular flossing. The patient can wear empty fluoride gel trays, bite blocks, athletic mouth guards, or gauze pads during radiation treatments. This prevents radiation scatter to the tongue and cheek from metal work in the mouth. Warm bland rinses, like those with salt and baking soda, 4 to 6 times daily may be helpful. Sucking on ice chips can help with the pain. Patients should avoid commercial mouthwashes and hot, spicy, or acidic foods because they are irritating.

Skin over the irradiated area often becomes reddened and sensitive to touch. Teach patients to use only prescribed lotions and skin products while undergoing radiation therapy and to not use any lotions within 2 hours before treatment. Skin care for patients having radiation therapy is discussed in Chapter 16.

Fatigue is a common side effect of radiation therapy and chemotherapy. Encourage patients to walk 15 to 30 minutes each day since regular exercise can give them more energy. Teach patients to do activities that are most important to them and to rest during periods of low energy. Identify support systems. Encourage patients to ask for help.

Stoma care. Should the patient have a stoma after surgery, teach the patient proper care of the stoma. The patient should wash the area around the stoma daily with a moist cloth. A nasal wash spray is used every 1 to 2 hours to keep the stoma moist and prevent crusting. Dried secretions can be removed with tweezers. If a laryngectomy tube is in place, the patient must remove the entire tube at least daily and clean it in the same manner as a tracheostomy tube. The inner cannula may have to be removed and cleaned more often. A scarf or loose shirt can hide the stoma.

The patient should cover the stoma when coughing (because mucus may be expectorated) and during any activity (e.g., shaving, applying makeup) that may lead to inhalation of foreign materials. Because water can easily enter the stoma, the patient should wear a plastic collar when taking a shower. Swimming is contraindicated. Humidification is given with mechanical ventilation or after extubation with a tracheostomy mask. After discharge, the patient can use a bedside humidifier.

Psychosocial needs. Psychosocial care of the patient with head and neck cancer is of utmost importance. Issues concerning depression, change in body image, and sexuality are common. Although we discuss changes before surgery, the patient may not be psychologically prepared for the extent of these changes. If the patient has a significant other, this person's reaction to the patient's altered appearance is important. Acceptance by another person can promote an improved self-image.

Depression may occur for many reasons: inability to speak because of surgical procedure and/or presence of ET or tracheostomy tube, altered physical appearance, edema, loss of independence and reliance upon others, and feelings of helplessness and hopelessness. Depression also may be related to concern about the prognosis.

Allow the patient and caregiver to express their feelings and emotions. Convey acceptance to help patients regain positive feelings about their body image and self-concept. Encourage participation in support groups. Provide information about groups available through the local branch of the American Cancer Society. Provide a psychiatric referral for the patient who has prolonged or severe depression.

Surgical devices such as tracheostomy and gastrostomy tubes may dramatically affect body image. Xerostomia and fatigue can physically affect sexuality. It may be hard for the patient to talk about sexual problems because of changes in communication. Help the patient and partner by allowing them to talk about their sexuality and how surgery and treatment may affect their relationship. Helping the patient see that sexuality involves much more than appearance may relieve some anxiety.

Ambulatory Care

The patient may be discharged with a tracheostomy and an NG or gastrostomy feeding tube. Some patients may need a home health care referral and assessment to evaluate the patient's or caregiver's ability to perform self-care activities. Both patient and caregiver need to learn how to manage tubes and whom to call if there are problems. Provide pictorial instructions for tracheostomy care, suctioning, stoma and skin care, and EN as appropriate. Encouraging the patient to take part in self-care is an important part of rehabilitation.

Teach the patient the importance of wearing a Medic Alert bracelet or other identification that alerts emergency personnel of the possible changes in breathing status because of surgery. Because the patient no longer breathes through the nose, they often lose the ability to smell smoke. Teach the patient to install smoke and carbon monoxide detectors in the home. The loss of smell and radiation therapy may lead to decreased taste. Encourage eating food that is colorful, attractive, and nutritious. Refer to a dietitian as needed.

The patient can resume exercise, recreation, and sexual activity when able. Most patients can return to work 1 to 2 months after surgery. However, many never return to a full-time job. The changes that follow a total laryngectomy can be upsetting. Loss of speech, loss of the ability to taste and smell, inability to make audible sounds (including laughing and weeping), and the presence of a permanent tracheal stoma that produces undesirable mucus are often overwhelming to patients.

Evaluation

Expected outcomes for the patient with head and neck cancer who is treated surgically are that the patient will:

- Have effective coughing and secretion clearance
- Swallow oral foods without aspiration
- Uses effective coping strategies
- Use effective communication techniques

Case Study

Laryngeal Cancer

(© iStockphoto/Thinkstoc.)

Patient Profile

M.R., a 69-years-old retired baker, is on your medical floor with influenza. He told his HCP that he has "a cough that just won't go away," difficulty swallowing, and "a sore throat that really hasn't gotten better" over the past year. His wife passed away 6 years ago. He has 3 adult children. One daughter lives in the same city. He has a history of hypertension, smoking, alcohol use, gastroesophageal reflux disease (GERD), and type 2 diabetes.

Subjective Data

- States that his symptoms worsened in the past 3 months
- Has used various cough and cold remedies over the past 6 months to relieve symptoms without relief
- Has lost weight because of decreased appetite and difficulty swallowing
- Has smoked 3 packs of cigarettes a day for the past 50 years
- Consumes 4 to 6 cans of beer a day

Objective Data

Physical Assessment

- Temp 102.4°F (39.1°C), heart rate 99 beats/min, BP 176/84 mm/Hg
- Respiratory rate 24 breaths/min; respirations short, shallow, slightly labored; SpO_2 87% on room air
- Awake and alert
- Appears gray, malnourished, dehydrated
- Small, irregular white patches on the sides of oral cavity
- Enlarged cervical nodes bilaterally, nontender
- Lung sounds diminished at bases with occasional fine crackles on expiration

Diagnostic Studies

- Chest x-ray: lung fields clear
- Laryngoscopy: mass in subglottic area (requires further evaluation)
- CT scan: subglottic lesion with lymph node involvement
- Diagnosis: laryngeal cancer

Continued

Case Study—cont'd

Laryngeal Cancer

Interprofessional Care

- *Surgery:* Suggests a total laryngectomy
- *Oncology:* Suggests radiation and chemotherapy after surgery
- *Gastroenterology:* Percutaneous gastrostomy tube preoperatively for EN
- *Dietary:* Review nutrition options with/without ET tube/tracheostomy
- *Physical therapy:* Visit pre-surgery to explain postoperative exercise routine
- *Social worker:* Assess social supports available postoperatively

Discussion Questions

1. ***Recognize:*** What assessment information suggests M.R. was at risk for laryngeal cancer?
2. ***Recognize:*** What factors may affect wound healing after surgery?
3. ***Prioritize:*** What are your priority teaching strategies before his total laryngectomy?
4. ***Act:*** How would you explain the gastrostomy tube to M.R.?

Case Progression

M.R. is transferred to the clinical unit after 24 hours in ICU. He is awake, alert, but slightly confused. His BP is 168/94 mm Hg. A tracheostomy tube is in place with O_2 via tracheal mask. Enteral feeding transfusing at 30 mL/hr via gastrostomy tube. The indwelling catheter is patent and draining a moderate amount of amber urine. M.R. is picking at his surgical drains. When you try to reassure him, he just starts waving his hands at you.

5. ***Analyze:*** What information would you want to know from the ICU nurse who has just transported M.R. to the clinical unit?
6. ***Prioritize:*** Based on the assessment data presented, what are your priority clinical problems?
7. ***Act:*** How would you best meet M.R.'s communication needs during the first few postoperative days?
8. ***Act:*** Four hours after transfer to the clinical unit, M.R. is tearful and is staring at the wall. What should you do?
9. ***Safety:*** What teaching does M.R. need to help him assume self-care after his surgery? What precautions should he take because of his stoma?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient is seen in the clinic for a nosebleed, which is controlled by placing anterior nasal packing. During discharge teaching, the nurse teaches the patient to
- **a.** use aspirin for pain relief.
- **b.** remove the packing later that day.
- **c.** avoid vigorous nose blowing and strenuous activity.
- **d.** insert more packing into the nose if re-bleeding occurs.

2. A patient with allergic rhinitis reports severe nasal congestion; sneezing; and watery, itchy eyes and nose at various times of the year. When teaching the patient about how to control these symptoms, the nurse teaches the patient to
- **a.** avoid all intranasal sprays and oral antihistamines.
- **b.** limit the usage of nasal decongestant spray to 10 days.
- **c.** use oral decongestants at bedtime to prevent symptoms during the night.
- **d.** keep a diary of when the allergic reaction occurs and what precipitates it.

3. A patient is seen at the clinic with fever, muscle aches, sore throat with yellowish exudate, and headache. The nurse anticipates that the interprofessional management will include *(select all that apply)*
- **a.** providing antipyretic for fever
- **b.** immediate treatment with antibiotics.
- **c.** a throat culture or rapid strep antigen test.
- **d.** supportive care, including cool, bland liquids.
- **e.** comprehensive history to determine possible cause.

4. A 19 year-old patient arrives at the clinic with a sore throat and fever of 102.4°F (39.1°C). Assessment findings include enlarged anterior cervical lymph nodes and exudate at the back of the throat. What is the priority nursing action?
- **a.** Administer morphine 1 mg IV for pain
- **b.** Administer acetaminophen for pain and fever
- **c.** Increase hydration by providing oral and IV fluids
- **d.** Document the assessment findings in the nursing notes.

5. When planning health care teaching to prevent or detect early head and neck cancer, which people would be the *priority* to target? *(select all that apply)*
- **a.** 65-years-old man who has used chewing tobacco most of his life
- **b.** 45-years-old rancher who uses chewing tobacco while driving his herds of cattle
- **c.** 21-years-old college student who drinks beer on weekends with his fraternity brothers
- **d.** 78-years-old woman who has been drinking liquor since her husband died 15 years ago
- **e.** 22-years-old woman who has been diagnosed with human papilloma virus of the cervix

6. While in the recovery room, a patient with a total laryngectomy is suctioned and has bloody mucus with some clots. Which nursing interventions would apply? (*select all that apply*)
- **a.** Notify the health care provider at once.
- **b.** Place the patient in semi-Fowler's position.
- **c.** Use a bag-valve-mask (BVM) and begin rescue breathing for the patient
- **d.** Instill 10 mL of normal saline into the tracheostomy tube to loosen secretions.
- **e.** Continue patient assessment, including O_2 saturation, respiratory rate, and breath sounds.

7. Appropriate discharge teaching for the patient with a permanent tracheostomy after a total laryngectomy for cancer would include (*select all that apply*)
- **a.** encouraging regular exercise such as swimming.
- **b.** washing around the stoma daily with a moist washcloth.
- **c.** encouraging participation in postlaryngectomy support group.

d. providing pictures and "hands-on" instruction for tracheostomy care.
e. teaching how to hold breath and trying to gag to promote swallowing reflex.

1. c; 2. d; 3. a, c, d, e; 4. b; 5. a, b, d, e; 6. b, d, e; 7. b, c, d.

CONCEPTUAL FOCUS

Cellular Regulation
Clotting
Functional Ability
Gas Exchange
Infection

LEARNING OUTCOMES

1. Compare and contrast the clinical manifestations and nursing and interprofessional management of patients with acute bronchitis and pertussis.
2. Distinguish among the types of pneumonia and their etiology.
3. Describe the pathophysiology, clinical manifestations, diagnostic studies, and interprofessional and nursing management of patients with pneumonia.
4. Explain the pathophysiology, classification, clinical manifestations, complications, diagnostic abnormalities, and interprofessional and nursing management of patients with tuberculosis.
5. Describe the pathophysiology, clinical manifestations, and nursing and interprofessional management of a patient with a lung abscess.
6. Identify the etiology, clinical manifestations, and nursing and interprofessional management of a patient with a pleural effusion.
7. Compare and contrast the pathophysiology, clinical manifestations, and nursing and interprofessional management of fractured ribs, flail chest, and pneumothorax.
8. Describe the pathophysiology, clinical manifestations, and nursing and interprofessional management of pulmonary embolism, pulmonary hypertension, and cor pulmonale.
9. Identify the causative factors, clinical manifestations, and nursing and interprofessional management of patients with environmental lung diseases.
10. State lung disorders in which lung transplantation may be a treatment option, explaining the nursing and interprofessional management of the transplant patient.
11. Describe the etiology, risk factors, pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with lung cancer.

KEY TERMS

pneumothorax
pulmonary edema
pulmonary embolism (PE)
pulmonary hypertension
tension pneumothorax
tuberculosis (TB)

A variety of problems affect the lower respiratory system. This chapter discusses lower respiratory tract diseases that influence gas exchange. We will focus on infectious, restrictive, traumatic, vascular, environmental, and oncologic problems that have the potential to impair gas exchange. Left untreated, many of these conditions will have profound consequences for the patient, as adequate oxygenation and ventilation are both essential for life.

LOWER RESPIRATORY TRACT INFECTIONS

Lower respiratory tract infection is a common and serious problem. It is the reason for thousands of clinic and emergency department (ED) visits and hospital admissions each year. In the United States, pneumonia and influenza cause around 50,000 deaths each year.[1]

ACUTE BRONCHITIS

Acute bronchitis is a self-limiting inflammation of the bronchi in the lower respiratory tract. It is the reason for 2.7 million outpatient clinic visits and 4 million ED visits per year. Viruses cause most acute bronchial infections. Air pollution, dust, inhalation of chemicals, smoking, chronic sinusitis, and asthma are other triggers.

Cough is the most common symptom. It may last for up to 3 weeks and is the main reason for seeking medical care. Coughing is more frequent at night. When present, sputum is often clear, although some patients have purulent sputum. Other symptoms may include headache, fever, malaise, hoarseness, myalgias, dyspnea, and chest pain.

Diagnosis is based on the assessment. Assessment may reveal normal breath sounds or crackles or wheezes, usually on expiration and with exertion. *Consolidation* (when fluid accumulates in the lungs), suggestive of pneumonia, is absent with bronchitis. Chest x-rays are normal and not needed unless we suspect pneumonia or some other lung problem.

The goal of treatment is to relieve symptoms and prevent pneumonia. Treatment is supportive. It includes cough suppressants (e.g., dextromethorphan), encouraging oral fluid intake, and using a humidifier. Throat lozenges, hot tea, and honey may help relieve cough. β_2-agonist (bronchodilator) inhalers are useful for patients with wheezes or underlying lung problems. We do not prescribe antibiotics for viral infections because they are not effective against viruses and giving them promotes antibiotic resistance. Antibiotics may be given to patients with underlying chronic conditions who are at risk for or have a prolonged infection with systemic symptoms.

Encourage patients to not smoke, avoid secondhand smoke, and wash their hands often (Box 30.1). If acute bronchitis is due to influenza, we may start treatment with antiviral drugs. If patients with acute bronchitis develop a fever, have trouble breathing, or have symptoms last longer than 4 weeks, they should see their HCP.

BOX 30.1 PROMOTING POPULATION HEALTH

Preventing Respiratory Diseases

- Wash hands often to prevent and avoid spreading infections.
- Get a Tdap, pneumococcal, COVID, and flu vaccines as directed by the HCP.
- Avoid smoking and exposure to environmental smoke.
- Wear proper personal protective equipment (PPE) when working in an occupation with prolonged exposure to dust, fumes, or gases.
- Avoid exposure to allergens, indoor pollutants, and ambient air pollutants.

PERTUSSIS

Pertussis is a highly contagious respiratory tract infection. It is caused by the gram-negative bacillus *Bordetella pertussis*. The bacteria attach to the cilia of the respiratory tract and release toxins that damage the cilia, causing inflammation and swelling. Cases of pertussis have been steadily increasing in the United States since the 1980s.[2] The largest increase is in teens and adults. We think that immunity from childhood tetanus, diphtheria, and pertussis vaccine (Tdap) vaccination may decrease over time, allowing a milder (but still contagious) infection to occur. The Centers for Disease Control and Prevention (CDC) currently recommends that all adolescents (11 years and older) and adults who have not received a dose of Tdap receive a one-time vaccination as soon as possible.[3]

Manifestations of pertussis occur in stages. The 1st stage, lasting 1 to 2 weeks, manifests as a mild upper respiratory tract infection (URI) with a low-grade or no fever, runny nose, watery eyes, malaise, and mild, nonproductive cough. The 2nd stage, from the 2nd to 10th weeks of infection, is characterized by paroxysms of cough. The last stage lasts 2 to 3 weeks. The cough is less severe. The patient may still be weak.

The hallmark characteristic of pertussis is uncontrollable, violent coughing. Inspiration after each cough produces the typical "whooping" sound as the patient tries to breathe in air against an obstructed glottis. The "whoop" is often not present in teens and adults (especially those who are vaccinated). Coughing is more frequent at night. Vomiting may occur with coughing. Unlike acute bronchitis, the cough with pertussis may last from 6 to 10 weeks.

In the community, diagnosis is mainly by history and assessment. In the acute care setting, the CDC recommends nasopharyngeal cultures, polymerase chain reaction (PCR) of nasopharyngeal secretions, or serology testing.[4] The treatment is macrolide (erythromycin, azithromycin) antibiotics to minimize symptoms and prevent disease spread (see Table 15.8). For the patient who cannot take macrolides, trimethoprim/sulfamethoxazole is used.

The patient is infectious from the beginning of the 1st stage through the 3rd week after onset of symptoms or until 5 days after starting antibiotic therapy. Place hospitalized patients on droplet precautions. Patients should not use cough suppressants and antihistamines as they are ineffective and may cause coughing. Corticosteroids and bronchodilators are also not helpful. The CDC recommends antibiotic therapy for those who had close contact with the patient.

PNEUMONIA

Pneumonia is an acute infection of the lung parenchyma. Despite progress in antibiotic therapy to treat pneumonia, pneumonia still has significant morbidity and mortality. Pneumonia and lower respiratory tract infections were the 4th leading cause of death worldwide in 2019.[5]

Etiology

Normally, various defense mechanisms protect the airway distal to the larynx from infection. Mechanisms that create a

mechanical barrier to microorganisms entering the tracheobronchial tree include air filtration, epiglottis closure over the trachea, cough reflex, mucociliary escalator mechanism, and reflex bronchoconstriction. Immune defense mechanisms include secretion of immunoglobulins A and G and alveolar macrophages.

Pneumonia is more likely to occur when defense mechanisms become incompetent or are overwhelmed by the virulence or quantity of infectious agents. A weakened cough or epiglottal reflex may allow aspiration of oropharyngeal contents into the lungs. Tracheal intubation bypasses normal filtration processes and interferes with the cough reflex and mucociliary escalator mechanism. Air pollution, smoking, viral URIs, and normal changes that occur with aging can impair the mucociliary mechanism. Chronic diseases can suppress the immune system's ability to inhibit bacterial growth. Risk factors for pneumonia are listed in Table 30.1.

Pathogens that cause pneumonia reach the lung in 3 ways:

1. *Aspiration* of normal flora from the nasopharynx or oropharynx. Many organisms that cause pneumonia are normal inhabitants of the mouth and pharynx in healthy adults.
2. *Inhalation* of microbes present in the air. Examples include *Mycoplasma pneumoniae* and fungal pneumonias.
3. *Hematogenous spread* from a primary infection elsewhere in the body. One example is *Staphylococcus aureus* from infective endocarditis.

Classifications of Pneumonia

There is no universally accepted classification system for pneumonia. Some classify pneumonia by the causative pathogens (e.g., bacterial, viral, fungal), disease characteristics, or appearance on chest x-ray. The most widely recognized and effective way to classify pneumonia is as either *community-acquired* or *hospital-acquired* pneumonia. This classification helps the HCP identify the most likely cause (Table 30.2) and the choice of antimicrobial therapy.

TABLE 30.1 Risk Factors for Pneumonia

- Abdominal or chest surgery
- Age >65 years
- Air pollution
- Altered level of consciousness (e.g., head injury, seizures, anesthesia, drug overdose, stroke)
- Bed rest and prolonged immobility
- Chronic diseases: chronic lung and liver disease, diabetes, heart disease, cancer, chronic kidney disease
- Debilitating illness
- Enteral feedings via naso- or orogastric or intestinal tubes
- Exposure to bats, birds, rabbits, and farm animal feces
- Immunosuppressive conditions and/or therapy (e.g., corticosteroids, cancer chemotherapy, HIV infection, immunosuppressive therapy after organ transplant)
- Inhalation or aspiration of noxious substances
- IV drug use
- Malnutrition
- Resident of a long-term care facility
- Smoking
- Tracheal intubation (endotracheal intubation, tracheostomy)
- URI

Community-Acquired Pneumonia

Community-acquired pneumonia (CAP) is an acute lung infection that occurs in patients who have not been hospitalized or lived in a long-term care facility within 14 days of symptom onset. The decision to treat the patient at home or admit to a hospital is based on several factors. These include the patient's age, vital signs, mental status, presence of co-morbid conditions, and condition. We can use various tools (Table 30.3) to support clinical judgment.

Hospital-Acquired Pneumonia

Hospital-acquired pneumonia (HAP), or nosocomial pneumonia, is pneumonia in a non-intubated patient that begins 48 hours or longer after admission to hospital and was not present when they were admitted. *Ventilator-associated pneumonia*

TABLE 30.2 Organisms Causing Pneumonia

Community-Acquired Pneumonia (CAP)

Typical

- *Escherichia coli*
- *Haemophilus influenzae*[a]
- *Klebsiella pneumoniae*[a]
- *Methicillin resistant staphylococcus aureus* (MRSA)
- *Moraxella catarrhalis*
- *Pseudomonas*
- *Staphylococcus aureus*[a]
- *Streptococcus pneumoniae*[a]

Atypical

- Chlamydophila pneumoniae
- Coxiella burnettii
- Influenza A and B
- Legionella pneumophilia
- Mycoplasma pneumoniae
- Mycobacterium tuberculosis

Respiratory Viruses

- Parainfluenza virus
- Respiratory syncytial virus
- Rhinovirus

Other Causes of CAP

- Fungi
- Oral anaerobes

Hospital-Acquired Pneumonia (HAP)

- *Escherichia coli*[b]
- *Haemophilus influenzae*
- *Klebsiella pneumoniae*[b]
- Microaspiration of bacteria that colonize the mouth, oropharynx
- *Pseudomonas aeruginosa*[b]
- *Proteus* species
- *Serratia marcescens*
- *Staphylococcus aureus*
- *Streptococcus pneumoniae*[a]

[a]Most common cause of CAP.
[b]Most common causes of HAP.

TABLE 30.3 Pneumonia Severity Index (PSI)

The PSI can supplement clinical judgment to determine the severity of pneumonia and if patients need to be hospitalized.

Factor	Points
Demographics	
Age in years	
Women	– 10
Extended care resident	+10
Other Conditions	
Stroke, kidney disease, heart failure	+10 each
Active cancer	+30
Liver disease	+20
Assessment	
Respiratory rate ≥30/min, BP < 90, altered mental status	+20 each
Pulse 125/min	+10
Temperature <95°F (35°C) or ≥104°F (40°C)	+15
Pleural effusion	+10
Laboratory Results	
pH < 7.35	+30
BUN ≥30 mg/dL, Sodium <130 mEq/L	+20 each
Glucose 250 mg/dL, Hematocrit < 30%, pAO_2 <60 mm Hg or O_2 <90 percent	+10 each
Scoring:	
<70 points	Outpatient
71-90 points	Outpatient vs. Observation
>91 points	Inpatient

(VAP), a type of HAP, refers to pneumonia that occurs more than 48 hours after endotracheal intubation.[6] VAP is discussed in Chapter 28. Both HAP and VAP are associated with longer hospital stays, increased associated costs, sicker patients, and increased mortality.

Once the diagnosis of CAP, HAP, or VAP is made, treatment is started based on risk factors, speed of onset, clinical presentation, underlying medical conditions, hemodynamic stability, and the most likely causative pathogen. *Empiric antibiotic therapy,* the initiation of treatment before a definitive diagnosis or causative agent is made, should be started as soon as pneumonia is suspected. Empiric antibiotic therapy is based on the drugs known to be effective for the most likely cause. Antibiotic therapy is adjusted once the results of sputum cultures identify the exact pathogen causing the infection.

Types of Pneumonia

There are several types of pneumonia. *Viral pneumonia* is the most common type. It occurs in one third of all pneumonia cases. It may be mild and self-limiting or cause potentially life-threatening problems, such as acute respiratory failure (ARF) in influenza. Patients with *bacterial pneumonia* may be extremely unwell and need hospital admission. *Mycoplasma pneumonia*, which has traits of both bacteria and viruses, is often called "atypical" pneumonia. It is mild and occurs in persons younger than 40 years of age.

Aspiration Pneumonia

Aspiration pneumonia results from the abnormal entry of material from the mouth or stomach into the trachea and lungs. Conditions that increase the risk for aspiration include decreased level of consciousness (e.g., seizure, anesthesia, head injury, stroke, alcohol use), swallowing problems, and having a nasogastric (NG) tube with or without enteral feeding. With loss of consciousness, the gag and cough reflexes are depressed, making aspiration more likely.

The aspirated material (food, water, vomitus, oropharyngeal secretions) triggers an inflammatory response. The most common form of aspiration pneumonia is a primary bacterial infection. Typically, the sputum culture shows more than 1 organism, including aerobes and anaerobes, since they both make up the flora of the oropharynx.

Until cultures are done and results obtained, initial antibiotic therapy is based on an assessment of probable cause, severity of illness, and patient factors (e.g., malnutrition, current use of antibiotic therapy). For patients who aspirate in hospitals, antibiotic coverage should include both gram-negative organisms and methicillin-resistant *Staphylococcus aureus* (MRSA). Aspiration of acidic gastric contents can cause *chemical (noninfectious) pneumonitis,* which may not need antibiotic therapy. However, secondary bacterial infection can occur in these patients 48 to 72 hours later.

Necrotizing Pneumonia

Necrotizing pneumonia is a rare complication of bacterial lung infection. It causes the lung tissue to turn into a thick, liquid mass. Cavitation and lung abscesses can occur. This sometimes happens with CAP. We do not know the exact mechanisms involved. Common causative organisms include *Staphylococcus, Klebsiella,* and *Streptococcus.* Signs and symptoms include respiratory insufficiency and/or failure, leukocytosis, and abnormalities on chest imaging.[7] Treatment includes long-term antibiotic therapy and possible surgery.

Opportunistic Pneumonia

Opportunistic pneumonia is inflammation and infection of the lower respiratory tract in immunocompromised patients. Persons at risk include those with altered immune responses. This can include people with severe protein-calorie malnutrition or immunodeficiencies (e.g., human immunodeficiency virus [HIV] infection) and those receiving radiation therapy, chemotherapy, and any immunosuppressive therapy, including long-term corticosteroid therapy. In addition to the risk for bacterial and viral pneumonia, the immunocompromised person may develop an infection from organisms that do not normally cause disease, such as *Pneumocystis jiroveci* pneumonia (PJP) or cytomegalovirus (CMV).[8]

PJP is occurring with greater frequency in HIV-negative, immunocompromised persons.[8] The onset is slow and subtle. Symptoms include fever, tachypnea, tachycardia, dyspnea,

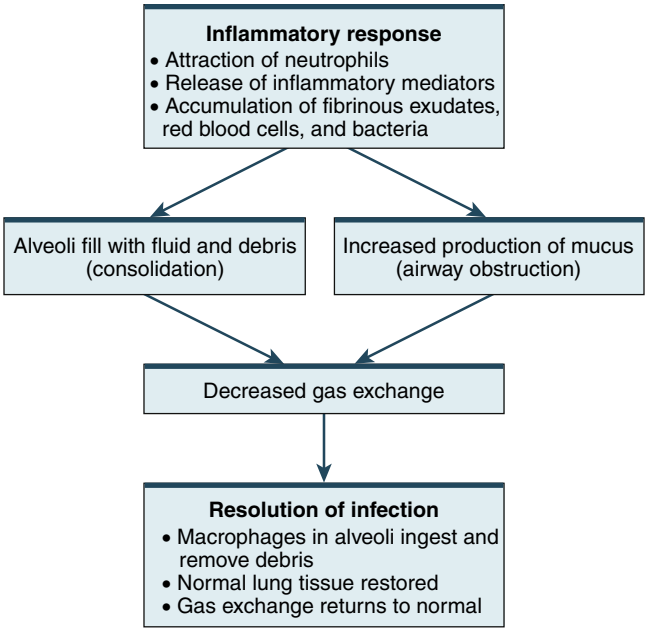

Fig. 30.1 Pathophysiologic course of pneumonia.

nonproductive cough, and hypoxemia. The chest x-ray usually shows diffuse bilateral infiltrates. In widespread disease, the lungs have massive consolidation.

PJP can be life-threatening, causing ARF and death. Infection can spread to other organs, including the liver, bone marrow, lymph nodes, spleen, and thyroid. Bacterial and viral pneumonias first must be ruled out because of the vague presentation of PJP. Although the causative agent is fungal, PJP does not respond to antifungal agents. Treatment consists of IV or oral trimethoprim/sulfamethoxazole, depending on the severity of disease, overall clinical condition, and the patient's response.

CMV, a herpes virus, can cause viral pneumonia. Most CMV infections are asymptomatic or mild. Severe disease can occur in people with an impaired immune response. CMV is one of the most important life-threatening infectious complications after hematopoietic stem cell transplant.[9] Antiviral medications (e.g., ganciclovir, cidofovir) and high-dose immunoglobulin are part of treatment.

Pathophysiology

Specific pathophysiologic changes related to pneumonia vary depending on the offending pathogen. Almost all pathogens trigger an inflammatory response in the lungs (Fig. 30.1). Inflammation, characterized by an increase in blood flow and vascular permeability, activates neutrophils to engulf and kill the offending pathogens. As a result, the inflammatory process attracts more neutrophils, airway edema occurs, and fluid leaks from the capillaries and tissues into alveoli. Normal O_2 transport is affected, leading to manifestations of hypoxia (e.g., tachypnea, dyspnea, tachycardia).

Atelectasis, the absence of gas or air in 1 or more areas of the lung, may occur with pneumonia (Fig. 30.2). Atelectasis may be asymptomatic. Some patients have extreme shortness of breath and severe chest pain. C*onsolidation,* a feature typical of bacterial pneumonia, occurs when the normally air-filled

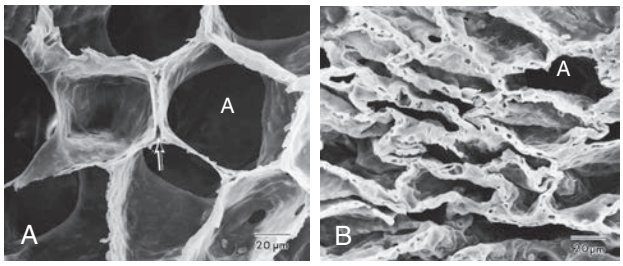

Fig. 30.2 Atelectasis. Scanning electron micrograph of lung parenchyma. (A) Alveoli *(A)* and alveolar-capillary membrane *(arrow).* (B) Effects of atelectasis. Alveoli *(A)* are partially or totally collapsed. (A, From Dantzker DR, Bone RC, George RB, editors: *Pulmonary and critical care medicine,* vol 1, St Louis, 1993, Mosby. B, From Albertine KH, Williams MC, Hyde DM: Anatomy of the lungs. In RJ Mason, VC Broaddus, JF Murray, et al., editors: *Murray and Nadel's textbook of respiratory medicine,* ed 4, Philadelphia, 2005, Saunders.)

Fig. 30.3 Chest x-ray of a patient with acute bacterial pneumonia. (© iStock.com/stockdevil.)

alveoli become filled with water, fluid, and/or debris (Fig. 30.3). This can potentially obstruct airflow, impair gas exchange, and cause significant respiratory insufficiency. Over time and with appropriate antibiotic therapy, macrophages lyse and process the debris. This allows lung tissue to recover and gas exchange to return to normal.

Clinical Manifestations

The most common presenting symptoms of pneumonia are cough, fever, chills, dyspnea, tachypnea, and pleuritic chest pain. The cough may or may not be productive. Sputum may be green, yellow, or even rust colored (bloody). Viral pneumonia may initially be seen as influenza, with respiratory symptoms appearing and/or worsening 12 to 36 hours after onset.

The older or debilitated patient may not have classic symptoms of pneumonia. Confusion or stupor (possibly related to hypoxia) may be the only finding. The older adult may have

hypothermia, rather than fever. Nonspecific manifestations include diaphoresis, anorexia, fatigue, myalgias, and headache.

Fine or coarse crackles may be auscultated over the affected region. If consolidation is present, bronchial breath sounds, egophony (an increase in the sound of the patient's voice), and increased fremitus (chest wall vibrations made by vocalization) may be present. Patients with pleural effusion may have dullness to percussion over the affected area.

Complications

A major problem today is pneumonia caused by multidrug-resistant (MDR) pathogens. Common culprits include MRSA and gram-negative bacilli. Risk factors for MDR pneumonia include advanced age, immunosuppression, history of antibiotic use, and prolonged mechanical ventilation. Antibiotic susceptibility tests can identify MDR pathogens. The virulence of these pathogens can severely limit the available and appropriate antimicrobial therapy. MDR pathogens increase mortality from pneumonia.

Other complications from pneumonia develop more often in older adults and those with underlying chronic diseases. These include:

- *Pleurisy,* inflammation of the pleura.
- *Pleural effusion,* or fluid in the pleural space. In most cases, the effusion is sterile and reabsorbed in 1 to 2 weeks. Sometimes, effusions require aspiration by thoracentesis.
- *Bacteremia*, bacterial infection in the blood, is more likely to occur in infections with *Streptococcus pneumoniae* and *Haemophilus influenzae.*
- *Pneumothorax* can occur when air collects in the pleural space, causing the lungs to collapse.
- *ARF* is a leading cause of death in patients with severe pneumonia. ARF occurs when pneumonia damages the lungs' ability to exchange O_2 and CO_2 across the alveolar-capillary membrane.
- *Sepsis* can occur when bacteria within alveoli enter the bloodstream. Severe sepsis can lead to shock and multisystem organ dysfunction syndrome (MODS) (see Chapter 42).

Lung abscess is not a common complication of pneumonia. It may occur with pneumonia caused by *S. aureus* and gram-negative organisms. *Empyema,* the accumulation of purulent exudate in the pleural cavity, may occur in up to 20% of cases. It requires antibiotic therapy and drainage of the exudate by a chest tube or open surgical drainage. Pleurisy, pleural effusion, and lung abscess are discussed later in this chapter.

Diagnostic Studies

The common diagnostic procedures for pneumonia are outlined in Table 30.4. History, physical assessment, and chest x-ray often give enough information to make immediate decisions about early treatment. Chest x-ray often shows patterns characteristic of the infecting pathogen and is important in diagnosing pneumonia. X-ray may also show pleural effusions. Bronchoscopy with bronchial washings or thoracentesis may be done to obtain cell and fluid samples from patients not responding to initial therapy.

Arterial blood gases (ABGs) may show hypoxemia, hypercapnia, and acidosis. Leukocytosis occurs in most patients with bacterial pneumonia. The white blood cell (WBC) count is usually greater than 15,000/μL (15×10^9/L) with the presence of bands (immature neutrophils). Ideally, we should obtain a sputum specimen for culture and Gram stain to identify the organism before starting antibiotic therapy. However, we should not delay starting antibiotic therapy if we cannot obtain a specimen. Delays in antibiotic therapy can increase the risk for mortality. Blood cultures are done for patients who are seriously ill.

C-reactive protein (CRP), procalcitonin, and interleukin 6 (IL-6) are currently being explored as ways to help tell pneumonia from other types of heart and respiratory failure.[10]

TABLE 30.4 Interprofessional Care

Pneumonia

Diagnostic Assessment
- History and physical assessment
- Chest x-ray
- Sputum: Gram stain, culture and sensitivity test
- Pulse oximetry and/or ABGs
- CBC, white blood cell differential, and routine blood chemistries
- Blood cultures (if indicated)

Management
- O_2 therapy
- Critical care management, with mechanical ventilation as needed
- Increased fluid intake (at least 2–3 L/day), IV fluids
- VTE prophylaxis
- Physiotherapy, early mobility
- Balance between activity and rest

Drug Therapy
- Appropriate antibiotic therapy (Table 30.6)
- Antipyretics
- Analgesics
- NSAIDs (if no contraindications)

Interprofessional Care

Prompt treatment with the appropriate antibiotic is essential. Antibiotics are highly effective for both bacterial and mycoplasma pneumonia. In uncomplicated cases, the patient responds to drug therapy within 48 to 72 hours. Signs of improvement include decreased temperature, improved breathing, and less chest discomfort. Abnormal physical findings can last more than 7 days.

Pneumococcal vaccine is used to prevent *S. pneumoniae* infection (Table 30.5). Although cough suppressants, mucolytics, bronchodilators, and corticosteroids are often prescribed as adjunctive therapy, the use of these drugs is debatable. However, they may be prescribed for patients with underlying chronic conditions.

Currently, there is no definitive treatment for most viral pneumonias. Care is generally supportive. In most circumstances, viral pneumonia is self-limiting and will often resolve in 3 to 4 days. Antiviral therapy may be used to treat pneumonia caused by influenza (e.g., oseltamivir, zanamivir) or a few other viruses (e.g., acyclovir for herpes simplex virus).

Drug Therapy

The HCP selects empiric therapy based on the likely pathogen. Table 30.6 presents the drug therapy for bacterial CAP.

TABLE 30.5 Pneumococcal Vaccines

Vaccine[a]	Recommendations for Use
Pneumococcal conjugate vaccine (PCV13, Prevnar 13): Protect against 13 types of pneumococcal bacteria	• Children <2 years • Adults ≥65 years • Anyone 2–64 years old with certain medical conditions (e.g., sickle cell disease, asplenia, immunodeficiencies, HIV infection, chronic kidney disease, leukemia, cancer, long-term immunosuppressive therapy)
Pneumococcal polysaccharide vaccine (PPSV23, Pneumovax 23): Protect against 23 types of pneumococcal bacteria	• Adults ≥50 years • Adults 19–64 years old who smoke • Anyone 2–64 years old who have high risk of pneumococcal disease (e.g., heart disease, lung disease, diabetes, alcohol use, cirrhosis, sickle cell disease, immunocompromised, cancer)

[a]For more details on scheduling of pneumococcal vaccinations, see https:www.cdc.gov/pneumococcal/vaccination.html.

TABLE 30.6 Drug Therapy

Bacterial Community-Acquired Pneumonia

Patient Variable	Treatment Options
Outpatient	
Healthy	
No comorbidities or risk factors for antibiotic-resistant infection	Beta lactam *OR* Macrolide *OR* doxycycline
Co-Morbidities	
COPD; diabetes; chronic liver, lung, heart, or renal disease; cancer; alcohol use; no spleen	Respiratory fluoroquinolone *OR* β-Lactam plus macrolide (doxycycline may be substituted for macrolide) OR Beta lactam plus doxycycline plus macrolide
Inpatient	
Medical Unit	Respiratory fluoroquinolone *OR* β-Lactam plus macrolide (doxycycline may be substituted for macrolide)
ICU	β-Lactam plus either azithromycin or respiratory fluoroquinolone
Special Considerations	
• Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA)	Vancomycin or linezolid (Zyvox)
• *Pseudomonas* infection	Antipneumococcal and antipseudomonal β-lactam *OR* Antipneumococcal, antipseudomonal β-lactam plus either respiratory fluoroquinolone or ciprofloxacin or levofloxacin *OR* Antipneumococcal, antipseudomonal β-lactam plus aminoglycoside plus either ciprofloxacin or levofloxacin
• *Pseudomonas* infection in patient with penicillin allergy	Substitute aztreonam for the above β-lactam

Source: Community acquired pneumonia in adults. Retrieved from https://www.clinicalkey.com/#!/content/clinical_overview/67-s2.0-77188ebd-e5b9-49a1-88a0-0211995a4b85#treatment-options-heading-35.

For all types of pneumonia, empiric antibiotic therapy is based on whether the patient has risk factors for MDR pathogens. The prevalence and resistance patterns of MDR pathogens vary among localities and agencies. Therefore, antibiotic therapy must be adapted to local patterns of antibiotic resistance. Multiple regimens exist. All treatment should initially include antibiotics that are effective against both resistant gram-negative and resistant gram-positive organisms.

Clinical improvement usually occurs in 3 to 5 days. Patients who do not respond to therapy or deteriorate need aggressive re-evaluation to assess for noninfectious causes, complications, coexisting infectious processes, or pneumonia caused by an MDR pathogen.

We switch the patient from IV to oral antibiotic therapy as soon as they are improving clinically and able to take oral medication. Stable patients can be discharged on oral antibiotics. Total treatment time for patients with CAP should be a minimum of 5 days. The patient should be afebrile for 48 to 72 hours before stopping treatment. Stress the importance of completing the full course of antibiotic treatment. Longer treatment time may be needed if initial therapy was not active against the identified pathogen or complications occur.

Nutrition Therapy

Hydration is important to prevent dehydration and thin and loosen secretions. Carefully monitor fluid intake. If the patient is an older adult, has heart failure (HF), or has a known preexisting respiratory condition, administer IV fluids carefully to avoid fluid overload. Pay close attention to intake and output. Monitor and replace electrolytes as needed.

Weight loss may occur in patients with pneumonia because of increased metabolic needs, difficulty eating due to dyspnea, nonspecific abdominal symptoms, and activity intolerance. Small, frequent meals are easier for dyspneic patients to tolerate. Offer foods high in calories and nutrients. A nutrition assessment by a dietitian may be done on admission to acute care.

❖ NURSING MANAGEMENT: PNEUMONIA

◆ Assessment

Table 30.7 presents subjective and objective data to obtain from a patient with pneumonia.

◆ Clinical Problems

Clinical problems for the patient with pneumonia may include:

- Impaired respiratory function
- Infection
- Fluid imbalance
- Activity intolerance
- Altered body temperature

Additional information on clinical problems and interventions for the patient with pneumonia is shown in eNursing Care Plan 30.1 on the website for this chapter.

◆ Planning

The overall goals are that the patient with pneumonia will have (1) no signs of hypoxemia, (2) normal breathing patterns, (3) clear breath sounds, (4) normal chest x-ray, (5) normal WBC count, and (6) no complications.

TABLE 30.7 NURSING ASSESSMENT

Pneumonia

Subjective Data

Important Health Information

Health history: Lung cancer, COPD, diabetes, chronic debilitating disease, malnutrition, immunosuppression, exposure to chemical toxins, dust, or allergens

Medications: Antibiotics, corticosteroids, chemotherapy, or any immunosuppressants

Surgery or other treatments: Recent abdominal or chest surgery, splenectomy, endotracheal intubation, enteral feedings, or any surgery with general anesthesia.

Functional Health Patterns

Health perception–health management: Smoking, alcohol use, illicit drug use, recent tract URI, malaise

Nutritional-metabolic: Anorexia, nausea, vomiting

Activity-exercise: Prolonged bed rest or immobility. Fatigue, weakness. Dyspnea, cough.

Cognitive-perceptual: Pain with breathing, nasal congestion, chest pain, sore throat, headache, abdominal pain, muscle aches

Objective Data

Cardiovascular

- Tachycardia

General

- Fever, restlessness, or lethargy. Splinting of thoracic cavity

Neurologic

- Changes in mental status, ranging from confusion to delirium

Respiratory

- Tachypnea, pharyngitis
- Asymmetric chest movements or retraction, decreased excursion
- Nasal flaring, use of accessory muscles (neck, abdomen)
- Crackles, friction rub on auscultation, dullness on percussion over consolidated areas, ↑ tactile fremitus on palpation
- Pink, rusty, purulent, green, yellow, or white sputum (amount may be scant to copious)

Possible Diagnostic Findings

- Leukocytosis, positive sputum on Gram stain and culture, Patchy or diffuse infiltrates, abscesses, pleural effusion, or pneumothorax on chest x-ray
- leftAbnormal ABGs with ↓ or normal PaO_2, ↓ or normal $PaCO_2$, and ↑ or normal pH initially, and later ↓ PaO_2, ↑ $PaCO_2$, and ↓ pH

TABLE 30.8 NURSING MANAGEMENT

Care of the Patient With Pneumonia

- Monitor respiratory status:
  - Breath sounds, noting areas of decreased or absent ventilation, and presence of adventitious sounds.
  - Rate, rhythm, depth, and effort of respirations.
  - Characteristics of any secretions.
  - Ability to cough effectively and presence of fatigue.
- Assess for signs of hypoxemia.
- Administer antibiotic and IV fluid therapy as ordered.
- Administer medications (e.g., bronchodilators and inhalers) to promote airway patency and gas exchange.
- Keep the head of the bed elevated at least 30 degrees.
- Turn and reposition the patient every 2 hrs to promote lung expansion and mobilize secretions.
- Encourage the patient to cough, deep breathe, and use the incentive spirometer.
- Implement measures to manage fever (see Table 12.5).
- Administer analgesics as ordered to relieve pain.
- Provide ordered VTE and GI prophylaxis.
- Monitor intake and output.
- Supervise AP:
  - Obtain vital signs and report to RN.
  - Provide personal hygiene, skin care, and oral care
  - Assist with frequent position changes, including early mobility
  - Report to RN any change in patient condition.

Collaborate With Respiratory Therapist

- Apply O_2 therapy as ordered.
- Perform chest physiotherapy (e.g., percussion, postural drainage).

Collaborate With Dietitian

- Assess and monitor nutrition status.
- Recommend optimal diet.

Collaborate With Physical and Occupational Therapist

- Perform ROM exercises.
- Assist with early and progressive ambulation.

Implementation

Health Promotion

To reduce the risk for pneumonia, teach patients to practice good health habits, such as frequent hand washing, good nutrition, adequate rest, regular exercise, and coughing or sneezing into the elbow rather than hands. Avoiding smoking is one of the most important health-promoting behaviors. If possible, avoid exposure to people with URIs. If a URI occurs, it requires prompt attention with supportive measures (e.g., rest, fluids). If symptoms persist for longer than 7 days, the person should seek medical care. Identifying patients at risk and taking measures to prevent pneumonia are important. Encourage those at risk for pneumonia (e.g., chronically ill, older adult) to obtain needed vaccines.

Acute Care

Nursing care for the patient with pneumonia is outlined in Table 30.8. Although many patients with pneumonia are treated on an outpatient basis, the nursing care plan for a patient with pneumonia (see eNursing Care Plan 30.1) applies to both patients at home and hospitalized.

Essential nursing care for hospitalized patients with pneumonia includes monitoring assessment findings and the response to therapy. We provide supportive measures according to the patient's needs. These may include O_2 therapy to treat hypoxemia and analgesics to relieve chest pain. Implement measures to reduce fever (see Table 12.5). Prompt collection of specimens and timely administration of antibiotics is critical. Hydration, nutrition support, and positioning are part of the care plan. Work with the respiratory therapist to monitor the patient's condition and provide chest physiotherapy.

Balance rest and activity to each patient's tolerance. Benefits of early mobility include improved lung and chest expansion, mobilization of secretions, and prevention of venous stasis.

Practice strict medical asepsis and adherence to infection control guidelines to reduce the incidence of possible transmission between staff and patients. Staff and visitors should wash their hands when entering and leaving the patient's room. Staff must wash hands or use hand sanitizer before and after providing care and on removing gloves.

Implement measures to reduce the incidence of pneumonia in patients at higher risk. To prevent aspiration in the patient who has problems swallowing, elevate the head-of-bed to at least 30 degrees. Assess for presence of a gag reflex before giving food or fluids. Patients who have an orogastric or NG tube are at risk for aspiration pneumonia. Although feeding tubes are small, any interruption in the integrity of the lower esophageal sphincter can allow reflux of gastric contents. Elevating the head of the bed can help prevent this complication.

After surgery, treat pain to a comfort level that permits the patient to deep breathe and cough yet remain awake and alert and achieve optimum mobility. Twice-daily oral hygiene with chlorhexidine swabs reduces the risk of pneumonia in postoperative patients.[11]

In the ICU, strictly adhere to the ventilator bundle (see Table 28.10), a group of interventions aimed at reducing the risk for VAP. Maintain sterile aseptic technique when suctioning the patient's trachea. Use caution when handling ventilator circuits, tracheostomy tubing, and nebulizer circuits that can become contaminated from patient secretions.

Ambulatory Care

Teach the patient about the importance of taking every dose of the prescribed antibiotic (see Table 15.9). Review any drug-drug and food-drug interactions. Explain the need for adequate rest to promote recovery. Tell the patient to drink plenty of liquids (at least 6 to 10 glasses/day, unless contraindicated) and avoid alcohol and smoking. A cool mist humidifier or warm bath may help the patient breathe easier. Tell them that it may be several weeks before their usual sense of well-being returns. Explain that a follow-up chest x-ray may be done in 6 to 8 weeks to evaluate resolution of pneumonia. The older adult or chronically ill patient may have a prolonged period of convalescence.

Teaching should include information about available influenza and pneumococcal vaccines. Patients can receive the pneumococcal vaccine and influenza vaccine at the same time but not in the exact same location. The vaccines cannot be mixed into 1 injection.

Evaluation

The expected outcomes are that the patient with pneumonia will have:

- Effective respiratory rate, rhythm, and depth of respirations
- Lungs clear to auscultation
- No complications

TUBERCULOSIS

Tuberculosis (TB) is an infectious disease caused by *Mycobacterium tuberculosis*. It usually involves the lungs, but can infect any organ, including the brain, kidneys, and bones.

BOX 30.2 PROMOTING HEALTH EQUITY

Tuberculosis

- 88% of TB cases in the United States occur in racial and ethnic minorities. 71.4% of these persons were born outside of the United States.
- Asians have the highest TB rate, followed by Hispanics (30%) and Blacks (20%).
- American Indian/Alaska Natives, and Native Hawaiian/Pacific Islanders have the lowest TB rates amongst all ethnic groups (1%).

Source: Centers for Disease Control and Prevention: Health disparities in TB. Retrieved from https://www.cdc.gov/tb/topic/treatment/default.htm.

About 25% of the world's population is infected with TB.[12] The incidence of TB worldwide declined until the mid-1980s. We are now seeing increasing rates of TB. This is attributed to HIV disease and the emergence of drug-resistant strains of *M. tuberculosis*. TB is the leading cause of mortality in patients with HIV infection.

TB occurs disproportionately in the poor, underserved, and minorities (Box 30.2). People most at risk include the homeless, residents of inner-city neighborhoods, foreign-born people, those living or working in institutions (long-term care facilities, prisons, shelters, hospitals), IV drug users, overcrowded living conditions, less than optimal sanitation, and those with poor access to health care. Immunosuppression from any cause (e.g., HIV infection, cancer, long-term corticosteroid use) increases the risk for active TB infection.

Etiology and Pathophysiology

M. tuberculosis is a gram-positive, aerobic, acid-fast bacillus (AFB). It is usually spread from person to person by airborne droplets expectorated when breathing, talking, singing, sneezing, and coughing. A process of evaporation leaves small droplet nuclei, 1 to 5 μm in size, suspended in the air for minutes to hours. Another person then inhales the bacteria. Humans are the only known reservoir for TB. TB is not highly infectious. Transmission requires close contact and frequent or prolonged exposure. TB does not spread by touching, sharing food utensils, kissing, or any other physical contact.

Factors that influence transmission include the (1) number of organisms expelled into the air, (2) concentration of organisms (small spaces with limited ventilation would mean higher concentration), (3) length of time of exposure, and (4) immune system of the exposed person. Once inhaled, these small droplets lodge in bronchioles and alveoli. A local inflammatory reaction occurs, and the infection is established. This is called the *Ghon lesion* or *focus*. It represents a calcified TB granuloma, the hallmark of a primary TB infection. The formation of a granuloma is a defense mechanism aimed at walling off the infection and preventing further spread. Bacillus replication is inhibited, stopping the infection.

Most immunocompetent adults infected with TB can completely kill the mycobacteria. Some people have the mycobacteria in a non-replicating dormant state. Of these persons, 5% to 10% develop active TB infection when the bacteria begin to

TABLE 30.9 Classification of Tuberculosis

Class	Exposure or Infection	Description
0	No TB exposure	No TB exposure, not infected (no history of exposure, negative tuberculin skin test)
1	TB exposure, no infection	TB exposure, no evidence of infection (history of exposure, negative tuberculin skin test)
2	Latent TB infection, no disease	TB infection without disease (positive reaction to tuberculin skin test, negative bacteriologic studies, no x-ray findings compatible with TB, no clinical evidence of TB)
3	TB, clinically active	TB infection with clinically active disease (positive bacteriologic studies or both a significant reaction to tuberculin skin test and clinical or x-ray evidence of current disease)
4	TB, but not clinically active	No current disease (history of previous episode of TB or abnormal, stable x-ray findings in a person with a positive reaction to tuberculin skin test. Negative bacteriologic studies if done. No clinical or x-ray evidence of current disease)
5	TB suspect	TB suspect (diagnosis pending). Person should not be in this classification for >3 months

TABLE 30.10 Latent Tuberculosis Infection (LTBI) Compared to Tuberculosis Disease

LTBI	TB Disease
Has no symptoms	Has symptoms that may include: • Bad cough that lasts ≥3 week • Pain in the chest • Coughing up blood or sputum • Weakness or fatigue • Weight loss, no appetite • Chills • Fever • Sweating at night
Does not feel sick	Usually feels sick
Cannot spread TB bacteria to others	May spread TB bacteria to others
Usually has a positive TST or blood test result showing TB infection	Usually has a positive TST or blood test result showing TB infection
Has a normal chest x-ray and a negative sputum smear	May have an abnormal chest x-ray or positive sputum smear or culture
Needs treatment for latent TB infection to prevent active TB disease	Needs treatment for active TB disease

Source: Centers for Disease Control and Prevention. Tuberculosis (TB) fact sheets: the difference between latent TB infection and TB disease. Retrieved from https://www.cdc.gov/tb/publications/factsheets/general/ltbiandactivetb.htm.

multiply months or years later. While *M. tuberculosis* is aerophilic (O_2 loving) and has an affinity for the lungs, the infection can spread through the lymphatic system and find good environments for growth in other organs. These include the cerebral cortex, spine, bone epiphyses, liver, kidneys, lymph nodes, and adrenal glands.

Once a strain of *M. tuberculosis* develops resistance to the first-line drug therapy (isoniazid and rifampin), it is defined as *multidrug-resistant tuberculosis (MDR-TB).*[13] Extensively drug-resistant TB (XDR-TB) is a rare type of MDR-TB. XDR-TB is also resistant to any fluoroquinolone and at least 1 second-line drug.[13] Resistance results from several problems, including incorrect prescribing, lack of case management, and nonadherence to the prescribed regimen.

Classification

We use several systems to classify TB. The American Thoracic Society classifies TB based on disease development (Table 30.9). We also classify TB by (1) its presentation (primary, latent, reactivated) and (2) whether it is pulmonary or extrapulmonary.

Primary TB infection starts when the bacteria are inhaled and trigger an inflammatory reaction. Most people have effective immune responses that encapsulate the organisms for the rest of their lives, preventing the initial infection from progressing to disease. If the initial immune response is not adequate, the body cannot contain the organism. As a result, the bacteria replicate and *active TB disease* results. When active disease develops within the first 2 years of infection, it is called *primary TB*. People co-infected with HIV are at greatest risk for developing active TB.

Post-primary TB, or *reactivation TB,* is defined as TB disease occurring 2 or more years after the initial infection. If the site of TB is pulmonary or laryngeal, the person is infectious and can transmit the disease to others.

Latent TB infection (LTBI) occurs in a person who does not have active TB disease (Table 30.10). People with LTBI have a positive skin test but are asymptomatic. They cannot transmit the TB bacteria to others but can develop active TB disease later. Immunosuppression, diabetes, poor nutrition, HIV, glucocorticoid therapy, pregnancy, stress, and chronic disease can reactivate the disease. Treatment of LTBI is as important as primary TB.

Clinical Manifestations

Symptoms of pulmonary TB usually do not develop until 2 to 3 weeks after infection or reactivation. The primary manifestation is an initial dry cough. It often becomes productive with mucoid or mucopurulent sputum. Active TB disease may initially present with constitutional symptoms (e.g., fatigue, malaise, anorexia, unexplained weight loss, low-grade fevers, night sweats). Dyspnea is a late symptom that may signify considerable pulmonary disease or a pleural effusion. Hemoptysis is also a late symptom.

Sometimes, TB has a more acute, sudden presentation. The patient may have a high fever, chills, flu-like symptoms, pleuritic pain, a productive cough, and ARF. Lung auscultation may be normal or reveal adventitious sounds, such as crackles. Hypotension and hypoxemia may be present.

Immunosuppressed (e.g., HIV-infected) people and older adults are less likely to have fever and other signs of an infection. In patients with HIV, classic manifestations of TB, such as fever, cough, and weight loss, may be wrongly attributed to PJP or other HIV-associated opportunistic diseases. Respiratory problems in patients with HIV are assessed to determine the

cause. A change in cognitive function may be the only initial presenting sign of TB in an older person.

The manifestations of extrapulmonary TB depend on the organs infected. For example, renal TB can cause dysuria and hematuria. Bone and joint TB may cause severe pain. Headaches, vomiting, and lymphadenopathy may be present with TB meningitis.

Complications

Properly treated, pulmonary TB typically heals without complications, except for scarring and residual cavitation within the lung. Significant lung damage, although rare, can occur in patients who are poorly treated or who do not respond to TB treatment.

Miliary TB is widespread dissemination of the mycobacterium through the bloodstream to several distant organs. The infection is characterized by a large amount of TB bacilli and may be fatal if untreated. It can occur with primary disease or reactivation of LTBI. Manifestations slowly progress over a period of days, weeks, or even months. Symptoms vary depending on the organs that are affected. Fever, cough, and lymphadenopathy are present. Hepatomegaly and splenomegaly may occur.

Pleural TB, a specific type of extrapulmonary TB, can result from either primary disease or reactivation of a latent infection. Chest pain, fever, cough, and a unilateral pleural effusion are common. A pleural effusion is caused by bacteria in the pleural space, which trigger an inflammatory reaction and a pleural exudate of protein-rich fluid. Empyema is less common than effusion but may occur from large numbers of TB organisms in the pleural space. Diagnosis is confirmed by AFB cultures and a pleural biopsy.

Because TB can infect organs throughout the body, other acute and long-term complications can result. TB in the spine (Pott disease) can lead to destruction of the intervertebral disc and adjacent vertebrae. Central nervous system (CNS) TB can cause bacterial meningitis. Abdominal TB can lead to peritonitis, especially in HIV-positive patients. The kidneys, adrenal glands, lymph nodes, and urogenital tract can be affected.

Diagnostic Studies

Tuberculin Skin Test

The tuberculin skin test (TST) (Mantoux test) using purified protein derivative (PPD) is the standard method to screen people for *M. tuberculosis*. The test is given by injecting 0.1 mL of PPD intradermally on the ventral surface of the forearm. We read the test by inspection and palpation 48 to 72 hours later for the presence or absence of induration. Induration, a palpable, raised, hardened area or swelling (not redness) at the injection site means the person has been exposed to TB and has developed antibodies. Antibody formation occurs 2 to 12 weeks after initial exposure to the bacteria. Any indurated area present is measured and recorded in millimeters. Based on the size of the induration and risk factors, we make an interpretation based on CDC standards for determining a positive test (see Table 27.15).

Two-step testing with the Mantoux test is recommended for baseline or initial screening for health care workers and those who have a decreased response to allergens. If the 1st test is positive, the person does not need the 2nd test. They do, however, need further evaluation for active disease. If the 1st test is negative, a 2nd test is done 1 to 3 weeks later. Some people with LTBI or who were previously infected with TB may have a false-negative result with the 1st test. Repeating the test may stimulate (boost) the body's ability to react in future tests.[14] A positive reaction to a subsequent test could be a new infection or the result of the boosted reaction to an old infection. A previously negative 2 step test ensures that any future positive results can be accurately interpreted as being caused by a new infection.

Interferon-γ Release Assays

Interferon-γ (INF-γ) release assays (IGRAs) are another screening tool for TB. IGRAs are blood tests that detect INF-γ release from T cells in response to *M. tuberculosis*.[15] Examples of IGRAs include QuantiFERON-TB Gold In-Tube test (QFT-GIT) and the T-SPOT.TB test. Test results are available in a few hours.

IGRAs have several advantages over the TST. IGRAs require only 1 patient visit, are not subject to reader bias, have no "booster" phenomenon, and are not affected by bacillus Calmette-Guérin (BCG) vaccination. The cost of an IGRA is much higher than the TST. Guidelines suggest that both tests are viable options. The choice should be based on context and reasons for testing. Neither IGRAs nor TST can tell between LTBI and active TB infection. LTBI can only be diagnosed by excluding active TB.

Chest X-Ray

Although the chest x-ray findings are important, it is not possible to make a diagnosis of TB based solely on chest x-ray findings. The chest x-ray may appear normal in a patient with TB. Findings suggestive of TB include upper lobe infiltrates, cavitary infiltrates, lymph node involvement, and pleural and/or pericardial effusion. Other diseases, such as sarcoidosis, can mimic the appearance of TB.

Bacteriologic Studies

Sputum culture is the gold standard for diagnosing TB. We need 3 consecutive sputum specimens, each collected at 8- to 24-hour intervals, with at least 1 early morning specimen. The initial test involves microscopic examination of stained sputum smears for AFB. A definitive diagnosis of TB requires mycobacterial growth, which can take up to 6 weeks. For patients in whom suspicion of TB is high, treatment is started while waiting for culture results. Samples for other suspected TB sites can be collected from gastric washings, cerebrospinal fluid (CSF), or fluid from an effusion or abscess.

Interprofessional Care

Most patients with TB are treated on an outpatient basis (Table 30.11). Many people can continue to work and maintain their lifestyles with few changes. Patients with sputum smear–positive TB are considered infectious for the first 2 weeks after starting treatment. Advise these patients to restrict visitors, and avoid travel, public transportation, and trips to public places. Teach them the importance of good hand washing and oral

TABLE 30.11 Interprofessional Care

Pulmonary Tuberculosis

Diagnostic Assessment

- History and physical assessment
- Tuberculin skin test (TST)
- QuantiFERON-TB Gold In-Tube test (QFT-GIT) or T-SPOT.TB test
- Chest x-ray
- Bacteriologic studies
- Sputum smear for acid-fast bacilli (AFB)
- Sputum culture

Management

- Long-term treatment with antimicrobial drugs (Tables 30.12 and 30.13)
- Follow-up AFB smears, cultures, and chest x-rays
- Follow-up care, addressing needs and concerns of patient and close contacts, and involving community health care workers and social workers

hygiene. Hospitalization may be needed for the severely ill or debilitated patient.

Drug Therapy

Active disease. The mainstay of TB treatment is drug therapy (Table 30.12). Because of the growing prevalence of MDR-TB, it is important to manage the patient with active TB aggressively. Drug therapy is divided into 2 phases: intensive and continuation (Table 30.13). In most circumstances the treatment regimen for patients with previously untreated TB consists of a plan with 4 drugs (isoniazid, rifampin, pyrazinamide, and ethambutol). If drug susceptibility test results show that the bacteria are susceptible to all drugs, ethambutol may be stopped. If the patient develops a toxic reaction to the primary drugs, other drugs can be used, including rifabutin and rifapentine (Priftin). If pyrazinamide is not included in the initial phase (e.g., liver disease, pregnancy), the remaining 3 drugs are used for the initial phase.

DRUG ALERT

Isoniazid

- Alcohol may increase risk for liver toxicity.
- Teach patient to avoid drinking alcohol during treatment.
- Monitor for signs of hepatitis before and while taking drug.

Sensitivity testing guides the treatment for MDR-TB. MDR-TB therapy in the initial phase typically includes 5 drugs: 1 or 2 first-line agents, a fluoroquinolone, an injectable antibiotic, and 1 or more second-line agents, for at least 6 months after sputum culture is negative. This is followed by at least 4 drugs, minus the injectable antibiotic, for 18 to 24 months. Two newer drugs, bedaquiline (Sirturo) and Delamanid (Deltyba), are used in combination with other drugs to treat MDR-TB and XDR-TB.

Many people do not adhere to the treatment program and complete the full course of therapy (Box 30.3). Nonadherence is a major factor in the emergence of MDR-TB and treatment failures. *Directly observed therapy* (DOT) involves providing the antitubercular drugs directly to patients and watching as they swallow the drugs. It is the preferred way to ensure adherence for all patients with TB, especially for those at risk

TABLE 30.12 Drug Therapy

Tuberculosis

Drug	Common Side Effects
For Active TB	
ethambutol (Myambutol)	Headache, blurred vision, ocular toxicity (decreased red-green color discrimination)
isoniazid	Liver toxicity, asymptomatic elevation of aminotransferases (ALT, AST)
	Vomiting, confusion, headache
pyrazinamide	Liver toxicity, joint pain, hyperuricemia
rifampin	Liver toxicity, thrombocytopenia
	Orange discoloration of bodily fluids (sputum, urine, sweat, tears)
	Anorexia, nausea, abdominal discomfort
For Drug Resistant TB	
Fluoroquinolones • levofloxacin • moxifloxacin	GI problems, neurologic effects (dizziness, headache), rash
Injectable antibiotics	Hepatitis, GI toxicity
Aminoglycosides	Prolonged QT interval
• amikacin	Ototoxicity, kidney toxicity
• capreomycin (Capastat)	Liver toxicity, nausea
• kanamycin	
bedaquiline (Sirturo)	Joint and muscle pain
	Nausea, vomiting, liver problems
pretomanid	Peripheral neuropathy
	Vision problems
	Nausea, vomiting, liver problems
streptomycin	Ototoxicity, neurotoxicity, kidney toxicity
Other Drugs Used in TB	
rifabutin (Mycobutin) (for TB and co-existing HIV infection)	Liver toxicity, thrombocytopenia, neutropenia
	Orange discoloration of bodily fluids (sputum, urine, sweat, tears)
	Nausea, vomiting, anorexia
rifapentine (Priftin) (as an alternate to rifampin)	Like those of rifampin

ALT, Alanine transaminase; *AST,* aspartate aminotransferase.

for nonadherence.[16] DOT is an expensive but essential public health measure. In many areas, the public health nurse administers DOT at a clinic site.

Fixed-dose combination drugs may enhance adherence. Combinations of isoniazid and rifampin and of isoniazid, rifampin, and pyrazinamide are available to simplify therapy. The therapy for people with HIV uses the same medications as outlined in Table 30.13, but in a slightly different schedule. In the intensive phase, HIV patients take isoniazid, ethambutol, pyrazinamide, and a rifamycin for the 1st 2 months, then isoniazid and a rifamycin for the last 4 months.[17]

Teach patients about the adverse effects of drug therapy and when to seek medical care. The major side effect of isoniazid, rifampin, and pyrazinamide is nonviral hepatitis. Baseline liver function tests (LFTs) are done at the start of treatment and monitored closely (e.g., every 2 to 4 weeks), especially if results are abnormal.

Latent tuberculosis infection. In people with LTBI, drug therapy helps prevent a TB infection from developing into active

TABLE 30.13 Drug Therapy

Tuberculosis Treatment Regimens

Intensive TB Medication Phase (2 Months)		Continuation TB Medication Phase (4 or 7 Months)	
Option #1: Preferred Method			
4 drugs: isoniazid rifampin pyrazinamide ethambutol[a]	Daily for 8 weeks (40–56 doses)	2 drugs: isoniazid rifampin	Daily for 18 weeks (90–126 doses) OR 3 times weekly for 18 weeks (54 doses)[b]
Alternative TB Drug Dosing—Option #1			
4 drugs: isoniazid rifampin pyrazinamide ethambutol[a]	Daily for 2 weeks (14 doses), then 3 times per week for 6 weeks (18 doses)[b]	2 drugs: isoniazid rifampin	3 times weekly for 18 weeks (54 doses)[b]
Alternative TB Drug Dosing—Option #2			
4 drugs: isoniazid rifampin pyrazinamide ethambutol[a]	3 times weekly for 8 weeks (24 doses)[b]	2 drugs: isoniazid rifampin	3 times weekly for 18 weeks (54 doses)[b]

[a]Ethambutol may be stopped if drug tests confirm susceptibility to first line drugs
[b]Any patient receiving TB medication less than 7 days/week must receive directly observed therapy (DOT).
Source: Centers for Disease Control and Prevention: Tuberculosis (TB) fact sheet: general considerations for treatment of TB disease. Retrieved from https://www. cdc.gov/tb/publications/factsheets/treatment/treatmenthivnegative.htm.

TB disease. Because a person with LTBI has fewer bacteria, treatment is much easier. Usually only 1 drug is needed. Drug regimens for LTBI are outlined in Table 30.14.

The standard treatment regimen for LTBI is 9 months of daily isoniazid. It is an effective and inexpensive drug that the patient can take orally. This plan is also recommended for patients with HIV and those with fibrotic lesions on chest x-ray. While the 9-month plan is more effective, adherence issues may make a 6-month plan preferable. An alternative 3-month regimen of isoniazid and rifapentine may be used for otherwise healthy patients who we presume are not infected with MDR bacilli. Patients who are resistant to isoniazid may receive 4-month therapy with rifampin. Because of severe liver injury and deaths, the CDC does not recommend the combination of rifampin and pyrazinamide for treatment of LTBI.

Bacille Calmette-Guérin vaccine. Bacille Calmette-Guérin (BCG) vaccine is a live, attenuated strain of *Mycobacterium bovis*. The vaccine is given to infants in parts of the world with a high prevalence of TB. In the United States, it is t rarely used because of the low risk for infection, the vaccine's variable effectiveness against adult pulmonary TB, and potential interference with TST reactivity. The BCG vaccination can result in a false-positive TST. IGRA results are not affected. The BCG

BOX 30.3 ETHICAL/LEGAL DILEMMAS

Patient Adherence

Situation

While working at a health clinic at a homeless shelter, you discover that F.C., a 64-year-old man with tuberculosis (TB), has not been taking his drug therapy. He tells you that it is hard for him to get to the clinic to obtain his medications, much less to keep on a schedule. You are concerned about F.C. and the risk he poses for the other people at the shelter, in the park, and at the meal sites where he often visits.

Ethical/Legal Points for Consideration

- Adherence is a complex issue involving a person's culture, values, and beliefs, perceived risk for disease, access to treatment, availability of resources, and perceived consequences of failure to adhere to treatment.
- State emergency detention laws provide public health officials with the legal authority to take action to apprehend and hold a person with TB who we believe to be a threat to public health.
- The federal government and many states have provisions for quarantine, detention, and treatment of patients with TB who do not adhere to treatment.
- Advocacy for both the patient and the community obliges you to involve other health care team members, such as social services, to aid in obtaining resources or support for the patient to complete a course of treatment.
- With the threats of bioterrorism and the globalization of infectious disease, it seems unlikely that the government's power to detain will change anytime soon.

Discussion Questions

1. How would you begin your initial conversation with F.C. about your concerns?
2. What alternatives of care can we offer to F.C.?
3. Under what circumstances, if any, are HCPs justified in overriding a patient's autonomy or decision making?

Source: Kavanagh MM, Gostin LO, Stephens J: Tuberculosis, human rights, and law reform: addressing the lack of progress in the global tuberculosis response. Retrieved from https://journals.plos.org/plosmedicine/article?id=10.1371/journal.pmed.1003324.

TABLE 30.14 Drug Therapy

LTBI Regimens

Drug	Duration (Months/ Weeks)	Interval	Number of Doses (Minimum)
isoniazid and rifapentine (preferred method)	3 months (12 weeks)	Once weekly[a]	12
rifampin	4 months (16 weeks)	Daily	112
isoniazid and rifampin	3 months (12 weeks)	Daily	84
isoniazid	6 months (24 weeks)	Daily	168
isoniazid	9 months (36 weeks)	Daily	252

[a]Use directly observed therapy (DOT).

vaccine should be considered only for select persons who meet specific criteria (e.g., health care workers who are continually exposed to patients with MDR-TB and when infection control precautions are not successful).

NURSING MANAGEMENT: TUBERCULOSIS

Assessment

Ask the patient about a previous history of TB, chronic illness, or any immunosuppressive disease or medications. Obtain a social and occupational history to determine risk factors for TB transmission. Assess the patient for productive cough, night sweats, fever, weight loss, pleuritic chest pain, and abnormal lung sounds. If the patient has a productive cough, early morning is the best time to collect sputum specimens for an AFB smear.

Clinical Problems

Clinical problems for the patient with TB may include:

- Impaired respiratory function
- Infection
- Deficient knowledge
- Lack of knowledge

Planning

The overall goals are that the patient with TB will (1) have normal lung function, (2) adhere to the treatment plan, (3) take measures to prevent the spread of TB, and (4) have no recurrence.

Implementation

Health Promotion

The goal is to eradicate TB worldwide. Screening programs in known risk groups are valuable in detecting persons with TB. For example, the person with a positive TST should have a chest x-ray to assess for active TB disease. Report people diagnosed with TB to public health authorities for identification and assessment of contacts and risk to the community. Treatment of LTBI reduces the number of TB carriers in the community.

Programs to address the social determinants of TB are needed to decrease TB transmission. Reducing HIV infection, poverty, overcrowded living conditions, malnutrition, smoking, and drug and alcohol use can help minimize TB infection rates. Improving access to health care and education are important.

Acute Care

Patients admitted to the ED or directly to the unit with respiratory symptoms should be assessed for the possibility of TB. Those strongly suspected of having TB should (1) be placed on airborne isolation; (2) receive a medical workup, including chest x-ray, sputum smear and culture; and (3) start appropriate drug therapy. Airborne infection isolation is needed for the patient with pulmonary or laryngeal TB until the patient is not infectious. Patients should be placed in a single-occupancy room with negative pressure and airflow of 6 to 12 exchanges per hour. Everyone entering the room should wear a high-efficiency particulate air (HEPA) or N95 mask.

Teach patients to cover the nose and mouth with paper tissues every time they cough, sneeze, or produce sputum. The tissues should be thrown into a paper bag and disposed of with the trash or flushed down the toilet. Emphasize careful hand washing after handling sputum and soiled tissues. If patients need to be out of the negative-pressure room, they must wear a standard surgical mask to prevent exposure to others. Minimize prolonged visitation to other parts of the hospital.

Identify and screen close contacts of the person with TB. Anyone testing positive for TB infection needs further evaluation and treatment for either LTBI or active TB disease.

Ambulatory Care

Patients who respond clinically are discharged home if their household contacts have already been exposed and the patient is not posing a risk to others. A sputum specimen for AFB smear and culture should be done monthly until 2 consecutive specimen cultures are negative. More frequent AFB smears may be done to assess the early response to treatment and determine infectiousness. Negative cultures are needed to declare the patient not infectious.

Teach the patient how to minimize exposure to close contacts and household members. Homes should be well ventilated, especially the areas where the infected person spends a lot of time. While still infectious, the patient should sleep alone and spend as much time as possible outdoors. Teach them to minimize time in congregate settings and public transportation.

Teach the patient and caregiver about adherence with the treatment plan. Most treatment failures occur because the patient does not take the drug, stops taking it too soon, or takes it irregularly. Strategies to improve adherence include teaching and counseling, reminder systems, incentives or rewards, contracts, and DOT.

Notify the public health department. They are responsible for follow-up on household contacts and assessing the patient for adherence. If adherence is an issue, the public health department may be responsible for DOT (Box 30.4). Most patients are considered adequately treated when drug therapy has been completed, cultures are negative, there is improvement in their condition, and improvement on chest x-ray.

Because about 5% of patients have relapses, teach the patient to recognize the symptoms that occur with recurrent TB. If these symptoms occur, the patient should seek immediate medical attention. Teach the patient about factors that could reactivate TB, such as immunosuppressive therapy, cancer, and prolonged debilitating illness. If the patient has any of these, we must notify the HCP so that the patient can be monitored for TB reactivation. In some situations, it is necessary to put the patient on anti-TB therapy. Because smoking is associated with poor outcomes, encourage patients who smoke to quit. Provide patients with teaching and resources to help them stop smoking.

Evaluation

The expected outcomes are that the patient with TB will have:

- Resolution of the disease
- Normal lung function
- Absence of any complications
- No further transmission of TB

BOX 30.4 EVIDENCE-BASED PRACTICE

Adherence to TB Treatment Program

You are a nurse working in an outpatient health clinic with C.J., a 42-year-old woman diagnosed 2 months ago with active TB. She is on directly observed therapy (DOT). You notice C.J. has started to miss and has been late for her appointments. She tells you it is hard to make her appointments as a new job requires long work hours. She asks if she needs to continue with her visits to get her drugs. She says she is "feeling better" and does not understand what all the fuss over the drugs is about. She adds that she is "perfectly capable of taking my own pills."

Making Clinical Decisions

Best Available Evidence

Guidelines for effective case management of patients with TB include education, home visits, patient reminders, and incentives. TB clinic attendance and treatment completion rates are higher when patients take part in DOT compared to self-administered therapy. When appointments are missed, phone calls, Web-based videos, or home visits will engage patients, resulting in improved attendance and treatment completion.

Clinician Expertise

You are aware that patient-centered care includes being responsive to patients' changing needs. You know that patients may stop attending appointments and taking their drugs when feeling well again. This can lead to treatment failure, the need to restart therapy, and multidrug resistance.

Patient Preferences and Values

C.J. tells you she has a busy job and does not always remember her appointments. She stated that she would like to be responsible for taking her drugs.

Implications for Nursing Practice

1. What information you want to obtain from C.J.?
2. What teaching would you provide to C.J. about taking her own medications?
3. How will you determine if C.J. is adhering to the drug treatment plan?

Source: Pradipta IS, Houtsma D, van Boven JFM, et al.: Interventions to improve medication adherence in tuberculosis patients: A systematic review of randomized controlled studies, *NPJ Prim Care Respir Med* 30:21, 2020.

ATYPICAL MYCOBACTERIA

There are more than 30 acid-fast mycobacteria that cause diseases other than TB. These include lung disease, lymphadenitis, skin or soft tissue disease, and disseminated disease. Atypical mycobacteria are not airborne or transmitted by droplets. They can be found in tap water, soil, bird feces, and house dust.

People who are immunosuppressed (e.g., HIV/AIDS) or have chronic lung disease are most susceptible to infection. Pulmonary symptoms include cough, shortness of breath, weight loss, fatigue, and blood-tinged sputum.

Diagnosis is challenging and differs based on the site of the infection. We cannot tell this type of lung disease from TB either clinically or radiologically. Diagnostic studies done include a chest x-ray and 3 sputum specimens tested for AFB. Treatment may include a prolonged course of antibiotics, depending on the organism cultured and patient's condition.

PULMONARY FUNGAL INFECTIONS

Pulmonary fungal pneumonia is an infectious process in the lungs caused by endemic (native and common) or opportunistic fungi (Table 30.15). *Endemic* fungal pathogens cause infection in healthy people and immunocompromised people in certain areas. For example, *Coccidioides,* which causes coccidioidomycosis, is a fungus found in the soil of dry, low-rainfall areas.[18] It is endemic in many areas of the southwestern United States. *Opportunistic* fungal infections occur in immunocompromised patients (e.g., those receiving chemotherapy, immunosuppressive drugs) and in patients with HIV and cystic fibrosis. Pulmonary fungal infections can be life-threatening.

TABLE 30.15 Fungal Lung Infections

Infection	Organism
Endemic Fungal Infections	
Blastomycosis	*Blastomyces dermatitidis*
Coccidioidomycosis	*Coccidioides immitis*
Histoplasmosis	*Histoplasma capsulatum*
Opportunistic Fungal Infections	
Aspergillosis	*Aspergillus niger, Aspergillus fumigatus*
Candidiasis	*Candida albicans*
Cryptococcosis	*Cryptococcus neoformans*

Pulmonary fungal infections are acquired by inhaling spores. They are not transmitted from person to person. The patient does not have to be placed in isolation. The manifestations are like those of bacterial pneumonia. Skin testing, serology, and biopsy methods help identify the infecting organism.

The choice of antifungal agent is based on the pathogen identified on culture or most likely suspected. Amphotericin B is the standard therapy for treating serious systemic fungal infections. It must be given IV to achieve adequate blood and tissue levels because the GI tract does not absorb it well. Less serious infections can be treated with oral antifungals, such as ketoconazole, fluconazole (Diflucan), voriconazole (Vfend), and itraconazole (Sporanox). We monitor therapy effectiveness with fungal serology titers.

LUNG ABSCESS

Etiology and Pathophysiology

A **lung abscess** is necrosis of lung tissue. It typically results from bacteria aspirated from the oral cavity in patients with periodontal disease. Lung abscess can also result from IV drug use, cancer, pulmonary emboli, TB, and various parasitic and fungal diseases. The abscess usually develops slowly, beginning with an enlarging area of infection that becomes necrotic and eventually forms a cavity filled with purulent material. Abscesses usually contain more than 1 type of microbe, most often anaerobic flora of the mouth and pharynx.

The lung area most often affected due to aspiration is the posterior segment of the upper lobes. The abscess may erode into the bronchial system, causing foul-smelling or sour-tasting sputum. It may grow toward the pleura and cause pleuritic pain. Multiple small abscesses, sometimes referred to as *necrotizing pneumonia,* can occur within the lung.

Clinical Manifestations and Complications

Manifestations usually occur slowly over a period of weeks to months, especially if anaerobic organisms are the cause. Symptoms of abscess caused by aerobic bacteria develop more acutely and resemble bacterial pneumonia. The most common is cough-producing purulent sputum (often dark brown) that is foul smelling and foul tasting. Hemoptysis is common, especially when an abscess ruptures into a bronchus. Other manifestations include fever, chills, weakness, night sweats, pleuritic pain, dyspnea, anorexia, and weight loss.

Assessment reveals decreased breath sounds on auscultation over the involved segment of lung. Bronchial breath sounds may be transmitted to the periphery if the communicating bronchus becomes patent, and the segment begins to drain. Crackles may be present in the later stages as the abscess drains.

The infection can spread through the bloodstream and cause several possible complications. Pulmonary abscess, bronchopleural fistula, bronchiectasis, and empyema from perforation of the abscess into the pleural cavity can occur.[19]

Diagnostic Studies

A chest x-ray is often the only test needed to diagnose a lung abscess. The presence of a single cavitary lesion with an air-fluid level and local infiltrate confirms the diagnosis. CT scanning may be helpful if the abscess is not clear on chest x-ray. If there is drainage via the bronchus, sputum will contain the microorganisms that are present in the abscess. However, expectorated sputum samples are often contaminated with oral flora, making it hard to determine the responsible organism(s).

Bronchoscopy may be used to (1) avoid oropharyngeal contamination, (2) collect a specimen if drainage is delayed, or (3) assess for underlying cancer. Pleural fluid and blood cultures may be used to identify the offending organisms. Although nonspecific, an elevated neutrophil count may indicate an infection. Necrotic pulmonary lesions also can be caused by lung infarction, pulmonary embolism, and sarcoidosis.

Interprofessional and Nursing Care

Monitor the patient's vital signs, LOC, and respiratory rate and rhythm. Note any signs and symptoms of respiratory distress. Observe for any signs of hypoxemia. Apply O_2 as needed.

Teach the patient how to cough effectively. Chest physiotherapy and postural drainage are not recommended because they may promote movement of microorganisms into adjacent bronchi and other lobes of the lungs, extending infection. Rest, optimal nutrition, and adequate fluid intake promote recovery. If dentition is poor or dental hygiene is not adequate, encourage the patient to obtain dental care. Collaborate with the social worker to evaluate options for dental care if the patient has limited resources.

IV antibiotic therapy should be started immediately. Clindamycin is first-line therapy for its effectiveness against *Staphylococcus* and anaerobic organisms. IV antibiotics are switched to oral antibiotics once the patient shows clinical and chest x-ray signs of improvement.

Because of the need for prolonged antibiotic therapy, teach the patient to take antibiotics as directed for the entire prescribed period (see Table 15.9). Sometimes the patient must return periodically during the course of antibiotic therapy for repeat cultures and sensitivity tests to ensure that the infecting organism is not becoming resistant to the antibiotic. When antibiotic therapy is complete, the patient is re-evaluated.

If the patient does not adequately respond to antibiotic treatment, percutaneous drainage of the abscess may be done. A small catheter, guided by CT or ultrasound, may be placed to drain the abscess. Surgery is sometimes done when reinfection of a large cavitary lesion occurs, when an empyema develops, or to establish a diagnosis when there is evidence of an underlying problem, such as cancer. The usual procedure in such cases is a lobectomy. A pneumonectomy may be needed for multiple abscesses.

RESTRICTIVE RESPIRATORY DISORDERS

Disorders that impair the ability of the chest wall and diaphragm to move with respiration are called *restrictive respiratory disorders*. There are 2 categories: *extrapulmonary conditions,* in which the lung tissue is normal, and *intrapulmonary conditions,* in which the primary cause is the lung or pleura. Examples of extrapulmonary and intrapulmonary conditions are listed in Table 30.16.

The hallmark characteristic of a restrictive lung disorder is a reduced total lung capacity (TLC). The hallmark characteristic of an obstructive disorder is reduced forced expiratory volume (FEV_1). Mixed obstructive and restrictive disorders sometimes occur together. For example, a patient may have both asthma

TABLE 30.16 Common Causes of Restrictive Lung Disease

Intrapulmonary Causes

Parenchymal Disorders

- Acute respiratory distress syndrome (ARDS)
- Atelectasis
- Chronic empyema
- Interstitial lung diseases
- Pneumonia

Pleural Disorders

- Pleural effusion
- Pleurisy (pleuritis)
- Pneumothorax

Extrapulmonary Causes

Central Nervous System

- Head injury, central nervous system lesion (e.g., tumor, stroke)
- Opioid and barbiturate overdose

Chest Wall

- Kyphoscoliosis
- Obesity-hypoventilation syndrome

Neuromuscular System

- Amyotrophic lateral sclerosis
- Guillain-Barré syndrome
- Muscular dystrophy
- Myasthenia gravis

(an obstructive problem) and pulmonary fibrosis (a restrictive problem). Pulmonary function tests are the best way to distinguish between restrictive and obstructive respiratory disorders.

ATELECTASIS

Atelectasis is a lung condition characterized by collapsed, airless alveoli. There may be decreased or absent breath sounds and dullness to percussion over the affected area. The most common cause is obstruction of the small airways with secretions. This is common in patients on bedrest and in almost all postoperative surgery patients. Normally, the pores of Kohn provide collateral passage of air from one alveolus to another. Deep inspiration opens the pores effectively. For this reason, deep-breathing exercises, coughing, incentive spirometry, and early mobility are important to prevent atelectasis and treat the patient at risk (see Chapter 20).

PLEURISY

Pleurisy (pleuritis) is an inflammation of the pleura. It can be caused by infectious diseases, cancer, autoimmune disorders, chest trauma, GI disease, and some drugs. The inflammation usually subsides once we treat the cause. The pain of pleurisy is typically abrupt, sharp in onset, and worse with inspiration. The patient's breathing is short, shallow, and rapid to avoid unnecessary pleura and chest wall movement. A pleural friction rub may occur. This is the sound heard over areas where inflamed visceral pleura and parietal pleura rub together during inspiration. This sound, like a squeaking door, is usually loudest at peak inspiration.

Treatment is directed at the underlying cause and providing pain relief. Teach the patient to splint the rib cage when coughing. If the pain is severe, intercostal nerve blocks may be considered.

PLEURAL EFFUSION

A **pleural effusion** is an abnormal collection of fluid in the pleural space. It is not a disease, but a sign of another condition. A balance among hydrostatic pressure, oncotic pressure, and capillary membrane permeability governs movement of fluid in and out of the pleural space. Fluid accumulation can be due to increased pulmonary capillary pressure, decreased oncotic pressure, increased pleural membrane permeability, or obstruction of lymphatic flow.

Types of Pleural Effusions

We classify pleural effusions as transudative or exudative depending on the protein content. A *transudate effusion* occurs mainly in non-inflammatory conditions. It is an accumulation of protein-poor, cell-poor fluid. The fluid is usually clear, pale yellow. Causes include (1) increased hydrostatic pressure found in HF or (2) decreased oncotic pressure from hypoalbuminemia (e.g., with chronic liver or renal disease). An *exudative effusion* results from increased capillary permeability due to an inflammatory reaction. The fluid is rich in protein. They most often occur with an infection or cancer (called a malignant effusion).

An **empyema** is a collection of purulent fluid in the pleural space. Common causes include pneumonia, TB, lung abscess, and infected surgical chest wounds.

Clinical Manifestations

Common manifestations are dyspnea, cough, and occasional sharp, non-radiating chest pain that may be worse on inhalation. Breath sounds may be decreased over the affected area. A chest x-ray may show decreased chest movement on the affected side. A chest x-ray and CT reveal the volume and location of the effusion. Additional manifestations seen with empyema include fever, night sweats, cough, and weight loss.

Interprofessional and Nursing Care

The management of pleural effusions is to treat the underlying cause. For example, adequate treatment of HF with diuretics and sodium restriction may result in a decreased incidence of pleural effusion. The treatment of malignant effusions is more difficult. These effusions often re-occur and re-accumulate quickly after thoracentesis.

Treatment options for an empyema include antibiotic therapy (to eradicate the causative organism), percutaneous drainage, chest tube insertion, and intrapleural fibrinolytic therapy (instilled through the chest tube to dissolve fibrous adhesions). Some patients may need surgery. Surgical options include drainage, decortication, or an open window thoracostomy.

Chemical pleurodesis is done to obliterate the pleural space and prevent re-accumulation of effusion fluid. This procedure first requires chest tube drainage of the effusion. Once the fluid is drained, a chemical slurry is instilled into the pleural space. Talc is the most effective agent used. Other agents we use include doxycycline and bleomycin. The chest tube is clamped for 8 hours while the patient is turned in different positions. This allows the chemical to contact the entire pleural space. After 8 hours, the chest tube is unclamped and attached to a drainage unit. Chest tubes are left in place until fluid drainage is less than 150 mL/day and no air leaks are noted. Fever and chest pain are common side effects after pleurodesis.

We provide supportive nursing care according to the patient's needs. This may include O_2 therapy to treat hypoxemia and analgesics to relieve chest pain. Implement measures to manage fever (see Table 12.5). Hydration, nutrition support, and positioning are part of the care plan. Work with the respiratory therapist to monitor the patient's condition and provide chest physiotherapy. Care of the patient with a chest tube is described in Chapter 28.

INTERSTITIAL LUNG DISEASES

Interstitial lung disease (ILD), or *diffuse parenchymal lung disease,* refers to more than 200 lung disorders in which the tissue between the air sacs of the lungs (the interstitium) is affected by inflammation or scarring (fibrosis).[20] Most ILDs are rare.

Many times, the cause of an ILD is unknown. Known causes are inhalation of occupational and environmental toxins, certain drugs, radiation therapy, connective tissue disorders, infection, and cancer. Treatment is aimed at reducing exposure to

the causative agent or treating the underlying disease process. While scarring is not reversible, treatment with corticosteroids and immunosuppressant drugs can minimize progression. A lung transplant may be an option for some patients.

IDIOPATHIC PULMONARY FIBROSIS

Idiopathic pulmonary fibrosis (IPF) is a progressive disorder characterized by chronic inflammation and formation of scar tissue in the connective tissue.[21] Risk factors include smoking and exposure to wood and metal dust. IPF affects more men. It typically first appears between the ages of 50 and 70 years. We do not know the cause of IPF.

Manifestations include exertional dyspnea, a dry, nonproductive cough, clubbing of the fingers, and inspiratory crackles. Fatigue, weakness, anorexia, and weight loss may occur as the disease progresses. Chest x-ray findings are generally nonspecific. Pulmonary function tests may be abnormal, with reduced vital capacity and impaired gas exchange. Open lung biopsy using video-assisted thoracic surgery (VATS) often helps to confirm the pathology. It is the gold standard for diagnosis.

The course is variable, and the prognosis is poor. The median survival rate is 2.5 to 3.5 years after diagnosis. There is no known cure for IPF. Many people diagnosed with IPF are first treated with a corticosteroid, sometimes in combination with other drugs that suppress the immune system (e.g., methotrexate, cyclosporine). Kinase inhibitor drugs, which block multiple pathways that are involved with scarring, include nintedanib (Ofev) and pirfenidone (Esbriet).

O_2 therapy and pulmonary rehabilitation should be prescribed for all patients. A lung transplant may be an option for those who meet criteria.

SARCOIDOSIS

Sarcoidosis is a chronic, multisystem granulomatous disease of unknown cause that mainly affects the lungs. The disease may also involve the skin, eyes, liver, kidney, heart, and lymph nodes. Signs and symptoms vary depending on what organs are affected. Pulmonary symptoms include dyspnea, cough, and chest pain. Many patients do not have symptoms.

Staging and treatment decisions are based on chest x-ray, pulmonary function tests, and severity of symptoms. Some patients have a spontaneous remission. Treatment is aimed at suppressing the inflammatory response. Patients are followed every 3 to 6 months with pulmonary function tests, chest x-ray, and CT scan to monitor disease progression.

CHEST TRAUMA AND THORACIC INJURIES

Traumatic injuries to the chest contribute to many deaths. Chest injuries range from simple rib fractures to cardiorespiratory arrest. We classify the primary mechanisms of injury as either blunt trauma or penetrating trauma.

Blunt trauma occurs when the chest strikes or is struck by an object. The impact can cause shearing and compression of chest structures. The external injury may appear minor, but internally, organs may be severely damaged. Rib and sternal fractures can easily tear lung tissue. In a high-velocity impact, shearing forces can result in tearing of the aorta. Compression of the chest may result in heart or lung contusion, crush injury, and organ rupture.

In *penetrating trauma,* a foreign object impales or passes through the body tissues, creating an open wound. Examples include knife wounds, gunshot wounds, and injuries with other sharp objects. Emergency care of the patient with a chest injury is outlined in Table 30.17. The most common chest emergencies and their management are described in Table 30.18.

FRACTURED RIBS

Rib fractures are the most common type of chest injury from blunt trauma. Ribs 5 through 9 are most often fractured because they are the least protected by chest muscles. A splintered or displaced fractured rib can damage the pleura, lungs, heart, and other internal organs.

Manifestations include pain at the site of injury, especially during inspiration and with coughing. The patient splints the affected area. They take shallow breaths to try to decrease the discomfort. Atelectasis and pneumonia may develop because of pain, decreased chest wall movement, and retained secretions.

The goal of treatment is to decrease pain so that the patient can breathe adequately and clear secretions. Strapping the chest with tape or using a thoracic binder is not recommended. These limit chest expansion and predispose the person to atelectasis and hypoxemia. NSAIDs, opioids, and thoracic nerve blocks can be used to reduce pain and assist with deep breathing and coughing. Surgical plating of fractured ribs may be done for those patients with extreme chest wall deformity. Teaching should emphasize deep breathing, coughing, incentive spirometry, appropriate use of pain medications, and when appropriate, early mobility.

FLAIL CHEST

Flail chest results from the fracture of 3 or more consecutive ribs, in 2 or more separate places, causing an unstable segment (Fig. 30.4). It also can be caused by fracture of the sternum and several consecutive ribs. The resulting chest wall instability causes paradoxical movement during breathing. During inspiration, the affected part is sucked in, and during expiration, it bulges out. In other words, the affected (flail) area moves in the opposite direction with respect to the intact part of the chest. This paradoxical chest movement may prevent adequate ventilation and increase the work of breathing.

A flail chest is usually apparent on assessment. The patient has rapid, shallow respirations and tachycardia. Movement of the thorax is asymmetric and uncoordinated. The patient may ventilate poorly and try to splint the chest to assist with breathing. Abnormal chest cavity movement, crepitus near the rib fractures, and chest x-ray all assist in the diagnosis.

Initial therapy consists of ensuring adequate ventilation and supplemental O_2 therapy. The goal is to promote lung expansion and ensure adequate oxygenation. The underlying injured

TABLE 30.17 EMERGENCY MANAGEMENT

Chest Trauma

Etiology	Assessment Findings	Interventions
Blunt • Assault with blunt object • Crush injury • Explosion • Fall • Motor vehicle collision • Pedestrian accident • Sports injury **Penetrating** • Arrow • Gunshot • Knife • Stick	**Respiratory** • Audible air escaping from chest wound • ↓ Breath sounds on side of injury • Cough with or without hemoptysis • Cyanosis of mouth, face, nail beds, mucous membranes • Dyspnea, respiratory distress • Frothy secretions • ↓ O_2 saturation • Tracheal deviation **Cardiovascular** • Asymmetric BP values in arms • ↓ BP • Chest pain • Distended neck veins • Dysrhythmias • Muffled heart sounds • Narrowed pulse pressure • Rapid, thready pulse **Surface Findings** • Abrasions • Asymmetric chest movement • Bruising • Contusions • Lacerations • Open chest wound • Subcutaneous emphysema	**Initial** • If unresponsive, immediately assess circulation, airway, and breathing. • If responsive, monitor airway, breathing, and circulation. • Apply high-flow O_2 to keep SpO_2 >90%. • Establish IV access with 2 large-bore catheters. Begin IV fluid resuscitation as appropriate. • Remove clothing to assess injury. • Cover sucking chest wound with nonporous dressing taped on 3 sides (vent dressing). • Stabilize impaled objects with bulky dressings. *Do not remove object.* • Assess for life-threatening injuries and treat appropriately. • Place patient in a semi-Fowler's position if breathing is easier *after* cervical spine injury has been ruled out. • Give small amounts of analgesia as needed for pain and to help with breathing. • Prepare for emergency needle decompression if tension pneumothorax or cardiac tamponade present. **Ongoing Monitoring** • Monitor LOC, vital signs, O_2 saturation, cardiac rhythm, respiratory rate and rhythm, urine output. • Anticipate intubation for respiratory distress. • Release vent dressing if tension pneumothorax develops after sucking chest wound is covered.

TABLE 30.18 EMERGENCY MANAGEMENT

Chest Injuries

Injury and Description	Manifestations	Intervention
Cardiac Tamponade Blood rapidly collects in pericardial sac, compresses myocardium because pericardium does not stretch, and prevents ventricles from filling.	Muffled, distant heart sounds, hypotension, neck vein distention, ↑ central venous pressure	Medical emergency. Pericardiocentesis with surgical repair as appropriate.
Flail Chest Fracture of 2 or more adjacent ribs in 2 or more places with loss of chest wall stability (see Fig. 30.4).	Paradoxical movement of chest wall, respiratory distress. May be associated hemothorax, pneumothorax, pulmonary contusion	O_2 as needed to maintain O_2 saturation, analgesia. Positive pressure mechanical ventilation for acute respiratory distress; will also help stabilize flail segment. Treat associated injuries. Possible surgical fixation for severe damage to chest wall.
Hemothorax Blood in the pleural space, may or may not occur in conjunction with pneumothorax.	Dyspnea, decreased or absent breath sounds, dullness to percussion, ↓ Hgb, shock (depending on blood volume lost)	Chest tube insertion with chest drainage system. Autotransfusion of collected blood, treatment of hypovolemia as needed with IV fluid, packed red blood cells.
Pneumothorax Air in pleural space (see Fig. 30.5).	Dyspnea, ↓ movement of involved chest wall, decreased or absent breath sounds on the affected side, hyperresonance to percussion	Chest tube insertion with chest drainage system.
Tension Pneumothorax Air in pleural space that does not escape. Increased air in the pleural space shifts organs and increases intrathoracic pressure (see Fig. 30.6).	Cyanosis, air hunger, extreme agitation, subcutaneous emphysema, neck vein distention, hyperresonance to percussion, tracheal deviation away from affected side (late sign)	Medical emergency: needle decompression followed by chest tube insertion with chest drainage system.

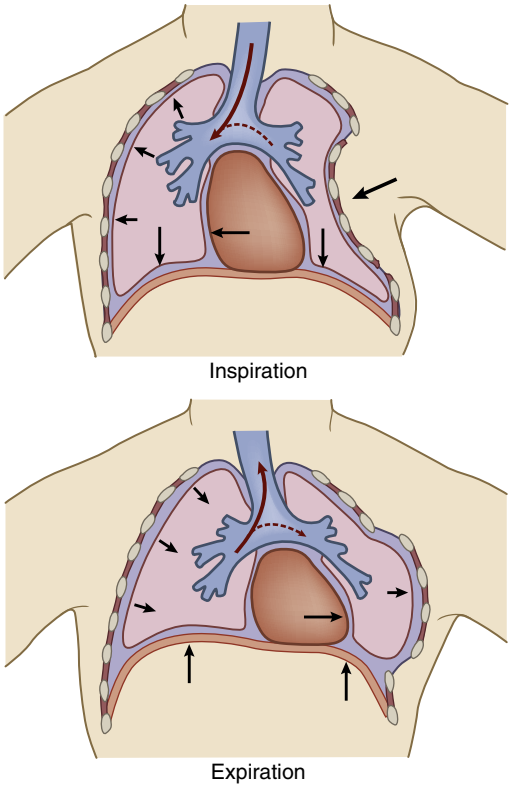

Fig. 30.4 Flail chest causes paradoxical respiration. On inspiration, the flail section moves inward with mediastinal shift to the uninjured side. On expiration, the flail section bulges outward with mediastinal shift to the injured side.

lung may be contused, worsening hypoxemia. Analgesia can help promote adequate respiration. Some patients may need mechanical ventilation. In cases of extreme deformity, surgical fixation of the flail segment may be done. The lung parenchyma and fractured ribs heal with time. Some patients continue to have intercostal pain several weeks after the flail chest has resolved.

PNEUMOTHORAX

A **pneumothorax** is caused by air entering the pleural cavity. Normally, negative (subatmospheric) pressure exists between the visceral pleura (surrounding the lung) and parietal pleura (lining the chest cavity), known as the *pleural space.* The pleural space has a few milliliters of lubricating fluid to reduce friction when the tissues move. When the volume of air that enters this normally subatmospheric space increases, lung volume decreases. As a result, the change to positive pressure causes a partial or complete lung collapse.

We can describe a pneumothorax as *open* (air entering through an opening in the chest wall) or *closed* (no external wound). Penetrating trauma allows air to enter the pleural space through an opening in the chest wall (Fig. 30.5). A penetrating chest wound may be called a *sucking chest wound,* since air enters the pleural space through the chest wall during inspiration. A pneumothorax should be suspected after any trauma to the chest wall.

If a pneumothorax is small, mild tachycardia and dyspnea may be the only manifestations. With a larger pneumothorax,

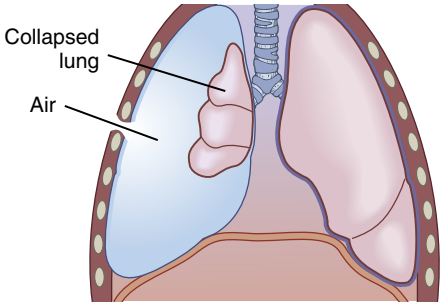

Fig. 30.5 Open pneumothorax. Collapse of lung results from disruption of chest wall and outside air entering the thoracic cavity.

respiratory distress may be present, including short, shallow, rapid respirations, dyspnea, and low O_2 saturation. On auscultation, breath sounds are absent over the affected area. A chest x-ray will show air or fluid in the pleural space and reduced lung volume.

Types of Pneumothoraxes

Spontaneous Pneumothorax

A spontaneous pneumothorax typically occurs due to the rupture of small blebs (air-filled sacs) on the surface of the lung. These blebs can occur in healthy, young people or from lung disease, such as COPD, asthma, cystic fibrosis, and pneumonia. Smoking increases the risk for bleb formation. Other risk factors include being tall and thin, male gender, family history, and previous spontaneous pneumothorax.

Iatrogenic Pneumothorax

Iatrogenic pneumothorax can occur due to laceration or puncture of the lung during medical procedures. For example, transthoracic needle aspiration, subclavian catheter insertion, pleural biopsy, and transbronchial lung biopsy all have the potential to injure the lung. Barotrauma from excessive ventilatory pressure during manual or mechanical ventilation can rupture alveoli, creating a pneumothorax. Esophageal procedures may result in a pneumothorax. For example, tearing of the esophageal wall during insertion of a gastric tube can allow air from the esophagus to enter the mediastinum and pleural space.

Tension Pneumothorax

Tension pneumothorax occurs when air enters the pleural space but cannot escape. The continued accumulation of air in the pleural space causes increasingly elevated intrapleural pressures. This results in compression of the lung on the affected side and pressure on the heart and great vessels, pushing them away from the affected side (Fig. 30.6). The mediastinum shifts toward the unaffected side, compressing the "good" lung, which further compromises oxygenation and ventilation. As the pressure increases, venous return decreases and cardiac output falls.

Tension pneumothorax may result from either an open or a closed pneumothorax. In an open chest wound, a flap may act as a one-way valve. Thus, air can enter on inspiration but cannot escape. Tension pneumothorax can occur with mechanical ventilation and resuscitative efforts. It can also occur if chest tubes are clamped or become blocked in a patient with a

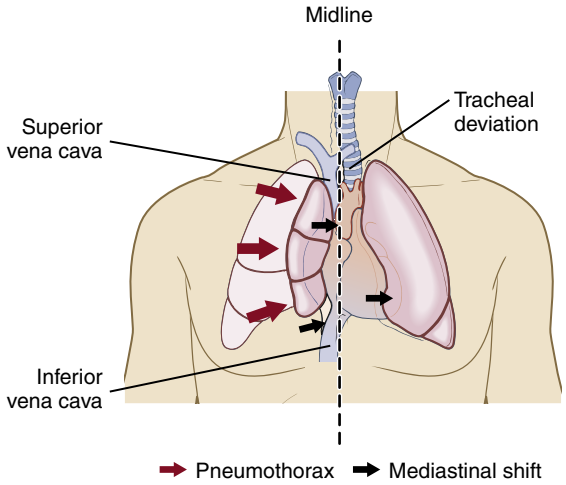

Fig. 30.6 Tension pneumothorax. As pleural pressure on the affected side increases, mediastinal displacement occurs, causing respiratory and cardiovascular compromise. Tracheal deviation is an external (but late) sign of mediastinal shift.

pneumothorax. Unclamping the tube or relieving the obstruction may correct this situation.

Tension pneumothorax is a medical emergency. It affects both the respiratory and cardiovascular systems. Manifestations include severe dyspnea, marked tachycardia, neck vein distention, and profuse diaphoresis. Decreased or absent breath sounds will be present on the affected side. Tracheal deviation is a very late sign. If the problem is not quickly identified and tension in the pleural space is not relieved (needle compression), the patient is likely to die from inadequate cardiac output and severe hypoxemia.

Hemothorax

Hemothorax is an accumulation of blood in the pleural space from injury to the chest wall, diaphragm, lung, blood vessels, or mediastinum. When it occurs with pneumothorax, it is called a *hemopneumothorax*. The patient with a traumatic hemothorax needs immediate insertion of a chest tube for evacuation of the blood. Sometimes, blood drained from a chest tube can be reinfused back into the patient (autotransfusion) after the injury. However, this requires special equipment and set-up prior to chest tube insertion.

Chylothorax

Chylothorax is the presence of lymphatic fluid in the pleural space. The thoracic duct is disrupted either traumatically or from cancer, allowing lymphatic fluid to fill the pleural space. This milky white fluid is high in lipids. Normal lymphatic flow through the thoracic duct is 1500 to 2500 mL/day. This amount can increase up to 10-fold after ingesting fats. Some cases heal with conservative treatment (chest drainage, bowel rest, diet). Octreotide may reduce the flow of lymphatic fluid. Surgery (thoracic duct ligation) and pleurodesis (the artificial production of adhesions between the parietal and visceral pleura) are options for some persons.

Interprofessional Care

Treatment of a pneumothorax depends on its severity, underlying cause, and hemodynamic stability of the patient. If the patient is stable and has minimal air and/or fluid accumulated in the intrapleural space, no treatment may be needed since the condition may resolve spontaneously.

Pre-hospital emergency care consists of covering the wound with an occlusive dressing that is secured on 3 sides (vent dressing). During inspiration, as negative pressure is created in the chest, the dressing pulls against the wound, preventing air from entering the pleural space. During expiration, as the pressure rises in the pleural space, the dressing is pushed out and air escapes through the wound and from under the dressing. If the object that caused the open chest wound is still in place, pre-hospital care providers will not remove it. They will stabilize the impaled object with a bulky dressing and arrange transport to the nearest medical facility.

In acute care, the most definitive and common treatment of pneumothorax and hemothorax is to insert a chest tube and connect it to water-seal drainage. Repeated spontaneous pneumothorax may need surgical treatment with a partial pleurectomy, stapling, or pleurodesis to promote adherence of the pleurae to one another. Tension pneumothorax is a medical emergency, requiring urgent needle decompression followed by chest tube insertion to water-seal drainage. Care of the patient with chest tubes is described in Chapter 28.

TABLE 30.19 Causes of Pulmonary Edema

- Acute respiratory distress syndrome (ARDS)
- Altered capillary permeability of lungs: aspiration, inhaled toxins, inflammation (e.g., pneumonia), severe hypoxia, near-drowning
- Anaphylactic (allergic) reaction
- Hypoalbuminemia: nephrotic syndrome, liver disease, nutritional disorders
- Left ventricular (heart) failure
- Lymph system cancer (e.g., non-Hodgkin lymphoma)
- Overhydration with IV fluids
- O_2 toxicity
- Unknown causes: neurogenic condition, opioid overdose, reexpansion pulmonary edema, high altitude

VASCULAR LUNG DISORDERS

PULMONARY EDEMA

Pulmonary edema is an abnormal accumulation of fluid in the alveoli and interstitial spaces of the lungs. It is a complication of various heart and lung problems (Table 30.19). In severe cases, pulmonary edema can be a life-threatening medical emergency. The most common cause of pulmonary edema is left-sided HF.

The patient often presents with varying degrees of dyspnea, diaphoresis, and wheezing, depending upon the severity of pulmonary edema and underlying medical condition. A 3rd heart sound may be present. Sputum may be blood-tinged and frothy sputum. A chest x-ray is the best option for confirming the diagnosis.

Treatment is often directed towards finding the underlying cause of the edema and reducing the amount of fluid in the lungs. Goals include simultaneously improving oxygenation, ventilation, and cardiac output.

Place the patient in a semi or high Fowler's position. Administer O_2 to keep SpO_2 greater than 90%. This may require low or high flow O_2 delivery devices, non-invasive ventilation (e.g., Bi-PAP), or mechanical ventilation. Preload reduction may be accomplished by giving IV diuretics (e.g., furosemide) or nitroglycerine. Small amounts of IV morphine can reduce afterload. Cardiac output can be supported with IV Dobutamine. Monitor the patient's vital signs, work of breathing, breath sounds, urinary output, electrolyte balance, and response to treatment.

PULMONARY EMBOLISM

Etiology and Pathophysiology

Pulmonary embolism (PE) is the blockage of 1 or more pulmonary arteries by a thrombus, fat or air embolus, or tumor tissue. A PE consists of material that gains access to the venous system and then to the pulmonary circulation. The PE travels with blood flow through ever-smaller blood vessels until it lodges and obstructs perfusion of the alveoli. The lower lobes are most often affected.

Most PEs arise from deep vein thrombosis (DVT) in the deep veins of the legs. *Venous thromboembolism (VTE)* is the preferred term to describe the spectrum from DVT to PE. Other sites of origin of PE include femoral or iliac veins, right side of the heart (atrial fibrillation), and pelvic veins (especially after surgery or childbirth). Upper extremity DVT sometimes occurs in the presence of central venous catheters or arterial lines. These cases may resolve with removal of the catheter. A *saddle embolus* refers to a large thrombus lodged at an arterial bifurcation (Fig. 30.7).

Less common causes include fat emboli (from fractured long bones), air emboli (from improperly administered IV therapy), bacterial vegetation on heart valves, amniotic fluid, and cancer.[22] Risk factors for PE include immobility or reduced mobility, surgery within the last 3 months (especially pelvic and lower extremity surgery), history of VTE, cancer, obesity, oral contraceptives, hormone therapy, smoking, prolonged air travel, HF, pregnancy, and clotting disorders.

Clinical Manifestations

The signs and symptoms of PE are varied and nonspecific, making diagnosis difficult. Manifestations depend on the type, size, and extent of emboli. Small emboli may go undetected or cause vague, transient symptoms. Symptoms may begin slowly or appear suddenly. Dyspnea is the most common presenting symptom in patients with PE. Mild to moderate hypoxemia may occur. Other manifestations include tachypnea, cough, chest pain, hemoptysis, crackles, wheezing, fever, accentuation of pulmonic heart sound, tachycardia, and syncope. Massive PE may cause a sudden change in mental status, hypotension, feelings of impending doom, and cardiorespiratory arrest.

Complications

About 10% of patients with massive PE die within the 1st hour. Identifying the patient "at-risk" for VTE is essential. Treatment with anticoagulants significantly reduces mortality.

Complications include pulmonary infarction and pulmonary hypertension. *Pulmonary infarction* (death of lung tissue) is most likely when there is (1) occlusion of a large or medium-sized pulmonary vessel (more than 2 mm in diameter), (2) insufficient collateral blood flow from the bronchial circulation, or (3) pre-existing lung disease. Infarction results in alveolar necrosis and hemorrhage. Sometimes the necrotic tissue becomes infected, and an abscess may develop. Pleural effusions are common.

Pulmonary hypertension results from hypoxemia or from involvement of a large surface area of the pulmonary bed. As a single event, a PE rarely causes pulmonary hypertension. Recurrent PEs or PEs that do not completely resolve gradually reduce capillary bed blood flow over time. This may eventually cause *chronic thromboembolic pulmonary hypertension*.[23] Dilation and hypertrophy of the right ventricle occurs. Depending on the severity of pulmonary hypertension and how

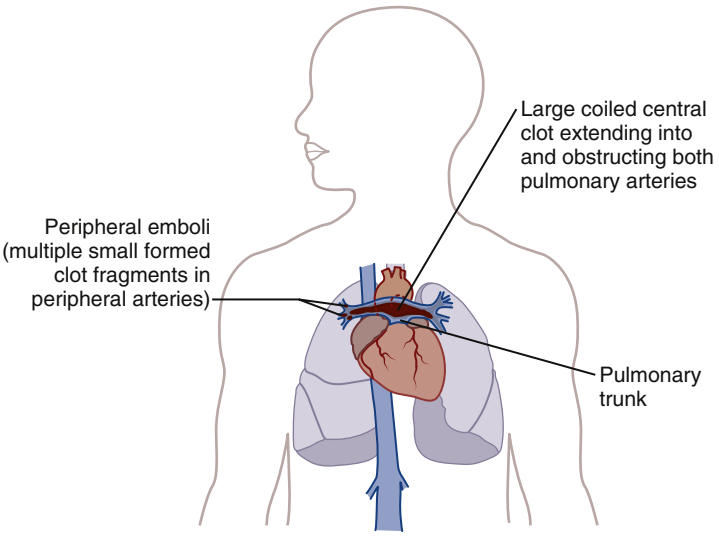

Fig. 30.7 Saddle pulmonary embolus. This embolus straddles the bifurcation of a major artery, with the clot extending down into both right and left branches of the major vessel.

quickly it develops, outcomes can vary. Some patients dying within months while and others live for decades.

Diagnostic Studies

ABG analysis is important but does not diagnose a PE. The PaO_2 may be low because of inadequate oxygenation from occluded pulmonary vessels preventing matching of perfusion to ventilation. The pH is often normal unless respiratory alkalosis develops because of prolonged hyperventilation or to compensate for lactic acidosis caused by shock.

Abnormal findings may be seen on a chest x-ray (atelectasis, pleural effusion) and ECG (nonspecific ST segment and T wave changes), but they are not diagnostic for PE. Serum troponin levels and b-type natriuretic peptide (BNP) levels are often high.

D-dimer is a laboratory test that measures the amount of cross-linked fibrin fragments. These fragments are the result of clot degradation. The disadvantage of D-dimer testing is that it is neither specific (many other conditions cause increases) nor sensitive, because up to 50% of patients with a small PE have normal results. Patients with suspected PE and an elevated D-dimer level but normal venous ultrasound may need a spiral CT or lung scan.

A *spiral (helical) CT scan* (CT angiography or CTA) is the most common test to diagnose PE. An IV injection of contrast media is needed to view the pulmonary blood vessels. The scanner continuously rotates around the patient while obtaining views (slices) of the pulmonary vasculature. This allows us to see all anatomic regions of the lungs. Computer reconstruction gives a 3-D picture and assists in seeing PEs.

If a patient cannot have contrast media, a ventilation-perfusion (V/Q) scan is done. The V/Q scan has 2 parts. It is most accurate when both are done:

1. *Perfusion scanning* involves IV injection of a radioisotope. A scanning device images the pulmonary circulation.
2. *Ventilation scanning* involves inhalation of a radioactive gas, such as xenon. Scanning reflects the distribution of gas through the lung. The ventilation portion requires the patient's cooperation. It may not be possible to perform in the critically ill patient, especially if the patient is intubated.

Interprofessional Care

To reduce mortality, we start treatment as soon as we suspect a PE (Table 30.20). The goals are to (1) facilitate optimal cardiorespiratory function, (2) ensure adequate blood flow, (3) prevent further growth or extension of thrombi, and (4) prevent and avoid further recurrence and any complications.

Immediate assessment should focus on cardiorespiratory status, which varies by the size and location of the PE. O_2 should be given by mask or cannula when hypoxemia is present. The FIO_2 is titrated based on ABG analysis. In some situations, mechanical ventilation is needed to maintain adequate oxygenation. Respiratory measures—including turning, coughing, deep breathing, and incentive spirometry—are important to help prevent atelectasis. Pain from pleural irritation or reduced coronary blood flow is treated with opioids. If HF is present, diuretics are used. If manifestations of shock are present, IV fluids and vasopressor agents are given as needed to support circulation.

TABLE 30.20 Interprofessional Care

Acute Pulmonary Embolism

Diagnostic Assessment

- History and physical assessment
- Chest x-ray
- Continuous ECG monitoring
- Pulse oximetry, ABGs
- Spiral (helical) CT scan (gold standard for ventilated or non-ventilated patient); if unavailable, computed tomography angiography (CTA) or pulmonary angiography
- Ventilation-perfusion (V/Q) lung scan (best for non-ventilated patient)
- Potentially useful lab tests (but not diagnostic); D-dimer level, troponin level, b-natriuretic peptide level
- Ultrasound of upper or lower extremities (based on likely source)

Management

- Supplemental O_2, intubation if needed
- Monitor hemoglobin, assess patient for bleeding
- Monitor activated partial thromboplastin time and international normalized ratio levels
- Balance activity and rest
- Inferior vena cava filter
- Pulmonary embolectomy in life-threatening situation

Drug Therapy

- Unfractionated heparin IV
- Low-molecular-weight heparin (e.g., enoxaparin [Lovenox])
- Factor Xa Inhibitors (e.g., apixaban [Eliquis], edoxaban)
- Thrombin Inhibitors (e.g., dabigatran [Pradaxa])
- Warfarin (Coumadin) for long-term therapy
- Fibrinolytics (e.g., activase) for life-threatening situation
- Analgesia

Drug Therapy

Immediate anticoagulation is required for patients with PE. Drug therapy for patients with acute PE occurs in 3 phases: initial (for the first 7 days), longer (up to 6 weeks), and extended (6 months and beyond). Subcutaneous low-molecular-weight heparin (LMWH) (e.g., enoxaparin, fragmin, fondaparinux) is the recommended treatment for patients with acute PE. LMWH is safer and more effective than unfractionated heparin. Monitoring the aPTT is not necessary or useful with LMWH. Unfractionated IV heparin is effective but hard to titrate to therapeutic levels.

Warfarin (Coumadin), an oral anticoagulant, should be started at the time of diagnosis. Warfarin should be given for at least 3 to 6 months and then reevaluated. Alternatives to warfarin include apixaban (Eliquis), dabigatran (Pradaxa), and edoxaban (Savaysa). Anticoagulant therapy may be contraindicated if the patient has complicating factors, such as liver problems (causing changes in the clotting), overt bleeding, a history of hemorrhagic stroke, heparin-induced thrombocytopenia (HIT), or other blood dyscrasias.

Some HCPs use direct thrombin inhibitors (see Table 41.10) in the treatment of PE. Similarly, fibrinolytic agents, such as tissue plasminogen activator (tPA) or alteplase (Activase), may help dissolve the PE and the source of the thrombus in the pelvis or deep leg veins, thus, decreasing the risk for recurrent emboli. Fibrinolytic therapy is discussed in Chapter 37.

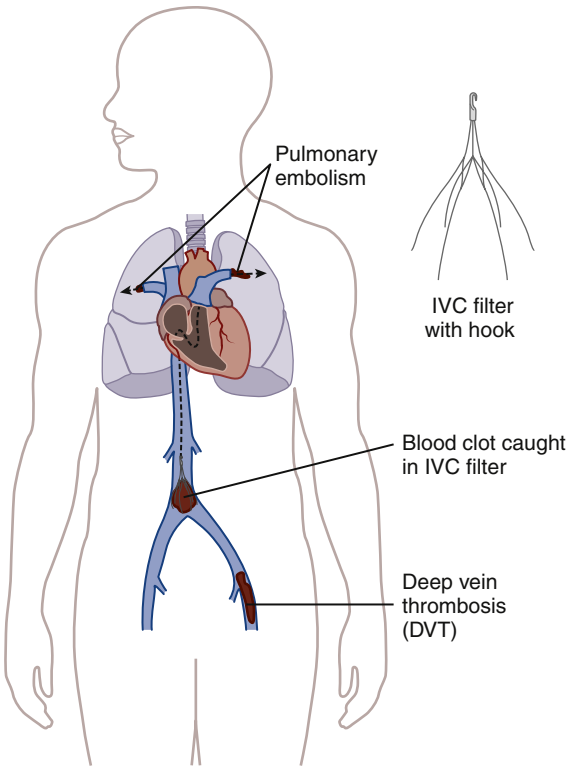

Fig. 30.8 Inferior vena cava *(IVC)* filter. This small device is placed in the inferior vena cava. It helps trap blood clots that may travel from the lower extremities up towards the brain and heart.

Surgical Therapy

Hemodynamically unstable patients with massive PE in whom thrombolytic therapy is contraindicated may be candidates for pulmonary embolectomy. Embolectomy, the removal of emboli, can be achieved through a diagnostic imaging (vascular catheter) or surgical approach. It can help decrease right ventricular afterload. Surgical outcomes have improved in recent years, in part due to rapid diagnosis and enhanced surgical procedures.

Percutaneous interventional techniques, surgical embolectomy, ultrasound-guided catheter thrombolysis, and aspiration thrombectomy are newer, moderately invasive procedures for PE. In patients who are at high risk and for whom anticoagulation is contraindicated, an inferior vena cava (IVC) filter may be the treatment of choice (Fig. 30.8). This device, inserted through the femoral vein, is placed at the level of the renal veins in the inferior vena cava. Once inserted, the filter expands and prevents the movement of large clots upwards and into the pulmonary system. Complications are rare but include misplacement, migration, and perforation.

❖ NURSING MANAGEMENT: PULMONARY EMBOLISM

Prevention of PE begins with prevention of DVT. Identifying the "at risk" patient is essential. Nursing measures aimed at prevention of PE are similar to those for prophylaxis of VTE. These include the use of intermittent pneumatic compression devices, early ambulation, and anticoagulant medications.

Initially, keep the patient on bed rest in a semi-Fowler's position to facilitate breathing. Assess cardiopulmonary status with careful monitoring of vital signs, cardiac rhythm, pulse oximetry, ABGs, and lung sounds. Apply O_2 therapy as directed. Maintain a patent IV line for medications and fluid therapy. Monitor laboratory results to ensure therapeutic ranges of INR (for warfarin) and aPTT (for IV heparin). Monitor platelet counts for thrombocytopenia and the development of HIT. Observe the patient for complications of anticoagulant and fibrinolytic therapy (e.g., bleeding, bruising). Implement fall precautions once the patient can be out of bed.

The patient may be anxious because of pain, inability to breathe, and fear of death. Provide emotional support and reassurance to help relieve the patient's anxiety.

Teaching about long-term anticoagulant therapy is essential. Anticoagulant therapy continues for at least 3 months. Patients with large or recurrent emboli may be treated indefinitely with anticoagulants. INR levels are drawn at intervals and warfarin dosage is adjusted. Some patients are monitored by nurses in an anticoagulation clinic.

Long-term management of PE is similar to that for the patient with VTE (see more about VTE in Chapter 41). Discharge planning is aimed at preventing worsening of the current condition and avoiding complications and recurrence. Reinforce the need for the patient to return to the HCP for regular follow-up care.

PULMONARY HYPERTENSION

In **pulmonary hypertension** there is an elevated pulmonary artery pressure (greater than 20 mm Hg) from an increase in resistance to blood flow through the pulmonary circulation. Normally, the pulmonary circulation is characterized by low resistance and low-pressure vessels. In pulmonary hypertension, the pulmonary pressures are high.

There are 5 classes of pulmonary hypertension.[24] Each class (group) is based on cause:

Group 1: Attributed to medication, specific diseases, genetic (inherited) link, or idiopathic
Group 2: Related to left-sided HF
Group 3: Related to the lungs and hypoxia
Group 4: Related to the cardiovascular system and thromboembolism
Group 5: Multifactorial (and often unclear) origins (e.g., hematologic, metabolic, renal involvement)

Pulmonary hypertension can occur as a primary disease *(idiopathic pulmonary arterial hypertension)* or as a secondary complication of a respiratory, heart, autoimmune, liver, or connective tissue problem *(secondary pulmonary arterial hypertension).*

IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION

Etiology and Pathophysiology

Idiopathic pulmonary arterial hypertension (IPAH) was previously known as *primary pulmonary hypertension* (PPH). The cause of IPAH is unknown. It is related to connective tissue diseases, cirrhosis, and HIV. The exact relationship between these

PATHOPHYSIOLOGY MAP

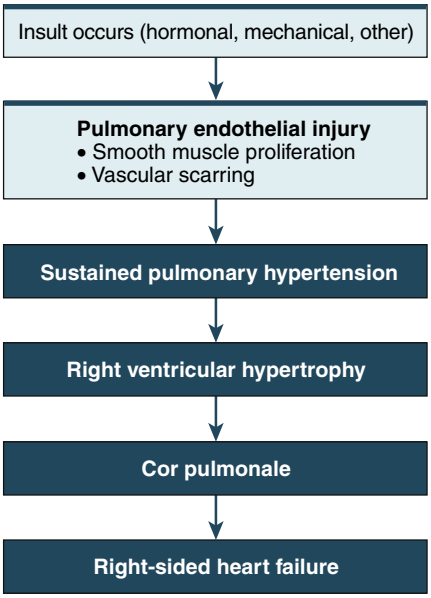

Fig. 30.9 Pathogenesis of pulmonary hypertension and cor pulmonale.

disorders and IPAH is unclear. Similarly, the pathophysiology of IPAH is poorly understood. We believe that some type of insult (e.g., hormonal, mechanical) to the pulmonary endothelium may occur, causing a cascade of events leading to vascular scarring, endothelial dysfunction, and smooth muscle proliferation (Fig. 30.9). IPAH affects more females.

Clinical Manifestations and Diagnostic Studies

The classic symptoms are dyspnea on exertion and fatigue. Exertional chest pain, dizziness, and syncope may occur. These are related to the inability of cardiac output to increase in response to increased O_2 demand. Abnormal heart sounds may be heard, including an S_3. Eventually, as the disease progresses, dyspnea occurs at rest. Pulmonary hypertension increases the workload of the right ventricle and causes right ventricular hypertrophy (a condition called *cor pulmonale*) and, eventually, HF.

Right-sided cardiac catheterization is the definitive test to diagnose any type of pulmonary hypertension. It gives an accurate measurement of pulmonary artery pressures, cardiac output, and pulmonary vascular resistance. Diagnostic evaluation often includes ECG, chest x-ray, pulmonary function tests, echocardiogram, and CT scan. Confirmation of IPAH requires a workup to exclude conditions that may cause secondary pulmonary hypertension.

The mean time between onset of symptoms and the diagnosis is about 2 years. By the time patients become symptomatic, the disease is already in the advanced stages and the pulmonary artery pressure is 2 to 3 times normal values.

Interprofessional and Nursing Care

Early recognition is essential to interrupt the vicious cycle responsible for disease progression. Encourage patients to report unexplained shortness of breath, syncope, chest discomfort, and feet and ankle edema to their HCP.

Although IPAH has no cure, treatment can relieve symptoms, improve quality of life, and prolong life. If untreated, IPAH can rapidly progress, causing right-sided HF and death within a few years. New drug therapy has greatly improved survival. Drug therapy consists of agents that dilate the pulmonary blood vessels, reduce right ventricular overload, and reverse remodeling (Table 30.21). Diuretics are used to manage peripheral edema. Anticoagulants reduce the risk of thrombus formation. Because hypoxia is a potent pulmonary vasoconstrictor, low-flow O_2 gives symptomatic relief. The goal is to keep O_2 saturation 90% or greater.

Surgical therapy includes pulmonary thromboendarterectomy (PTE), in which clots are removed from the pulmonary arteries. It is a technically demanding, high risk procedure, done only at certain centers. Atrial septostomy (AS) is a palliative procedure that involves the creation of an intra-atrial right-to-left shunt to decompress the right ventricle. It is used for some patients awaiting a lung transplant. A lung transplant is an option for patients who do not respond to drug therapy and progress to severe right-sided HF. Disease recurrence has not been reported in persons who had a lung transplant.

SECONDARY PULMONARY ARTERIAL HYPERTENSION

Secondary pulmonary arterial hypertension (SPAH) occurs when another disease causes a chronic increase in pulmonary artery pressures. The primary disease can cause anatomic or vascular changes that result in the pulmonary hypertension. SPAH can develop due to parenchymal lung disease, left ventricular dysfunction, intracardiac shunts, chronic PE, or systemic connective tissue disease.[25]

The symptoms can reflect the underlying disease, but some are directly related to SPAH. These include dyspnea, fatigue, lethargy, and chest pain. Initial physical findings can include right ventricular hypertrophy and signs of right-sided HF (increased pulmonic heart sound, S_4 heart sound, peripheral edema, hepatomegaly).

Diagnosis of SPAH is like that of IPAH. With SPAH, we treat the underlying primary disorder. When irreversible pulmonary vascular damage has occurred, therapies for IPAH are started. A PTE may offer a cure for patients with chronic pulmonary hypertension caused by PE.

COR PULMONALE

Cor pulmonale is enlargement of the right ventricle caused by a primary respiratory disorder. Almost any disorder that affects the respiratory system can cause cor pulmonale. The most common cause is COPD. Pulmonary hypertension is usually a pre-existing condition in the person with cor pulmonale. Overt HF may be present. Fig. 30.9 outlines the cause and pathogenesis of pulmonary hypertension and cor pulmonale.

Clinical Manifestations and Diagnostic Studies

Manifestations are subtle and often masked by symptoms of the lung problem. Common symptoms include exertional dyspnea,

TABLE 30.21 Drug Therapy

Pulmonary Hypertension

Drug	Mechanism of Action	Considerations
Calcium Channel Blockers		
diltiazem (Cardizem, cardizem LA) nifedipine (Procardia)	• ↓ BP • Act on vascular smooth muscle, causing dilation • Lower pulmonary artery pressure	• Successful in a very small number of patients • Only used in patients who do not have right-sided HF • Used at high doses in comparison to other uses of calcium channel blockers
Endothelin Receptor Antagonists		
ambrisentan (Letairis) bosentan (Tracleer) macitentan (Opsumit)	• Binds to endothelin-1 receptors and blocks the constriction of pulmonary arteries • Promotes relaxation of pulmonary arteries • ↓ Pulmonary artery pressure	• Given orally • For patients with New York Heart Association (NYHA) class II to IV symptoms • Hepatotoxic • Monitor liver function tests monthly
Phosphodiesterase (Type 5) Enzyme Inhibitors		
sildenafil (Revatio) tadalafil (Adcirca)	• Promote smooth muscle relaxation in lung vasculature	• Given orally • Contraindicated in patients taking nitroglycerin, since may cause refractory hypotension
Vasodilators		
iloprost (Ventavis) treprostinil (Tyvaso)	• Synthetic analogs of prostacyclin (PGI_2) • Dilate systemic and pulmonary arterial vasculature • Help relieve dyspnea	• Given by inhalation • For patients with NYHA class III or IV HF • Given 6–9 times a day using a disk inserted into a nebulizer • Can cause orthostatic hypotension. Do not give to patients with systolic BP <85 mm Hg.
Vasodilators		
epoprostenol (Flolan, Veletri) treprostinil (Remodulin)	• Promote pulmonary vasodilation and reduce pulmonary vascular resistance • Relieves dyspnea and chest congestion	• For patients who do not respond to calcium channel blockers or have NYHA class III or IV right-sided HF • Given by continuous IV (central line) or continuous subcutaneous route • Half-life of epoprostenol is short. Potential clinical deterioration from abrupt withdrawal if infusion disrupted

tachypnea, cough, and fatigue. Physical signs include evidence of right ventricular hypertrophy on ECG and an increase in intensity of S_2. Chronic hypoxemia leads to polycythemia and increased total blood volume and viscosity. Polycythemia is often present in cor pulmonale from COPD.

If HF accompanies cor pulmonale, peripheral edema, weight gain, distended neck veins, full, bounding pulse, and enlarged liver may occur. Various laboratory tests and imaging studies are used to confirm the diagnosis of cor pulmonale (Table 30.22).

Interprofessional and Nursing Care

Early identification is essential before changes to the heart occur that may be irreversible. Management is directed at determining the cause and treating the underlying problem.

Long-term O_2 therapy, the mainstay of treatment to correct the hypoxemia, reduces vasoconstriction and pulmonary hypertension. All other interventions are tailored for each patient. If fluid, electrolyte, and/or acid-base imbalances are present, they must be corrected. Diuretics may help decrease plasma volume and reduce the workload on the heart but must be used with caution. In some cases, decreases in fluid volume from diuresis can worsen heart function. Bronchodilator therapy is needed if the underlying respiratory problem is due to an obstructive disorder.

Other treatments may include vasodilator therapy, calcium channel blockers, anticoagulants, digitalis, and phlebotomy. All have varying degrees of success. Chronic management of cor pulmonale from COPD is like that described for COPD (see Chapter 31).

ENVIRONMENTAL LUNG DISEASES

Environmental or occupational lung diseases result from inhaled dust or chemicals. The extent of lung damage is influenced by the toxicity of the inhaled substance, amount and duration of exposure, and individual susceptibility. Environmentally induced lung disease includes pneumoconiosis, chemical pneumonitis, and hypersensitivity pneumonitis.

Pneumoconiosis is a general term for a group of lung diseases caused by inhalation and retention of mineral or metal dust particles. The literal meaning of *pneumoconiosis* is "dust in the lungs." We classify these diseases by the origin of the dust (e.g., silicosis, asbestosis, berylliosis). For example, silicosis occurs from inhaling silica from sand and rock. Coal worker's pneumoconiosis (CWP), or *black lung,* is caused by inhaling large amounts of coal dust. It is a hazard for underground coal miners. The inhaled substance is ingested by macrophages, which releases substances that cause cell injury and death.

TABLE 30.22 Interprofessional Care

Cor Pulmonale

Diagnostic Assessment
- History and physical assessment
- ABGs, SpO_2
- Serum and urine electrolytes
- b-Type natriuretic peptide (BNP)
- ECG
- Chest x-ray
- Echocardiography
- CT scan, MRI
- Cardiac catheterization

Management
- Treat the cause (which may be difficult, often involves improving O_2 delivery to the patient and right ventricular function)
- O_2 therapy
- Low-sodium diet

Drug Therapy (Depending on the Primary Cause)
- Bronchodilators
- Diuretics (use with caution)
- Pulmonary vasodilators
- Calcium channel blockers
- Inotropic agents
- Digitalis
- Anticoagulation therapy

Fibrosis occurs from tissue repair after inflammation. Breathing problems become evident after many years of repeated exposure, resulting in diffuse *pulmonary fibrosis* (excess connective tissue).

Asbestos is a group of minerals composed of microscopic fibers. For many years, asbestos was used for insulation and to help fireproof buildings. When disturbed, asbestos releases tiny filament particles into the air. Once inhaled, the tiny fibers become deposited within the lung. Asbestosis causes chronic lung inflammation. People with repeated exposure are at a greater risk for disease. Lung cancer, either squamous cell carcinoma or adenocarcinoma, is the most frequent cancer from asbestos exposure. There is a lapse of at least 15 to 19 years between first exposure and development of lung cancer. Mesothelioma, both pleural and peritoneal, is associated with asbestos exposure.[26]

Chemical pneumonitis results from exposures to toxic chemical fumes. There are 2 types of chemical pneumonitis: acute and chronic. In the acute form, there is diffuse lung injury characterized by pulmonary edema. Chronically, the clinical picture is that of *bronchiolitis obliterans* (obstruction of the bronchioles due to inflammation and fibrosis). The chest x-ray is normal or shows hyperinflation.

Hypersensitivity pneumonitis, or extrinsic allergic alveolitis, is a form of parenchymal lung disease seen when a person inhales an antigen to which they are allergic. There are acute, subacute, and chronic forms. Examples include bird fancier's lung (exposure to particles in feathers and droppings of birds) and farmer's lung (inhalation of hay dust particles).

Clinical Manifestations

Symptoms of many environmental lung diseases may not occur until at least 10 to 15 years after the initial exposure to the inhaled irritant. Manifestations common to all pneumoconiosis include dyspnea, cough, wheezing, and weight loss. Pulmonary function studies often show reduced vital capacity. A chest x-ray often shows lung involvement specific to the primary problem. CT scans have been useful in detecting early lung involvement.

COPD is the most common complication of environmental lung disease. Other associated problems include acute pulmonary edema, lung cancer, mesothelioma, and TB. Appearance of these symptoms and complications are often the reason the patient seeks medical care. Cor pulmonale is a late complication. It is more common in conditions where there is diffuse pulmonary fibrosis.

Interprofessional and Nursing Care

The best approach to managing environmental lung diseases is to prevent or decrease environmental and occupational exposure. Teach those at risk about the use of appropriate PPE. Wearing masks and ensuring well-designed, effective ventilation systems are in place are appropriate for some occupations. Smoke inhalation by nonsmokers has led to laws requiring a smoke-free workplace. Periodic inspections and monitoring of workplaces by agencies such as the Occupational Safety and Health Administration (OSHA) and the National Institute for Occupational Safety and Health (NIOSH) reinforce employers' obligations to provide a safe work environment. NIOSH is responsible for workplace safety and health regulations in the United States.

Encourage regular medical check-ups for those in high-risk occupations. Early diagnosis is essential to halting the disease process. Care is directed toward preventing disease progression and monitoring, improving, or controlling respiratory symptoms. Treatment depends on the cause and severity of the condition. Acute care may include O_2 therapy, IV fluid, percussion therapy, inhaled bronchodilators, corticosteroids, and NSAIDs. Some patients need mechanical ventilation. Longer term care includes pulmonary rehabilitation. Patients should be immunized against pneumococcal pneumonia and influenza. Discontinuing exposure to the offending inhalant and smoking cessation may or may not be effective in stopping disease progression.

LUNG TRANSPLANTATION

Lung transplantation has become an important alternative option for patients with end-stage lung disease. Unfortunately, the limiting factor is the lack of donors. A variety of pulmonary problems are potentially treatable with a lung transplant (Table 30.23). Better patient selection criteria, improvements in surgical techniques, enhanced immunosuppression, and excellent postoperative care have resulted in improved survival rates.

Preoperative Care

Patients being considered for a lung transplant have an extensive evaluation. Absolute contraindications include cancer

TABLE 30.23 Common Indications for a Lung Transplant

- Progressive lung disease and greater than 50% chance of death in the next 2 years without a lung transplant
- Chronic obstructive pulmonary disease (COPD)
- Cystic fibrosis
- Emphysema with α_1-antitrypsin deficiency
- Idiopathic pulmonary fibrosis
- Interstitial lung disease
- Pulmonary arterial hypertension

within the past 2 years (excluding some types of skin cancer), untreatable advanced dysfunction of another major organ system (e.g., heart, liver, renal failure), uncorrectable bleeding condition, *mycobacterium tuberculosis,* severe obesity (BMI >35kg/m^2), and significant psychosocial problems.[27] The patient and family must be able to cope with complex postoperative care (e.g., adherence to immunosuppressive therapy, monitoring for infection). Many transplant centers require outpatient pulmonary rehabilitation before surgery to maximize physical conditioning.

In the United States, the United Network for Organ Sharing (UNOS) designates recipients of donor lungs based on a lung allocation score (LAS). The LAS helps prioritize waiting list recipients based on the urgency of need and expected post-transplant survival expectations.

Patients who are accepted as transplant candidates must always carry a pager in case a donor organ becomes available. They must be prepared to be at their transplant center at a moment's notice. Patients may have to limit their travel in case they need to quickly return to the transplant center.

Surgical Procedure

Four types of lung transplant procedures are available: single-lung, bilateral lung, heart-lung, and transplantation of lobes from a living-related donor.

A *single-lung transplant* involves a thoracotomy incision on the affected side of the chest. The opposite lung is ventilated while the diseased lung is excised, and the donor lung implanted. There are 3 anastomoses: bronchus, pulmonary artery, and pulmonary veins. In a *bilateral lung transplant,* the incision is made across the sternum and the donor lungs are implanted separately. A median sternotomy incision is used for a *heart-lung transplant* procedure. *Lobar transplantation* from living donors is reserved for those who urgently need a transplant and are unlikely to survive until a donor becomes available. Most of these recipients are patients with cystic fibrosis. The donors are their parents or relatives. Once anastomosis is complete, the lung is gently reinflated, perfusion is re-established, chest tubes are inserted, and the surgical incision is closed.

Postoperative Care

Immediate postoperative care often includes mechanical ventilation and hemodynamic monitoring in the ICU. IV therapy, immunosuppression, nutrition support, detection of early rejection, and preventing or treating complications, including infection, are priorities. Once hemodynamic stability has been achieved and mechanical ventilation discontinued, the patient is transferred to a high-acuity observation or surgical unit.

Lung transplant recipients are at high risk for multiple complications. Infections are the leading cause of death, especially within the 1st year after transplant.[28] Bacterial bronchitis and pneumonia are the most common infections. CMV, fungi, viruses, and mycobacteria are also causative agents. Noninfectious issues may include VTE, diaphragmatic dysfunction, and cancer.

Immunosuppressive therapy usually includes a 3 drug regimen of tacrolimus, mycophenolate mofetil (CellCept), and prednisone. (The mechanisms of action of these drugs are discussed in Table 14.17.) Drug levels are monitored on a regular basis. Lung transplant recipients usually receive higher levels of immunosuppressive therapy than other organ recipients.

Acute rejection is fairly common. Between 28% and 64% of patients will have 1 episode of acute rejection in the 1st year after their transplant.[29] When acute rejection occurs, it typically occurs in the first 5 to 10 days after the transplant. Signs include low-grade fever, fatigue, dyspnea, dry cough, and O_2 desaturation. Accurate diagnosis of rejection is by transbronchial biopsy completed via bronchoscopy. Treatment consists of high doses of IV corticosteroids for 3 days, followed by high doses of oral prednisone. In patients with persistent or recurrent acute rejection, antilymphocyte therapy may be useful.

Bronchiolitis obliterans (BOS) is a manifestation of chronic rejection in lung transplant patients. BOS is characterized by airflow obstruction that progresses over time. The onset is often subacute, with gradual development of exertional dyspnea, nonproductive cough, wheezing, and/or low-grade fever. Airway obstruction is not responsive to bronchodilators and corticosteroid therapy. Additional immunosuppressive agents may be used to treat chronic rejection. Because acute rejection is a major risk factor for BOS, preventing acute rejection is key to decreasing chronic rejection.

Before discharge, the patient needs to be able to perform self-care activities, including managing their medication plan, and know when to call the transplant team. Patients are taught pulmonary clearance measures, including chest physiotherapy and deep-breathing and coughing techniques to help minimize complications. Home spirometry is used to monitor trends in lung function. Teach patients to keep medication logs, laboratory results, and spirometry records. An outpatient rehabilitation program can improve physical endurance.

After discharge, the transplant team follows the patient for transplant-related issues. Patients return to their HCP for health maintenance and routine illnesses. Care coordination among the transplant team, inpatient team, and primary care team is essential for ongoing successful management. Information about organ transplants, histocompatibility, rejection, and immunosuppressive therapy is found in Chapter 14.

LUNG CANCER

Lung cancer is the leading cause of cancer-related deaths in the United States.[30] Lung cancer accounts for 25% of all cancer

deaths, more than those caused by breast, prostate, and colon cancer combined. In 2021, around 235,000 new cases of lung cancer will be diagnosed, and 131,000 Americans will die.[30] Although lung cancer has a high mortality and low cure rate, advances in medical treatment are improving the response to treatment.

Etiology

Smoking causes 80% to 90% of all lung cancers.[31] There is no safe form of tobacco or tobacco product. Using smokeless tobacco, pipes and cigars, hookah and waterpipe, bidis, and kreteks all pose significant risk for lung cancer.

Tobacco smoke contains over 7000 chemicals, of which 250 are harmful. Of the harmful substances in tobacco smoke, 69 interfere with normal cell development and are linked to lung cancer. Exposure to tobacco smoke causes changes in the bronchial epithelium. These changes usually return to normal with smoking cessation. The risk for lung cancer gradually decreases with smoking cessation, reaching that of nonsmokers within 10 to 15 years of quitting.

The risk for developing lung cancer is directly related to total exposure to tobacco smoke. Measures of exposure include the total number of cigarettes smoked in a lifetime, age of smoking onset, depth of inhalation, tar and nicotine content, and the use of unfiltered cigarettes. Nonsmokers can also develop lung cancer. Sidestream smoke (smoke from burning cigarettes, cigars) has the same carcinogens found in mainstream smoke (smoke inhaled and exhaled by the smoker). This exposure to secondhand smoke creates a health risk for nonsmoking adults and children.

Other risk factors include exposure to high levels of pollution, radiation (especially radon exposure), and asbestos. Heavy or prolonged exposure to industrial agents, such as radon, coal dust, asbestos, chromium, silica, arsenic, and diesel exhaust, increases risk, especially in smokers.[31]

Marked variations exist in a person's tendency to develop lung cancer. Differences in incidence, risk factors, and survival exist between men and women (Box 30.5). Genetic, hormonal, and molecular influences may contribute to these differences. At the same time, the incidence and survivability vary between racial and ethnic populations (Box 30.6).

Pathophysiology

We think most primary lung tumors arise from mutated epithelial cells. The growth of mutations, which are caused by carcinogens, is influenced by various genetic factors. Once underway, epidermal growth factor promotes tumor development. Tumor cells grow slowly, taking 8 to 10 years for a tumor to reach 1 cm in size, the smallest lesion detectable on x-ray. Lung cancers occur mainly in the segmental bronchi or beyond and usually occur in the upper lobes.

There are 2 broad subtypes of primary lung cancer: non–small cell lung cancer (NSCLC) (84%) and small cell lung cancer (SCLC) (13%) (Table 30.24).[32] Lung cancers metastasize mainly by direct extension and through the blood and lymph system. The common sites for metastasis are the lymph nodes, liver, brain, bones, and adrenal glands.

BOX 30.5 BIOLOGIC SEX CONSIDERATIONS

Lung Cancer

Men

- Have a 1 in 15 chance of developing lung cancer (smokers and nonsmokers)
- Diagnosed with lung cancer more than women
- Die from lung cancer more than women
- Male smokers are 10 times more likely to develop lung cancer than nonsmokers
- Lung cancer incidence and deaths are decreasing in men

Women

- Have a 1 in 17 chance of developing lung cancer (smokers and nonsmokers)
- Lung cancer incidence and deaths are increasing in women.
- Develop lung cancer after fewer years of smoking than men
- Develop lung cancer at a younger age than men
- Nonsmoking women are at greater risk for developing lung cancer than nonsmoking men
- Women with lung cancer live, on the average, 12 months longer than men

BOX 30.6 PROMOTING HEALTH EQUITY

Lung Cancer

Blacks

- Have the highest incidence of lung cancer
- Are more likely to die from lung cancer than any other ethnic group
- Have a higher rate of lung cancer among men than in other ethnic groups

Whites

- Have the 2nd highest death rate from lung cancer
- Have a higher rate of lung cancer among women than in other ethnic groups

Asians/Pacific Islanders and Hispanics

- Have the lowest rates of lung cancer in both men and women

Other Types of Lung Tumors

SCLC and NSCLC account for 97% of lung tumors. The other 3% include:

- *Hamartomas,* the most common benign tumor, is a slow-growing congenital tumor composed of fibrous tissue, fat, and blood vessels.
- *Mucous gland adenoma* is a benign tumor arising in the bronchi. It consists of columnar cystic spaces.
- *Mesotheliomas* are either malignant or benign. They start in the visceral pleura. Malignant mesotheliomas are related to asbestos exposure. Benign lesions are localized.

Secondary metastases from other cancers can occur. Cancer cells from another part of the body reach the lungs through the pulmonary capillaries or lymphatic network. The main cancers that spread to the lungs often start in the breast, GI, or genitourinary tract.

Paraneoplastic Syndrome

Lung cancer can cause *paraneoplastic syndrome*. Paraneoplastic syndrome may be initiated by hormones, cytokines, enzymes (secreted by tumor cells), or antibodies (made by the body in

TABLE 30.24 Types of Primary Lung Cancer

Type	Growth Rate	Characteristics	Response to Therapy
Non–Small Cell Lung Cancer (NSCLC)			
Adenocarcinoma	Moderate	• Accounts for 40% of lung cancers • Most common lung cancer in United States • Most common cancer in people who have not smoked • Found in peripheral areas of lung • Often has no manifestations until widespread metastasis is present	• Surgical resection may be tried depending on staging • Does not respond well to chemotherapy
Large cell (undifferentiated) cancer	Rapid	• Accounts for 10% of lung cancers • Composed of large cells that are anaplastic • Often arise in bronchi • Is highly metastatic via lymphatics and blood	• Surgery is not usually done because of high rate of metastases • Tumor may be radiosensitive but often recur
Squamous cell cancer	Slow	• Accounts for 25%–30% of lung cancers • Centrally located • Causes early symptoms of nonproductive cough and hemoptysis • Does not have a strong tendency to metastasize	• Surgical resection may be tried • Adjuvant chemotherapy and radiation • Depending on the staging, life expectancy is better than for SCLC
Small Cell Lung Cancer (SCLC)			
Small cell cancer	Very rapid	• Accounts for about 10%–15% of lung cancers • Very aggressive form of lung cancer • Spreads early via lymphatics and bloodstream • Frequent metastasis to brain • Associated with endocrine problems	• Chemotherapy mainstay of treatment; more responsive to chemotherapy than NSCLC • Radiation used as adjuvant therapy and palliative measure • Overall poor prognosis

response to the tumor) that destroy healthy cells. Sometimes, paraneoplastic syndrome manifests before the cancer is diagnosed.

Examples of paraneoplastic syndrome include hypercalcemia, syndrome of inappropriate antidiuretic hormone secretion (SIADH), adrenal hypersecretion, polycythemia, and Cushing syndrome. SCLCs are most often associated with paraneoplastic syndrome. The conditions may stabilize with treatment of the underlying cancer. SIADH, adrenal hypersecretion, and Cushing syndrome are discussed in Chapter 54.

Clinical Manifestations

The manifestations of lung cancer are usually nonspecific. They may appear late in the disease process. Symptoms may be masked by a chronic cough attributed to smoking or smoking-related lung disease. Manifestations depend on the type of primary lung cancer, its location, and extent of metastatic spread. Lung cancer often presents as a lobar pneumonia that does not respond to treatment.

The most common symptom and often the one that is reported first is a persistent cough. The patient may have dyspnea or wheezing. Blood-tinged sputum may be present because of bleeding caused by the cancer. Chest pain, if present, may be localized or unilateral, ranging from mild to severe.

Later manifestations include nonspecific systemic symptoms, such as anorexia, nausea and vomiting, fatigue, and weight loss. Hoarseness may be present due to laryngeal nerve involvement. Dysphagia, unilateral paralysis of the diaphragm, and superior vena cava obstruction may occur because of intrathoracic spread of the cancer. Lymph nodes are often palpable in the neck or axillae. Mediastinal involvement may lead to pericardial effusion, cardiac tamponade, and dysrhythmias.

Diagnostic Studies

A chest x-ray is the first diagnostic test done for patients with suspected lung cancer. The x-ray may be normal or identify a lung mass or infiltrate (Fig. 30.10). Evidence of metastasis to the ribs or vertebrae and a pleural effusion may be seen on chest x-ray. CT scanning is used to further evaluate the lung mass. CT scans can identify the location and extent of masses in the chest, any mediastinal involvement, and lymph node enlargement.

Fig. 30.10 Lung cancer lesion. (© iStock.com/Sutthaburawonk.)

Sputum cytology can identify cancer cells, but sputum samples are rarely used in diagnosing lung cancer because cancer cells are not always present in the sputum. A definitive diagnosis requires a biopsy. Cells for biopsy can be obtained by CT-guided needle aspiration, bronchoscopy, mediastinoscopy, or VATS. If a thoracentesis is done to relieve a pleural effusion, the fluid is analyzed for cancer cells.

TABLE 30.25 Interprofessional Care

Lung Cancer

Diagnostic Assessment

- History and physical assessment
- Chest x-ray
- Bronchoscopy
- Cytologic study of bronchial washings or pleural space fluid
- Transbronchial or percutaneous fine-needle aspiration
- CT scan, MRI, PET
- Mediastinoscopy
- Video-assisted thoracoscopic surgery (VATS)
- Laboratory tests: CBC, electrolytes, BUN, creatinine, WBC and differential, liver function tests, calcium chemistries

Management

- Surgery (segmental or wedge resection, lobectomy, pneumonectomy)
- Radiation therapy
- Chemotherapy
- Targeted therapy and immunotherapy
- Prophylactic cranial radiation
- Bronchoscopic laser therapy
- Photodynamic therapy
- Airway stenting
- Radiofrequency ablation

Accurate assessment of lung cancer is critical for staging and determining appropriate treatment. Bone scans and CT scans of the brain, pelvis, and abdomen assess for metastases. A CBC with differential, electrolyte panel, and liver and renal function tests are done. Sometimes pulmonary function tests may be done. MRI and/or positron emission tomography (PET) may be used to evaluate and stage lung cancer. Table 30.25 outlines the diagnostic assessment and management of lung cancer.

Staging

Staging of NSCLC is done using the TNM staging system.[33] Under the TNM system, cancer is grouped into 4 stages with A or B subtypes. A simplified version of staging of NSCLC is shown in Table 30.26. Patients with stages I, II, and IIIA disease may be surgical candidates. Stage IIIB or IV disease is usually inoperable and has a poor prognosis. Many NSCLCs are not resectable at the time of diagnosis.

Staging of SCLC by TNM has not been useful because this cancer is aggressive and always considered systemic. The stages of SCLC are *limited* and *extensive*. *Limited* means that the tumor is only on 1 side of the chest and regional lymph nodes. *Extensive* SCLC means that the cancer extends beyond the limited stage. Unfortunately, most patients with SCLC have extensive disease at time of diagnosis.

Screening for Lung Cancer

Many medical groups recommend cancer screening for high-risk patients. Adults ages 50 to 80 with a history of smoking (20 pack-year smoking history or currently smoke) or who quit smoking but less than 15 years ago should have annual screening for lung cancer.[34] Screening is done using low-dose CT.

TABLE 30.26 Staging of Non–Small Cell Lung Cancer

Stages	Characteristics
0	Cancer cells found in first layer of cells in the respiratory airway or alveoli
I	Tumor is small and localized to lung. No lymph node involvement
A	Tumor <3 cm, minimally invasive
B	Tumor 3–4 cm and invading main airway (but not into right or left bronchi), visceral pleura.
II	Increased tumor size, some lymph node involvement
A	Tumor 4–5 cm with invasion of main airway (but not right or left bronchi), visceral pleura
B	Tumor 5–7 cm involving the bronchus and lymph nodes near bronchi on same side of chest; tumor 5–7 cm with visceral and parietal pleura, diaphragm, phrenic nerve involvement; 2 or more tumors in same lobe of lung
III	Increased spread of tumor
A	1 or more tumors ≤5 cm or smaller spread to the nearby (same side) structures (chest wall, pleura, pericardium), or metastases into diaphragm, hear, bone, and regional lymph nodes below carina
B	1 or more tumors >5 cm in the same lung, involving heart, trachea, esophagus, mediastinum; lymph node involvement (same side or opposite side, or below carina),
C	Tumor >5 cm and more than 1 tumor in a different lobe of the lung; lymph nodes on opposite side involved
IV	Distant metastasis (to the other lung)
A	Metastases to the other lung, pleura, pericardium; 1 new tumor outside of chest
B	Metastases widespread and 2 or more tumors outside of the chest

Interprofessional Care

Surgical Therapy

Surgical resection is the treatment of choice in NSCLC stages I to IIIA without mediastinal involvement. Resection gives the best chance for a cure. Factors that affect survival include the size of the primary tumor and preexisting co-morbidities. For other NSCLC stages, patients may have surgery in conjunction with radiation therapy, chemotherapy, and targeted therapy.

Surgical procedures include segmental or wedge resection procedures, lobectomy (removal of 1 or more lobes of the lung), or pneumonectomy (removal of 1 entire lung). VATS may be used to treat lung cancers near the outside of the lung. Surgery is generally not done for SCLC because of its rapid growth and dissemination at the time of diagnosis.

When the tumor is operable, the patient's cardiopulmonary status must be evaluated to determine the ability to have surgery. Pulmonary function studies, ABGs, and anesthesia and critical care consults are often done to assess the patient's cardiopulmonary status and overall surgical risk.

Radiation Therapy

Radiation therapy may be used as treatment for both NSCLC and SCLC. Radiation therapy may be given as curative, palliative, or adjuvant therapy in combination with surgery, chemotherapy, or targeted therapy.

Radiation therapy may be the primary therapy in the person who cannot undergo surgical resection because of co-morbidities. Radiation therapy relieves dyspnea and hemoptysis from

bronchial obstructive tumors and treats superior vena cava syndrome. It can treat pain from metastatic bone lesions or brain metastasis. Radiation before surgery can reduce the tumor mass before surgical resection. Complications of radiation therapy include esophagitis, skin irritation, nausea and vomiting, anorexia, and radiation pneumonitis (see Chapter 16).

Stereotactic body radiotherapy (SBRT), or *stereotactic radiosurgery (SRS),* is a type of radiation therapy that uses high doses of radiation delivered to tumors outside the CNS. SBRT uses special positioning procedures and radiology techniques to deliver a higher dose of radiation to the tumor and expose only a small part of healthy lung. It does not destroy the tumor, but damages tumor DNA. Therapy is given over 1 to 3 days. SBRT is an option for patients with early-stage lung cancers who cannot have surgery.

Chemotherapy

Chemotherapy is the main treatment for SCLC. In NSCLC, chemotherapy may be used to treat nonresectable tumors or as adjuvant therapy to surgery. A variety of chemotherapy drugs and multidrug protocols are used. Chemotherapy for lung cancer typically consists of combinations of 2 of these drugs: etoposide, carboplatin, cisplatin, paclitaxel, vinorelbine, docetaxel, gemcitabine, and pemetrexed (Alimta).

Targeted Therapy

Targeted therapy uses drugs that block the growth of molecules involved in specific aspects of tumor growth (see Chapter 16). Because this therapy inhibits growth rather than directly killing cancer cells, targeted therapy may be less toxic than chemotherapy. One targeted therapy for NSCLC is tyrosine kinase inhibitors. They block signals for growth in the cancer cells. Agents include cetuximab (Erbitux), erlotinib (Tarceva), afatinib (Gilotrif), gefitinib (Iressa), osimertinib (Tagrisso), and necitumumab (Portrazza).

Another type of kinase inhibitor is used to treat patients with NSCLC who have an abnormal *anaplastic lymphoma kinase (ALK)* gene. Drugs in this class include crizotinib (Xalkori), brigatinib (Alunbrig), and ceritinib (Zykadia). These drugs directly inhibit the kinase protein made by the ALK gene that is responsible for cancer development and growth.

Another targeted therapy used to treat lung cancer inhibits the growth of new blood vessels (angiogenesis) by targeting vascular endothelial growth factor. Bevacizumab (Avastin) is an angiogenesis inhibitor.

Immunotherapy

Nivolumab (Opdivo), atezolizumab (Tecentriq), and pembrolizumab (Keytruda) are drugs that target PD-1, a protein on T cells that normally helps keep these cells from attacking other cells in the body. By blocking PD-1, these drugs boost the immune response against cancer cells. This can shrink some tumors or slow their growth. Nivolumab and pembrolizumab can be used in people with metastatic NSCLC whose cancer has progressed after other treatments and with tumors that express PD-1.

Other Therapies

Prophylactic cranial irradiation. Patients with SCLC have early metastases, especially to the CNS. Most chemotherapy does not penetrate the blood-brain barrier. As a result, after successful systemic treatment, the patient is at risk for brain metastases. Prophylactic radiation can decrease the incidence of brain metastases and may improve survival rates in patients with limited SCLC.

Bronchoscopic laser therapy. Bronchoscopic laser therapy makes it possible to remove obstructing bronchial lesions. The laser's thermal energy is transmitted to the target tissue. It is a safe and effective treatment of endobronchial obstructions from tumors. Symptoms of airway obstruction are relieved due to thermal necrosis and tumor shrinkage. The procedure may be repeated as needed.

Photodynamic therapy. Photodynamic therapy (PDT) is a form of treatment for early-stage lung cancers that uses a combination of a drug and a specific type of light. Cancer cells are killed when the drug, known as a photosynthesizer, is exposed to a specific wavelength of light. Porfimer (Photofrin) is the most used photosynthesizer. After an IV injection, it selectively concentrates in tumor cells in the esophagus and outer layers of the airways. After a set time (usually 48 hours), the tumor is exposed to laser light via bronchoscopy, activating the drug and causing cell death. Necrotic tissue is removed with bronchoscopy a few days later. This process can be repeated as needed. PDT can affect nutrient delivery to cancer cells and stimulate the immune system to attack the cancer cells.

Airway stenting. Stents are used alone or in combination with other techniques for relief of dyspnea, cough, or respiratory insufficiency. The stent is inserted during a bronchoscopy. The advantage of a stent is that it supports the airway wall against collapse or external compression and can delay extension of tumor into the airway lumen. At this time, we do not know which patients will benefit most from airway stents.

Radiofrequency ablation. Radiofrequency ablation therapy is used to treat small NSCLC lung tumors that are near the outer edge of the lungs. This therapy is an alternative to surgery in patients who cannot or choose not to have surgery. A thin, needle-like probe is inserted through the skin into the tumor. CT scans are used to guide placement. An electric current is then passed through the probe, which heats and destroys cancer cells. Local anesthesia is used for this outpatient procedure.

❖ NURSING MANAGEMENT: LUNG CANCER

◆ Assessment

It is important to determine the patient and caregiver's understanding of the condition, diagnostic tests (those completed as well as those planned), treatment options, and prognosis. Assess the patient's anxiety level and support available from family and significant others. Subjective and objective data that you should obtain are described in Table 30.27.

◆ Clinical Problems

Clinical problems for the patient with lung cancer may include:

- Impaired respiratory function
- Difficulty coping
- Pain
- Deficient knowledge

TABLE 30.27 NURSING ASSESSMENT

Lung Cancer

Subjective Data

Important Health Information

Health history: Exposure to secondhand smoke, airborne carcinogens (e.g., asbestos, radon, hydrocarbons), other pollutants. Urban living environment. Chronic lung disease (e.g., TB, COPD, bronchiectasis). History of cancer.

Medications: Cough medicines, bronchodilators, expectorants, other respiratory medications

Functional Health Patterns

Health perception–health management: Smoking history, including what was smoked, amount per day, and number of years. Family history of lung cancer. Frequent respiratory tract infections

Activity-exercise: Fatigue. Persistent cough (productive or nonproductive). Dyspnea at rest or with exertion, hemoptysis (late symptom)

Cognitive-perceptual: Chest pain or tightness, shoulder and arm pain, headache, bone pain (late symptom)

Objective Data

Cardiovascular

- Pericardial effusion, cardiac tamponade, dysrhythmias (late signs)

General

Fever, nose and/or throat infection, neck and axillary lymphadenopathy, paraneoplastic syndrome (e.g., syndrome of inappropriate ADH secretion)

GI

- Anorexia, nausea, vomiting, weight loss, dysphagia (late)

Musculoskeletal

- Pathologic fractures, muscle wasting (late)

Neurologic

- Confusion, disorientation, unsteady gait (brain metastasis)

Respiratory

- Wheezing, hoarseness, stridor, dyspnea on exertion (unilateral diaphragm paralysis), pleural effusions (late signs)

Skin

- Edema of neck and face (superior vena cava syndrome), digital clubbing. Jaundice (liver metastasis)

Other Possible Diagnostic Findings

- Lesions and any metastases found on chest x-ray, CT scan, MRI, PET scan
- Positive sputum or bronchial washings for cytologic studies.
- Positive fiberoptic bronchoscopy and biopsy findings

Planning

The overall goals are that the patient with lung cancer will have a (1) patent airway, (2) adequate tissue oxygenation, (3) minimal discomfort, and (4) understanding about the type of lung cancer, and (5) a realistic outlook about treatment and prognosis.

Implementation

Health Promotion

The best way to halt the epidemic of lung cancer is to prevent people from smoking, help smokers stop smoking, and decrease exposure to environmental pollutants. Because most smokers start in the teenage years, prevention of teen smoking has the most significant role in reducing the incidence of lung cancer. A wealth of material is available to the smoker who is interested in smoking cessation.

Modeling healthy behavior by not smoking, promoting smoking cessation programs, and actively supporting education and policy changes related to smoking are important nursing activities. Many changes have occurred because we know that secondhand smoke is a health hazard. Laws prohibit smoking in most public places and limit public smoking to designated areas.

Acute Care

Care of the patient with lung cancer initially involves support and reassurance during diagnostic evaluation. It is important to recognize the multiple stressors that occur when someone receives a lung cancer diagnosis. The stress response is a normal and adaptive response but can become detrimental when stress is overwhelming and intense. Patients have the stress of their symptoms, including dyspnea and cough. Diagnostic and therapeutic interventions provide more stress by placing patients in unfamiliar environments with unusual and perhaps painful procedures. Emotional stressors include waiting for test results and awareness of the high mortality rate from lung cancer. Worries about role performance and ability to care for their family while undergoing cancer treatment provide further stress. Assess every patient since each will have unique stressors. The insight gained will help the patient and caregiver cope with the stress of both illness and treatment.

Patient-centered care depends on the diagnosis and plan for treatment. Teach signs and symptoms to report (e.g., hemoptysis, dysphagia, chest pain, hoarseness). Provide comfort, teach ways to reduce pain, and monitor for drug side effects. Teach the patient to recognize signs and symptoms that may indicate progression or recurrence of disease. Be available to listen to the patient and their families. Encourage them to share their thoughts, fears, and concerns. Foster appropriate coping strategies for both the patient and caregiver and help them access resources to deal with the illness.

Care of the patient undergoing radiation therapy and chemotherapy is discussed in Chapter 16.

CHECK YOUR PRACTICE

You are completing discharge teaching with E.S., a 72- year-old patient who had a lobectomy for NSCLC. She tells you, "I'm not going to give up smoking my cigarettes because I am just going to die anyhow. I might as well enjoy smoking while I can."

- How would you respond?

Ambulatory Care

Counseling patients on smoking cessation and prevention is essential in decreasing mortality from lung cancer. Assess smoking cessation readiness. Some patients may not perceive value in quitting smoking once they have a diagnosis of lung cancer. As

nurses, however, we can encourage the patient to perhaps quit or decrease the number of cigarettes smoked per day. We might be able to gain support from family members who may wish to quit smoking with the patient. Explain the importance of maintaining a smoke-free environment in the home, particularly if O_2 will be in use. If the treatment plan includes home O_2, the teaching plan must include the safe use of O_2.

For many patients with lung cancer, little can be done to significantly prolong their lives. Radiation therapy and chemotherapy can provide palliative relief from distressing symptoms. Constant pain may become a major problem. Measures used to relieve pain are discussed in Chapter 9. Care of the patient with cancer is discussed in Chapter 16. The palliative care team should be involved as the patient and family move toward the end of life (see Chapter 10). Social workers and spiritual care advisors are invaluable in end-of-life situations. The team can provide information about disability, financial planning, and community resources for end-of-life care, such as hospice and home care.

Evaluation

The expected outcomes are that the patient with lung cancer will:

- Have adequate breathing patterns
- Maintain adequate oxygenation
- Have minimal to no pain
- Convey feelings openly and honestly, with a realistic attitude about prognosis

Case Study

Pneumonia and Lung Cancer

(©iStockphoto/Thinkstock.)

Patient Profile

J.H. is a 52-year-old male who comes to the ED with shortness of breath. He says it has really increased over the past several months. J.H. has not been to a doctor for many years, as he is often "too busy with work." His wife told him to get his "cough checked out."

Subjective Data

- 38 pack-year history of cigarette smoking
- Has had 25-lb weight loss despite a normal appetite in the past few months
- Admits to a "smoker's cough" for the past 2 to 3 years
- Recently started coughing up a small amount of blood-tinged sputum
- Married and the father of 3 adult children

Objective Data

Physical Assessment

- Thin, pale man who looks older than stated age
- Height 6 ft (182.9 cm); weight 135 lb (61.2 kg)
- Intermittently confused and anxious
- Vital signs: temperature 102.6°F (39.2°C), heart rate 120, respiratory rate 36 (shallow, slightly labored), BP 98/54
- Lung auscultation: Coarse crackles (left upper and left lower lobes) that clear with cough; decreased breath sounds (right middle lobe and right lower lobe)
- Chest wall has limited excursion on right side

Diagnostic Studies

- ABGs: pH 7.51, PaO_2 62 mm Hg, $PaCO_2$ 30 mm Hg, HCO_3^- 22 mEq/L
- SpO_2 saturation 88% (room air)
- Chest x-ray: Right lung (RML, RLL) consolidation, with visible mass around right bronchus; small pleural effusion (<150mL) on the right side
- Bronchoscopy: Biopsy of mass reveals small cell lung cancer (SCLC)

Interprofessional Care

- Diagnosis: Pneumonia with SCLC
- Follow-up and discuss with patient and family appropriate treatment options

Discussion Questions

1. ***Recognize:*** How would you classify J.H.'s pneumonia? Why is this important?
2. ***Analyze:*** Which findings concern you?
3. ***Analyze:*** What is your analysis of J.H.'s ABG results?
4. ***Plan***: How would you expect other health care team members to be involved in J.H.'s care?
5. ***Prioritize:*** Based on the assessment data presented, what are the priority clinical problems?
6. ***Prioritize:*** What are the priority nursing interventions for J.H.?
7. ***Act:*** Identify activities that you can delegate to assistive personnel (AP).
8. ***Act:*** You are planning a meeting with J.H. and his family at 1400 hours to discuss their needs. The morning of the meeting, the HCP informs you that J.H. is terminally ill. Who will you include in this meeting?
9. ***Act:*** J.H.'s children tell you that they are worried they will get lung cancer, since their father has it and they grew up around his secondhand smoke. They want to know what kind of screening is available for them. How will you respond?
10. ***Evaluate:*** How would radiation therapy help J.H.?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. When caring for a patient with acute bronchitis, the nurse will *prioritize* interventions by
   a. auscultating lung sounds.
   b. encouraging fluid restriction.
   c. administering antibiotic therapy.
   d. teaching the patient to avoid cough suppressants.

2. Which patient(s) have the greatest risk for aspiration pneumonia? *(select all that apply)*
   a. Patient who had thoracic surgery
   b. Patient with acute opioid overdose
   c. Patient who had a myocardial infarction
   d. Patient who is receiving nasogastric enteral feeding
   e. Patient who has a traumatic brain injury from blunt trauma

3. An appropriate nursing intervention to help a patient with pneumonia manage thick, purulent secretions would be to
   a. perform postural drainage every hour.
   b. provide analgesics every 3 hours to promote comfort.
   c. administer O_2 as prescribed to maintain optimal O_2 levels.
   d. teach them how to cough effectively and expectorate secretions.
4. A patient with TB is admitted to the hospital and placed in a single patient room on airborne precautions. What should the nurse teach the patient? *(select all that apply)*
   a. No visitors will be allowed while in airborne isolation.
   b. Expect regular TB skin testing to evaluate for infection.
   c. Adherence to precautions includes coughing into a paper tissue.
   d. Take all medications for full length of time to prevent multidrug-resistant TB.
   e. Wear a standard isolation mask if leaving the airborne infection isolation room.
5. When caring for a patient with a lung abscess, what is the nurse's *priority* intervention?
   a. Postural drainage
   b. Antibiotic administration
   c. Obtaining a sputum specimen
   d. Asking the patient about a family history of lung cancer
6. The patient with a right-side pleural effusion has stable vital signs and O_2 at 6 L/min via nasal cannula. A right-side chest tube is attached to straight drainage. Which actions would the nurse include in the plan of care? *(select all that apply)*
   a. Placing the patient on NPO status
   b. Administering analgesia as ordered
   c. Maintaining high-Fowler's position
   d. Encouraging deep breathing and coughing
   e. Monitoring color and amount of chest tube drainage
7. You are caring for a patient with several traumatic injuries after a multiple-vehicle accident. Which assessment finding would lead you to suspect a flail chest?
   a. Chest-tube is draining bright red blood
   b. Tracheal deviation to the unaffected side
   c. Paradoxical chest movement during respiration
   d. Little to no movement of the involved chest wall
8. When planning care for a patient at high risk for pulmonary embolism, the nurse prioritizes
   a. maintaining the patient on strict bed rest.
   b. using intermittent pneumatic compression devices.
   c. encouraging the patient to cough and deep breathe.
   d. encouraging a fluid intake of 2000 mL per 8-hour shift.
9. The nurse would closely monitor patients exposed to a chlorine leak from a local factory for
   a. pulmonary edema.
   b. anaphylactic shock.
   c. respiratory acidosis.
   d. acute tubular necrosis.
10. Management of a patient after a lung transplant includes which measures? *(select all that apply)*
    a. Mechanical ventilation in the early postoperative period
    b. Assisting with a lung biopsy if acute rejection is suspected
    c. IV fluid therapy accompanied by accurate intake and output
    d. Immunosuppressant therapy, which usually involves a 3 drug regimen
    e. Pulmonary clearance measures, including deep-breathing and coughing
11. Nursing care of a patient with Stage 4 lung cancer would include
    a. Coordinating a referral to palliative care
    b. Limiting visitors to decrease infection risk
    c. NPO status and starting parenteral nutrition
    d. Avoiding talking about the cancer diagnosis

1. a; 2. b, d, e; 3. d; 4. c, d, e; 5. b; 6. b, c, d, e; 7. c; 8. b; 9. a; 10. a, b, c, d, e; 11. a.

Obstructive Pulmonary Diseases

Eugene E. Mondor

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Fatigue
Functional Ability
Gas Exchange
Infection
Self-Management

LEARNING OUTCOMES

1. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with bronchiectasis.
2. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of the patient with cystic fibrosis.
3. Describe the etiology, pathophysiology, and clinical manifestations of asthma.
4. Explain the difference between an acute asthma exacerbation and status asthmaticus.
5. Describe the interprofessional care and nursing management of the patient with asthma.
6. Identify the classes of drugs used in the treatment of asthma and chronic obstructive pulmonary disease (COPD).
7. Describe the etiology, pathophysiology, clinical manifestations, and interprofessional care of the patient with COPD.
8. Explain the nursing management of the patient with COPD.

KEY TERMS

α_1-antitrypsin deficiency (AATD)
asthma
bronchiectasis
chronic bronchitis
chronic obstructive pulmonary disease (COPD)
cor pulmonale
cystic fibrosis (CF)
emphysema
peak expiratory flow rate
status asthmaticus

Imagine needing to consciously think about every breath that you take each minute, each hour, and every day of your life. Many people with obstructive lung disease have this experience. Obstructive pulmonary diseases are the most common chronic lung diseases. They have in common increased resistance to airflow because of airway obstruction or airway narrowing.

The 4 obstructive lung diseases discussed in this chapter are bronchiectasis, cystic fibrosis (CF), asthma, and chronic obstructive pulmonary disease (COPD). Drug therapy plays a key role in managing these conditions. Knowing common terms used in discussing respiratory care will help you better understand this content (Table 31.1).

BRONCHIECTASIS

In **bronchiectasis,** the bronchioles are dilated, making it hard to clear secretions. It most often results from poorly treated or untreated lung infections, immune system problems, or genetic factors. Bronchiectasis affects more than 500,000 people in the US.[1] It is more common in women. It affects 1 in every 150 people over age 75.[2]

Etiology and Pathophysiology

The hallmark characteristic of bronchiectasis is permanent, abnormal dilation of medium-sized bronchi. It results from inflammatory changes that destroy elastic and muscular structures supporting the bronchial wall. There is a continuing cycle of inflammation, airway damage, and remodeling, enhanced by the accumulation of neutrophils in the airways. Airways can become colonized with microorganisms (e.g., *Pseudomonas*), causing the bronchial walls to weaken and pockets of infection to form (Fig. 31.1).

When the walls of the bronchial system are injured, the mucociliary mechanism is damaged. This allows bacteria and mucus to accumulate within the pockets. Bacteria attract neutrophils, which enhances inflammation and causes edema.

TABLE 31.1 Common Terms Used in Respiratory Care

Respiratory Terms	
FeNO	Fractional concentration of exhaled nitric oxide (NO)
FEV1	Forced expired volume in 1 second
FEV1/FVC	Volume of air exhaled during the 1st second of a forced exhalation, expressed as a percentage (%) of FVC
FVC	Forced vital capacity
Pharmacologic Terms	
ICS	Inhaled corticosteroid
LABA	Long-acting B2 agonist
LAMA	Long-acting muscarinic antagonist
SABA	Short-acting B2 agonist
SAMA	Short-acting muscarinic antagonist

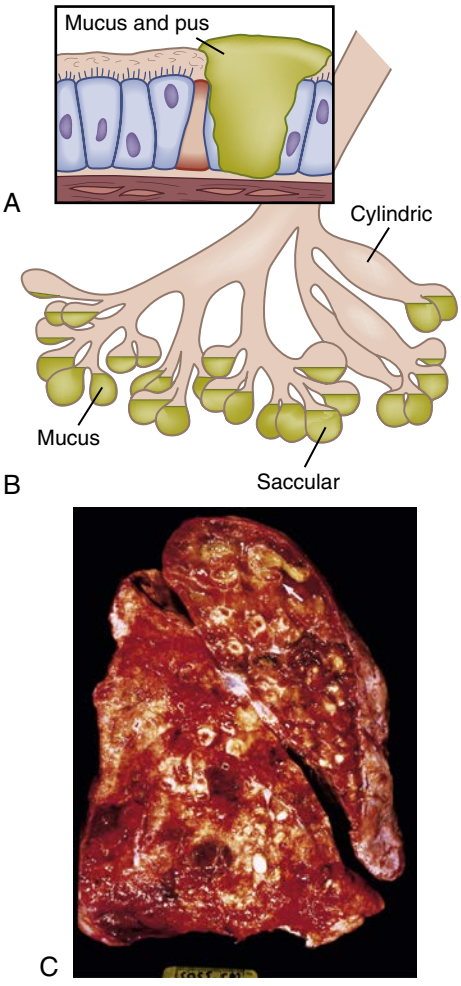

Fig. 31.1 Pathologic changes in bronchiectasis. (A) Longitudinal section of bronchial wall where chronic infection has caused damage. (B) Collection of purulent material in dilated bronchioles, leading to persistent infection. (C) Bronchiectasis in a patient with CF who underwent lung transplantation. Cut surfaces of the lung show markedly distended peripheral bronchi filled with mucopurulent secretions. (*C,* From Kumar V, Abbas AK, Aster JC: *Robbins and Cotran pathologic basis of disease,* ed 10, Philadelphia, 2021, Saunders.)

Impaired clearance of mucus by the cilia leads to stasis of thick mucus. This results in a reduced ability to clear mucus from the lungs and decreased expiratory airflow.

Around 40% of cases have no known cause.[1] CF is the main cause of bronchiectasis in children. Bacterial infection of the lungs is the main cause in adults. It can follow a single episode of severe pneumonia or infection that was either not treated or received inadequate or delayed treatment. Other risk factors include airway obstruction with mucus plugs, impaired pulmonary defenses, and repeated aspiration. Several systemic problems, such as diabetes, inflammatory bowel disease, rheumatoid arthritis, immune disorders (e.g., acquired immunodeficiency syndrome [AIDS]), and α-1 antitrypsin deficiency (AATD), are risk factors.[3]

Clinical Manifestations

The key sign is a persistent cough with consistent production of thick, tenacious, purulent sputum. In rare situations, some patients with severe disease and upper lobe involvement may have no sputum production and little cough. Recurrent infections injure blood vessels. Large connections (anastomoses) may develop between blood vessels in the lungs, and hemoptysis may occur. In severe cases, bleeding can be life-threatening. Other manifestations include pleuritic chest pain, dyspnea, wheezing, clubbing, weight loss, and anemia. Adventitious sounds are heard (e.g., crackles, wheezes) over the lung fields.

Complications

Complications include pulmonary hypertension and repeated exacerbations of the condition, often accompanied by chronic inflammation and hypoxemia. Colonization with multi-drug resistant organisms can occur, especially if the patient has received antibiotic therapy over long periods of time.

Neovascularization (development of new blood vessels after injury) of the bronchial arteries is a significant complication.[4] This can lead to hemoptysis and in some situations hemorrhage. Massive hemoptysis is a life-threatening emergency.

Diagnostic Studies

A person who presents with a chronic productive cough with copious purulent sputum (which may be blood streaked) should be suspected of having bronchiectasis. A CT scan is the gold standard for diagnosing bronchiectasis.

Chest x-rays may show nonspecific abnormalities. Spirometry usually shows an obstructive pattern, including decreases in FEV_1 and FEV_1/FVC (see Table 27.18). Sputum cultures may confirm the presence of infection. Patients often have *Hemophilus influenzae, Staphylococcus aureus,* or *Pseudomonas aeruginosa.*[4] *P. aeruginosa* leads to frequent exacerbations and rapid decline in lung function. A complete blood cell count and AAT level may be done.

INTERPROFESSIONAL CARE

There is no cure for bronchiectasis. Most patients are safely managed on an outpatient basis. Contact with the health care system is often related to an exacerbation. When the patient is

not responding to care, hospitalization may be needed for monitoring and further treatment.

Therapy is aimed at treating acute flare-ups and preventing a decline in lung function. Antibiotics are the mainstay of treatment. They are often given for a minimum of 14 days. Antibiotics may be given orally, IV, or inhaled (nebulizer). Choice of antibiotic mainly depends on culture results or the most likely organism. Long-term antibiotic therapy is given to patients who have symptoms that recur a few days after stopping antibiotics.

Bronchodilator therapy with short-acting β-2 agonists (SABAs), long-acting β-2 agonists (LABAs), or anticholinergics can prevent bronchospasm and stimulate mucus clearance. Patients may receive oral or inhaled corticosteroids (ICS) depending on the severity of the condition.

Surgical resection of parts of the lungs was common in the past. It has largely been replaced by more effective supportive therapy and antibiotic treatment. For select patients who are disabled despite maximal therapy, a lung transplant may be an option.

❖ NURSING MANAGEMENT: BRONCHIECTASIS

◆ Assessment

When the patient in immediate distress, priorities include maintaining a patent airway, ensuring an adequate route for ventilation, and stable vital signs. Notify the HCP, especially if the patient is expectorating large amounts of blood.

For the patient not in immediate distress, obtain a patient and family history. If possible, identify onset, risk factors, and any past complications. Review the current drug therapy and treatments the patient is receiving.

◆ Clinical Problems

Clinical problems for the patient with bronchiectasis may include:

- Impaired respiratory function
- Activity intolerance
- Deficient knowledge

◆ Planning

The overall goals for the patient with bronchiectasis include (1) maintain a patent airway; (2) have slow, steady, and unlabored breathing; and (3) develop a routine that permits as much functional independence as possible with activities of daily living (ADLs).

◆ Implementation

◆ Health Promotion

Patient teaching is important. Encourage them to follow as healthy a lifestyle as possible. Stress the need to quit smoking or, at minimum, reduce the amount smoked. Stress the need to follow a healthy diet. Encourage the patient to engage in some type of regular exercise (within the comfort and safety of their condition). Discuss how to prevent exacerbations and review airway clearance techniques (ACTs).

Maintaining hydration is important to liquefy secretions. Unless contraindicated, the patient should drink at least 2 to 3 L of fluid daily. To achieve this, tell the patient to increase intake by 1 glass per day until they reach that goal. Have the patient use low-sodium fluids to avoid fluid retention. Rest is important to prevent overexertion.

Teach the patient and caregiver signs and symptoms to report to the HCP. These include increased work of breathing (WOB), sputum production, or dyspnea. Fever, chills, and chest pain may or may not occur with an exacerbation. Teach patients when to contact the HCP if hemoptysis occurs. Some patients expectorate a "spot" of blood at times. This is usual for them and does not require urgent attention. However, if the patient expectorates a moderate to large amount of blood, they should contact the HCP at once.

◆ Acute Care

In the acute care setting, elevate the head of the bed to at least 30 degrees. Monitor vital signs and respiratory status, including rate, rhythm, and SpO_2. Apply O_2 therapy via a low-flow delivery device (e.g., nasal cannula) if O_2 saturation is less than 90% on room air. If you suspect that the patient may be bleeding from the airways, place the patient in a side-lying position with the suspected bleeding side down. Have oral suction available. Ensure there is a valid type and crossmatch.

One important goal is to promote drainage and removal of mucus. Various ACTs can help with secretion removal. Chest physiotherapy (CPT) with postural drainage is widely used. Direct hydration of the respiratory system may help with the expectoration of secretions. Hyperosmolar agents (e.g., hypertonic saline) given by nebulizer can liquefy secretions. At home, a steamy shower can be effective. Active bleeding is a contraindication to CPT.

Good nutrition is important. It may be hard to maintain because the patient is often anorexic. Oral hygiene to cleanse the mouth and remove dried sputum crusts may improve the patient's appetite. Foods that are appealing, provided in smaller quantities, and offered more often may increase the desire to eat.

◆ Evaluation

The expected outcomes of a patient with bronchiectasis include:

- Maintain a patent airway
- Have a normal respiratory rate and rhythm
- Demonstrate a health balance between activity and rest with ADLs
- Perform optimal self-management

CYSTIC FIBROSIS

Cystic fibrosis (CF) is an inherited, autosomal recessive genetic disorder, characterized by altered transport of sodium and chloride ions in and out of epithelial cells. Airway obstruction occurs because of changes in exocrine glandular secretions, resulting in increased mucus production. This defect also affects the gastrointestinal (GI) system (pancreas and biliary tract) and reproductive organs. There are about 30,000 people in the US living with CF. More than 50% of the CF population are adults.[5]

BOX 31.1 GENETICS IN CLINICAL PRACTICE

Cystic Fibrosis

Genetic Basis

- Autosomal recessive disorder
- Caused by mutations in CF transmembrane regulator *(CFTR)* gene
- *CFTR* gene provides the instructions for making the protein that controls the channel that transports sodium and chloride
- There are more than 1,700 different mutations of the *CFTR* gene
- Mutations in the *CFTR* gene disrupt the function of the channels, preventing them from regulating the flow of sodium, chloride, and water across cell membranes
- The most common mutation is 2 copies (homozygous) of the *F508* mutation in the *CFTR* gene

Incidence

- In the US, 1 in 2500–3000 White births
- One in 25–30 Whites are carriers of the gene
- 10,000 new cases diagnosed each year, most before 1 year of age

Clinical Implications

- Most people who have a child with CF are not aware of a family history of CF.
- We should offer CF screening to all people of reproductive age regardless of family history.

Genetic Testing

- Can identify if a person is a carrier of the mutation for the *CFTR* gene
- Blood-based DNA testing is available for disease and carrier states
- All 50 states require newborn CF screening
- Testing is usually done in children if CF is suspected or if parents are possible carriers
- In parents who are known carriers, amniocentesis between 15 and 20 weeks or chorionic villus sampling between 10 and 13 weeks of pregnancy can be done (although testing can also occur in pregnant women beyond these dates)

The median age at diagnosis is 6 to 8 months of age. Two-thirds of patients are diagnosed in the first year of life.[5] Some are not diagnosed until they are adults. The severity and progression of CF vary. With early diagnosis and improvements in therapy, the prognosis of patients with CF has significantly improved. The median predicted survival in 1970 was 16 years of age. Today it has increased to more than 46 years.[6] There are many persons with CF who have lived beyond this age.

Genetic Link

CF is an autosomal recessive disorder (Box 31.1). The CF gene is found on chromosome 7, which makes a protein called *CF transmembrane conductance regulator (CFTR)*.[7] The CFTR protein localizes to the epithelial surface of the airways, GI tract, and ducts of the liver, pancreas, and sweat glands. Under normal conditions, CFTR regulates sodium and chloride movement in and out of epithelial cells.

Mutations in the *CFTR* gene change this protein so that the channels are blocked. As a result, cells that line the passageways of the lungs, pancreas, intestines, and other organs make secretions that are low in sodium chloride content (thus low in water content), making them abnormally thick and sticky

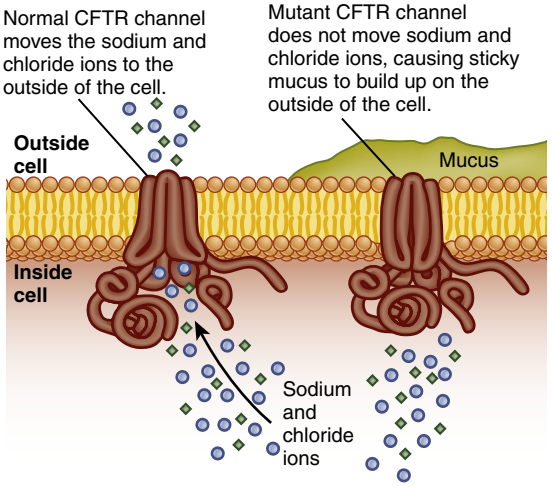

Fig. 31.2 Cystic fibrosis transmembrane conductance regulator *(CFTR)* is a protein of the cell membrane that normally helps sodium and chloride move in and out of cells. People with CF inherit a defective gene. As a result, movement of sodium and chloride is blocked. Abnormally thick sticky mucus is produced on the outside of the cell.

(Fig. 31.2). The thick secretions plug up the ducts in these organs. This causes scarring in the organs and results in organ failure. The high concentrations of sodium and chloride in the sweat of the patient with CF result from decreased chloride reabsorption in the sweat duct.

Pathophysiology

CF has a significant effect on the airways. It can affect both the upper and lower respiratory tracts. CF progresses from being a disease of the small airways to involving the larger airways with destruction of lung tissue. The mucus lining the airways becomes dehydrated and tenacious due to defects in chloride secretion and sodium absorption. Cilia become overwhelmed with thick secretions. As a result, cilia motility is decreased, allowing mucus to adhere to the airways. At the same time, the bronchioles become obstructed with the thick mucus, leading to scarring of the airways, air trapping, and hyperinflation of the lungs.

With CF, there is a persistent, chronic airway infection that cannot be cured. *Pseudomonas* is the most common organism in adults.[7] Antibiotic resistance can develop after multiple exposures to antibiotics. Lung inflammation is associated with chronic infection. It can narrow airways and cause a decrease in lung function. An increase in inflammatory mediators (e.g., interleukins, oxidants, proteases released by neutrophils) contributes to disease progression.

Lung disorders that initially occur are chronic bronchiolitis and bronchiectasis. Over a long period, pulmonary vascular remodeling occurs because of local hypoxia and arteriolar vasoconstriction. Enlarged pulmonary arteries, pulmonary hypertension, and cor pulmonale occur in the later phases of the disease. Blebs and large cysts are severe manifestations of lung destruction. Pneumothorax may occur. There is a proliferation of capillaries in response to chronic infection. During exacerbations, there may be erosion of these capillaries and hemoptysis can occur. Hemoptysis may range from scant streaking to major bleeding, which can be fatal.

Mucous plugging of the pancreatic exocrine ducts causes pancreatic insufficiency. This results in atrophy and progressive fibrotic cyst formation. The pancreas's exocrine function may be completely lost. Because of this, the pancreas does not make enough pancreatic enzymes, such as lipase, amylase, and proteases (trypsin, chymotrypsin), to allow for the absorption of nutrients. Malabsorption of fat, protein, and fat-soluble vitamins (A, D, E, and K) occurs. Fat malabsorption results in steatorrhea (large, oily, frequent bowel movements). Protein malabsorption results in the failure to grow and gain weight. Osteopenia and osteoporosis are common. They are related to malnutrition, malabsorption of vitamin D, low testosterone levels, and chronic infections. Pancreatitis may occur.

CF-related diabetes (CFRD) is caused by the underdevelopment of pancreatic islet cells (in utero) and destruction of islet cells over the person's lifetime. CFRD is unique because it has characteristics of both type 1 and type 2 diabetes. The pancreas in people with CF makes insulin, but they make it too late to fully respond to carbohydrate intake.

Persons with CF often have other GI problems, including gastroesophageal reflux disease GERD, gallstones, and cirrhosis. Mucus deposits in the ducts can damage the liver and gall bladder. Liver enzymes may become chronically increased. Cirrhosis develops over time. Portal hypertension can occur. *Distal intestinal obstruction syndrome (DIOS)* results from an intermittent obstruction, often in the terminal ileum at the point of the ileocecal junction. It is caused by thickened, dehydrated stool and mucus. DIOS develops because of chronic malabsorption related to exocrine dysfunction, under- or over-dosing of pancreatic replacement enzyme supplements, dehydration, and swallowing of mucus. The patient may appear to have a small bowel obstruction.

Clinical Manifestations

The manifestations vary depending on the severity of the disease. Severity may vary greatly, both within families and among different families. Carriers do not have symptoms.

Meconium ileus in a newborn prompts the diagnosis in 20% of people. Other signs that suggest a CF diagnosis in childhood are acute or persistent respiratory symptoms (wheezing, coughing, frequent pneumonia), failure to thrive, malnutrition, steatorrhea, bronchiectasis, and family history. Without treatment, a large, protuberant abdomen may develop with an emaciated appearance of the extremities.

In adults, patients often present with atypical symptoms, such as new-onset diabetes or infertility problems. A common symptom of CF in the adult is a frequent cough. With time, the cough becomes persistent and produces thick, purulent sputum. URI manifestations may include chronic sinusitis and nasal polyposis. Other lung problems include recurring lung infections, such as bronchiolitis, bronchitis, and pneumonia. With advanced lung disease, clubbing occurs. As the disease progresses, periods of clinical stability are interspersed by exacerbations characterized by increased cough, weight loss, increased sputum production, and decreased lung function. Over time, exacerbations become more frequent, bronchiectasis worsens, and the recovery of lost lung function is less complete. These changes may lead to respiratory failure.

Patients with DIOS may have right lower quadrant pain (the area of the ileocecal valve), nausea, vomiting, and a palpable mass. Insufficient pancreatic enzyme release causes the typical pattern of protein and fat malabsorption. Many persons are thin with a low body mass index (BMI). They may have frequent bulky, foul-smelling stools.

Both males and females have delayed puberty. Some women have difficulty conceiving. The cervical mucus may be thick. During exacerbations, menstrual irregularities and secondary amenorrhea are common. Most women with CF can become pregnant. Most pregnancies result in viable infants.

Nearly all men with CF have reproductive issues. Because the vas deferens fails to develop in utero, there is no transport of sperm from storage in the testes to the penile urethra. However, they make sperm normally and can father a child with assisted reproductive technology.

Complications

Complications include CFRD and bone, sinus, and liver disease. Respiratory failure and cor pulmonale caused by pulmonary hypertension are late complications of CF. Pneumothorax, a rare but serious complication, is caused by the formation of bullae and blebs on the surface of the lung. A small amount of blood in sputum is common because of chronic lung infection. Massive hemoptysis, though rare, can be life-threatening. Liver failure and bowel obstruction may occur in severe CF.

Diagnostic Studies

The diagnostic criteria for CF include a combination of clinical presentation, family history, and laboratory and genetic testing. The sweat glands of patients with CF secrete normal volumes of sweat. They do not absorb sodium chloride from their sweat as it moves through the sweat duct. As a result, they excrete 4 times the normal amount of sodium and chloride in sweat. This problem usually does not directly affect the person's health but helps confirm a diagnosis of CF.

The sweat chloride test is the gold standard for diagnosing CF. It is done with the pilocarpine iontophoresis method.[8] Pilocarpine is placed on the skin and carried by a small electric current to stimulate sweat production. This part of the process takes about 5 minutes. Explain to the patient they may feel a slight tingling or warmth. Next, the area (usually an arm) is wrapped in plastic to promote sweating. The sweat is collected on filter paper or gauze and then analyzed for sweat chloride concentrations. The test takes about 1 hour. Sweat chloride values above 60 mmol/L are considered positive for the diagnosis of CF.[8] A second sweat chloride test is done at the same time (1 test in each arm) to confirm the diagnosis.

Genetic testing is often done if the results from a sweat chloride test are uncertain. We can send a blood or cell sample to a laboratory that specializes in genetic testing. Most laboratories test for only the most common mutations of the CF gene. Because more than 1700 mutations cause CF, screening for all mutations is difficult and done only at specialized laboratories.

Interprofessional Care

An interprofessional team should be involved in the care of a patient with CF. The Cystic Fibrosis Foundation funds more

than 120 CF care centers nationwide. The high quality of specialized care from the care center network has led to the improved length and quality of life for people with CF. These care centers offer the best care, treatments, and support for those with CF. The teams at these care centers include a nurse, physician, respiratory therapist, physical therapist, dietitian, social worker, and often a nurse practitioner.

Management of lung problems aims at relieving airway obstruction and controlling infection. Aerosol and nebulizer treatments promote drainage of thick bronchial mucus. The drugs we use dilate the airways, liquefy mucus, and promote clearance.

The abnormal viscosity of secretions is increased by concentrated DNA from neutrophils involved in chronic infection. Drugs that degrade the DNA in CF sputum (e.g., inhaled dornase alfa [Pulmozyme]) increase airflow and reduce the number of acute exacerbations. Inhaled hypertonic saline (7%) increases osmolality, allowing water to collect on airway surfaces. It is effective in clearing mucus and decreases the frequency of exacerbations. Some patients need bronchodilators (e.g., β_2-adrenergic agonists) to control bronchospasm, but the long-term benefit is not known.

ACTs are critical since the normal ciliary motion in CF airways is impaired. CPT (including postural drainage with percussion and vibration) and high-frequency chest wall oscillation loosen mucus. Specialized expiratory techniques that use airflow to remove the loosened secretions help clear secretions. Examples include breathing exercises, pursed-lip breathing, and huff coughing (see Chapter 28). Patients may prefer a certain technique or device that works well for them in their daily routine. No ACT is better than the others.

Most patients with CF die of complications from lung infection. Thus, early intervention with antibiotics is key when infection is present. Antibiotic choice should be based on sputum culture results. The usual treatment is 2 antibiotics with different mechanisms of action (e.g., cephalosporin and an aminoglycoside). They may be given for 10 days to 3 weeks or longer. Prolonged high-dose therapy (larger doses, more frequent dosing) may be needed because many drugs are abnormally metabolized and rapidly excreted in the patient with CF. Some need chronic suppressive therapy. If home support and resources are adequate, the patient and caregiver may be able to administer IV antibiotic therapy at home independently.

Oral agents used for mild exacerbations (e.g., increased cough and sputum) include a semisynthetic penicillin, trimethoprim/sulfamethoxazole (to treat *S. aureus*), or oral quinolones, especially ciprofloxacin (to treat *Pseudomonas*). Quinolones are used with caution because of the rapid development of resistant strains.

Most patients have *Pseudomonas* infection, which can be hard to treat over time because the organism develops resistance to antibiotics. *Pseudomonas* can form a biofilm that protects the organism from antibiotics. A common antibiotic used to treat patients with chronic *Pseudomonas* infection is aerosolized tobramycin. It is given twice a day, every day, every other month. Azithromycin used longer than 6 months decreases the frequency of exacerbations, especially in those infected with *Pseudomonas*. We also think it acts as an antiinflammatory.

The patient with cor pulmonale or hypoxemia may need home O_2 therapy. Those with a large pneumothorax need chest tube drainage, sometimes repeatedly. Sclerosing of the pleural space or partial pleural stripping and pleural abrasion may be done for recurrent episodes of pneumothorax. With massive hemoptysis, bronchial artery embolization is done. CF has become a leading reason for lung transplantation.

The management of pancreatic insufficiency includes pancreatic enzyme replacement of lipase, protease, and amylase (e.g., pancrelipase [Pancreaze, Creon, Zenpep]) taken before each meal and snack. Adequate intake of fat, calories, protein, and vitamins is important. Fat-soluble vitamins (A, D, E, and K) must be supplemented since they are malabsorbed. Caloric supplements improve nutrition status. Extra salt is needed when sweating is increased, such as during hot weather, with a fever, or from intense physical activity. Hyperglycemia may need insulin treatment.

If the patient develops DIOS with partial or complete bowel obstruction, we make every attempt to manage the condition medically. Options include prokinetic agents (e.g., macrolide antibiotics, metoclopramide), mucolytics (oral N-acetylcysteine [NAC]), stimulant laxatives, lactulose, and polyethylene glycol (PEG) electrolyte solution.[9] Careful monitoring of bowel habits and patterns is essential for CF patients. If DIOS does not resolve with medical treatment, surgery may be done to prevent ischemic bowel.

All patients with CF should have CFTR genotyping. This will help see if they carry a mutation that is a target of CFTR modulator therapy. Drugs, such as ivacaftor/lumacaftor (Orkambi) and Ivacaftor (Kalydeco), are used to treat patients with specific *CFTR* gene mutations.[10]

NURSING MANAGEMENT: CYSTIC FIBROSIS

Assessment

Subjective and objective data you should obtain from the patient with CF are shown in Table 31.2.

Clinical Problems

Clinical problems for the patient with CF may include:

- Impaired respiratory function
- Nutritionally compromised
- Deficient knowledge

Planning

The overall goals are that the patient with CF will have (1) adequate airway clearance, (2) absence of respiratory infection, (3) adequate nutrition to maintain appropriate weight, (4) ability to independently (or with assist) perform ADLs, (5) recognize and treat complications related to CF, and (6) actively take part in planning and implementing the treatment plan.

Implementation

Acute Care

Acute care for the patient with CF includes relief of bronchoconstriction, airway obstruction, and airflow limitation. Interventions include aggressive CPT, antibiotics, and O_2

TABLE 31.2 NURSING ASSESSMENT

Cystic Fibrosis

Subjective Data	Objective Data
Important Health Information • *Health history:* Recurrent respiratory and sinus infections, persistent cough with excess sputum production • *Medications:* Use of and compliance with bronchodilators, antibiotics	**Cardiovascular** • ↑ Heart rate **Eyes** • Scleral icterus **General** • Restlessness, failure to thrive
Functional Health Patterns • *Health perception–health maintenance:* Family history of CF, when diagnosed, genetic testing • *Nutritional-metabolic:* Diet intolerances, voracious appetite, weight loss, heartburn • *Elimination:* Intestinal gas. Large, frequent bowel movements, constipation • *Activity-exercise:* Fatigue, ↓ exercise tolerance, amount and type of exercise. Dyspnea, cough, excess mucus or sputum production, coughing up blood, ACTs • *Cognitive-perceptual:* Abdominal pain • *Sexuality-reproductive:* Delayed menarche, menstrual problem, infertility • *Coping–stress tolerance:* Anxiety, depression, difficulty coping	**GI** • Protuberant abdomen; abdominal distention; foul, fatty stools **Respiratory** • Sinus congestion, postnasal drip, persistent runny nose • Decreased breath sounds, adventitious breath sounds (crackles, wheezes) • Sputum (thick, tenacious) • ↑ WOB, accessory muscle use, barrel chest **Skin** • Salty skin; clubbing; cyanosis (circumoral, nail bed) **Possible Diagnostic Findings** • Abnormal sweat chloride test, abnormal ABGs and pulmonary function tests • Abnormal chest x-ray, fecal fat analysis

therapy in severe disease. Measures to optimize nutrition are important.

In severe cases, patients may be cared for in the intensive care unit (ICU). Reasons for ICU admission include acute respiratory insufficiency or failure and hemoptysis. The patient may need mechanical ventilation and hemodynamic monitoring.

◆ Ambulatory Care

A focus on ACTs, treatment of infection with antibiotic therapy, nutrition support (including pancreatic enzymes), and psychosocial support are important components of care. This may involve many members of the health care team, including physician, nursing, dietary, pharmacy, physiotherapy, occupational therapy, and psychology.

We should encourage the patient to take part in aerobic exercise. It is effective in clearing the airways. Considerations when planning an exercise program include (1) meeting increased nutrition demands of exercise, (2) observing for dehydration, (3) drinking large amounts of fluid, and (4) replacing salt losses.

As these persons continue into adulthood, you can help them achieve greater independence by allowing them to assume more responsibility for their care and life goals. One issue to discuss with the patient is sexuality. Delayed development of secondary sex characteristics and irregular menses are common. The issue of marrying and having children is complicated. Genetic counseling is appropriate when the patient is considering having children. Another concern is uncertainty surrounding the shortened life span of the parent with CF.

Other crises and life transitions that must be dealt with in the young adult include identifying employment goals, developing motivation, learning to cope with the treatment, and adjusting to the need for dependence if health fails. Disclosing the CF diagnosis to friends, potential spouses, and/or employers may pose significant emotional, social, and financial challenges. Referral to counseling may help depending on the patient's ability to cope with the condition and availability of support networks.

CF imposes a significant emotional and financial burden on the patient and family. In many situations, the cost of drugs, special equipment, and health care poses financial hardship. The burden of living with a chronic disease at a young age can be emotionally overwhelming. There is a higher incidence of anxiety and depression among persons with CF than their unaffected peers.[11] Issues related to costs of health care, burden of self-care, career choices, fertility, and decreased life expectancy may lead to depression. Community resources are available to help patients and caregivers. The Cystic Fibrosis Foundation can be a source of information and support.

ASTHMA

Asthma is a diverse disease characterized by bronchial hyperreactivity with reversible expiratory airflow limitation, either spontaneously or with treatment. Signs and symptoms can be variable. For example, there may be mild shortness of breath and chest tightness with a minor asthma attack. A major asthma attack may include severe shortness of breath, accessory muscle use, stridor, and severe hypoxemia. If left untreated, respiratory and/or cardiac arrest can occur.

Asthma affects around 25 million adult Americans.[12] It is a major public health concern. There are more than 2 million emergency department (ED) visits, 10 million outpatient visits, and 500,000 hospitalizations each year.[13] The clinical course of asthma is unpredictable. It ranges from periods of adequate control to frequent attacks with poor control of symptoms. The mortality for asthma has decreased over the past 10 years. Unfortunately, more than 4000 people still die each year from asthma.[13]

Risk Factors and Triggers

Risk factors for asthma and triggers of asthma attacks are related to the patient (e.g., genetic factors) or the environment (e.g., pollen) (Table 31.3 and Box 31.2). We discuss the most important risk factors and triggers of asthma attacks here.

Nose and Sinus Problems

Most patients have a history of allergic rhinitis. Treatment of allergic rhinitis usually improves asthma symptoms. Acute and chronic sinusitis, especially bacterial rhinosinusitis, may worsen

TABLE 31.3 Triggers of Asthma Attacks

Air Pollutants	• Aerosol sprays • Cigarette smoke • Exhaust fumes • Oxidants • Perfumes • Sulfur dioxides
Allergen Inhalation	• Animal dander (e.g., dogs, cats, mice, guinea pigs) • Cockroaches • House dust mite • Molds • Pollens
Drugs	• Aspirin • β-Adrenergic blockers • NSAIDs
Food Additives	• Beer, wine, dried fruit, shrimp, processed potatoes • Monosodium glutamate • Sulfites (bisulfites and metabisulfites) • Tartrazine
Occupational Exposure	• Agriculture, farming • Industrial chemicals and plastics • Laundry detergents • Metal salts • Paints, solvents • Wood and vegetable dusts
Pulmonary	• Sinusitis, allergic rhinitis • Viral URI
Other Factors	• Exercise and cold, dry air • GERD • Hormones, menses • Stress

BOX 31.2 BIOLOGIC SEX CONSIDERATIONS

Asthma

Men
- Before puberty, asthma affects more boys.
- Boys most likely to have less severe symptoms by late teen years.

Women
- In adulthood, asthma affects more women.
- Between 40 and 60 years of age, have a higher incidence and severity.
- Women who present to the emergency department are more likely to need hospitalization.
- Have a higher overall mortality.

asthma. Patients often have chronic sinus problems that cause inflammation of the mucous membranes and can trigger an asthma attack. Sinusitis must be treated and large nasal polyps removed for the patient to have good control of their asthma.

Allergens

Allergens cause varying degrees of allergic reactions in susceptible persons. Indoor and outdoor allergens, such as cockroaches, furry animals, fungi, pollen, and molds, can trigger asthma attacks. However, we are not clear about their role in the development of asthma.

Cigarette Smoke

The Centers for Disease Control and Prevention (CDC) estimates that 21% of persons with asthma smoke.[14] In a person with asthma, smoking is associated with a faster decline of lung function, increased severity, more frequent HCP visits, and a decreased response to treatment. *Passive smoking* is the exposure of non-smokers to cigarette smoke. It is also known as *environmental tobacco smoke* (ETS) or secondhand smoke. It is also a risk factor.

Air Pollutants

Various air pollutants, such as wood smoke or vehicle exhaust, can trigger asthma attacks. In heavily industrialized or densely populated areas, climate conditions often lead to concentrated pollution in the atmosphere, especially with thermal inversions and stagnant air masses. News sources often report ozone alert days. Patients with breathing problems should minimize outdoor activity during these times.

Respiratory Tract Infections

Respiratory tract infections are often a major trigger of an acute asthma attack. Acute URIs can decrease the diameter of the airways and induce airway hyperresponsiveness. Viral-induced changes in epithelial cells, the accumulation of cells that enhance inflammation, and edema of airway walls contribute to altered respiratory function. These changes may worsen asthma.

Immune Response

People who have a lower incidence of asthma were exposed to certain infections early in life. They received fewer antibiotics, were around other children (e.g., siblings, day care), or lived in rural settings or with pets. The *hygiene hypothesis* suggests that in extremely clean environments, a newborn and child's immune system will not fully mature and develop. In other words, exposure to different germs and various infections during infancy and childhood helps strengthen your immune system. However, we know that this view does not tell the full story. The link between respiratory problems and the predisposition to develop certain conditions, like asthma, is complicated.

Genetics

The genetics of asthma are complex. Many genes may be involved. They are likely responsible for different responses to triggers and asthma drugs. Atopy, the genetic predisposition to develop an allergic (immunoglobulin E [IgE]–mediated) response to common allergens, is a major risk factor.

Gastroesophageal Reflux Disease

GERD is more common in people with asthma. GERD can worsen asthma symptoms because reflux may trigger bronchoconstriction and cause aspiration. Asthma drugs can also worsen GERD symptoms. β_2-Agonists used to treat asthma (especially when given orally) relax the lower esophageal sphincter. This allows stomach contents to reflux into the esophagus and potentially be aspirated. GERD treatment can improve nocturnal

asthma control, improve quality of life, and prevent asthma symptoms in some patients. GERD is discussed in Chapter 46.

Drugs and Food Additives

Some people with asthma have what we call the *asthma triad:* nasal polyps, asthma, and sensitivity to aspirin and nonsteroidal antiinflammatory drugs (NSAIDs).[15] Some persons with asthma who use salicylic acid (e.g., aspirin) or NSAIDs can develop wheezing within 2 hours. In addition, there is usually profound rhinorrhea, congestion, and tearing. Angioedema can occur. These patients must avoid salicylic acid and NSAIDs. Teach the patient the importance of reading labels. Salicylic acid is in many OTC drugs and some foods, beverages, and flavorings. Under the care of an allergist, daily administration of the drug can desensitize some patients.

β-Adrenergic blockers in oral form (e.g., metoprolol) or topical eye drops (e.g., timolol) may trigger an asthma attack because they can cause bronchospasm. ACE inhibitors (e.g., lisinopril) may cause a dry, hacking cough, making asthma symptoms worse. Asthma attacks can occur after the use of sulfite-containing preservatives found in topical ophthalmic solutions, IV corticosteroids, and some inhaled bronchodilator solutions.

Food and drug additives that may trigger asthma include tartrazine (yellow dye no. 5) and sulfiting agents. They are common preservatives and sanitizing agents. Sulfiting agents are in fruits, beer, and wine. They are used in salad bars to protect vegetables from oxidation. Food allergies triggering asthma reactions in adults are rare.

Exercise

We call asthma that is induced or becomes worse during physical exertion exercise-induced asthma (EIA) or exercise-induced bronchoconstriction (EIB).[16] Typically, symptoms of EIA or EIB are worse during activities in which there is exposure to cold, dry air. For example, swimming in an indoor heated pool is less likely to cause symptoms than skiing.

Varying degrees of airway obstruction may occur due to changes in airway mucosa caused by hyperventilation during exercise. Inhaling either cool or re-warmed air and airway edema from capillary leakage in the airway wall contributes to this condition. EIB often occurs after less than 10 minutes of vigorous exercise. It most often resolves within 60 minutes.[16]

Occupational Factors

Occupational asthma is the most common job-related respiratory problem. Occupational irritants cause a change in the responsiveness of the airways. The development of symptoms may not occur until the patient has had months to years of exposure. These agents are diverse and include wood dusts, laundry detergents, metal salts, chemicals, paints, solvents, and plastics. Often, people with occupational asthma give a history of arriving at work feeling well but gradually develop symptoms, which may become progressively worse, by the end of the day.

Psychologic Factors

Many people report that symptoms worsen with stress. An asthma attack caused by any trigger can cause panic, stress, and anxiety. These emotions, and other psychologic factors, can lead to bronchoconstriction through stimulation of the cholinergic reflex pathways. Extreme behavioral expressions (e.g., crying, laughing, anger, fear) can lead to hyperventilation and hypocapnia, which can cause airway narrowing and an asthma attack.

Pathophysiology

The main pathophysiologic process in asthma is persistent but variable inflammation of the airways. Airflow is limited because inflammation results in bronchoconstriction, airway hyperresponsiveness (hyperreactivity), and edema of the airways. Exposure to allergens or irritants starts the inflammatory cascade (Fig. 31.3). A variety of inflammatory cells are involved, including mast cells, macrophages, eosinophils, neutrophils, T and B lymphocytes, and epithelial cells of the airways.

As the inflammatory process begins, mast cells (found beneath the basement membrane of the bronchial wall) degranulate and release multiple inflammatory mediators. IgE antibodies are linked to mast cells, and the allergen cross-links the IgE. As a result, inflammatory mediators, such as leukotrienes, histamine, cytokines, prostaglandins, and nitric oxide, are released (Fig. 31.4). Inflammatory mediators have effects on the (1) blood vessels, causing vasodilation and increasing capillary permeability (runny nose); (2) nerve cells, causing itching; (3) smooth muscle cells, causing bronchial spasms and airway narrowing; and (4) goblet cells, causing mucus production. As a result, edema of airway mucosa, muscle spasm, and accumulation of secretions produce varying degrees of expiratory airflow obstruction (Fig. 31.5).

This process is the *early-phase response* of asthma. Clinically, it occurs within minutes after exposure to an allergen or irritant. It generally resolves within 1 to 2 hours. Symptoms can recur 4 to 6 hours after the early response because of the influx of inflammatory cells, which are set in motion by the initial response. At this later time, the patient may develop symptoms again or worsening of symptoms.

We call this the *late-phase response.* It occurs in about 50% of people with asthma. In the late-phase response, the body activates more inflammatory cells, with continuing airway inflammation. Bronchoconstriction with symptoms can last for 24 hours or more. Corticosteroids are often effective in treating inflammation in this late phase. Chronic inflammation may cause structural changes in the bronchial wall, known as *remodeling.* Over time, a progressive loss of lung function occurs that therapy cannot fully reverse. Structural changes include fibrosis of the subepithelium, hypertrophy of the smooth muscle of the airways, mucus hypersecretion, continued inflammation, and angiogenesis. Remodeling and genetic factors may explain why some persons have persistent asthma and limited response to therapy.

Clinical Manifestations

The characteristic manifestations of an asthma attack are wheezing, cough, dyspnea, and chest tightness after exposure to a risk factor or trigger. Normally, the bronchioles constrict during expiration. However, in asthma, the airways become narrower than usual because of bronchospasm, edema, and mucus. As a

PATHOPHYSIOLOGY MAP

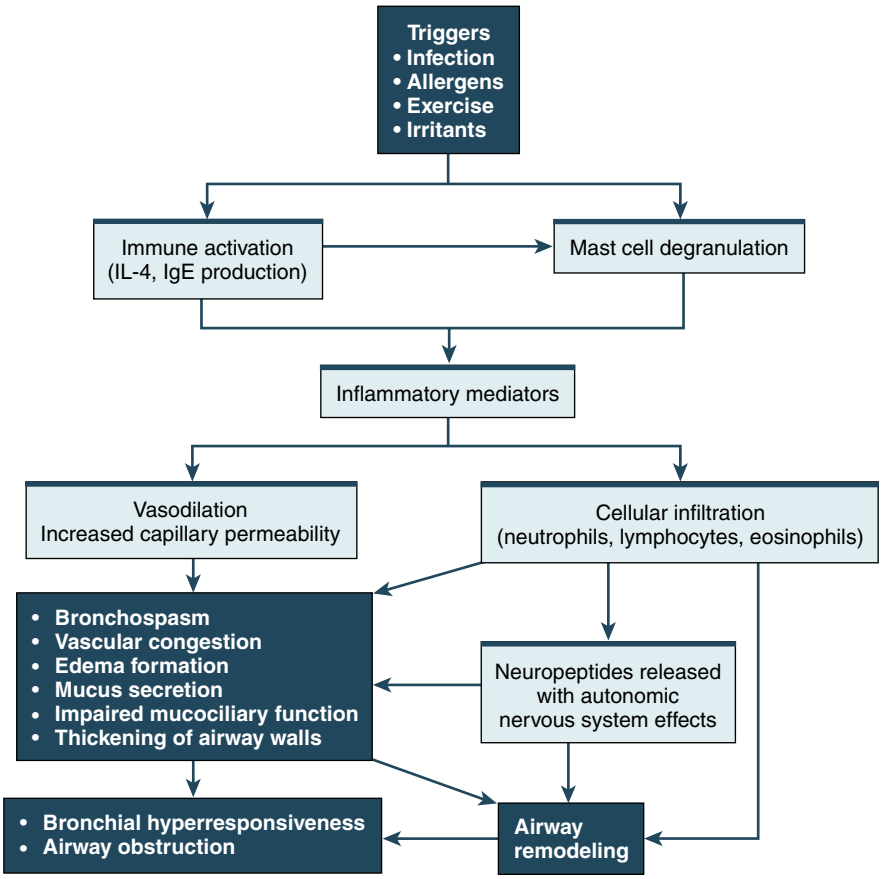

Fig. 31.3 Pathophysiology of asthma. *IL,* Interleukin; *IgE,* immunoglobulin E. (Adapted from McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children*, ed 7, St. Louis, 2015, Elsevier.)

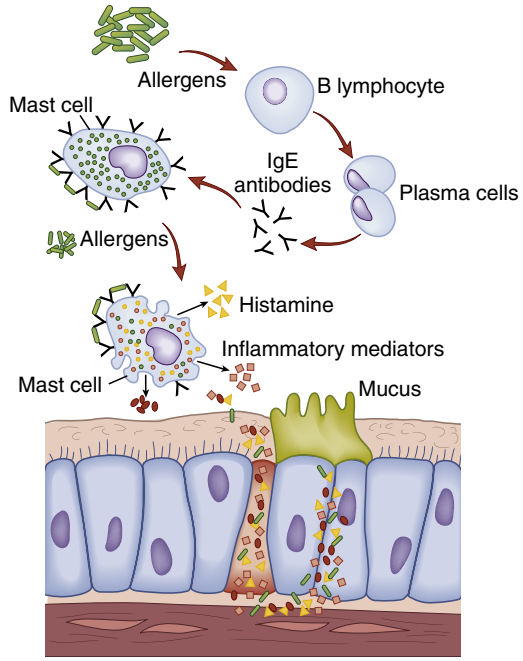

Fig. 31.4 Allergic asthma is triggered when an allergen cross-links immunoglobulin E *(IgE)* receptors on mast cells, which are then activated to release histamine and other inflammatory mediators (early-phase response). A late-phase response may occur due to further inflammation and edema.

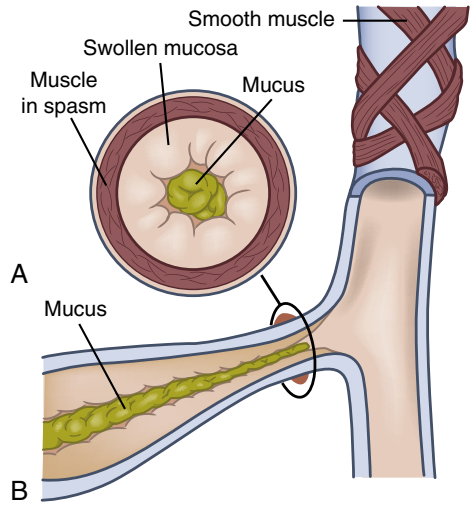

Fig. 31.5 Factors causing expiratory obstruction in asthma. (A) Cross section of a bronchiole occluded by muscle spasm, edema of mucosa, and mucus in the lumen. (B) Longitudinal section of a bronchiole. (Redrawn from Price SA, Wilson SM: *Pathophysiology: clinical concepts of disease processes*, ed 6, St. Louis, 2003, Mosby.)

result, it takes longer for the air to move out of the bronchioles (airflow obstruction). This causes the characteristic wheezing, air trapping, and hyperinflation of the lungs. As a result, expiration may be prolonged.

The most common finding during an acute asthma event is wheezing. For wheezing to occur, the patient must be able to move enough air to make the sound. Wheezing usually occurs first on exhalation. As asthma progresses, the patient may wheeze during inspiration and expiration.

However, wheezing is an unreliable sign to gauge the severity of an attack. Many patients with minor attacks wheeze loudly. Others with severe attacks do not wheeze. The patient with a severe asthma attack may wheeze only during forced expiration or have no audible wheezing because of the marked reduction in airflow.

Decreased or absent breath sounds may signal a significant decrease in air movement resulting from exhaustion and an inability to generate enough muscle force to breathe. Severely decreased breath sounds, often referred to as the "silent chest," are an ominous sign. This often means severe airway obstruction and impending acute respiratory failure (ARF).

! SAFETY ALERT

Silent Chest

- If the patient with asthma has been wheezing, followed by a sudden absence of a wheeze (e.g., silent chest) and the patient struggling to breathe, this is a life-threatening emergency.
- Call for help immediately.
- The patient may need mechanical ventilation.

Hyperventilation occurs during an asthma attack as lung receptors respond to the increase in lung volume from trapped air and airflow limitation. Decreased alveolar perfusion and ventilation and increased alveolar gas pressure lead to V/Q mismatch. The patient may be hypoxemic early with decreased $PaCO_2$ and increased pH (respiratory alkalosis) because they are hyperventilating. As the airflow limitation worsens with subsequent air trapping, the patient works much harder to breathe. The $PaCO_2$ normalizes as the patient tires but then increases to produce respiratory acidosis. A rising $PaCO_2$ level and decreasing pH is an ominous sign of ARF.

In some patients with asthma, cough is the only symptom. This is termed *cough variant asthma.* Bronchospasm is not present or may not be severe enough to cause airflow obstruction or wheezing, but it can increase bronchial tone and cause irritation with stimulation of the cough receptors. The cough may be nonproductive or with secretions. Sputum may be thick, tenacious, and gelatinous, making removal difficult.

CHECK YOUR PRACTICE

A patient with asthma is in the ED with acute respiratory distress. He has been receiving therapy and seems to be responding. You suddenly notice he is no longer wheezing.

- Should you consider this finding a sign that he is doing better?

Asthma Classifications

Several sets of national and international guidelines exist for classifying asthma. Each guideline has a slightly different perspective about asthma and how to classify the severity of an asthma attack. The severity of an asthma attack is used to guide treatment decisions. All the guidelines focus on assessing the severity of the disease at diagnosis and initial treatment and periodic monitoring to control the disease. All groups endorse the use of "stepping up" or "stepping down" medications during and after an acute asthma attack and having an "action plan" to help prevent future attacks. They promote patient teaching and adherence to the treatment plan.

The Global Initiative for Asthma (GINA) guidelines are the most widely recognized evidence-based strategies for addressing asthma worldwide.[17] Many HCPs use the 2012 National Heart, Lung, and Blood Institute (NIH) guidelines for classifying asthma severity (Table 31.4). They describe asthma as intermittent, mild persistent, moderate persistent, or severe persistent.[18]

Complications

Asthma attacks range from minor interferences in breathing to life-threatening episodes. Depending on a person's physiologic response, asthma can rapidly progress from normal breathing to an acute, severe attack or a life-threatening medical emergency within a few minutes.

In some people, airway remodeling predisposes them to respiratory-related issues. As bronchi become thicker and less elastic and airways become narrower, this may increase WOB. Compromised lung function may lead to a state of continuous symptoms and chronic debilitation, including fatigue, headaches, and lack of activity. Asthma predisposes patients to pneumonia, worse episodes of the flu, and in rare situations, tension pneumothorax. ARF and status asthmaticus are the most severe complications of an asthma attack.

Status Asthmaticus

A life-threatening medical emergency, **status asthmaticus** is the most extreme form of an acute asthma attack. It is characterized by hypoxia, hypercapnia, and ARF. The patient is unresponsive to treatment with bronchodilators and corticosteroids. They may have chest tightness, a severely marked increase in shortness of breath, or suddenly be unable to speak. Hypotension, bradycardia, and respiratory and/or cardiac arrest may occur if we do not recognize that the patient is getting worse.

IV magnesium sulfate has a bronchodilator effect. It may be given to patients with a very low FEV_1 or peak flow (less than 40% of predicted or personal best) or those who do not respond to initial treatment. IV magnesium should not delay the need for intubation of the patient who is with status asthmaticus.

The patient needs immediate mechanical ventilation. Hemodynamic monitoring is critical. Continuous analgesic infusions (e.g., ketamine, morphine) and sedation with drugs such as propofol help decrease WOB and promote synchrony with the ventilator. In some circumstances, neuromuscular blocking agents (e.g., rocuronium) may be used. Inhaled anesthetics, such as isoflurane, are an option for those not responding to conventional treatment. These patients are cared for in the ICU.

TABLE 31.4 Diagnostic Criteria

Asthma Severity Classification

	ASTHMA SEVERITY			
		PERSISTENT		
Components of Severity	**Intermittent**	**Mild**	**Moderate**	**Severe**
Impairment				
Symptoms	>2 days/week	>2 days/week, not daily	Daily	Continuous
Flare-ups	Brief, vary in intensity	Noticeable	More frequent	Daily
Interference with ADLs	Usually none	May affect ADLs	Some limitations, may affect ADLs	Often restricts ADLs
Nighttime awakenings	>2/month	3–4/month	>1/week, but not nightly	Every night (7/week)
Lung function[a]	FEV_1 >80% (normal FEV_1 between attacks); FEV_1/FVC normal	FEV_1 >80% predicted; FEV_1/FVC normal	FEV_1 60%–80% predicted; FEV_1/FVC reduced by 5%	FEV_1 <60% predicted; FEV_1/FVC reduced by >5%
Risk				
	Consider severity and interval since last attack. →			
	Frequency and severity may fluctuate over time. →			
	Relative annual risk for exacerbation may be related to FEV_1. →			
Recommended Step for Initiating Treatment	**Step 1**	**Step 2**	**Step 3**	**Step 4 or 5**
	Reevaluate asthma control in 2–6 weeks and adjust therapy as needed			

Guidelines for Using Table

- This stepwise approach is meant to help guide the HCP. It is not a substitute for patient assessment and clinical decision making.
- Assign patients to the most severe step in which any feature occurs.
- Clinical features may overlap across steps. Determine level of severity by assessing impairment and risk. Assess impairment by recall of previous 2 to 4 weeks spirometry results.
- A person's classification should change over time with treatment. After treatment, the focus switches to the level of control, not the classification of severity.

[a]Percent predicted values for FEV_1 or ratio of FEV_1/FVC. Normal FEV_1/FVC: 8–19 years, 85%; 20–39 years, 80%; 40–59 years, 75%; 60–80 years, 70%.
Source: Adapted from National Asthma Education and Prevention Program, National Heart, Lung, and Blood Institute: *Expert Panel report 3: guidelines for the diagnosis and management of asthma,* NIH pub no 08-4051, Bethesda, MD, 2007, National Institutes of Health.

Diagnostic Studies

Tests used to diagnose asthma are shown in Table 31.5. In general, the HCP should consider a diagnosis of asthma if various indicators (e.g., manifestations, health history, peak flow variability, spirometry) are positive.

Under-diagnosis of asthma is common. The history is important to determine if a person has had similar attacks, which are often precipitated by a known trigger. Because wheezing and cough occur with a variety of disorders (e.g., COPD, GERD, vocal cord problems, heart failure [HF]), it is important to determine if asthma or another disease is causing these problems. Table 31.6 shows a comparison of asthma and COPD.

The **peak expiratory flow rate** (PEFR) measured by the peak flow meter (at home or in a health care setting) is a test of lung function. PEFR measures the maximum rate of airflow after a forceful exhalation. When monitored routinely, PEFR measurements can provide a baseline of the patient's health status. PEFR can help predict an asthma attack or monitor the severity of disease. Test results depend on the patient's age, gender, and height. Since peak flow meters vary, PEFR should be compared with the patient's previous best measurements using their meter.

Spirometry is usually normal between asthma attacks if the patient has no other underlying lung disease. The patient may show an obstructive pattern including a decrease in forced vital capacity (FVC), PEFR, FEV_1, and FEV_1/FVC ratio.

When a spirometry test is scheduled, the patient must stop taking any bronchodilator drugs for 6 to 12 hours before the test. Spirometry can be done before and after the administration of a bronchodilator to assess the degree of the response. This helps determine the reversibility of airway obstruction, which is important in diagnosing asthma. A positive (favorable) response to the bronchodilator is an increase of more than 200 mL and an increase of more than 12% between pre-administration and post-administration values.[19]

A hand-held, point-of-care device to measure fractional exhaled nitric oxide (FeNO) can help determine asthma severity. FeNO levels are increased in people with asthma from eosinophilic-induced airway inflammation. FeNO can gauge loss of asthma control and attacks, adherence to therapy, or if more inhaled or oral antiinflammatory medication is needed.[20]

Increased serum eosinophil counts and IgE levels suggest an allergen or genetic link with asthma. Allergy skin testing can assess sensitivity to specific allergens. A positive skin test does not necessarily mean that the allergen is causing the asthma attack. On the other hand, a negative allergy test does not mean that the asthma event is not allergy related.

TABLE 31.5 Interprofessional Care

Asthma

Diagnostic Assessment

- History and physical assessment
- Spirometry, including response to bronchodilator therapy
- Peak expiratory flow rate (PEFR)
- Chest x-ray
- Pulse oximetry
- Allergy skin testing (if indicated)
- Blood level of eosinophils and IgE (if indicated)

Management

- Identify and avoid or eliminate triggers
- Patient and caregiver teaching
- Drug therapy (Tables 31.8 and 31.9 and Figs. 31.6 and 31.7)
- Asthma action plan (Fig. 31.11)
- Desensitization (immunotherapy) if indicated
- Assess for control (e.g., Asthma Control Test [ACT])

Acute Attacks

- Inhaled corticosteroids (alternatives: IV or oral corticosteroids)
- Inhaled β_2-adrenergic agonists
- Inhaled anticholinergics
- Position upright (semi to high-Fowler's)
- O_2 by nasal cannula or mask
- SpO_2 monitoring
- ABGs
- IV fluids
- IV magnesium
- As required: Mechanical ventilation

A chest x-ray in an asymptomatic patient with asthma is usually normal. Chest x-rays are usually not done unless other manifestations, such as fever or chills, are present. It can show if something else is causing symptoms similar to those of asthma (e.g., pneumonia, foreign body in the airway). A sputum specimen for culture may be done to rule out bacterial infection, especially if the patient has purulent sputum, a history of URI, a fever, or an increased white blood cell (WBC) count.

Interprofessional Care

The goal of care is to achieve and maintain control of the asthma. Guidelines provide direction about medications (based on steps) the patient needs (Figs. 31.6 and 31.7). The HCP will step up medication therapy as asthma symptoms worsen and step down the medication as the patient achieves control (Table 31.7). The level of control is determined by the patient's medication use, symptoms, and PEFR or FEV_1.

Drug Therapy

Drug therapy for asthma can be complex. Asthma drugs are divided into 2 general types: (1) *short-term controller*, ("rescue") agents, to treat attacks, and (2) *preferred reliever* agents (Table 31.8). You need to understand the different classes of drugs used to treat asthma and asthma attacks, their desired effects, side effects, and when to use different drugs.

The history, drug therapy, and frequency and severity of attacks help the HCP decide which types of drugs are best suited to control asthma symptoms. Current guidelines all suggest a stepwise approach to drug therapy. Common drugs used in asthma therapy are discussed in Table 31.9.

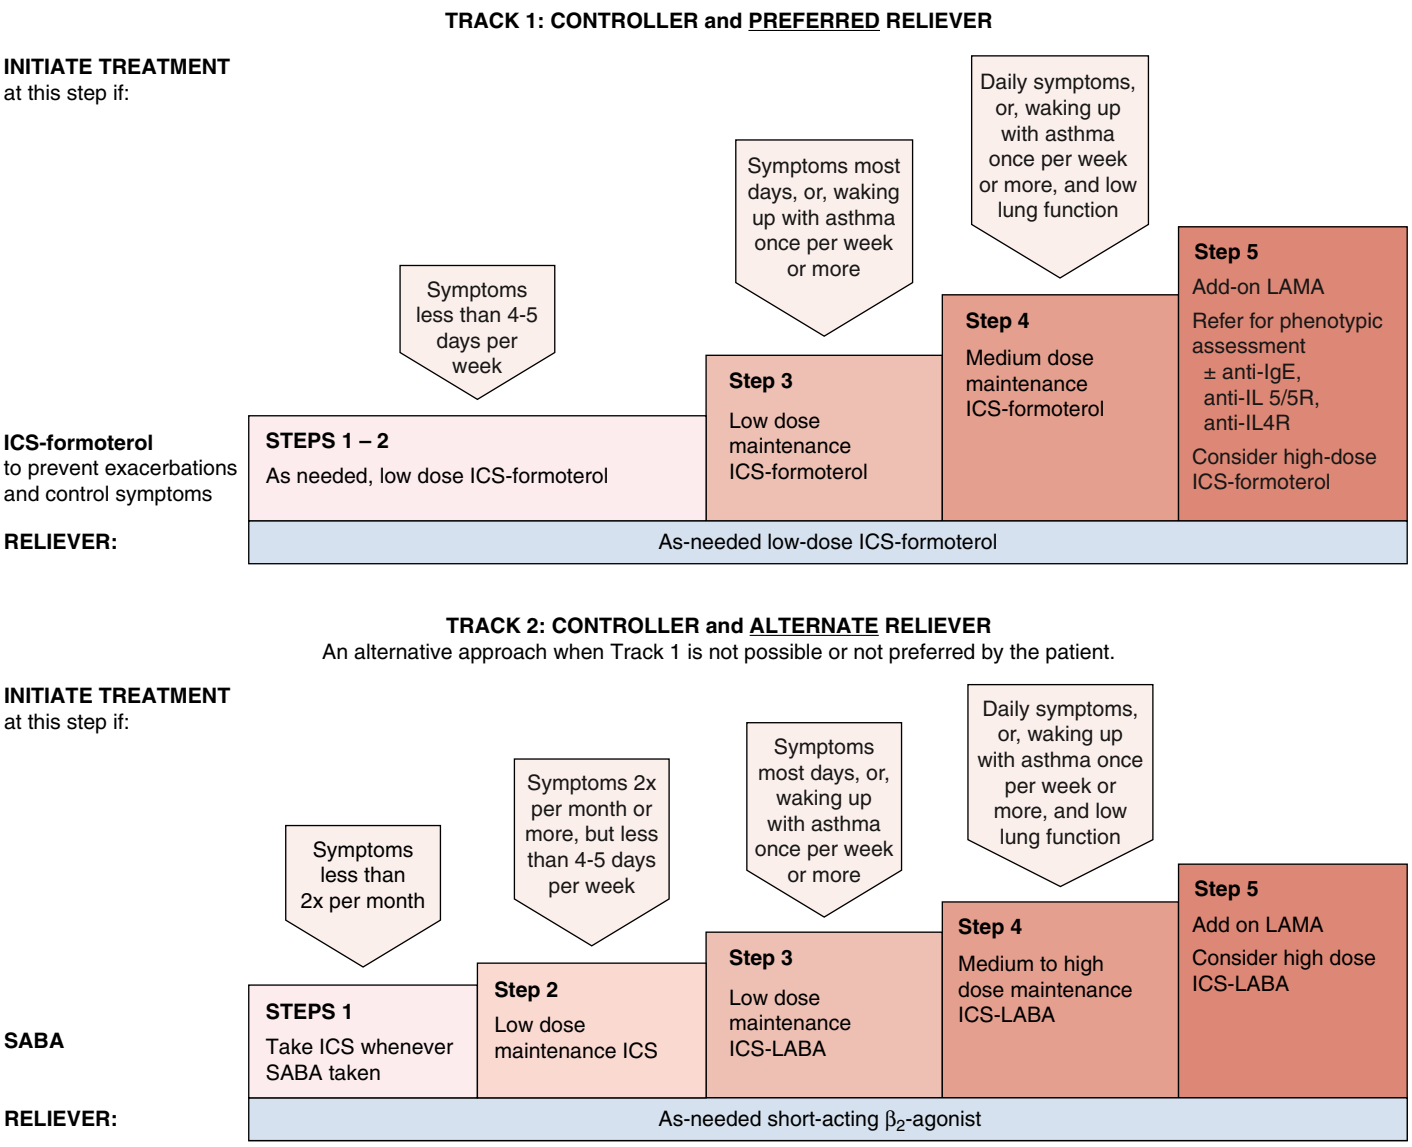
TABLE 31.6 Comparison of Asthma and COPD[a]

	Asthma	COPD
Clinical Features		
Age	Usually <40 years (onset)	Usually 30–45 years (onset)
Smoking history	No causal relationship	Causal relationship: Often long history (>10–20 pack-years)
Health and family history	Presence of allergy, rhinitis, eczema. Family history of asthma	Infrequent allergies. May have exposure to environment pollutants. With AATD, family history of lung or liver disease without smoking
Clinical symptoms	Intermittent, vary day to day. May be worse at night or early morning	Slowly progressive, persistent. Worsening of condition over time
Dyspnea	Absent except in attacks or poor control	Dyspnea during exercise and/or ADL's
Sputum	Infrequent	Often
Disease course	Often stable (with varying number and severity of attacks each year)	Progressive worsening (with increasingly more frequent exacerbations)
Diagnostic Study Results		
ABGs	Normal between or during attacks	Between exacerbations in advanced COPD • Often low-normal pH and PaO_2 • High-normal $PaCO_2$ with normal to high HCO_3– (may be fully or partially compensated respiratory acidosis)
pH	↑ Early in attack, then ↓ if prolonged or severe attack	Normal →↓
PaO_2	↓	N→↓
$PaCO_2$	↓ Early in attack, then ↑ if prolonged or severe attack	N→↑
Chest x-ray	May be normal or show some degree of hyperinflation	Hyperinflation, flattened diaphragm. May have cardiac enlargement
Lung volumes	Often normal	Usually not normal as disease progresses
• Total lung capacity	↑	↑
• Residual volume	↑	↑
• FEV_1	↓→ N	↓
• FEV_1/FVC	N→↓	↓ (<70%)

[a]Patients may have features of both asthma and COPD.

Corticosteroids

All guidelines recommend using ICS as first-line agents in an acute asthma attack and as the first step in acute asthma management.[21] They are the most effective short-term controller drugs for asthma. Corticosteroids are antiinflammatory drugs. They reduce bronchial hyperresponsiveness, block the



ICS: Inhaled corticosteroid; SABA: Short-acting B2 agonist; LABA: Long-actina β_2 agonist; LTRA: Leutrotriene receptor agonist; OCS: Oral corticosteroid

Fig. 31.6 Stepwise approach to asthma treatment. *IL,* Interleukin; *LABA,* long-acting β-2 agonist; *OCS,* oral corticosteroid.

late-phase response, and inhibit the migration of inflammatory cells. They are more effective in improving asthma control than any other drug.

ICSs side effects include easy bruising and decreased bone mineral density. Oropharyngeal candidiasis, hoarseness, and dry cough are local side effects. These problems can be reduced or prevented by using a spacer with the metered-dose inhaler (MDI) and by gargling with water or mouthwash after each use. Using a spacer or holding device can help get more drug into the lungs.

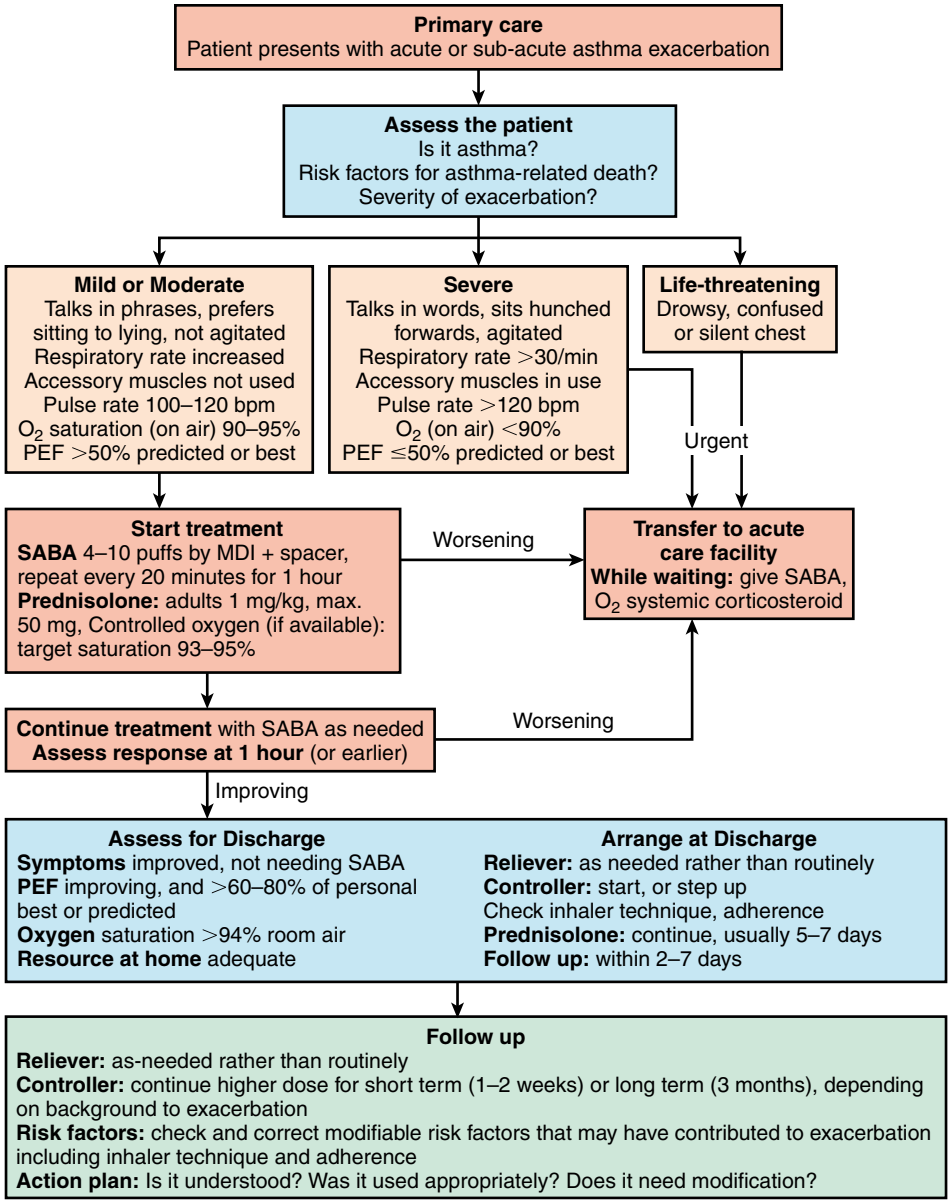
Bronchodilators

The 3 classes of bronchodilator drugs used in asthma therapy are β_2-adrenergic agonists (also referred to as β_2-agonists), methylxanthines, and anticholinergics.

β_2-Adrenergic agonist drugs. β_2-Adrenergic agonists may be SABAs or LABAs. While inhaled SABAs remain effective drugs for relieving acute bronchospasm (as seen in an acute asthma attack), they are no longer first-line therapy. They do play a key role in asthma management. These drugs have an onset of action within minutes and are effective for 4 to 8 hours. They stimulate β-adrenergic receptors in the bronchioles, producing bronchodilation. They also increase mucociliary clearance.

β_2-Adrenergic agonists can prevent bronchospasm caused by different triggers because they prevent the release of inflammatory mediators from mast cells. They do not inhibit the late-phase response of asthma or have antiinflammatory effects. If used often, inhaled β_2-adrenergic agonists may cause tremors, anxiety, nausea, tachycardia, and palpitations.[22]

Too frequent use of β_2-adrenergic agonists indicates poor asthma control, may mask the severity of the condition, and lead to reduced drug effectiveness. SABAs should not be used alone for recurrent, repeated asthma attacks, or for long-term control. Guidelines suggest that they may be an alternate



O_2: oxygen; PEF: peak expiratory flow; SABA: short-acting beta$_2$-agonist (doses are for salbutamol)

Fig. 31.7 Management of patient with acute asthma attack. (Modified from GINA evidence-based strategy document, 2021. Retrieved from https://ginasthma.org.)

reliever medication when the patient does not respond to low-dose ICS.

Like SABAs, LABAs should not be used alone as primary treatment. They should only be used only if the patient does not respond to medium-dose ICS. In other words, LABAs can be used as an adjunct to treatment. Examples of LABAs used in the treatment of asthma attacks include salmeterol and formoterol.

LABAs are effective for 12 hours. Tell patients that LABAs should not be used to treat acute symptoms or to obtain quick relief from bronchospasm. Teach the patient that these drugs are used only once every 12 hours. Combination therapy using an ICS and a LABA is available in several inhalers (e.g., fluticasone/salmeterol [Advair], budesonide/formoterol [Symbicort]). Combinations are more convenient, improve adherence, and ensure that patients receive the LABA with an ICS.

DRUG ALERT

β_2-Adrenergic Agonists

- Use with caution in patients with heart problems.
- Both SABAs and LABAs may cause increased BP and heart rate, central nervous system stimulation, and dysrhythmias.

DRUG ALERT

Long-Acting β_2-Adrenergic Agonists (LABAs)

- Should not be the first or only drug used to treat asthma.
- Should be added to the treatment plan only if other drugs do not control asthma.
- Do not use to treat wheezing that is getting worse.

TABLE 31.7 Components of Asthma Control

Components of Control	CLASSIFICATION OF ASTHMA CONTROL Well Controlled	Not Well Controlled	Poorly Controlled
Impairment			
Symptoms	≤2 days/week	>2 days/week	Throughout the day
Nighttime awakenings	≤2/months	1–3/weeks	≥4/weeks
Interference with normal activity	None	Some limitation	Extremely limited
FEV_1 or PEFR	>80% predicted/personal best	60%–80% predicted/personal best	<60% predicted/personal best
Risk			
Attacks requiring additional pharmacologic management	0–1/year	≥2/years	≥2/years
Progressive loss of lung function	Evaluation requires long-term follow-up. →		
Treatment-related adverse effects	Can vary in intensity from none to very troublesome and worrisome. Level of intensity does not correlate to specific levels of control but should be considered in the overall assessment of risk. →		
Recommended Action for Treatment (based on assessment of control)	• Maintain current step. • Regular follow-up every 1–6 months to maintain control. • Consider step down if well controlled for at least 3 months.	• Step up 1 step. • Reevaluate in 2–6 weeks. • For side effects, consider alternative treatment options.	• Consider oral corticosteroids. • Step up 1 or 2 steps and reevaluate in 2 weeks. • For side effects, consider alternative treatment options.

TABLE 31.8 Drug Therapy

Asthma

Types of Drugs	Drug Class
Controller Drugs	Corticosteroids Short-acting β_2 adrenergic agonists (SABA)
Maintenance, Reliever and Alternate Reliever Drugs (MART)	Anticholinergics • Short-acting muscarinic antagonist (SAMA) • Long-acting muscarinic antagonist (LAMA) β_2 adrenergic agonists • Short-acting β-adrenergic agonist (SABA) • Long-acting β-adrenergic agonist (LABA) Corticosteroids Leukotriene modifiers • Leukotriene receptor antagonist • Leukotriene inhibitor Methylxanthines Monoclonal antibodies • Anti-IgE • Anti-interleukin 5 Phosphodiesterase inhibitors Combination preparations • SAMA/SABA • ICS/LABA • LAMA/LABA

Methylxanthines. Sustained-release methylxanthine preparations are not a first-line controller medication. They are used only as an alternative therapy. One example is theophylline, a methylxanthine that is a weak bronchodilator with mild anti-inflammatory effects. Theophylline use has been replaced by newer drugs, namely inhaled ICS and β_2-adrenergic agonists. GINA no longer recommends theophylline as part of its treatment guidelines.

There are several problems with theophylline. First, there are many side effects. Second, there is well interactions with many other drugs. Third, because theophylline has a very narrow margin of safety, we must check serum blood levels regularly to see if drug levels are within therapeutic range.

Anticholinergic drugs. Anticholinergic drugs affect the muscles around the bronchi (large airways). When the lungs are irritated, these bands of muscle can tighten, causing bronchoconstriction via the parasympathetic nervous system. Anticholinergics work by preventing these muscles from tightening. Consequently, these drugs promote bronchodilation.

Anticholinergic drugs are less effective than equivalent doses of SABAs. Therefore, short-acting anticholinergic drugs are not used except for in severe acute asthma attacks. Examples include ipratropium and tiotropium.

Leukotriene Modifiers

Leukotrienes are inflammatory mediators produced from arachidonic acid metabolism. They are potent bronchoconstrictors. Some leukotrienes cause airway edema and inflammation, contributing to the worsening symptoms of an acute asthma attack.

Leukotriene receptor antagonists (LTRAs) block the release of some substances from mast cells and eosinophils, producing bronchodilator and antiinflammatory effects. LTRAs do not reverse bronchospasm in acute asthma attacks. They are less effective than corticosteroids and used only as adjunct therapy for those patients who do not respond to treatment with ICS. LTRAs include zafirlukast (Accolate), montelukast (Singulair), and zileuton (Zyflo CR).

Monoclonal Antibodies

Anti-immunoglobulin E. Omalizumab (Xolair) is a monoclonal antibody to IgE that decreases circulating free IgE levels. Omalizumab prevents IgE from attaching to mast cells, thus

TABLE 31.9 Drug Therapy

Asthma and COPD

Drug	Use	Route	Considerations
Anticholinergics			
Short Acting (SAMA)			
ipratropium (Atrovent HFA)	Asthma, COPD	Nebulizer, MDI	Can be monotherapy. Produces bronchodilation within minutes. Side effects: Headache, dry mouth, dizziness, palpitations.
Long Acting (LAMA)			
aclidinium bromide (Tudorza Pressair)	COPD	DPI	Side effects: Headache, cough, cold symptoms. Do not take with other anticholinergics.
revefenacin (Yupelri)	COPD	Nebulizer	Dosed once daily as maintenance treatment. Does not cause usual side effects of other anticholinergics. Do not take with other anticholinergics.
tiotropium bromide (Spiriva Handi-Haler)	COPD	DPI	Side effects: Headache, dry mouth, dizziness, palpitations. Dosed once daily as maintenance treatment. Do not take with other anticholinergics. Blurred vision if powder comes in contact with eyes. Maximum effect 1 week after starting drug.
umeclidinium (Incruse Ellipta)	COPD	DPI	Dosed once daily as maintenance treatment. Side effects: Cough, cold symptoms, arthralgia
β_2-Adrenergic Agonists			
Inhaled: Short Acting (SABA)			
albuterol (Proventil HFA, Ventolin HFA, Proair HFA)	Asthma COPD	Nebulizer, MDI Oral	Produces bronchodilation within 5 minutes; effects last 2–5 hr. Oral tablets (long-acting, extended release) not for acute situation. Side effects: Tremors, headache, tachycardia, nausea. MDI may be more effective than nebulizer as drug delivered more quickly to the lungs. Use with caution in patients with cardiac disorders because of ↑ BP and heart rate, CNS stimulation, and ↑ risk for dysrhythmias.
Epinephrine (Primatene Mist HFA)	Asthma	MDI	Sold OTC. Side effects: tachycardia, ↑ BP. Do not take with MAO inhibitors.
levalbuterol (Xopenex, Xopenex HFA)	Asthma COPD	Nebulizer, MDI	Response occurs within 15 minutes of administration, and peak effect in 90 min. Do not use if solution discolored. Side effects: Tremors, headache, rash
Inhaled: Long Acting (LABA)			
In asthma: Never use as monotherapy. Use in combination with ICSs. In COPD: Some drugs used as monotherapy. Not used for rapid relief of dyspnea.			
arformoterol (Brovana)	COPD	Nebulizer	Monitor for paradoxical bronchospasm at high doses. Side effects: GI distress, edema, leg cramps.
formoterol (Foradil Perforomist)	Asthma	DPI, nebulizer (Perforomist)	Side effects: Tremors, tachycardia, GI distress. Use with caution in diabetes, can increase glucose levels.
indacaterol	COPD	DPI	Once daily use. Use with caution in diabetes, can increase glucose levels. Side effects: Nausea, headache, sore throat.
olodaterol (Stiolto, Striverdi Respimat)	COPD	MDI	Once daily use. Side effects: Dizziness, cold symptoms.
salmeterol (Serevent Diskus)	COPD	DPI	Do not use more than twice daily. Side effects: Tremors, tachycardia, muscle pain, cold symptoms. Helps prevent exercise-induced asthma in those with persistent asthma.
Corticosteroids			
hydrocortisone (Solu-Cortef)	Asthma	IV	Oral preferred over IV.
methylprednisolone (Medrol, Solu-Medrol)	Asthma	Oral, IV	Side effects: hyperglycemia, fluid retention. May take 2 weeks for results to be seen in severe COPD exacerbation.
prednisone	Asthma COPD	Oral	Take oral dose in morning with food or milk. High dose may cause GI distress. Long-term therapy requires vitamin D and calcium supplements to prevent osteoporosis. Long-term steroid therapy: discontinue gradually to prevent adrenal insufficiency.

TABLE 31.9 Drug Therapy—cont'd

Asthma and COPD

Drug	Use	Route	Considerations
Inhaled			
beclomethasone dipropionate (Qvar)	Asthma	MDI	Do not use in acute attack. May not see effects until after at least 2 weeks of regular treatment. Side effects: Headache, hoarseness.
budesonide (Pulmicort Flexhaler)	Asthma	DPI	Do not use in acute attack. May not see effects until after at least 2 weeks of regular treatment. Side effects: Headache cold symptoms.
ciclesonide (Alvesco)	Asthma	MDI	Do not use in acute attack. Side effects: Cold symptoms, nose bleeds.
fluticasone (Flovent HFA, Flovent Diskus)	Asthma	MDI, DPI	Do not use in acute attack. Rinse mouth with water or mouthwash after use to prevent oral fungal infections. Side effects: Headache, cold symptoms. Spacer device with MDI may decrease incidence of oral candidiasis. May not see effects until after at least 2 weeks of regular treatment.
mometasone (Asmanex HFA, Asmanex Twisthaler)	Asthma	DPI	Do not use in acute attack. May not see effects until after at least 2 weeks of regular treatment.
Leukotriene Modifiers			
Leukotriene Receptor Antagonists			
montelukast (Singulair)	Asthma	Oral	Do not use in acute attack. Can be used to prevent wheezing and SOB caused by asthma during exercise. Side effects: Headache, fatigue, dizziness, GI distress.
zafirlukast (Accolate)	Asthma	Oral	Do not use in acute attack. No specific side effects. Take at least 1 hr before or 2 hr after meals. Contraindicated in cirrhosis. Affects metabolism of oral warfarin (drug ↑ prothrombin time).
Leukotriene Inhibitor			
zileuton (Zyflo, Zyflo CR)	Asthma	Oral tablets	Do not use in acute attack. Do not crush, chew, or cut tablets. Monitor liver enzymes. May interfere with metabolism of warfarin and theophylline. Changes in sleep pattern and behavioral abnormalities reported.
Methylxanthines			
IV agent: aminophylline (second-line therapy) *Oral:* theophylline	Asthma COPD	IV, oral	Side effects: CNS stimulation, headache, tachycardia, dysrhythmias, nausea, vomiting, altered glucose levels. Nicotine ↑ metabolism of methylxanthines in liver (dosage increase needed for those who smoke). Many drug interactions. Taking drug with food or antacids may help GI effects. Very limited use.
Monoclonal Antibodies			
Anti-IgE			
omalizumab (Xolair)	Asthma	Subcutaneous	Dose and frequency based on total IgE levels and pre-treatment weight. Total IgE levels elevated up to 1 year after therapy stopped; do not use as a guide for dosing drug. Side effects: Dizziness, joint pain, fatigue Pain, burning at injection site, anaphylactic reaction possible. Give only under direct medical supervision every 2–4 weeks.
Anti-Interleukin 5			
mepolizumab (Nucala)	Asthma	Subcutaneous	Add-on therapy in patients with severe asthma attacks despite receiving other asthma drugs. Give only under direct medical supervision every 4 weeks. Side effects: Headache, back pain. Hypersensitivity reactions have been known to occur hours and days later.
reslizumab (Cinqair)	Asthma	IV	Add-on therapy in patients receiving other asthma drugs. Given every 4 weeks as an IV infusion over 1 hr. Risk for anaphylactic reactions.
Phosphodiesterase Inhibitor Type 4 (PDE-4)			
roflumilast (Daliresp)	COPD	Oral	Do not use in acute attack. Used in severe COPD to reduce exacerbation frequency. Side effects: GI distress, headache, suicidal thoughts, insomnia. Do not take with theophylline, phenytoin.

Continued

TABLE 31.9 Drug Therapy—cont'd

Asthma and COPD

Drug	Use	Route	Considerations
Combination Agents			
These are a few of the many combination drugs available for long-term management of asthma and COPD.			
SAMA/SABA			
ipratropium/albuterol (Combivent Respimat)	COPD	Nebulizer, MDI	Do not use in acute attack. Long-term therapy only.
ICS/LABA			
budesonide/formoterol (Symbicort)	Asthma	MDI	Do not use in acute attacks.
fluticasone/salmeterol (Advair Diskus or HFA)	Asthma COPD	DPI, MDI	Long-term therapy only. Side effects: Headache, cold symptoms.
fluticasone/vilanterol (Breo Ellipta)	COPD	DPI	Rinse mouth after using.
mometasone furoate/formoterol fumarate (Dulera)	Asthma	MDI	
LAMA/LABA			
umeclidinium/vilanterol (Anoro Ellipta)	COPD	DPI	Do not use in acute attacks. Long-term therapy only. Side effects: Sore throat, cold symptoms.

preventing the release of chemical mediators. It is given to patients with moderate to severe asthma or those not controlled with ICSs alone. There is a risk for anaphylaxis, so patients must receive the injection in a setting where this emergency can be treated.

Anti-interleukin 5. Interleukin (IL)-5 is a cytokine involved in the inflammatory response in asthma by promoting eosinophil activity.[23] By inhibiting IL-5, monoclonal antibodies inhibit the production and survival of eosinophils. As a result, inflammation and edema of the airway subside. They are mainly used for patients with a history of severe asthma attacks and as an adjunct with other asthma medication. These drugs include mepolizumab (Nucala), reslizumab (Cinqair), and benralizumab (Fasenra).

Nonprescription Combination Drugs

Several combination drugs are available OTC. They are usually combinations of a bronchodilator (ephedrine) and an expectorant (guaifenesin). Often, patients seek OTC drugs because they are less expensive than prescription drugs. Many people consider these drugs safe because they can be obtained without a prescription. In general, they should be avoided due to their potential side effects.

Inhalers containing epinephrine may be available. These agents are advertised as relieving bronchospasm. Those containing ephedrine and epinephrine are potentially dangerous because they stimulate the central nervous and cardiovascular systems. Side effects include nervousness, palpitations, dysrhythmias, tremors, insomnia, and increased BP. Teach patients about the dangers of OTC combination drugs. They are possibly unsafe to a patient with underlying heart problems For the patient who insists on taking these drugs, encourage them to discuss their use with the HCP. Caution them to read and follow the directions on the label. They should notify their HCP if an untoward reaction occurs.

Inhalation Devices for Drug Delivery

Many asthma drugs are given by inhalation because the onset of action is faster and systemic side effects are reduced. Inhalation devices include MDIs, dry powder inhalers (DPIs), and nebulizers.

Fig. 31.8 Example of an AeroChamber spacer used with a metered-dose inhaler. (From Potter PA, Perry AG, Stockert P, et al.: *Fundamentals of nursing,* ed 9, St Louis, 2017, Mosby.)

Inhalers. MDIs are small, hand-held, pressurized devices that deliver a measured dose of drug with each activation. The dose is usually 1 or 2 puffs. Depending on the specific MDI, a spacer or holding chamber is used to reduce the amount of drug delivered to the oropharynx and improve the amount of drug delivered to the lungs. Examples include AeroChamber and InspirEase (Fig. 31.8). Spacers help people who have hand-breath coordination problems. The number of times and frequency that an MDI must be primed vary widely. Follow the package insert.

The patient who needs to use several MDIs is often unclear about the order in which to use them. In most circumstances, a quick-acting drug (e.g., ICS) is used, followed by reliever medications (as needed) for clinical conditions that do not improve. Teach the patient about the different drugs used to treat asthma, how they work, and the indications for use. Review the order in which the patient should take their medications.

Using an inhaler seems simple, but most patients do not use it the right way. When you use your inhaler the wrong way, less medicine gets to your lungs. (Your physician may give you other types of inhalers.)

For the next 2 weeks, read these steps aloud as you do them or ask someone to read them to you. Ask your physician or nurse to check how well you are using your inhaler.

Use your inhaler in one of the three ways pictured below (**A** or **B** is best, but **C** can be used if you have trouble with **A** or **B**).

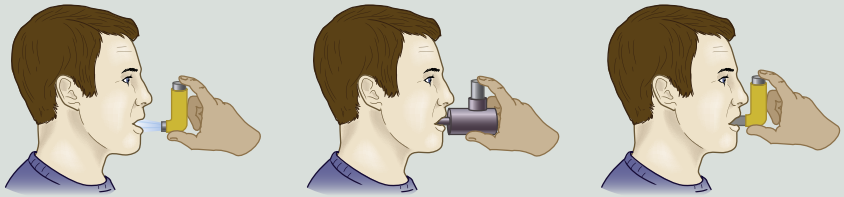
Steps for Using Your Inhaler

Getting ready	1. Take off the cap and shake the inhaler. 2. Breathe out all the way. 3. Hold your inhaler the way your doctor said (**A, B,** or **C** below).
Breathe in slowly	4. As you start breathing in **slowly** through your mouth, press down on the inhaler **one** time. (If you use a holding chamber, first press down on the inhaler. Within 5 seconds, begin to breathe in slowly.) 5. Keep breathing in **slowly,** as deeply as you can.
Hold your breath	6. Hold your breath as you count to 10 slowly, if you can. 7. For inhaled quick-relief medicine (β_2-agonists), wait about 1 minute between puffs. There is no need to wait between puffs for other medicines.

A. Hold inhaler 1 to 2 inches in front of your mouth (about the width of two fingers).

B. Use a spacer/holding chamber. These come in many shapes and can be useful to any patient.

C. Put the inhaler in your mouth.



Clean Your Inhaler as Needed

Look at the hole where the medicine sprays out from your inhaler. If you see "powder" in or around the hole, clean the inhaler. Remove the metal canister from the L-shaped plastic mouthpiece. Rinse only the mouthpiece and cap in warm water. Let them dry overnight. In the morning, put the canister back inside. Put the cap on.

Know When to Replace Your Inhaler

For medicines you take each day (an example): Say your new canister has 200 puffs (number of puffs is listed on canister) and you are told to take 8 puffs per day.

$$8 \text{ puffs per day} \overline{)\ 200 \text{ puffs in canister}} \quad 25 \text{ days}$$

So this canister will last 25 days. If you started using this inhaler on May 1, replace it on or before May 25. You can write the date on your canister.

For **quick-relief medicine take as needed** and count each puff.

Do not put your canister in water to see if it is empty as water may enter MDI and impair inhaler.

Fig. 31.9 How to use your metered-dose inhaler.

Another potential problem is patient technique when using drug delivery devices. An MDI drug is effective only if taken properly. Review MDI technique during each visit. The patient needs to know how to use the MDI correctly (Fig. 31.9), how to determine whether the MDI is empty, and how to effectively clean and care for the device. Problems using an MDI are listed in Table 31.10.

Dry powder inhalers. DPIs are simpler to use than MDIs. The DPI contains dry, powdered medication and is breath activated (Fig. 31.10). DPIs have several advantages over MDIs. They require less manual dexterity. There is no need to coordinate device puffs with inhalation. Some disadvantages are that some common drugs are not available in DPIs. The medication may clump if exposed to humidity. Since the medicine is delivered only by the patient's inspiratory effort, patients with a low FEV_1

TABLE 31.10 Problems Using a Metered-Dose Inhaler (MDI)

- Not coordinating activation with inspiration
- Activating MDI in the mouth while breathing through nose
- Inhaling too rapidly
- Not holding the breath for 10 sec (or as close to 10 sec as possible)
- Holding MDI upside down or sideways
- Inhaling more than 1 puff with each inspiration
- Not shaking MDI before use (if indicated)
- Not waiting enough time between each puff
- Not opening mouth wide enough (if using open mouth technique), causing medication to bounce off teeth, tongue, or palate
- Not having adequate strength to activate MDI
- Not being able to understand and follow directions
- Inadvertently using an empty container

Fig. 31.10 Example of a dry powder inhaler (DPI). (From Potter PA, Perry AG, Stockert P, Hall A: *Fundamentals of nursing,* ed 9, St Louis, 2017, Mosby.)

TABLE 31.11 PATIENT & CAREGIVER TEACHING

How to Use a Dry Powder Inhaler (DPI)

Include the following instructions when teaching a patient to use a DPI:

1. Remove mouthpiece cap or open the device according to manufacturer's instructions. If there is an external counter, note the number of doses left.
2. Load the medicine into the inhaler or engage the lever to allow the medicine to become available. Some DPIs are held upright while loading. Others are held sideways or in a horizontal position.
3. Do not shake your medicine.
4. Tilt your head back slightly and breathe out, getting as much air out of your lungs as you can. Do not breathe into your inhaler because this could affect the dose.
5. Close your lips tightly around the mouthpiece of the inhaler.
6. Breathe in deeply and quickly. This will ensure that the medicine moves down deeply into your lungs. You may not taste or sense the medicine going into your lungs.
7. Hold your breath for 10 sec or as long as you can to disperse the medicine into your lungs.
8. If there is an external counter, note the number of doses left. It should be 1 less than the number in step 1 above.
9. Do not keep your DPI in a humid place, such as a shower room, because the medicine may clump.

(less than 1 L) may not be able to inspire the medication. Table 31.11 describes how to use a DPI.

Differences between MDIs and DPIs are described in Table 31.12. Both systems when used with comparable drug doses provide equal efficacy. Costs vary widely. Therefore, patients should use the device best suited to their needs.

Nebulizers. Nebulizers are small machines used to convert drug solutions into mists. The mist can be inhaled through a face mask or mouthpiece held between the teeth with the lips closed around the device. Nebulizers are usually used for those who have severe asthma or difficulty with the MDI inhalation. They do not provide better delivery of medication than a spacer with an inhaler.

TABLE 31.12 Comparison of Metered-Dose and Dry Powder Inhalers

	Metered-Dose Inhaler (MDI)	Dry Powder Inhaler (DPI)
Shake before use	May be needed for some (e.g., albuterol), but not for others (read package insert)	No
Inspiration	Slow	Rapid
Spacer	May be used with ICS or for more effective delivery	Not used
Counting device	Many have an external device (some devices do not)	Most preloaded forms include counter
Inhalations/dose	Often 2/dose	Often 1/dose

Nebulizers are usually powered by a compressed air or O_2 generator. At home, the patient may have an air-powered compressor. In the hospital, wall O_2 or compressed air powers the nebulizer.

Aerosolized medication orders must include the drug, dose, diluent, and whether it is to be nebulized with O_2 or compressed air. The advantage of nebulized therapy is that it is easy to use. Common nebulized agents include albuterol and ipratropium.

The patient is positioned upright, as this position allows for efficient breathing. The upright position also helps ensure adequate penetration and deposition of the aerosolized drug into the lungs. The patient must breathe slowly and deeply through the mouth and hold each inspiration for 2 to 3 seconds. Deep diaphragmatic breathing helps ensure delivery of the drug. Tell the patient to breathe normally in between large, inhaled breaths. After treatment, have the patient cough effectively.

To reduce the potential for bacterial growth, review cleaning procedures for respiratory equipment. An effective home-cleaning method is to wash the nebulizer daily in soap and water, rinse it with water, and soak it for 20 to 30 minutes in a 1:1 white vinegar–water solution, followed by a water rinse and air drying.

❖ NURSING MANAGEMENT: ASTHMA

◆ Assessment

If a patient is not in acute distress, obtain a detailed health history. Include information about when the condition was first diagnosed, triggers, and what helped relieve past asthma attacks. Assessment of the patient with asthma may be normal, especially between attacks. Subjective and objective data you should obtain from a patient with asthma are outlined in Table 31.13.

◆ Clinical Problems

Clinical problems for the patient with asthma may include:

- Impaired respiratory function
- Activity intolerance
- Anxiety
- Deficient knowledge

Additional information on clinical problems and interventions is presented in eNursing Care Plan 31.1 on the website for this chapter.

TABLE 31.13 NURSING ASSESSMENT

Asthma

Subjective Data

Important Health Information

Health history: Allergic rhinitis, sinusitis, or skin allergies. Previous asthma attacks (frequency, severity) and required hospitalization. Symptoms worsened by triggers in the environment. GERD. Occupational exposure to chemical irritants (e.g., paints, dust)

Medications: Use of medications. Adherence, inhaler technique. Use of antibiotics. Pattern and amount of "controller" and "preferred reliever" (or "alternate" reliever) used per week. Drugs that may trigger an attack in susceptible persons, such as aspirin, NSAIDs, β-adrenergic blockers

Functional Health Patterns

Health perception–health management: Family history of allergies and/or asthma. Recent URI or sinus infection

Activity-exercise: Fatigue, decreased or absent exercise tolerance. Dyspnea, cough (especially at night), productive cough with yellow or green sputum or sticky sputum. Chest tightness, feelings of suffocation, air hunger, talking in short sentences or words or phrases, sitting upright to breathe

Sleep-rest: Awakened from sleep because of cough or breathing difficulties, insomnia

Coping–stress tolerance: Emotional distress, stress in work environment or home

Objective Data

Cardiovascular

Tachycardia, pulsus paradoxus, jugular venous distention, hypertension or hypotension, premature ventricular contractions

General

Restlessness or exhaustion, confusion, upright or forward-leaning body position

Respiratory

Nasal discharge, nasal polyps, mucosal swelling

Crackles, decreased or absent breath sounds, and wheezes (inspiratory, expiratory, or both) on auscultation

Hyperresonance on percussion

Sputum (thick, white, tenacious)

↑ work of breathing with use of accessory muscles.

Intercostal and supraclavicular retractions.

Tachypnea with hyperventilation.

Prolonged expiration

Skin

Diaphoresis, cyanosis (circumoral, nail bed), eczema

Possible Diagnostic Findings

Abnormal pulmonary function tests: ↓ flow rates; FVC, FEV_1, PEFR, and FEV_1/FVC ratio (often improve between attacks with drug therapy). Abnormal ABGs during attacks, ↓ O_2 saturation, serum and sputum eosinophilia, ↑ serum IgE, chest x-ray showing hyperinflation with attacks.

◆ Planning

The overall goals are that the patient with asthma will achieve asthma control, as evidenced by (1) minimal symptoms during the day and night, (2) acceptable activity levels (including exercise), (3) maintaining greater than 80% of personal best PEFR, (4) few or no adverse effects of drug therapy, (5) no acute asthma attacks, and (6) adequate knowledge to carry out the treatment plan.

◆ Implementation

◆ Health Promotion

Your role in preventing asthma attacks or decreasing their severity focuses mainly on teaching the patient and caregiver. Teach the patient to identify and avoid known personal triggers for asthma (e.g., cigarette smoke, pet dander) and irritants (e.g., cold air, aspirin, foods, cats, indoor air pollution) (Table 31.3). Washing bedclothes in hot water or cooler water with detergent and bleach has some effect on allergen levels.

When cold air cannot be avoided, dressing properly with scarves or using a mask helps reduce the risk for an asthma attack. Aspirin and NSAIDs should be avoided if they are known to trigger an attack. Many OTC drugs contain aspirin. Teach the patient to read the labels carefully. Nonselective β-blockers (e.g., propranolol) are contraindicated because they inhibit bronchodilation. Selective β-blockers (e.g., atenolol) should be used with caution. Desensitization (immunotherapy) may be partially effective in decreasing the patient's sensitivity to known allergens.

Prompt diagnosis and treatment of URIs and sinusitis may help prevent an asthma attack. If occupational irritants are involved, the patient may need to consider changing jobs. Those who are obese often find that weight loss improves asthma control. If exercise is planned or if the patient had an asthma attack before with exercise, the HCP can suggest a pre-treatment or long-term control plan to prevent bronchospasm.

◆ Acute Care

During an acute attack, signs and symptoms, medication use, and PEFR or FEV_1 measurements can be used to help identify the severity of an asthma attack and guide health care teams in providing the most appropriate treatment. The goal is to achieve rapid control of the symptoms and return the patient to their previous level of functioning as quickly as possible. Therapy is tailored to patient history, severity of symptoms, frequency of exacerbations, and patient response.

Patients with mild or moderate asthma attacks may be seen in an outpatient clinic or ED. These attacks occur no more than twice per week, with minimal interference in day-to-day activity. The patient is alert, oriented, and speaks in sentences. The patient may describe chest tightness, varying degrees of difficulty breathing, and a slight increase in the use of asthma drugs. O_2 saturation is usually greater than 90% on room air and PEFR greater than 50% of predicted or personal best.

ICS are the mainstays of treatment for mild to moderate asthma attacks. Monitor vital signs. Most patients improve shortly after receiving medication. When the patient improves, review the asthma action plan with them. Teach the patient the importance of a follow-up appointment with the HCP. If the patient's condition is slow to respond, does not respond, or the

HCP suspects another condition may be occurring or contributing to the acute attack, we should transfer the outpatient to an acute care facility.

A severe acute attack is usually frightening enough for most patients to go to the ED. In many cases, a severe attack will call for hospital admission. Managing the patient with a severe attack focuses on correcting hypoxemia and continually observing and/or improving ventilation.

In a severe attack, continuously monitor vital signs and WOB. The patient may be tachycardic, tachypneic, and solely focused on breathing. Respiratory rates greater than 30 breaths/min may be present. They may use accessory muscles. The patient may be agitated, restless, or confused from hypoxemia. The patient often sits forward to maximize diaphragmatic movement.

Bedside PEFR may be used to monitor airflow obstruction. Serial PEFR results, oximetry, and measurement of arterial blood gases (ABGs) give information about the severity of the attack and the response to therapy. Obtaining a PEFR during a severe asthma attack is usually not possible. However, if it can be obtained, PEFR less than 200 L/min or 50% or less of predicted or of personal best indicates severe obstruction.

$O_{2\ therapy}$ is given to achieve a PaO_2 of at least 60 mm Hg or O_2 saturation greater than 90%. O_2 monitoring should be continuous with pulse oximetry. Give drugs as ordered. If the patient can swallow, oral corticosteroids will be part of the treatment plan. Otherwise, IV steroids will be given. SABAs may be part of a patient's asthma plan. Symptoms may gradually diminish after medication therapy but often re-occur.

Auscultate lung sounds. If not immediately audible, auscultation may reveal inspiratory or expiratory wheezing. Louder wheezing may occur in airways that are responding to therapy as airflow increases. As improvement continues and airflow increases, breath sounds increase and wheezing decreases. The "silent chest" is an ominous clinical finding. It often signals impending ARF. Immediately notify the HCP.

The disappearance of most bronchospasm, resolution of edema and cellular infiltration of airway mucosa, and elimination of mucous plugs may take several days to improve after a severe attack. As a result, therapy must be continued even after clinical improvement. Always evaluate the patient's response to therapy.

An important nursing goal during an acute attack is to decrease the patient's anxiety and sense of panic. Assess the patient's level of anxiety. Position the patient comfortably (usually sitting, in semi- to high-Fowler's position) to maximize chest expansion. A calm, quiet, reassuring attitude may help the patient relax. A technique called "talking down" can help the patient remain calm. In talking down, you gain eye contact with the patient. In a firm, calm voice, coach the patient to use pursed-lip breathing. Pursed-lip breathing keeps the airways open by maintaining positive pressure (see Table 28.1). Stay with the patient until the respiratory rate has slowed.

When the acute attack subsides, encourage rest. Provide a quiet, calm environment. When the patient is less exhausted, can breathe easier, and is beginning to recover, try to obtain a history and do a physical assessment. If caregivers are present, they may be able to provide information about the patient's health history. This information is important in planning and implementing a patient-centered plan of care.

◆ Ambulatory Care

A major goal in asthma care is to maximize the patient's ability to safely manage an acute asthma episode using an asthma action plan (Fig. 31.11). Action plans are important for all people with asthma, especially those who have frequent, acute attacks. They are based on the patient's asthma symptoms and PEFR. The action plan dictates what symptoms or PEFR necessitate a change in asthma drug therapy to gain control.

The patient must measure PEFR at least daily. PEFR monitoring, when done correctly, is a reliable, objective measure of asthma control (Table 31.14). Some patients may not perceive minimal but important changes in their breathing. They may have a significant decrease in lung function without any noticeable symptoms other than a change in PEFR.

If a patient's PEFR is in the green zone (usually 80% to 100% of the patient's personal best), the patient should take their usual medications. A PEFR within the yellow zone (usually 50% to 80% of personal best) indicates caution. A PEFR in the red zone (50% or less of personal best) indicates a serious problem. In other words, something is triggering the patient's asthma (e.g., viral infection). The patient should seek out their HCP as soon as possible.

The written asthma action plan needs to clearly identify the "step-up" increase in medications during the acute phase of an infection. For example, the patient can use different strategies, such as using the low dose ICS more often. Although it may happen, it is unusual for a patient's PEFR to drop from the green zone to the red zone quickly. Usually, the patient has time to make changes in medications, avoid triggers, and notify the HCP. The dose is "stepped down" once the symptoms subside.

Involve caregivers in asthma action plans. They should know where to find the patient's medications. Teach them how to decrease the patient's anxiety if an asthma attack occurs. When the patient is stabilized or controlled, the caregiver can gently remind the patient about monitoring daily PEFR by asking questions, such as "What zone are you in?" or "How's your peak flow today?" A patient and caregiver teaching guide for the patient with asthma is shown in Table 31.15.

Exercise (e.g., swimming, walking, cycling) within the patient's limit of tolerance is beneficial. It may require pre-treatment with medication. Good nutrition and uninterrupted sleep are important. If a patient with asthma reports poor sleep because of symptoms, their asthma is not under good control and their plan should be re-evaluated. Encourage the patient to maintain a fluid intake of 2 to 3 L/day.

Validated questionnaires (e.g., Asthma Control Test [ACT] available at www.asthmacontroltest.com) can be used to assess quality-of-life. Patients may have frequent absences from school or work. They may have psychologic issues, such as stress, anxiety, and depression. Asthma support groups are available online and around the country. Relaxation therapies (e.g., yoga, meditation, breathing techniques) may help a patient lessen respiratory muscle workload and decrease the respiratory rate.

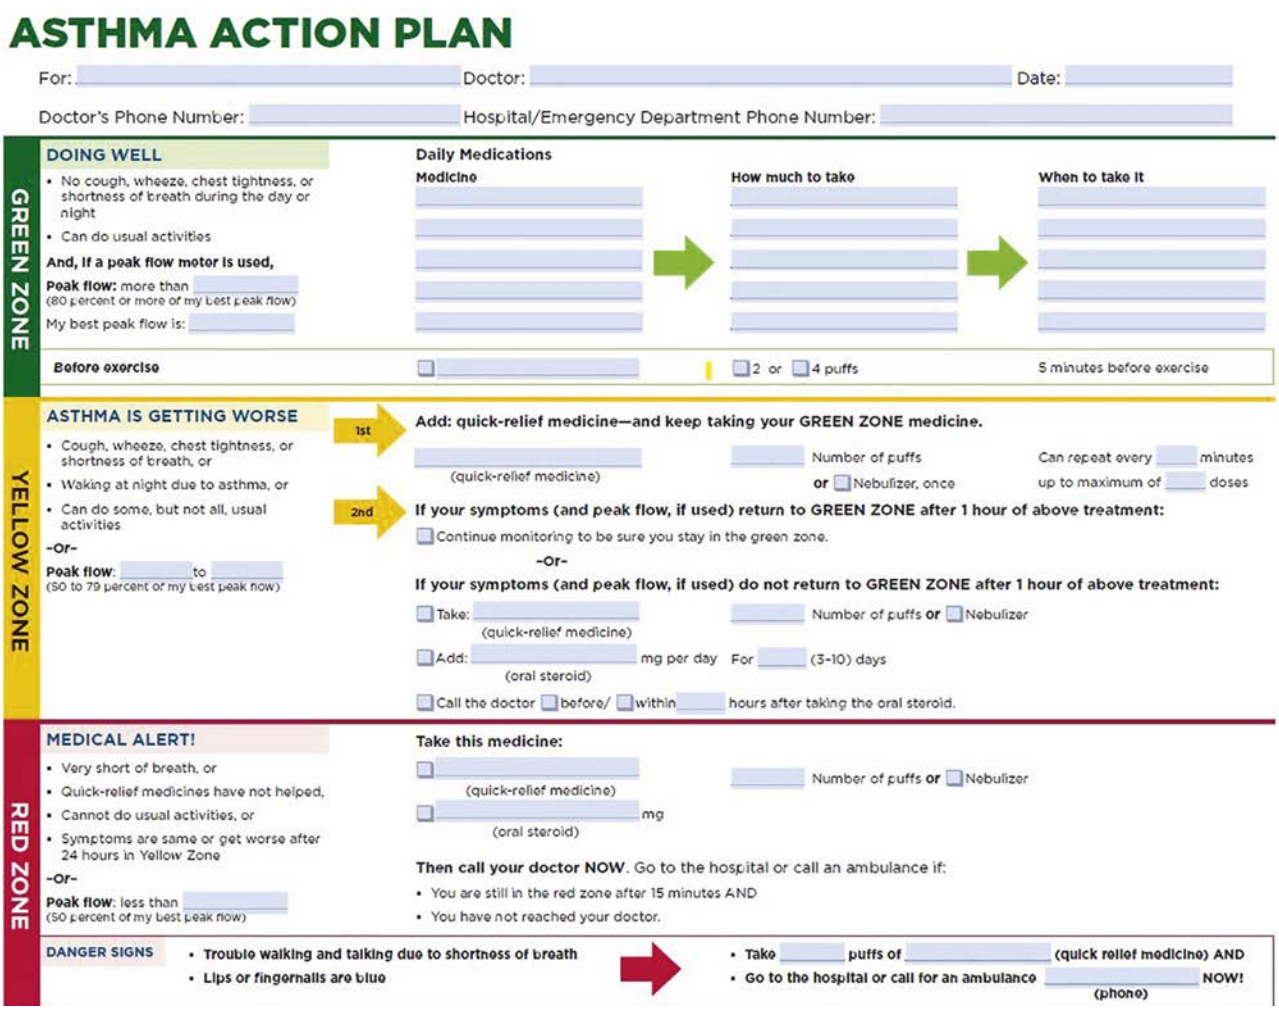


Fig. 31.11 Asthma action plan. (Source: National Heart, Lung, and Blood Institute, 2021, Bethesda, MD. Retrieved from https://www.nhlbi.nih.gov/health-topics/all-publications-and-resources/asthma-action-plan-2020.)

Disparities in socioeconomic status and access to health care may be part of the reason some people have poorly controlled asthma. Explore and try to eliminate any potential barriers to health care. Use culturally appropriate resources and educational material in languages other than English to help improve knowledge about asthma.

Patient Teaching Related to Drug Therapy

Two factors that promote successful asthma management include knowing about asthma drugs and taking them correctly. The drug regimen for asthma can be confusing and complex. Reinforcement and frequent repetition of key learning points are often needed.

Teach patients about their medications. Include the name, purpose, dose, method of administration, and when to use. Help the patient understand the differences between "controller," "preferred reliever," and "alternate reliever" drugs. They need to be able to monitor their response to therapy and know when symptoms are not improving and they need help. Review side effects and what to do if they occur. Teach patients about how to properly prime, use, and clean devices. Some patients may benefit from keeping a diary to record medication use, wheezing, or coughing, PEFR, side effects of drugs, and activity level. This information will help the HCP adjust the medication if needed.

Several factors can affect the correct use of inhalation devices. These include advanced age, changes in dexterity (e.g., arthritis in hands, coordination), cognition, affordability, convenience, and administration time and preference. A social service referral can help lower-income patients obtain access to care.

Make sure that patients understand how to use their inhaler device. Review package inserts with the patient. Give the patient printed instructions. At every visit, reassess their inhaler and device techniques and asthma action plan.

Adherence with drug therapy is a major challenge in the management of chronic asthma. Lack of adherence often occurs when the patient is symptom free and does not use drug therapy regularly because they do not feel an immediate benefit. The patient does not realize that the medications treat the ongoing inflammation that accompanies asthma. Explain the importance and purpose of taking the long-term agents. Stress that maximum improvement may take some time. Tell them that

TABLE 31.14 PATIENT & CAREGIVER TEACHING

How to Use Your Peak Flow Meter

Include the following instructions when teaching the patient to use a peak flow meter:

Why Use a Peak Flow Meter?

- A peak flow meter is a device that measures how well air moves out of your lungs.
- During an asthma episode, the airways of the lungs usually begin to narrow slowly. The peak flow meter may tell you if there is narrowing in the airways, sometimes even before asthma symptoms occur.
- By taking your medicines early (before symptoms), you may be able to stop an acute episode quickly and avoid a severe asthma attack.
- The peak flow meter is used to help you and your HCP:
  - Learn what makes your asthma worse.
  - Decide if your treatment plan is working well.
  - Decide when to add or stop medicine.
  - Decide when to seek emergency care.

How to Use Your Peak Flow Meter

1. Move the indicator to the bottom of the numbered scale.
2. Stand up.
3. Take a deep breath, filling your lungs completely.
4. Place the mouthpiece in your mouth and close your lips around it. Do not put your tongue inside the hole.
5. Blow out as hard and fast as you can in a single blow.
   - Write down the number you get. But if you cough or make a mistake, do not write down the number. Perform the action again.
   - Repeat steps 1 through 5 two more times. Write down the best (highest number) of the 3 blows in your asthma diary.

What is Your Personal Best Peak Flow Number?

- Your personal best peak flow number is the highest (peak flow) number you can achieve over a 2-week period when your asthma is under good control. Good control is when you feel good and do not have any asthma symptoms.
- Asthma is different for every patient. Your best peak expiratory flow rate (PEFR) may be higher or lower than the peak flow of someone of your height, weight, and gender. This means that it is important for you to test yourself and find your own personal best peak flow number, which is the basis for your treatment plan.
- To find your personal best peak flow number, take peak flow readings:
  - At least twice a day for 2–3 weeks, between 12 noon and 2 PM when your peak flow is the highest
  - 15 to 20 minutes after taking inhaled short-acting β_2-agonist (SABA) for quick relief
  - And as instructed by your HCP

The Peak Flow Zone System

Once you know your personal best peak flow number, your HCP will help you place the peak flow numbers into zones. Zones are set up like a traffic light (red, yellow, green). As you trend your peak flow numbers over time, this will help you know what to do when the number changes. For example:

- *Green Zone* (more than __L/min [80% of your personal best number]) signals good control. No asthma symptoms are present. Take your medicines as usual.
- *Yellow Zone* (between __ and __L/min [50% to <80% of your personal best number]) signals caution. If you stay in the yellow zone after several measures of peak flow, follow your plan, including taking any reliever medications. If you continue to register peak flow readings in the yellow zone, your asthma may not be under good control. Contact your HCP and ask if you need to change or increase your daily medicines.
- *Red Zone* (<__L/min [<50% of your personal best number]) signals a medical alert. Take your reliever medication right away. Call your HCP and ask what to do or go directly to the ED.

Use a Logbook to Keep Track of Your Peak Flow

- Record your personal best peak flow number and peak flow zones in your asthma logbook.
- Measure your peak flow when you wake up, *before* taking medicine. Write down your peak flow number in the diary every day, or as instructed by your HCP.

without regular use, swelling in the airways may progress and asthma will likely worsen over time.

◆ Evaluation

The expected outcomes are that the patient with asthma will

- Maintain patent airway with removal of secretions
- Have normal respiratory rate, unlabored breathing, and adequate breath sounds
- Report decreased anxiety with increased control of breathing
- Correctly use medications
- Manage asthma and acute asthma attacks with a written asthma action plan

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Chronic obstructive pulmonary disease (COPD) is a progressive lung disease characterized by persistent airflow limitation. COPD is associated with an enhanced chronic inflammatory response in the airways and lungs. The main causes are cigarette smoking and other noxious particles and gases. Exacerbations and other coexisting problems may contribute to the severity of the disease.

Previous definitions of COPD have included such terms as *chronic bronchitis* and *emphysema*. Each condition has features of COPD, but neither by itself is COPD. **Chronic bronchitis**

TABLE 31.15 PATIENT & CAREGIVER TEACHING

Asthma

Include the following information in a teaching plan for the patient with asthma and the caregiver to help to improve the patient's quality of life and promote lifestyle changes that support successful living with asthma:

What Is Asthma?
- Basic anatomy and physiology of lung
- Pathophysiology of asthma
- Relationship of pathophysiology to signs and symptoms
- Measurement and correlation of spirometry and peak expiratory flow rate

What Is Good Asthma Control?
- Personal ideas of good control
- Use the Asthma Control Test available at www.asthmacontroltest.com

Obstacles to Asthma Treatment and Control
- Discuss with patient and caregiver possible obstacles (e.g., denial, poor perception of asthma severity by patient, cost of medications)

Environment and Trigger Control
- Identify triggers and preventive measures (use trigger diary)
- Avoiding allergens and other triggers
- Need to maintain good hydration

Medications
- Classes (include mechanism of action)
- Terms: Controller, reliever, and alternate reliever
- Correct use of inhalers, spacer, and nebulizer
- Write out a medication list, identify schedule
- Asthma Action Plan (Fig. 31.11)

Pursed-Lip Breathing (see Chapter 28)
Correct Use of Peak Flow Meter (Table 31.14)
Asthma Action Plan (Fig. 31.11)
- Peak flow zones
- Patient-centered care asthma action plan with HCP and patient
- Early recognition of infection
- Building a partnership with the HCP

For more information, visit the American Lung Association website at www.lung.org/lung-disease/asthma.

is the presence of cough and sputum production for at least 3 months in each of 2 consecutive years. It is an independent disease that may precede or follow the development of airflow limitation. **Emphysema**, the destruction of alveoli without fibrosis, describes one of several structural abnormalities in COPD.

Around 16 million adults in the US have COPD.[24] The number of people with COPD is underestimated because the disease is usually not diagnosed until it is moderately advanced. COPD is the 3rd leading cause of death in the US, causing more than 140,000 deaths each year.[25]

Risk Factors

Many factors affect the development and progression of COPD (Box 31.3). Next, we discuss the most common risk factors.

BOX 31.3 BIOLOGIC SEX CONSIDERATIONS

COPD

Men
- COPD is slightly more common in men
- Have a poorer response to O_2 therapy

Women
- Prevalence of COPD is increasing
- The increase is likely due to more women smoking and increased susceptibility (e.g., smaller lungs and airways)
- Women who smoke are 50% more likely to develop COPD compared to men who smoke
- Women with COPD have a lower quality of life, more exacerbations, less phlegm, and increased dyspnea

TABLE 31.16 Effects of Tobacco Smoke on the Respiratory System

Area of Defect	Acute Effects	Long-Term Effects
Respiratory mucosa		
• Nasopharyngeal	↓ Sense of smell	Cancer
• Tongue	↓ Sense of taste	Cancer
• Vocal cords	Hoarseness	Chronic cough, cancer
• Bronchus and bronchioles	Bronchospasm, cough	Chronic bronchitis, asthma, cancer
Cilia	Paralysis, sputum accumulation, cough	Chronic bronchitis, cancer
Mucous glands	↑ Secretions, ↑ cough	Hyperplasia and hypertrophy of glands, chronic bronchitis
Alveolar macrophages	↓ Function	↑ Incidence of infection
Elastin and collagen fibers	↑ Destruction by proteases ↓ Function of antiproteases (α_1-antitrypsin) ↓ Synthesis and repair of elastin	Emphysema

Cigarette Smoking

The major risk factor for developing COPD is cigarette smoking. Of the 16 million people in the US who have COPD, around 38% report that they currently smoke.[26] COPD should be considered in any person who is over the age of 40 with a smoking history of 10 or more pack-years.

Cigarette smoke has several direct effects on the respiratory tract (Table 31.16). The irritating effect of smoke causes hyperplasia of cells, including goblet cells, increasing mucus production. Hyperplasia reduces airway diameter and makes it harder to clear secretions. Smoking reduces ciliary activity and may cause actual loss of cilia. Smoking causes abnormal dilation of the distal air space and destruction of alveolar walls. Many cells develop large, atypical nuclei, which we consider pre-cancerous. Smoking is the source of chronic, enhanced inflammation of various parts of the lung with structural changes and repair (*remodeling*) over time.

Cigarette smoking causes oxidative stress and an imbalance between proteases that break down connective tissue in the lung

and antiproteases that protect the lungs. These changes increase with more severe disease and persist even after the patient has stopped smoking. In adults, ETS can cause decreased lung function, increased respiratory symptoms, and severe lower respiratory tract infections (e.g., pneumonia). ETS increases the risk for nasal sinus and lung cancer.

Infection

Severe recurring respiratory tract infections in childhood are associated with reduced lung function and increased respiratory symptoms in adulthood. We are not sure if COPD is related to recurrent infections in adults. People who smoke and have human immunodeficiency virus (HIV) infection have faster development of COPD.[27] Tuberculosis is also a risk factor.

Asthma

Patients with COPD may have asthma. Asthma may be a risk factor for COPD. There is a considerable pathologic and functional overlap between asthma and COPD, especially among older adults, who may have components of both. We call this *asthma-COPD overlap syndrome*.

Air Pollution

High levels of urban air pollution are harmful to people with existing lung disease. The effect of outdoor air pollution as a risk factor for developing COPD is unclear. Another risk factor is exposure to coal and other biomass fuels people use for indoor heating and cooking. Many people who have never smoked are at increased risk because of cooking with these fuels in poorly ventilated areas.

Occupational Chemicals and Dusts

If a person has intense or prolonged exposure to various dusts, vapors, irritants, or fumes in the workplace, symptoms of lung impairment consistent with COPD can develop. If a person has occupational exposure and smokes, the risk for COPD increases significantly.

Aging

Many believe aging is a risk factor for COPD, but the research is not clear. Does the aging process lead to COPD? Or is COPD a result of cumulative exposures that occur over a lifetime?

Normal aging results in stiffening of the chest wall and decrease in exercise tolerance. The lungs gradually lose their elastic recoil. The thoracic cage becomes stiff and rigid, and the ribs are less mobile. The shape of the rib cage gradually changes because of the increased residual volume (RV), causing it to enlarge and become more rounded. Decreased chest compliance and loss of elastic recoil together affect the mechanical aspects of ventilation and increase the WOB. The number of functional alveoli decreases as peripheral airways lose supporting tissues. Over time, the surface area for gas exchange decreases and the PaO_2 decreases. Changes in the elasticity of the lungs reduce the ventilatory reserve. These age-related changes are similar to those seen in the patient with COPD.

BOX 31.4 GENETICS IN CLINICAL PRACTICE

α_1-Antitrypsin Deficiency

Genetic Basis

- Autosomal recessive disorder
- Gene provides instructions for the liver to make the protein α_1-*Antitrypsin* (AAT), which protects the lungs and liver from proteolytic enzymes
- Mutations in *SERPINA1* gene cause α_1-antitrypsin deficiency (AATD)
- Without enough functional AAT, proteolytic enzymes destroy alveoli and cause lung disease

Incidence

- Occurs in 1 in 3000–5000 live births in the US
- People of northern European and Iberian descent most affected

Clinical Implications

- AATD can cause lung and liver disease
- Disease onset and first diagnosis usually occurs between ages 30 to 45 years of age
- Disease predisposes to early-onset emphysema
- Purified AAT replacement therapy helps prevent worsening of the condition

Genetic Testing

- DNA testing is available
- Serum assay is available to measure the amount of AAT

Genetics

An intriguing question is why some smokers develop COPD and others do not. The fact that a small number of smokers get COPD suggests genetic factors may play a role in who develops COPD. Because of genetic-environment interaction, 2 people may have the same smoking history, but only 1 develops COPD. Genetics may play a role in why people who never smoked but were exposed to ETS over long periods of time develop COPD. We have identified 1 genetic factor: "Z" allele of the AAT protein.[28]

Alpha-1 Antitrypsin Deficiency

Alpha-1 (α1) antitrypsin deficiency (AATD) is an autosomal recessive disorder that may eventually affect the lungs and liver (Box 31.4). AAT is a protein made by the liver and normally found in the lungs. The main function of AAT is to protect lung tissue from attack by proteases during inflammation related to smoking and infections. Unfortunately, few people are tested for AATD until symptoms are present and they are seeking medical care. About 2% of all people diagnosed with COPD in the US have undetected AATD.[29] Smoking speeds the disease process in these patients. Genetic counseling may be appropriate for the patient with AATD who is planning to have children.

Pathophysiology

COPD is characterized by chronic inflammation of the airways, lung parenchyma (respiratory bronchioles and alveoli), and pulmonary blood vessels (Fig. 31.12). The pathophysiology of COPD is complex and involves many mechanisms. The defining feature of COPD is airflow limitation not fully reversible during

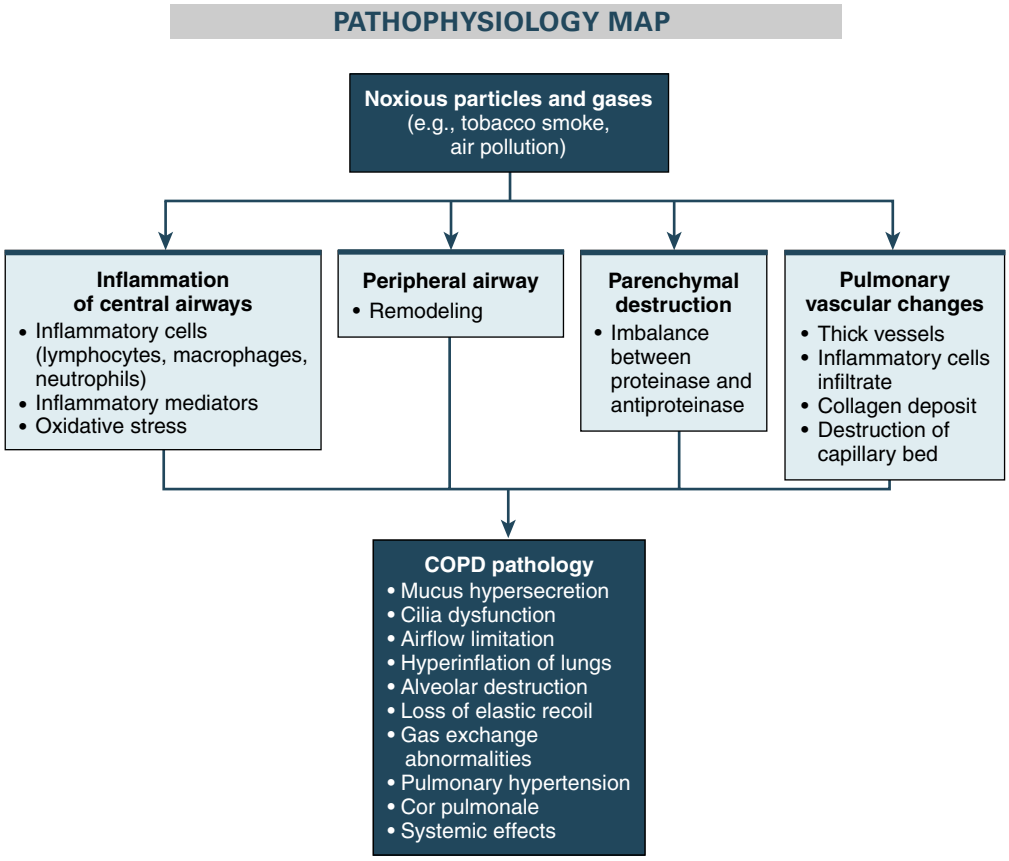

Fig. 31.12 Pathophysiology of COPD.

forced exhalation. The main cause is the loss of elastic recoil and airflow obstruction, from mucus hypersecretion, mucosal edema, and bronchospasm.

As the disease progresses, abnormalities in airflow limitation, air trapping, and gas exchange worsen. In severe COPD, pulmonary hypertension and systemic manifestations occur. COPD has an uneven distribution of pathologic changes. Severely impaired and/or destroyed areas of lung tissue exist alongside areas of relatively normal lung.

The inflammatory process most often starts with inhaling noxious particles and gases (e.g., cigarette smoke). With repeated exposure, chronic inflammation causes tissue destruction and disrupts the normal defense mechanisms and repair process of the lung. We do not clearly understand the exact mechanisms for the enhanced inflammatory response. In some people, it may be genetically determined.

The predominant inflammatory cells in COPD are neutrophils, macrophages, and lymphocytes. This is different from that of asthma, in which eosinophils, mast cells, neutrophils, lymphocytes, and macrophages are the main culprits. Inflammatory cells attract other inflammatory mediators (e.g., leukotrienes) and proinflammatory cytokines (e.g., tumor necrosis factor).

The inflammatory process may be increased by the oxidants made by cigarette smoke and other inhaled particles and released from the inflammatory cells. Oxidants adversely affect the lungs as they inactivate antiproteases (which prevent the natural destruction of the lungs), stimulate mucus secretion, and increase fluid in the lungs. A result of the inflammatory process is structural changes in the lungs.

After inhaling oxidants in tobacco or air pollution, the activity of proteases (which break down connective tissue of the lungs) increases and antiproteases (which protect against breakdown) are inhibited. So, the natural balance of protease/antiprotease is tipped in favor of alveolar destruction and loss of the lungs' elastic recoil.

Inability to expire air is a main characteristic of COPD. The main site of the airflow limitation is in the smaller airways. As the peripheral airways become obstructed, air is progressively trapped during expiration. The volume of residual air that is in the lungs at end expiration becomes greatly increased in severe COPD. As air is trapped in the lungs, the chest hyper-expands and becomes barrel shaped because the respiratory muscles cannot function effectively. As a result, functional residual capacity (FRC) is increased. The residual air, combined with the loss of elastic recoil, makes passive expiration of air difficult. The patient must now inhale when the lungs are in an "overinflated" state. As a result, the patient becomes dyspneic with limited exercise capacity.

Typically, the patient does not have problems with hypoxemia at rest until late in the disease. At first, hypoxemia may develop during exercise and the patient may benefit from supplemental O_2. Gas exchange problems result in hypoxemia and hypercapnia (increased CO_2) as the disease worsens. As the air trapping increases, walls of alveoli are destroyed (Fig. 31.13). Bullae (large air spaces in the parenchyma) and blebs (air spaces

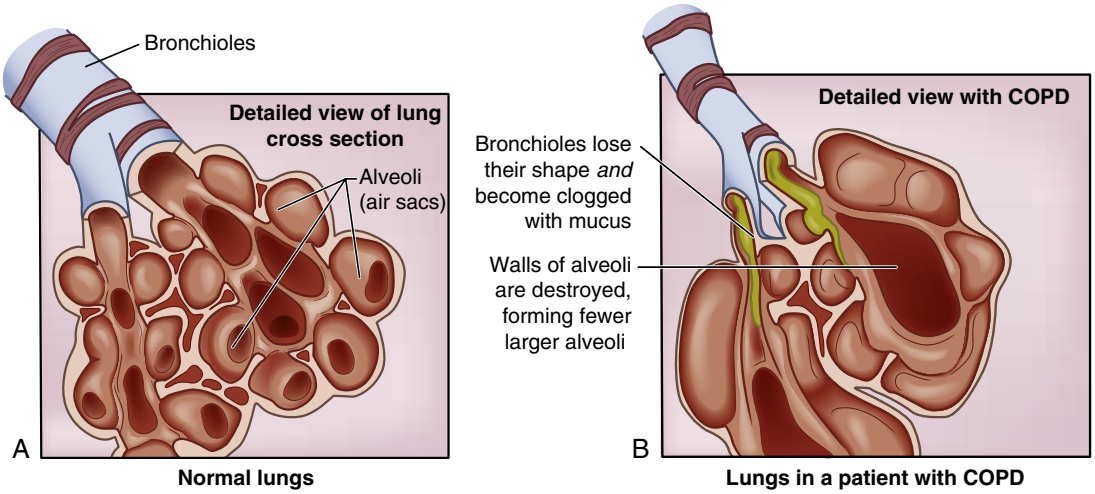

Fig. 31.13 (A) Normal lungs showing bronchioles and alveoli. (B) Changes in the bronchioles and alveoli in the lungs of a patient with COPD.

next to pleurae) can form in and on the lungs. Bullae and blebs are not effective in gas exchange because they do not contain a capillary that normally surrounds each alveolus. Therefore, a significant V/Q mismatch and hypoxemia result. Peripheral airway obstruction also results in V/Q imbalance and combined with respiratory muscle impairment leads to CO_2 retention, particularly in severe forms of the disease.

Excess mucus production, resulting in a chronic productive cough, is a feature of persons with predominant chronic bronchitis. However, not all COPD patients have sputum production. When present, excess mucus production results from an increased number of mucus-secreting goblet cells, enlarged submucosal glands, cilia dysfunction, and stimulation from inflammatory mediators.

Pulmonary vascular changes causing mild to moderate pulmonary hypertension may occur late in the course of COPD. The small pulmonary arteries vasoconstrict due to hypoxia. As the disease advances, the structure of the pulmonary arteries changes, resulting in thickening of the vascular smooth muscle. Because of the loss of alveolar walls and the capillaries surrounding them, pressure in the pulmonary circulation increases. Pulmonary hypertension may progress and lead to hypertrophy of the right ventricle. The right ventricle dilates and may lead to right HF.

Chronic inflammation is an underlying problem for many COPD patients. Common diseases, including osteoporosis and diabetes, have occurred.

Classification of COPD

We classify COPD as mild, moderate, severe, and very severe (Table 31.17). An FEV_1/FVC ratio of less than 70% establishes the diagnosis of COPD. The severity of obstruction (as shown by FEV_1) determines the stage of COPD. Management of COPD is based on the patient's symptoms, classification, and exacerbation history.

Clinical Manifestations

The manifestations of COPD typically develop slowly. A clinical diagnosis of COPD should be considered in any patient who has chronic cough or sputum production, dyspnea, and a history of exposure to risk factors for the disease (e.g., tobacco smoke, occupational dusts). It is sometimes hard to tell COPD from asthma, especially if the person has a history of smoking.

A chronic intermittent cough is often the first symptom. Patients often dismiss the cough as they associate it with smoking or environmental exposure. The cough may be productive. Significant airflow limitation may exist without cough or sputum. Typically, dyspnea is progressive, usually occurs with exertion, and is present every day.

Patients may report chest heaviness, not being able to take a deep breath, gasping, increased effort to breathe, and air hunger. They tend to ignore symptoms and rationalize that "I'm getting older" or "I'm out of shape." Some change behaviors to avoid dyspnea, such as taking the elevator instead of the stairs. Patients will seek medical care when dyspnea becomes severe or impairs their ability to complete ADLs.

In late stages of COPD, dyspnea may be present at rest. The patient must work harder to breathe. As more alveoli become overdistended, increasing amounts of air are trapped. This causes the diaphragm to flatten. Effective abdominal breathing is decreased because of the flattened diaphragm. As a result, the patient becomes more of a chest breather, relying on the intercostal and accessory muscles. Chest breathing is not particularly efficient, especially over long periods.

Wheezing and chest tightness may be present. These symptoms may vary by time of the day or from day to day, especially

TABLE 31.17 Diagnostic Criteria

Classification of COPD Severity

Classification	Level of Severity	FEV_1 Results
GOLD 1	Mild	FEV_1 ≥80% predicted
GOLD 2	Moderate	FEV_1 50%–80% predicted
GOLD 3	Severe	FEV_1 30%–50% predicted
GOLD 4	Very severe	FEV_1 <30% predicted

Adapted from Global strategy for diagnosis, management and prevention of COPD 2021. Retrieved from www.goldcopd.org. © Global Initiative for Chronic Obstructive Pulmonary Disease.

in those with severe disease. Chest tightness, which often follows activity, may feel like muscle contractions.

The person with advanced COPD often has fatigue, weight loss, and anorexia. Even with adequate caloric intake, the patient may still lose weight. Fatigue is a highly prevalent symptom that affects ADLs.

The expiratory phase is often prolonged. We may hear decreased breath sounds and/or wheezes in all lung fields. Because the anteroposterior diameter of the chest increases ("barrel chest") from the chronic air trapping, the patient may need to breathe louder than normal for us to hear breath sounds with a stethoscope. The patient may sit upright with arms supported on a fixed surface, such as an overbed table *(tripod position)*. They may naturally purse lips on expiration (pursed-lip breathing).

Over time, hypoxemia (PaO_2 less than 60 mm Hg or O_2 saturation less than 88% on room air) may develop with hypercapnia ($PaCO_2$ over 45 mm Hg). A bluish-red skin color results from polycythemia and cyanosis. Polycythemia develops from the increased production of red blood cells as the body tries to compensate for chronic hypoxemia. Hemoglobin concentrations may reach 20 g/dL (200 g/L) or more. Some persons, though, have low hemoglobin and hematocrit because of chronic anemia.

Complications

Primary complications of COPD include pulmonary hypertension, cor pulmonale, acute exacerbations, and ARF.

Pulmonary Hypertension and Cor Pulmonale

In COPD, the main cause of pulmonary hypertension is constriction of the pulmonary vessels from alveolar hypoxia. Chronic hypoxia stimulates red blood cell production, which causes polycythemia. This results in increased viscosity of the blood. These patients have increased pulmonary vascular resistance, and, as a result, develop pulmonary hypertension.

Normally, the right ventricle and pulmonary circulatory system are low-pressure systems compared with the left ventricle and systemic circulation. With pulmonary hypertension (pressure within the lungs increases), the pressures on the right side of the heart must increase to push blood into the lungs. Eventually, because the pressure in the lungs is so high, right HF develops.

Cor pulmonale results from pulmonary hypertension (Fig. 31.14). It is a late manifestation of COPD. Once the patient develops cor pulmonale, the prognosis worsens. Not all patients with COPD develop cor pulmonale.

Dyspnea is the most common symptom of chronic cor pulmonale. Lung sounds are normal, or crackles may be present in the bases. Heart sounds may include S_3, S_4, and systolic murmurs. Other manifestations of right HF may develop. These include distended neck veins, hepatomegaly with right upper quadrant tenderness, peripheral edema, and weight gain.

Typically, the patient has large pulmonary vessels on chest x-ray and increased pressure on the right heart.

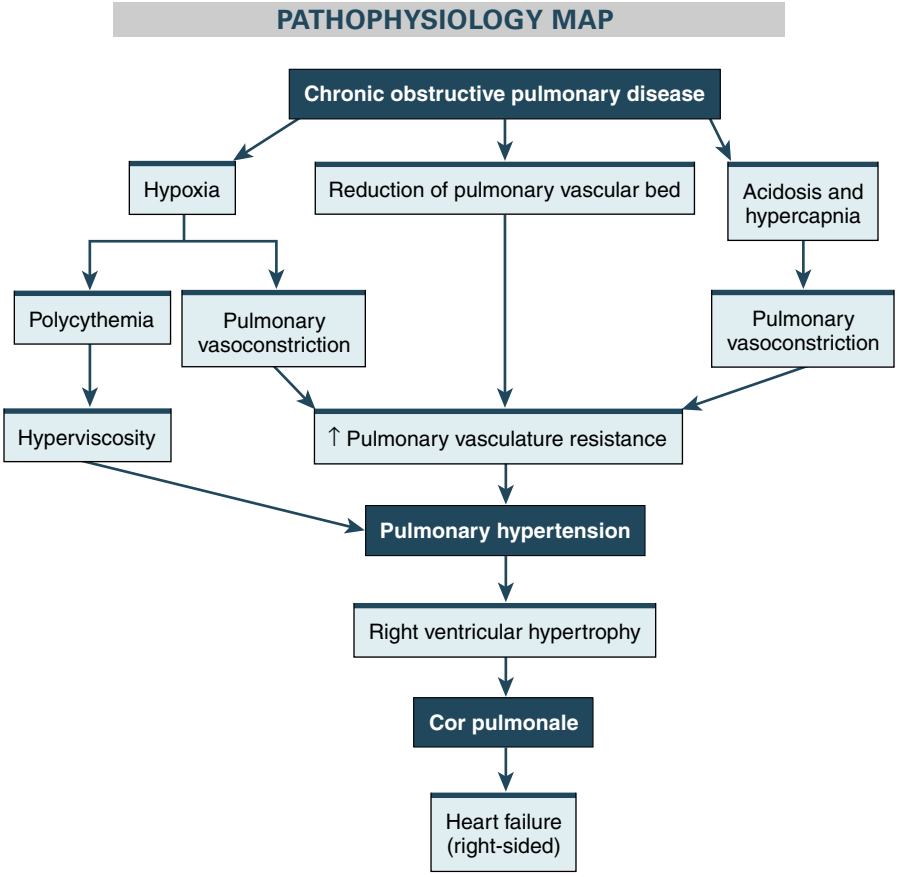

Fig. 31.14 Mechanisms involved in the pathophysiology of pulmonary hypertension and cor pulmonale from COPD.

The initial treatment of cor pulmonale is aimed at managing the underlying cause, including COPD. Continuous, long-term, low-flow O_2 therapy is often part of care. Diuretics may be given if left HF or pulmonary edema are present but must be used with caution. In some cases, decreases in fluid volume from diuresis can worsen heart function. Long-term anticoagulation therapy is started to help decrease the risk for venous thromboembolism (VTE). HF is the focus of Chapter 38.

Acute Exacerbations

An exacerbation of COPD is an acute event characterized by a worsening of the patient's respiratory symptoms. Exacerbations are signaled by a sudden change in the patient's usual dyspnea, cough, and/or sputum (e.g., something different from the usual daily patterns). Respiratory infections are a common cause.[30] Exacerbations are common and increase in frequency (on average 1 or 2 per year) as the disease progresses. As the severity of COPD increases, exacerbations are associated with poorer outcomes.

Acute Respiratory Failure

Patients with severe COPD who have severe exacerbations are at risk for ARF. Suddenly stopping a medication may cause ARF. All too often, COPD patients wait too long to contact their HCP when they first develop symptoms suggestive of an exacerbation. By the time the patient seeks out medical attention, their condition has worsened to the point that they need mechanical ventilation and ICU admission. ARF is discussed in Chapter 32.

Diagnostic Studies

A history and physical assessment are important in the diagnostic workup. Validated questionnaires, such as the COPD Assessment Test (www.catestonline.org) or Clinical COPD Questionnaire (www.ccq.nl), help assess symptoms.

Spirometry confirms the diagnosis in those suspected of having COPD. It confirms the presence of airflow obstruction and determines the severity of COPD. A diagnosis of COPD is made when the FEV_1/FVC ratio is less than 70%.[31] The FEV_1 value is a guideline for the degree of severity of COPD. The lower the FEV_1, the more obstructed are the airways.

Other diagnostic studies that may be done are outlined in Table 31.18. Chest x-rays often show a flat diaphragm because of hyperinflated lungs. Patients often have exercise-induced hypoxemia. A physical or respiratory therapist may do a 6-minute walk test. During this test, pulse oximetry readings are taken when the patient is walking and at rest. If values of O_2 saturation are 88% or lower when at rest and the patient is breathing room air, they qualify for O_2 therapy.

We usually monitor ABGs in patients hospitalized with acute COPD exacerbations. ABGs help identify the severity of the exacerbation by assessing abnormal oxygenation. In early stages, there may be a normal or only slightly decreased PaO_2 and usually a normal or slightly increased $PaCO_{2\ level}$. In the later stages of COPD, typical findings are a low-normal pH, high-normal or above-normal $PaCO_2$, and high-normal bicarbonate (HCO_3^-). This may indicate either partially or fully compensated respiratory acidosis. In a fully compensated state, the kidneys conserve HCO_3^- to increase the pH to within the normal range.

An ECG may be normal or show signs of right HF. An echocardiogram or (MUGA) (cardiac blood pool) scan can evaluate heart function. Sputum for culture and sensitivity may be done if an infection, such as pneumonia, is suspected.

- Spirometry
- ABGs
- 6-Min walk test
- Serum α_1-antitrypsin levels
- COPD Assessment Test (CAT) or Clinical COPD Questionnaire (CCQ)

Management

- Smoking cessation
- Drug therapies (Tables 31.9 and 31.19)
- Airway clearance techniques
- Breathing exercises and retraining
- Hydration of 2–3 L/day (if not contraindicated)
- Immunizations: Influenza, pneumococcal, COVID-19
- Long-term O_2 (if indicated)
- Progressive exercise plan, especially walking and upper body strengthening
- Pulmonary rehabilitation program
- Nutrition supplements
- Treatment of complications
  - Pulmonary hypertension
  - Cor pulmonale
  - Acute exacerbations
  - ARF
- Surgical therapy (if suitable candidate, based on age, medical history, severity and stage of COPD)
  - Lung volume reduction
  - Bullectomy
  - Lung transplant

Interprofessional Care

Most patients with COPD are treated as outpatients. They are hospitalized for an acute exacerbation of COPD or complications, such as pneumonia, HF, or ARF.

Oxygen Therapy

O_2 therapy is often part of the treatment of COPD. It is the only treatment linked to improved survival.[32] For most patients, the goal of O_2 therapy is to keep the SaO_2 greater than 90% during rest, sleep, and exertion or the PaO_2 greater than 60 mm Hg. These goals may be modified for the patient with moderate to severe COPD. For example, based upon the patient's condition, the HCP may accept a SaO_2 or PaO_2 greater than 88%.

Drug Therapy

Drug therapy for COPD can reduce symptoms, increase exercise capacity, and improve overall health. This will hopefully

TABLE 31.19 Drug Therapy

Suggested Options for COPD Treatment

	Fewer Daily Symptoms	More Daily Symptoms
Less than 2 exacerbations, no hospitalizations	Short-acting β-2 agonist (SABA) OR Long-acting β-2 agonist (LABA)	LAMA or LABA
More than 2 exacerbations, 1 hospitalization	Long-acting muscarinic agents (LAMA)	LAMA or LABA and LAMA or LABA and ICS

reduce the number and severity of exacerbations. Choice of drug therapy is based on several factors. These include the patient's symptoms, how quickly they occur, FEV_1 results, the perceived risk of or number of exacerbations, and the ability to maintain spontaneous ventilation.[33] Table 31.19 shows suggestions for drug therapy.

Like asthma, medications are given in a stepwise fashion. In COPD, they are usually stepped up. Stepping down is rare because continual symptoms are present. The inhaled route is preferred. Changes in therapy are usually based on symptoms and repeated exacerbations.[33]

Bronchodilator drug therapy relaxes bronchial smooth muscle in the airway and improves the ventilation of the lungs, thus reducing the degree of breathlessness. Bronchodilator therapy is the first-line treatment for most patients. They do not respond as dramatically to bronchodilator therapy as those with asthma. However, bronchodilator therapy reduces dyspnea and increases FEV_1.

Bronchodilator drugs commonly used are β_2-adrenergic agonists, anticholinergics, and, to a much lesser extent, methylxanthines (Table 31.8). The choice of bronchodilator depends on the patient's response. These drugs are given on a scheduled or as-needed basis.

A short-acting β_2-adrenergic agonist (SABA) is a mainstay of COPD treatment. The most common SABA is albuterol. LABAs are often can be used as monotherapy. Salmeterol and formoterol are widely used LABAs.

Anticholinergics block the action of acetylcholine on the muscarinic receptors in the smooth muscle of the bronchotracheal tree. The most common short-acting muscarinic agent (SAMAs) is ipratropium bromide. For the patient who needs a drug with a more prolonged effect, long-acting muscarinic agents (LAMAs) such as tiotropium are an option.

Combining short-acting bronchodilators with anticholinergic medications into 1 "combination" drug may help improve bronchodilation of the airways and potentially decrease the risk for side effects. Albuterol and ipratropium can be nebulized together or delivered by inhalation spray (Combivent Respimat).

Depending upon the severity of symptoms and stage of COPD, regular treatment with ICS may be prescribed. However, unlike asthma, an ICS is not used as monotherapy in COPD because of the side effects. An ICS is often combined with a LABA for enhanced effect. Examples of combinations of ICSs with LABAs are fluticasone/salmeterol (Advair) and budesonide/formoterol (Symbicort). Oral corticosteroids should not be used for long-term therapy in COPD but are effective for short-term use to treat acute exacerbations.

We rarely use methylxanthines such as theophylline because of the development of newer drugs. The methylxanthines have serious side effects. Careful monitoring is needed. Theophylline interacts with many drugs and has a very narrow therapeutic window. A low dose of theophylline with an ICS may help a few patients who do not respond to other inhaled medications.

Roflumilast (Daliresp) is an oral agent used to decrease exacerbations in patients with severe COPD and chronic bronchitis. It is an antiinflammatory drug used for long-term therapy. It does not treat acute problems.

Mucolytic agents, such as NAC, may be used for COPD patients who have an acute exacerbation. They have antiinflammatory and mucolytic properties. NAC may help improve overall health and quality of life in some patients.

Inhaled long-acting anticholinergics, LABAs, and ICSs all help reduce COPD exacerbations. Some patients with COPD are on "triple therapy," which includes a LABA, LAMA, and ICS. Fluticasone/umeclidinium/vilanterol is one example of a "triple therapy" agent. New drugs and delivery devices are becoming available at a rapid pace for the treatment of patients with COPD.

Respiratory Care

Teaching the patient with COPD breathing retraining exercises is important. The 2 main types of breathing retraining exercises are (1) pursed-lip breathing and (2) diaphragmatic breathing (see Table 28.1). Diaphragmatic breathing in some patients with COPD may increase the WOB and dyspnea.

Many patients have ineffective coughing patterns that do not clear their airways of sputum. We can teach the patient ways to cough effectively to bring the secretions to the central airways to expectorate them. Effective coughing techniques are discussed in Chapter 28.

ACTs loosen mucus and secretions so they can be cleared by coughing (see Chapter 28). ACTs are especially helpful in patients who have a COPD exacerbation. They are often used in conjunction with other treatments. Typically, the patient receives bronchodilator therapy through an inhaler device (e.g., nebulizer) before ACT. Then, the ACT is used, followed by effective coughing (e.g., huff coughing). Airway clearance devices can also help mobilize secretions (see Chapter 28).

Nutrition Therapy

Many COPD patients with advanced disease are underweight with loss of muscle mass and cachexia. Weight loss, malnutrition, and muscle dysfunction can affect quality of life and contribute to increased mortality.[34] Factors that contribute to malnutrition include increased inflammatory mediators, increased metabolic rate from ventilatory effort, and lack of appetite. Other factors include taste changes caused by chronic mouth breathing, excess sputum, fatigue, anxiety, depression, and drug side effects.

There is no specific diet for the patient with COPD. Consensus is that a well-balanced diet that includes fresh fruits,

whole grains, and vegetables is best.[34] A diet high in protein, moderate in carbohydrates, and moderate to high in fat is recommended for most patients. Meals can be divided into 5 or 6 small portions a day. Offer high-protein and moderate calorie nutrition supplements between meals. The dietitian is an excellent resource for what combination of nutrients and supplements are best.

Underweight patients need extra protein and calories. They may need 25 to 45 kcal/kg body weight and more than 1.5 g of protein/kg body weight to maintain their weight. The patient with malnutrition may need up to 2.5 g of protein/kg of body weight to maintain muscle mass.

To decrease dyspnea and conserve energy, the patient should rest for at least 30 minutes before eating and use a bronchodilator before meals. Teach the patient to avoid exercise and treatments for at least 1 hour before and after eating. If a patient desaturates while eating, O_2 therapy by nasal cannula may help. Encourage activity, such as walking, to stimulate appetite.

Getting the patient to eat adequate amounts of nutritionally sound foods may be difficult. Teach the patient or those responsible for meal preparation ways to make mealtime easier and more nutritious by increasing calories and protein without increasing the amount of food eaten (Table 31.20).

Surgical Therapy

Various surgical procedures can help manage severe COPD. However, it is important to remember that many patients with severe COPD are not candidates for surgery.

One type of surgery is *lung volume reduction surgery* (LVRS). The goal of LVRS is to reduce the size of the lungs by removing some of the diseased lung tissue so that the remaining healthy lung tissue can perform better. Reducing the diseased lung tissue by about 30% results in decreased airway obstruction and increased room for the remaining normal alveoli (small air sacs at the end of each bronchiole) to expand and function.[35] Besides improving lung and chest wall mechanics, LVRS can allow the diaphragm to return to its normal shape. This allows the patient to breathe more efficiently.

Another surgical procedure is *bronchoscopic lung volume reduction (BLVR)*. It involves placing multiple 1-way valves, by bronchoscopy, in the airways leading to the diseased parts of the lung. The valves allow air to leave the lung during exhalation and prevent air from entering during inspiration. By completely occluding a specific area of the lung, this collapses that area. BLVR produces a result similar to LVRS.[36] Pneumothorax is a common complication.

In a *bullectomy*, 1 or more very large bullae are removed. Removal of bullae helps decrease WOB. A lung transplant helps a very small number of patients with advanced COPD. Although single-lung transplant is most common because of a shortage of donors, a bilateral transplant can be done. Lung transplants are discussed in Chapter 28.

TABLE 31.20 NUTRITION THERAPY

Maximizing Food Intake in COPD

- Eat high-calorie foods first.
- Limit liquids at mealtimes.
- Rest before meals.
- Try more frequent meals and snacks.
- Try cold foods, which can make you feel less full than hot foods.
- Keep ready-prepared meals available for times when you have increased shortness of breath.

NURSING MANAGEMENT: COPD

Assessment

Subjective and objective data that you should obtain from a person with COPD are outlined in Table 31.21.

Clinical Problems

Clinical problems for the patient with COPD may include:

- Impaired respiratory function
- Activity intolerance
- Nutritionally compromised
- Ineffective coping

Additional information on clinical problems and interventions is presented in eNursing Care Plan 31.2 available on the website for this chapter.

Planning

The overall goals are that the patient with COPD will have (1) relief from symptoms, (2) ability to perform ADLs and improved exercise tolerance, (3) no complications related to COPD, (4) knowledge and ability to implement a long-term treatment plan, (5) prevention of disease progression, and (6) overall improved quality of life.

Implementation

Health Promotion

The incidence of COPD would decrease dramatically if people would not begin smoking or would stop smoking. Counseling the patient in smoking cessation is vital. It is the only way to slow the progression of the disease. After a person stops smoking, the fast decline in lung function found with smoking slows to almost non-smoking levels. The sooner the smoker stops, the less lung function is lost and the sooner the symptoms decrease, especially cough and sputum production. Smoking cessation is discussed in Chapter 11.

Nurses who smoke should evaluate their own smoking behavior and its relationship to their health. Nurses and other HCPs who smoke should be aware that the odor of smoke is obvious on their clothes and hair. It can be offensive or tempting to patients.

People with COPD should avoid others who are sick, practice good hand-washing techniques, take drugs as prescribed, exercise regularly, and maintain a healthy weight. The patient is very susceptible to lung infections. Early treatment of respiratory tract infections and COPD exacerbations helps prevent progression and complications of COPD. They should receive influenza and COVID-19 vaccinations. The pneumococcal

TABLE 31.21 NURSING ASSESSMENT

COPD

Subjective Data

Important Health Information

Health history: Long-term exposure to chemical pollutants, respiratory irritants, occupational fumes, dust; recurrent respiratory tract infections; previous hospitalizations

Medications: Use of O_2 (include frequency and duration of O_2 use), bronchodilators, corticosteroids, antibiotics, anticholinergics, OTC drugs, illicit substances

Functional Health Patterns

Health perception–health management: Smoking (pack-years, including passive smoking, willingness to stop smoking, and previous attempts); what was smoked (e.g., cigarettes, pipes, cigars, e-cigarettes); family history of respiratory disease (especially α_1-antitrypsin deficiency [AATD])

Nutritional-metabolic: Anorexia, weight loss or gain

Activity-exercise: Increasing dyspnea and/or increase in sputum volume or purulence; fatigue, ability to perform ADLs; swelling of feet; progressive dyspnea, especially on exertion; ability to walk up 1 flight of stairs without stopping; wheezing; recurrent cough; sputum production (especially in the morning); orthopnea

Elimination: Constipation, gas, bloating

Sleep-rest: Insomnia; sitting up position for sleeping, paroxysmal nocturnal dyspnea

Cognitive-perceptual: Headache, chest or abdominal soreness

Coping–stress tolerance: Anxiety, depression

Objective Data

Cardiovascular

Tachycardia, dysrhythmias, jugular venous distention, distant heart tones, right HF, S_3 (cor pulmonale), pedal edema

General

Debilitation, restlessness, upright position

GI

Ascites, hepatomegaly (cor pulmonale)

Musculoskeletal

Muscle atrophy, ↑ anteroposterior diameter (barrel chest)

Respiratory

Rapid, shallow breathing
Prolonged expiratory phase; pursed-lip breathing
Use of accessory muscles
↓ Chest excursion and diaphragm movement
Wheezing, crackles, decreased or bronchial breath sounds inability to speak

Skin

Cyanosis (bronchitis), pallor or ruddy color, digital clubbing, poor skin turgor, thin skin, easy bruising; peripheral edema (cor pulmonale)

Possible Diagnostic Findings

Abnormal ABGs (compensated respiratory acidosis, ↓ PaO_2 or SaO_2, ↑ $PaCO_2$), pulmonary function tests showing expiratory airflow obstruction (e.g., low FEV_1, low FEV_1/FVC. Chest x-ray: flattened diaphragm and hyperinflation with/without infiltrates. Echocardiogram: Large right ventricle. Polycythemia

vaccine is recommended for all smokers ages 19 or older and all patients with COPD.

Avoiding or controlling exposure to occupational and environmental pollutants and irritants is another preventive measure to maintain healthy lungs. Assess exposure to environmental or occupational irritants. Determine ways to control or avoid them. For example, teach the patient to avoid smoke-filled rooms and air pollutants.

◆ Acute Care

The patient with COPD may need hospitalization for other complications, such as cor pulmonale or ARF or an acute exacerbation. Exacerbations may be treated at home or in the hospital, depending on severity. The severity is determined by the patient's history leading up to the exacerbation, symptoms, hemodynamic stability, O_2 requirements, WOB, ABGs, and the presence of co-existing diseases. The presence of other problems often complicates exacerbations.

The nursing management of the patient with an acute COPD exacerbation is outlined in Table 31.22. Assess patients for manifestations of exacerbation, including increased dyspnea, increased sputum volume, or increased sputum purulence. They may have malaise, insomnia, fatigue, depression, confusion, decreased exercise tolerance, increased wheezing, or fever.

Are these new symptoms or worsening of usual symptoms? Be alert for signs of severity, such as using accessory muscles, central cyanosis, edema in the lower extremities, unstable BP, right HF, and altered alertness. Assess ABGs for respiratory acidosis and worsening hypoxemia, indicating an "acute-on-chronic" respiratory failure. Ask about the number of exacerbations per year and if treatment occurred in the home or hospital.

SABAs and oral systemic corticosteroids are the usual treatments for exacerbations. SABAs with short-acting anticholinergics are an option. Drug administration by MDI or nebulizer works equally well. Sicker patients often prefer the nebulizer. Antibiotics are given if the exacerbation is caused by a bacterial infection (e.g., pneumonia). Patients with HF may receive small doses of diuretics.

In the hospital, most patients receive O_2 therapy. We try to use non-invasive mechanical methods (e.g., bi-level positive airway pressure [Bi-PAP]) to support ventilation rather than invasive ventilatory support. If needed, the patient will receive mechanical ventilation.

Once the immediate crisis has resolved, reassess the degree and severity of any underlying problems. The information obtained will help in planning care going forward and assist with changes in the treatment plan that may be needed after discharge.

◆ Ambulatory Care

The health care team works together to formulate a patient-centered treatment plan. The most important aspect in the long-term care of the patient with COPD is teaching. A large part of your role is to help the patient self-manage their disease. A patient and caregiver teaching guide is shown in Table 31.23.

TABLE 31.22 NURSING MANAGEMENT

Acute COPD Exacerbation

Regularly monitor indicators of respiratory function:
- Vital signs with SpO_2
- Auscultate lung sounds; note respiratory rhythm and WOB
- ABGs (as needed)
- Manifestations of hypoxia

Give drug therapy as ordered, included bronchodilators, diuretics, and/or antibiotics

Place the patient in high-Fowler's or other position to optimize respiratory function

Give IV fluids as ordered and encourage fluids as tolerated

Promote adequate rest periods, such as 90 minutes of undisturbed sleep and limited visitors, as needed.

Ensure adequate nutrition with small frequent meals and supplements

Provide measures to promote comfort and reduce anxiety

Evaluate the patient's response to treatment

Be prepared to institute resuscitation protocols and respiratory support

Notify the HCP should the patient's condition worsen

Provide patient and caregiver teaching about COPD (Table 31.23)

Supervise AP
- Assist with hygiene and ADLs as needed
- Provide frequent oral hygiene and encourage oral fluids
- Obtain daily weights, vital signs, and intake and output

Collaborate With Interprofessional Team Members

Respiratory Therapist
- Administer O_2 therapy
- Provide chest physiotherapy
- Monitor respiratory status

Dietitian
- Assess nutrition status
- Recommend interventions to meet patient's nutrition needs
- Provide instructions for diet changes as needed

Physical Therapist
- Assess current level of fitness
- Assist with ambulation and exercise

Social Worker
- Assist with obtaining medical equipment after discharge
- Assist with financial resources

Stress the importance of regular follow-up appointments. Regular follow-ups help us monitor response to treatment and see if any changes must be made. Each visit is an opportunity for you to discuss nonpharmacologic approaches to manage COPD to further enhance the treatment plan. Teach the patient and caregiver early recognition of the 3 main manifestations of exacerbations (increased dyspnea, increased sputum volume, increased sputum purulence) to promote early treatment. This may prevent hospitalization and ARF.

Pulmonary rehabilitation. Pulmonary rehabilitation can be done in an inpatient or outpatient setting or in the home.

TABLE 31.23 PATIENT & CAREGIVER TEACHING

COPD

Include the following information in the teaching plan to assist the patient with COPD and the caregiver to improve quality of life through promoting lifestyle practices that support successful living with COPD:

What Is COPD?
- Basic anatomy and physiology of lung
- Basic pathophysiology of COPD
- Signs and symptoms of COPD, acute exacerbation
- How to tell COPD from the common cold, flu, pneumonia
- Tests to assess breathing

Breathing and Airway Clearance Exercises
- Pursed-lip breathing (see Chapter 28)
- Airway clearance technique: huff cough (see Chapter 28)

Energy Conservation Techniques
- Daily activities (e.g., waking up, bathing, grooming, shopping, traveling)
- Consult with physical therapist and occupational therapist

Medications
- Types (include class, mechanism of action, types of devices)
- Establishing medication schedule
- Correct use of inhalers, spacer, and nebulizer
- Reason for use of O_2 equipment
- Guide for home O_2 use and equipment

Psychosocial Support

Allow opportunity for open discussion (with patient and/or caregiver, depending on patient comfort level)
- Worries about dependency
- Problems with emotions (e.g., depression, anxiety, panic)
- Concerns about interpersonal relationships (e.g., intimacy)
- Worry about chronic condition and fear of dying
- Treatment decisions and end-of-life issues
- Support and rehabilitation groups

COPD Management Plan

Nurse, patient, and other health care team members, as necessary develop and write up COPD management plan that meets patient needs.
- Focus on self-management
- Reduce risk factors, especially smoking cessation
- Exercise program of walking and arm strengthening
- Recognition of signs and symptoms of respiratory infection, HF
- Need to report changes in condition
- Cause of acute exacerbations
- Importance of annual flu vaccinations
- Importance of yearly follow-up

Nutrition Support (Table 31.20)
- Ways to lose weight (if overweight)
- Ways to gain weight (if underweight)
- Dietitian consult

For more information, see American Lung Association at www.lung.org/lung-disease/copd.

Components vary. They usually include exercise training, smoking cessation, nutrition counseling, and teaching. Physical therapists or nurses with experience in respiratory care are often responsible for managing pulmonary rehabilitation. Pulmonary rehabilitation is generally indicated for any degree of airway obstruction or GOLD classification. It works best if the patient starts when COPD is in a moderate stage, but even patients who have advanced COPD can benefit. Outcomes include relief of dyspnea and fatigue, improved emotional function, and enhanced sense of control that people have over their COPD.

Pulmonary rehabilitation may be inaccessible to some because of location, cost, disability, or transportation. One alternative program to in-person rehabilitation uses the Internet or gaming technology. The HCP must assess each patient and approve the program to ensure patient safety.

Activity. The patient with severe COPD typically uses upper thoracic and neck muscles to breathe rather than the diaphragm. Thus, the patient may have difficulty with upper extremity activities, especially those that require raising the arm above the head. Exercise training may improve muscle function and help to reduce dyspnea. It also leads to energy conservation, which is an important part of COPD rehabilitation.

Often, the patient is already using some alternative energy-saving practices for ADL. Ask about and explore alternative methods of hair care, shaving, showering, and reaching. In severe COPD, the patient should try to sit as much as possible when performing activities. If the patient uses home O_2 therapy, O_2 should be used during hygiene because these tasks are energy consuming. The occupational therapist is an excellent resource for activity suggestions.

Encourage the patient to make a schedule and plan daily and weekly activities, leaving plenty of time for rest periods. Another energy-saving tip is to exhale when pushing, pulling, or exerting effort during an activity and inhale during rest.

Regular exercise is important (Box 31.5). To ensure long-term adherence, the exercise plan must be appropriate and safe for the patient and easy to perform. Walking or other endurance exercises (e.g., stationary cycling, treadmills at a slow rate) combined with strength training are the best ways to strengthen muscles and improve endurance. Many patients with moderate or severe COPD are anxious and fearful of walking or performing exercise. Teach the patient coordinated walking with slow, pursed-lip breathing. Both patients and caregivers need support while they build the confidence they need to walk, perform daily exercises, or help with these activities.

Developing exercise endurance is important. If it takes longer than 5 minutes to return to baseline, the patient has most likely "overdone it." They should go at a slower pace during the next exercise period. Keeping a diary or log of the exercise program may help.

Patients often ask whether moving to a warmer or drier climate will help. In general, such moves are generally not beneficial. Discourage moves to places with an elevation of 4000 ft or more because of the lower partial pressure of O_2 found in the air at higher elevations. Other disadvantages of moving may be that a person leaves a job, friends, and familiar environment, which could be stressful. This may outweigh any advantage gained from being in a different climate.

BOX 31.5 EVIDENCE-BASED PRACTICE

Physical Activity and Chronic Obstructive Pulmonary Disease

You are working as a nurse in a pulmonary clinic with N.T., a 71-year-old man who was just discharged from the hospital with a new diagnosis of COPD. He tells you he has been inactive for most of the past 8 months because "my breathing seems to worsen with any type of activity."

Making Clinical Decisions

Best Available Evidence

Patients with COPD who take part in regular moderate activity (e.g., brisk walking) have fewer severe flare-ups and are less likely to be admitted or re-admitted to the hospital. Activity improves lung function and lessens depressive symptoms. The season of the year and temperature can be barriers to outdoor exercise.

Clinician Expertise

Physical inactivity is common in patients with COPD. You are aware that inactivity may place N.T. at a greater risk for functional decline and readmission.

Patient Preference and Values

N.T. tells you that he misses taking walks every day with his wife and dog. He is wondering if he would be able to resume this activity at a slower pace.

Implications for Practice

1. What factors will you discuss with N.T. about activity and COPD?
2. How would you assess N.T.'s willingness and motivation to engage in activity?
3. How would you involve interprofessional team members to assist N.T. in regular activity?

Reference

da Silva MMC, Arcuri JF, Di Lorenzo VAP: Individualized, low-cost and accessible pulmonary rehabilitation program based on functional clinical tests for individuals with COPD, *Trials* 22:367, 2021.

Psychosocial care. Coping is a challenge for the patient and family. As COPD progresses, patients are often confronted with many lifestyle changes that may involve decreased ability to care for themselves, decreased energy for social activities, and loss or change in a job.

When a patient is first diagnosed or has complications that require hospitalization, expect a variety of responses. Emotions often expressed include denial, anger, frustration from perceived or real increased dependence, and loneliness from social isolation. Guilt may result if the disease is related to smoking.

Patients experience losses as the disease progresses. Because many patients have depression and anxiety, assess for both. Ask patients if they "feel down" or "feel blue." Do they appear anxious about being able to control their breathlessness? Do they know what to do if they have an exacerbation? Are they showing concern over more difficulty in self-care activities, such as preparing meals and bathing? How is the family coping?

It is important to convey a sense of understanding and caring. Teach patients about COPD and their treatment, which can help provide a sense of control. The patient may benefit from stress management techniques (e.g., massage, muscle relaxation). Include caregivers so they can help the patient

cope. Support groups at local American Lung Association chapters (e.g., the Better Breathers Club), hospitals, and clinics can be helpful.

A mental health referral may be needed for proper screening and diagnosis of depression or other problems. Cognitive and behavioral therapy may improve quality of life. Drugs may be used to treat both depression and anxiety. When the patient becomes anxious because of dyspnea, pursed-lip breathing and SABAs may be appropriate.

Sexuality and sexual activity. Modifying sexual activity can contribute to well-being. First, assess if the patient has any concerns related to sexuality and functioning. Ask open-ended questions to assess if the patient wants or is willing to discuss their concerns with you. For example, you could ask, "How does your shortness of breath affect your desire for intimacy with your partner?" This type of general, open-ended question gives the patient an opportunity to discuss concerns with you.

Dyspnea, the predominant symptom in COPD, should not be a major problem in sexual activity, except for patients in severe late stages. Generally, if the patient can walk up 2 flights of stairs or walk briskly, they should have enough energy for sexual activity. The patient with heart disease should discuss appropriate levels of activity with their HCP. Using an inhaled bronchodilator before sexual activity can help ventilation. Other suggestions that may be helpful: (1) plan sexual activity during the part of the day when breathing is best, which is usually late morning or early afternoon; (2) use slow pursed-lip breathing; (3) refrain from sexual activity after eating or drinking alcohol; (4) choose less stressful positions (e.g., side-lying); and (5) use O_2 if prescribed.

Most patients with COPD are older. Their sexual performance issues may be related to aging. This is a good opportunity to teach the patient about the normalcy of age-related changes. Encourage open communication between partners about their needs, expectations, and any problems they encounter.

Sleep. Adequate sleep is important to maintain quality of life and productivity. Most patients with COPD have sleep problems. Current tobacco use, depression, and anxiety are all common in COPD and lead to more trouble sleeping. β_2-Agonists may cause restlessness and insomnia. Postnasal drip or nasal congestion may cause coughing and wheezing at night.

Hyperinflation of the lungs and reduction in ventilation can result in severe drops in O_2 saturation (down to 60% or less) during sleep. This leads to an increased workload on the heart. Hypercapnia may contribute to more frequent awakening. The net result is sleeping poorly and waking up unrefreshed and fatigued.

Nasal saline sprays or rinses before sleep and in the morning may help. If the patient is prescribed O_2 therapy, using it at night may decrease insomnia. If the patient is a restless sleeper, snores, stops breathing while asleep, and tends to fall asleep during the day, the patient may need testing for sleep apnea (see Chapter 8).

End-of-life considerations. The trajectory of COPD is a gradual decline in health characterized by increasing exacerbations with an increased risk of death. In the later, severe stages of this disease, palliative, end-of-life, and hospice care are important components of care for the patient with advanced COPD.

Patients need to know that symptoms can be managed, but COPD cannot be cured. End-of-life issues and advance directives are important topics for discussion in the latter stages of COPD. This may be hard for the patient and family to consider because of the uncertainty of the disease.

◆ Evaluation

The expected outcomes are that the patient with COPD will

- Maintain a patent airway by effectively coughing
- Maintain an effective rate, rhythm, and depth of respirations
- Have clear breath sounds
- Return to pre-exacerbation baseline respiratory function
- Have $PaCO_2$ and PaO_2 values within normal for the patient
- State ways to promote an optimal level of functioning with ADLs

Gerontologic Considerations: COPD

Older adults have physiologic changes, including reduced lean body mass, decreased respiratory muscle strength, increased dyspnea, and lower exercise tolerance that may increase the burden of disease from COPD. This may lead to a higher incidence of acute exacerbations, which require hospitalization. Smoking cessation is a key intervention but may be hard to achieve. Older adults may have difficulty handling increased secretions during an exacerbation.

COPD is often complicated by the presence of other problems, such as diabetes, heart disease, hypertension, osteoporosis, impaired cognition, and lung cancer. These problems can make it harder for patients to cope with the stress of an exacerbation. Some drugs used to treat common problems, such as hypertension, can worsen COPD symptoms. If possible, we avoid using nonspecific β-blockers since they can block the β_2 receptors in the airway and cause bronchoconstriction. ACE inhibitors may cause a dry cough or worsen a present cough.

Drugs used to manage an exacerbation can complicate disease management and increase the chance of adverse events. Assess for potential drug-drug interactions, especially in patients being treated for other problems.

Cognitive impairment and complex medication plans can contribute to nonadherence. Writing action plans in large font and setting reminders can help patients with poor memory and vision problems. Arthritis can hinder the person from using proper techniques for MDIs. Review MDI technique during visits. Have DPI or spacers prescribed (if possible) because they are easier to use.

Older patients with COPD often have impaired quality of life. An important role for us is to focus on ways to improve quality of life. Psychologic support becomes imperative to help patients achieve successful outcomes. In the later stages of COPD, palliative and hospice care can help manage symptoms and improve the quality of the rest of their lives (Box 31.6).

BOX 31.6 ETHICAL/LEGAL DILEMMAS

Advance Directives

Situation

L.H., an 84-year-old man with end-stage COPD, is admitted to the hospital in ARF. He is placed on full support mechanical ventilation and transferred to the ICU. L.H. is making no spontaneous breaths. He infrequently responds by opening his eyes, sometimes to the sound of voice, and other times only to painful stimuli. A chest x-ray shows pneumonia in both lungs. Antibiotics are ordered. A Foley drains a small amount of cloudy, dark amber urine.

L.H. had his advance directives (AD) drawn up 5 years ago. Copies were given to his wife and HCP at that time. His wife brings the documents to the ICU and tells you that the hospital must stop treating her husband. She insists that per his AD, the health care team should allow him to die. However, their oldest son, who lives out of state and is currently on his way to see his dad, tells you over the telephone that he will file a lawsuit against the hospital if they do not provide full care to his father.

Ethical/Legal Points for Consideration

- A living will permits persons to share their preferences and refusals should they become terminally ill or be in a situation in which there is no hope of recovery and they cannot speak for themselves.
- The durable power of attorney for health care permits persons to name a proxy to make health care decisions in the event the person is incapacitated.
- AD laws vary from state to state concerning the need for witnesses and naming the proxy.
- Families may be divided about decisions for their loved ones. Conflicts often arise when feelings of remorse or guilt and money and/or property are involved. This situation requires you to notify the HCP, engage social work and spiritual care, and ask for a family conference. In some circumstances, a consult from the ethics committee may be needed.
- HCPs are obligated to follow the patient's AD when a patient is no longer able to speak for themselves.
- In your scope of nursing practice, you may need to (1) teach patients and families about ADs; (2) make AD documents available to patients; (3) determine if all involved HCPs are aware of the patient's AD; (4) assist the patient and family in communicating with the HCP when a "no code" or "DNR" (do not resuscitate) order is requested; and (5) assist the conflicted family in obtaining appropriate counseling when needed.
- You need to be aware and informed about the decision-making laws and regulations in your state about ADs and your role with respect to ADs.

Discussion Questions

1. What should you do with the information provided by L.H.'s wife?
2. The HCP asks that you organize a family conference. How would you address the family's needs at the conference?
3. What other health care team members could you invite to the meeting to help facilitate discussion and decision making?
4. The family conference does not go well. While L.H.'s wife accepts her husband's end-stage COPD diagnosis, the son does not. The wife and son have different views on how L.H.is to be managed. What would be your approach to L.H.'s plan of care? How might you involve the family members in L.H.'s plan of care?

Case Study

COPD

(© iStockphoto/Thinkstock.)

Patient Profile

H.M. a 68-year-old female patient, has been in the hospital for 6 days with an acute COPD exacerbation (GOLD 3 [severe]). She was admitted after 4 days of increasing shortness of breath. She noted an increased volume of sputum. It was initially white but turned "greenish." H.M. is scheduled for discharge tomorrow. Her 73-year-old husband will care for her at home.

Subjective Data

Preadmission

- Husband said her skin tone looked "bluish"
- Increased Ventolin HFA use at home to 5 or 6 times a day for dyspnea
- Described having "jitters" and "racing heart"

Medical History

- Had 3 or 4 COPD exacerbations in the past year that were managed at home
- 30 pack-year history of smoking; smokes half a pack per day now to "clear out lungs" in the morning
- Eats a regular diet but "gets full fast"
- Cannot climb 1 flight of stairs without stopping; is able to walk down the flat driveway about 20 ft (6 m) without difficulty
- Awakens 2–3 times per night coughing and short of breath
- Sleeping in the recliner sitting upright
- Last spirometry: decreased FEV_1 (48%) and FEV_1/FVC (62%)

Objective Data

Emergency Department

Physical Assessment

- Weight 129 lb (58.5kg), height 5 ft 8 in (172cm), BMI 20 kg/m^2
- Temp 100°F (37.8°C), pulse 86 (regular), respiratory rate 28 (shallow, slightly labored), BP 136/76 mm Hg
- Increased anteroposterior diameter of chest
- Slight use of accessory neck muscles with breathing
- Distant breath sounds with occasional expiratory wheezes
- 2+ non-pitting pedal edema

Diagnostic Studies

- ABG: pH 7.34, $PaCO_2$ 59 mm Hg, HCO_3^- 27 mEq/L, PaO_2 68 mm Hg
- WBC: 16,500/μL
- Chest x-ray: hyperinflation, flat diaphragm, no sign of pneumonia
- Sputum: negative (no organisms present)

24.Hours Post-Admission to Hospital

- ABG: pH 7.30, $PaCO_2$ 63 mm Hg, HCO_3^- 29 mEq/L, PaO_2 64 mm Hg

Interprofessional Care

- O_2 @ 4 L/min via nasal catheter
- Prednisone 40 mg/day PO for 5 days
- Doxycycline 100 mg/day PO for 10 days

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Continued

Case Study—cont'd

COPD

- Ipratropium HFA MDI 2 puffs 4 times a day
- Lasix 10 mg po twice daily
- At discharge: Advair Diskus 250/50 one inhalation q12hr

Discussion Questions

1. ***Recognize:*** What manifestations show H.M. had a COPD exacerbation?
2. ***Analyze:*** What is the most likely cause of her exacerbation?
3. ***Analyze:*** Why would H.M. "feel full fast" when eating? What could you do to address this issue?
4. ***Analyze:*** What symptoms indicate overuse of inhalers? Which drug would cause the symptoms described?
5. ***Analyze:*** Interpret the ABG on admission and 24 hours post-admission. In comparing both ABGs, do you see a pattern?
6. ***Prioritize:*** Based on the assessment data presented, what are the priority clinical problems?
7. ***Act:*** What is one suggestion you could make to H.M. that could halt the progression of her COPD?
8. ***Act:*** What should you include in her discharge planning and teaching?
9. Develop a conceptual care map for H.M.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The nurse teaches a patient with bronchiectasis that which problem would warrant a call to the clinic?"
   a. Blood clots in the sputum
   b. Sticky sputum on a hot day
   c. Producing large amounts of sputum daily
   d. Increased shortness of breath after eating a large meal

2. Which treatment(s) would the nurse expect to implement in the management plan of an adult patient with cystic fibrosis? *(select all that apply)*
   a. Airway clearance techniques
   b. Bronchodilators and mucolytics
   c. Pancreatic enzyme replacement
   d. IV corticosteroids on a chronic basis
   e. Inhaled tobramycin to combat *Pseudomonas* infection

3. A 37-year-old patient is concerned they have asthma. Of the symptoms they describe to you, which ones suggest asthma or risk factors for asthma? *(select all that apply)*
   a. Prolonged inhalation
   b. Gastric reflux or heartburn
   c. Cough worse at night or early in the morning
   d. History of allergic rhinitis or chronic sinusitis
   e. Chest pain and syncope after exercising with a stationary bicycle for 5 minutes

4. Which finding indicate that a patient with asthma is developing status asthmaticus? *(select all that apply)*
   a. Anxiety and panic
   b. Positive sputum culture
   c. Unable to speak in complete sentences
   d. Chest x-ray shows hyperinflated lungs
   e. Lack of response to conventional treatment

5. Which statement indicates the patient with asthma requires further teaching about self-care?
   a. "I use my corticosteroid inhaler every time I feel short of breath."
   b. "I get a flu shot every year and see my HCP if I have an upper respiratory tract infection."
   c. "I use my inhaler before I visit my aunt who has a cat, but I only visit for a few minutes because of my allergies."
   d. "I walk 30 minutes every day, but sometimes I have to use my bronchodilator inhaler before walking to prevent me from getting short of breath."

6. Which medication would be appropriate to administer to a patient experiencing an acute asthma attack?
   a. IV theophylline
   b. Montelukast (Singulair)
   c. Inhaled hypertonic saline
   d. Albuterol (Proventil HFA)

7. The plan of care for the patient with chronic obstructive pulmonary disease (COPD) would include *(select all that apply)*
   a. exercise such as walking.
   b. high flow rate of O_2 administration.
   c. low-dose oral corticosteroid therapy.
   d. use of monthly chest x-rays to monitor the progression of COPD.
   e. breathing exercises, such as pursed-lip breathing that focus on exhalation.

8. What would the nurse include when teaching a patient how to use a metered-dose inhaler (MDI)?
   a. After activating the MDI, breathe in as quickly as you can.
   b. Estimate the amount of remaining medicine in the MDI by floating the canister in water.
   c. Disassemble the plastic canister from the inhaler and rinse both pieces under running water every week.
   d. To determine how long the canister will last, divide the total number of puffs in the canister by the puffs needed per day.

1. a; 2. a, b, c, e; 3. b, c, d; 4. a, c, e; 5. a; 6. d; 7. a, c, e; 8. d.

Acute Respiratory Failure and Acute Respiratory Distress Syndrome

Eugene E. Mondor

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Acid-Base Balance
Anxiety
Gas Exchange

LEARNING OUTCOMES

1. Discuss the etiology, pathophysiology, and clinical manifestations of hypoxemic and hypercapnic acute respiratory failure (ARF).
2. Describe the nursing and interprofessional management of hypoxemic and hypercapnic respiratory failure.
3. Discuss the pathophysiology and clinical manifestations of acute respiratory distress syndrome (ARDS).
4. Describe the nursing and interprofessional management of ARDS.
5. Identify interventions to prevent and manage complications of ARF and ARDS.

KEY TERMS

acute respiratory distress syndrome (ARDS)
acute respiratory failure (ARF)
alveolar hypoventilation
chronic respiratory failure (CRF)
hypercapnic respiratory failure
hypoxemia
hypoxemic respiratory failure
hypoxia
PaO_2/FIO_2 (P/F) ratio
permissive hypercapnia
refractory hypoxemia
shunt
V/Q mismatch
work of breathing (WOB)

This chapter discusses acute respiratory failure (ARF) and acute respiratory distress syndrome (ARDS). The management of patients with ARF and ARDS focuses on interventions to promote adequate oxygenation, ensure effective ventilation, identify and treat the underlying causes, and prevent complications. When respiratory function is insufficient, it affects all body systems.

ACUTE RESPIRATORY FAILURE

The major function of the respiratory system is gas exchange. **Acute respiratory failure (ARF)** occurs when oxygenation, ventilation, or both are inadequate. ARF is not a disease. It is a symptom that reflects insufficient lung function (Fig. 32.1). In ARF, not enough O_2 is transferred to the blood, or inadequate CO_2 is removed from the lungs. ARF occurs with problems involving the lungs or other body systems (Table 32.1).

Conditions that interfere with diffusion of O_2 result in **hypoxemia**. This causes a decrease in arterial O_2 (PaO_2) and saturation (SaO_2) to less than the normal values. Insufficient CO_2 removal results in hypercapnia. This causes an increase in arterial CO_2 ($PaCO_2$). We use arterial blood gases (ABGs) to assess changes in pH, PaO_2, $PaCO_2$, bicarbonate, and SaO_2. We use pulse oximetry to assess arterial O_2 saturation (SpO_2).

We classify ARF as hypoxemic or hypercapnic (Fig. 32.2). **Hypoxemic respiratory failure** is a PaO_2 less than 60 mm Hg (on room air and at sea level) with either normal or slightly subnormal $PaCO_2$ levels.[1] In hypoxemic respiratory failure (also called *oxygenation failure*), the main problem is the inadequate exchange of O_2 between the alveoli and pulmonary capillaries. The PaO_2 level shows an inadequate amount of oxygen in arterial blood (O_2 saturation). This low PaO_2 level may exist despite supplemental O_2.

Hypercapnic respiratory failure (or *ventilatory failure*) is a $PaCO_2$ greater than 50 mm Hg, which may be accompanied by hypoxemia and/or acidemia (arterial pH less than 7.35).[2] The main problem is insufficient CO_2 removal. This causes the

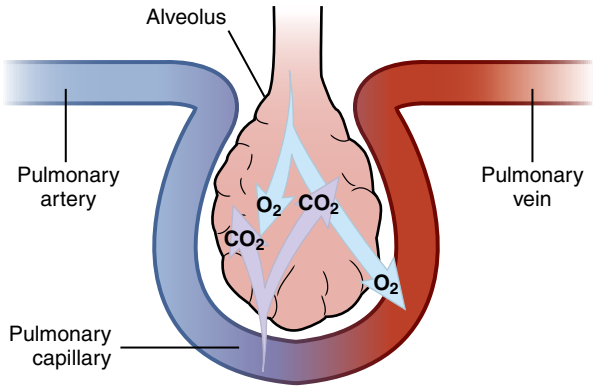

Fig. 32.1 Normal gas exchange unit in the lung: the alveolus and pulmonary capillary.

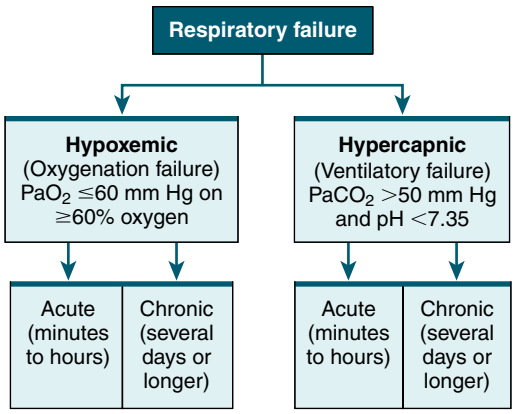

Fig. 32.2 Classification of ARF.

TABLE 32.1 Common Causes of ARF

Hypoxemic Respiratory Failure	Hypercapnic Respiratory Failure
ARDS	**ARDS**
Asthma	**Asthma**
Chronic bronchitis	**Chronic bronchitis**
Emphysema	**Emphysema**
Pulmonary edema	**Pulmonary edema**
Respiratory system	**Respiratory system**
• Bronchiectasis	• COPD
• Hepatopulmonary syndrome (e.g., low-resistance flow state, V/Q mismatch)	• Cystic fibrosis
• Pneumonia	• Hypoventilation syndrome (causes include CNS, obesity, chest wall, and neuromuscular)
• Pneumothorax	• Upper airway obstruction
• Pulmonary embolism (e.g., thrombus emboli, fat emboli)	**Chest wall**
• Pulmonary Fibrosis	• Kyphoscoliosis
• Toxic inhalation (e.g., smoke inhalation)	• Pain
Cardiac	• Severe obesity
• Anatomic shunt (e.g., ventricular septal defect)	• Thoracic trauma (e.g., flail chest)
• Cardiogenic pulmonary edema	**CNS**
• Cardiogenic shock (decreasing blood flow through pulmonary vasculature)	• Brainstem injury or infarction
• High CO states: diffusion limitation	• Sedative and opioid overdose
	• Severe head injury
	• Spinal cord injury
	Neuromuscular
	• Amyotrophic lateral sclerosis
	• Critical illness polyneuropathy
	• Guillain-Barré syndrome
	• Muscular dystrophy
	• Multiple sclerosis
	• Myasthenia gravis
	• Phrenic nerve injury
	• Poliomyelitis
	• Toxin exposure or ingestion

$PaCO_2$ to be higher than normal. As the $PaCO_2$ level climbs, the body will eventually be unable to compensate for the increase. This causes acidemia to worsen.

Significant changes in PaO_2 and $PaCO_2$ may occur with ARF. These develop over several minutes to a few hours to 1 or 2 days. The patient may have hemodynamic instability (e.g., tachycardia, hypotension), increased respiratory effort, and decreased level of consciousness. Urgent intervention is needed. On the other hand, **chronic respiratory failure** (CRF) develops more slowly, over days to weeks. The patient is usually more stable as the body had time to compensate for the small but subtle changes. CRF does not typically present as an immediate, life-threatening condition.

Patients may have both types of respiratory failure at the same time. For example, a patient with chronic obstructive pulmonary disease (COPD) who has pneumonia can have "acute-on-chronic" respiratory failure. Here, the patient has an underlying chronic respiratory problem. The new infection, when added to the chronic problem, results in the "acute-on-chronic" clinical picture.

Etiology and Pathophysiology

Hypoxemic Respiratory Failure

Four physiologic mechanisms may cause hypoxemia and hypoxemic respiratory failure: (1) mismatch between ventilation (V) and perfusion (Q), referred to as **V/Q mismatch**; (2) shunt; (3) diffusion limitation; and (4) alveolar hypoventilation. The most common causes are V/Q mismatch and shunt.

Ventilation-perfusion mismatch. In normal lungs, the volume of blood perfusing the lungs and the amount of gas reaching the alveoli are almost identical. So, when you compare normal alveolar ventilation (4 to 6 L/min) to pulmonary blood flow (4 to 6 L/min), you have a V/Q ratio of 0.8 to 1.2.[3] In a perfect match, ventilation and perfusion yield a V/Q ratio of 1:1, expressed as V/Q = 1. When the match is not 1:1, a V/Q mismatch occurs.

This example implies that ventilation and perfusion are perfectly matched in all areas of the lung. This situation does not normally exist. In reality, some regional mismatch occurs. For example, at the apex of the lung, V/Q ratios are greater than 1 (more ventilation than perfusion). At the base of the lung, V/Q ratios are less than 1 (less ventilation than perfusion). Because changes at the lung apex balance changes at the base, the net effect is a close overall match (Fig. 32.3).

Many problems can cause a V/Q mismatch (Fig. 32.4). The most common are those in which increased secretions are present in the airways (e.g., COPD) or alveoli (e.g., pneumonia) or bronchospasm is present (e.g., asthma). V/Q mismatch may result from pain, alveolar collapse (atelectasis), or pulmonary emboli.

V/Q	PaO_2	$PaCO_2$
3.3	132	28
1.0	108	39
0.63	89	42

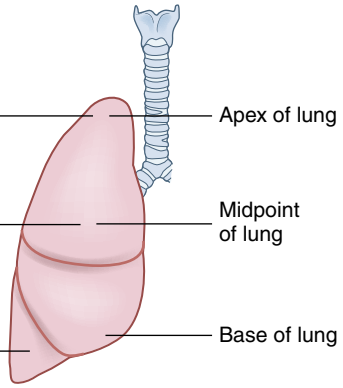

Fig. 32.3 Regional V/Q differences in the normal lung. The PaO_2 is higher at the apex of the lung and lower at the base. Values for $PaCO_2$ are the opposite (i.e., lower at the apex and higher at the base). Blood that exits the lung is a mixture of these values.

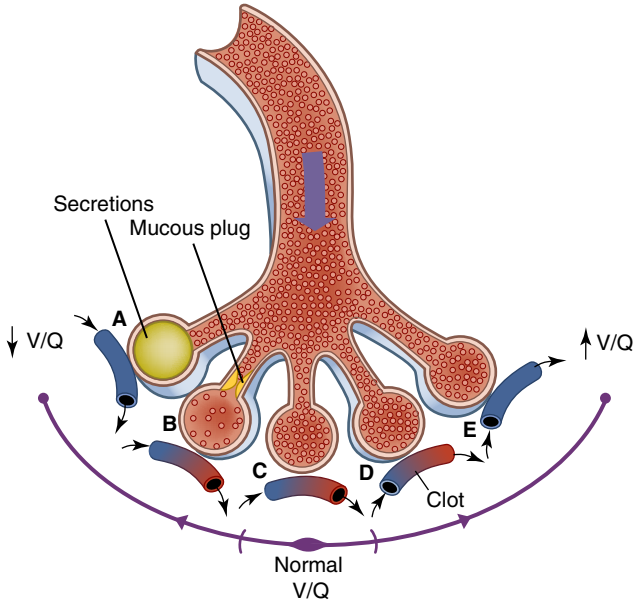

Fig. 32.4 Causes of V/Q mismatch. (A) Absolute shunt: no ventilation occurs because of fluid filling the alveoli. (B) Ventilation partially compromised by secretions in the airway. (C) Normal lung unit. (D) Perfusion partially compromised by emboli obstructing blood flow. (E) Dead space, no perfusion because of obstruction of the pulmonary capillary.

Pain interferes with chest and abdominal wall movement and increases muscle tension. This can compromise ventilation. The patient may be unwilling to take big, deep breaths. As a result, short, shallow respirations contribute to the development of atelectasis. This is the beginning of a V/Q mismatch. At the same time, pain activates the stress response, increasing baseline metabolic state. O_2 consumption and CO_2 production (as a by-product of cell and tissue metabolism) increase. The increased O_2 demand, increased CO_2 levels, and decreased O_2 supply all increase ventilation demands. Since there is no effect on blood flow to the lungs, the V/Q mismatch worsens.

Pulmonary emboli affect perfusion. When a pulmonary embolus occurs, it limits blood flow distal to the occlusion. Some areas of normal lung ventilation remain, but there is decreased perfusion to other parts from the vessel occlusion. This results in a V/Q mismatch. If the embolus is large enough to block a major pulmonary artery, it can cause severe hemodynamic instability.

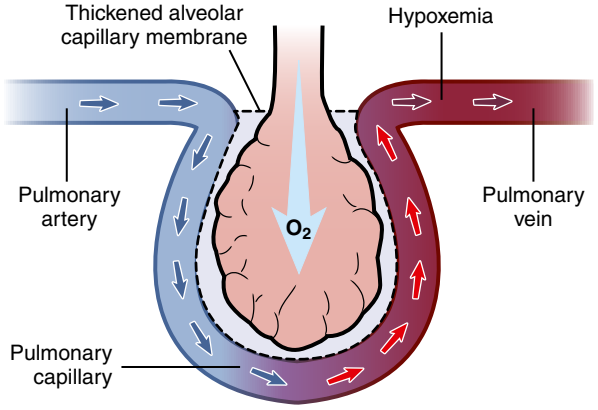

Fig. 32.5 Diffusion impairment. Reduced exchange of CO_2 and O_2 because of the thickened alveolar-capillary membrane.

The best way to treat hypoxemia caused by a V/Q mismatch is to treat the cause. O_2 therapy is an appropriate first step to reverse hypoxemia. Most patients with a hypoxemic V/Q mismatch will respond to O_2 therapy. Frequent ABG analysis, pulse oximetry, and continuous assessment of level of consciousness, respiratory rate and rhythm, and response to O_2 therapy are important.

Shunt. A **shunt** occurs when blood exits the heart without having taken part in gas exchange. A shunt is an extreme V/Q mismatch. There are 2 types of shunt: anatomic and capillary. An *anatomic shunt* occurs when blood passes through an anatomic channel in the heart (e.g., a ventricular septal defect) and bypasses the lungs.[4] A *capillary shunt* occurs when blood flows through the pulmonary capillaries without taking part in gas exchange.[4] It occurs in conditions where the alveoli fill with fluid (e.g., pneumonia) and gas exchange is severely impaired at the alveolar-capillary membrane.

O_2 therapy alone is not effective at increasing the PaO_2 if hypoxemia is due to shunt. Patients with a shunt are usually more hypoxemic than patients with V/Q mismatch. They often need mechanical ventilation with a high fraction of inspired O_2 (FIO_2) to improve gas exchange.

Diffusion impairment. *Diffusion impairment* occurs when gas exchange across the alveolar-capillary membrane is compromised by a process that damages or destroys the alveolar membrane or affects blood flow through the pulmonary capillaries (Fig. 32.5).[5] Conditions that cause the alveolar-capillary membrane to become thicker (fibrotic) slow gas transport. These include pulmonary fibrosis, interstitial lung disease, and ARDS. The accumulation of fluid, white blood cells, or protein in the alveoli contributes to a decrease in gas exchange between the alveolus and capillary bed. This occurs with pulmonary edema.

The classic sign of diffusion impairment is hypoxemia that worsens with exercise but not at rest. With exercise, blood moves quickly through the lungs. This decreases the time for O_2 diffusion across the alveolar-capillary membrane. Diffusion impairment can occur in conditions where CO is markedly

increased (e.g., high-output heart failure [HF]). As blood circulates rapidly through the pulmonary capillary bed, there is less time for gas exchange, and hypoxemia occurs.

Alveolar hypoventilation. **Alveolar hypoventilation** is a decrease in ventilation that increases the $PaCO_2$. Common causes include central nervous system (CNS) problems, chest wall dysfunction, acute asthma, or restrictive lung disease. Although alveolar hypoventilation is mainly a mechanism of hypercapnic respiratory failure, it contributes to hypoxemia.

Interrelationship of mechanisms. Rarely is acute hypoxemic respiratory failure caused by a single factor. More often, it is a combination of 2 or more factors. For example, the patient with ARF from pneumonia may have a V/Q mismatch and shunt. Inflammation, edema, and exudate obstruct the airways (V/Q mismatch) and fill the alveoli with exudate (shunt). Contributing factors include increases in O_2 demand from anxiety and unrelieved pain.

Consequences of Hypoxemia

Hypoxemia can lead to hypoxia if not corrected. **Hypoxia**, a decrease in O_2 supply at the cellular level, occurs when the PaO_2 falls enough to cause signs and symptoms of inadequate oxygenation. If hypoxia is severe, the cells shift from aerobic to anaerobic metabolism. Anaerobic metabolism uses more fuel, produces less energy, and is less efficient than aerobic metabolism. The waste product of anaerobic metabolism is lactic acid. Lactic acid is harder to remove from the body than CO_2 because it must be buffered with sodium bicarbonate. When the body does not have enough sodium bicarbonate to buffer the lactic acid, metabolic acidosis occurs. Left uncorrected, tissue and cell dysfunction, and ultimately cell death, occurs.

Hypercapnic Respiratory Failure

In acute hypercapnic respiratory failure, or *ventilatory failure,* the respiratory system cannot maintain CO_2 levels within normal limits. This condition occurs from either an increase in CO_2 production or a decrease in alveolar ventilation. Hypercapnic respiratory failure can be acute or chronic.

Many problems can cause hypercapnic respiratory failure. We group these into 4 categories: (1) CNS problems, (2) neuromuscular problems, (3) chest wall abnormalities, and (4) problems affecting the airways and/or alveoli. Hypercapnic ARF due to CNS problems, neuromuscular problems, and/or chest wall abnormalities can occur in the presence of normal lungs.

Central nervous system problems. Several CNS problems can suppress the drive to breathe. An example is an overdose of a respiratory depressant drug (e.g., opioid). In a dose-related manner, CNS depressants decrease CO_2 reactivity in the brainstem. This allows arterial CO_2 levels to rise. Brainstem infarction or traumatic brain injury (TBI) may interfere with the function of the respiratory center in the medulla. The medulla does not sense a change in $PaCO_2$, and as a result, an increase in respiratory rate does not occur.

TBI with a decreased level of consciousness can hinder the patient's ability to protect the airway, breathe, or manage secretions. High-level spinal cord injuries (SCI) can affect nerve supply to the respiratory muscles of the chest wall and diaphragm.

Neuromuscular problems. Various neuromuscular problems place patients at risk for respiratory failure. For example, patients with Guillain-Barré syndrome and multiple sclerosis have respiratory muscle weakness or paralysis. As a result, they cannot eliminate CO_2 and maintain normal $PaCO_2$ levels. Exposure to toxins (e.g., carbamate/organophosphate pesticides, chemical nerve agents) can interfere with the nerve supply to muscles and lung ventilation. Respiratory muscle weakness can occur from muscle wasting during critical illness or peripheral nerve damage.

Chest wall abnormalities. Several conditions can prevent normal chest wall or diaphragm movement and limit lung expansion. With severe obesity, the weight of the chest and abdominal contents limit lung expansion. In patients with flail chest, fractures prevent the rib cage from expanding normally. With kyphosis, the change in spinal configuration compresses the lungs and prevents normal chest wall expansion.

Problems of the airway and alveoli. Patients with COPD, asthma, and cystic fibrosis are at higher risk for hypercapnic respiratory failure because the underlying pathophysiology results in airflow obstruction and air trapping. Respiratory muscle fatigue and ventilatory failure occur from the added work of breathing (WOB) needed to inspire air against increased airway resistance and air trapped within the alveoli.

Consequences of hypercapnia. The body can tolerate increased CO_2 levels better than low O_2 levels. This is because with slow changes in $PaCO_2$, the body may have time to compensate. For example, consider the patient with COPD who develops an upper respiratory tract infection. Because a slow, steady increase in $PaCO_2$ level occurred over several days, there was time for the kidneys to compensate (e.g., by retaining bicarbonate). This will initially minimize the change in arterial pH. However, unless we identify and correct the primary cause, the patient will likely get worse.

Clinical Manifestations

Respiratory failure may develop suddenly (acute, minutes or hours) or gradually (chronic, several days or weeks). A sudden decrease in PaO_2 and/or a rapid rise in $PaCO_2$ implies a severe respiratory problem, which can quickly become a life-threatening emergency. An example is a patient with asthma who develops severe bronchospasm and a marked decrease in airflow. This results in respiratory muscle fatigue, acidemia, and ARF.

Signs of respiratory failure are related to the extent of change in PaO_2 or $PaCO_2$, the speed of change (acute versus chronic), and the patient's ability to compensate for this change. When the patient's compensatory mechanisms fail, respiratory failure occurs. Because clinical signs vary, frequent patient assessment is a priority.

A lack of O_2 affects all body systems (Table 32.2). For example, a decreased level of consciousness may occur without enough blood, O_2, and glucose supplied to the brain. Permanent brain damage can result if hypoxia is severe and prolonged. Gastrointestinal (GI) system changes include tissue ischemia and increased intestinal wall permeability. Bacteria can migrate from the GI tract into systemic circulation. Renal function may be impaired. Sodium retention, peripheral edema, and acute kidney injury (AKI) may occur.

TABLE 32.2 Common Manifestations of Hypoxemia and Hypercapnia

Specific	Nonspecific
Hypoxemia	
Respiratory	Cardiovascular
Accessory muscle use	↑ BP (early), ↓ BP (late)
Dyspnea	Dysrhythmias (late)
Intercostal muscle retraction	↑ HR
Nasal flaring	Skin cool, clammy, and diaphoretic
Paradoxical chest or abdominal wall movement with respiratory cycle (late)	CNS
	Agitation
	Confusion
Prolonged expiration	Disorientation
↓ SpO_2 (<90%)	↓ Level of consciousness
Tachypnea	Restless, combative behavior
Cyanosis (late)	Coma (late)
	Other
	Fatigue
	Inability to speak in complete sentences without pausing to breathe
Hypercapnia	
Respiratory	Cardiovascular
Dyspnea	↑ BP
Limited chest wall movement	Dysrhythmias
Pursed-lip breathing	↑ HR
Tripod position	CNS
↓ Respiratory rate or rapid rate with shallow respirations	Agitation
	Confusion, disorientation
	Morning headache
↓ Tidal volume	Progressive somnolence
↓ Minute ventilation	↑ ICP
	Coma (late)
	Neuromuscular
	↓ Deep tendon reflexes
	Muscle weakness
	Tremors, seizures (late)

One of the first signs of hypoxemic ARF is a change in mental status. Mental status changes occur early because the brain is sensitive to changes in O_2 (and to a lesser degree CO_2) levels and acid-base balance. Restlessness, confusion, and agitation suggest inadequate O_2 delivery to the brain. A morning headache and low respiratory rate with a decreased level of consciousness may indicate problems with CO_2 removal.

Tachycardia, tachypnea, pallor, and a mild increase in WOB are early signs of ARF.[6] These changes indicate attempts by the heart and lungs to compensate for decreased O_2 delivery and rising CO_2 levels. It is important to understand that cyanosis is an unreliable indicator of hypoxemia. It is a late sign in ARF. It often does not occur until deoxygenated hemoglobin concentration in the capillaries is around 5 g/dL.[7]

Observing the patient's position helps assess the effort associated with the **work of breathing (WOB)**. WOB is the effort needed by the respiratory muscles to inhale air into the lungs. Patients with mild respiratory distress may be able to lie down. In moderate distress, patients may prefer to sit. With severe distress, they may be unable to breathe unless sitting upright. The tripod position helps decrease the WOB in patients with moderate to severe COPD and ARF. The patient sits with the arms propped on the overbed table or the knees. Propping the arms increases the anteroposterior diameter of the chest and changes pressure in the thorax.

The patient in ARF may have a rapid, shallow breathing pattern or a slower respiratory rate. Both predispose the patient to hypoxemia and insufficient CO_2 removal (hypercarbia). Increased respiratory rates require a substantial amount of work and can lead to respiratory muscle fatigue. A change from a rapid rate to a slower rate in a patient in respiratory distress, such as that seen with acute asthma, suggests severe respiratory muscle fatigue. There is an increased chance of respiratory arrest.

The patient's ability to speak is related to the severity of dyspnea. The dyspneic patient may be able to speak only a few words at a time between breaths. For example, the patient may have "2-word" or "3-word" dyspnea. This means the patient can say only 2 or 3 words before pausing to breathe.

You may see dyspneic patients using pursed-lip breathing. This technique increases SaO_2 by slowing respirations, increasing time for expiration, and preventing small bronchioles from collapsing. You may see *retraction* (inward movement) of the intercostal spaces or supraclavicular area and accessory muscle use (e.g., sternocleidomastoid) during inspiration or expiration. Using accessory muscles often signifies a moderate degree of respiratory distress.

Paradoxical breathing occurs with severe respiratory distress. Normally, the thorax and abdomen move outward on inspiration and inward on exhalation. With paradoxical breathing, the abdomen and chest each move in the opposite direction. Paradoxical breathing results from maximal use of the accessory muscles of respiration. The patient may be diaphoretic from the increased WOB.

Auscultate breath sounds. Note the presence and location of any abnormal breath sounds. Fine crackles may occur with pulmonary edema. Coarse crackles heard on expiration indicate fluid in the airways. This may be a sign of pneumonia or some degree of HF. Absent or decreased breath sounds occur with atelectasis, pleural effusion, or hypoventilation. Bronchial breath sounds over the lung periphery occur with lung consolidation from pneumonia. You may hear a pleural friction rub if pneumonia involves the pleura.

Diagnostic Studies

The most common diagnostic studies used to evaluate ARF are chest x-ray and ABG analysis. A chest x-ray helps identify possible causes of respiratory failure (e.g., atelectasis, pneumonia). ABGs evaluate oxygenation (PaO_2) and ventilation ($PaCO_2$) status and acid-base (pH, bicarbonate) balance. Pulse oximetry monitors oxygenation status indirectly.

Other diagnostic studies that may be done include a complete blood cell count, serum electrolytes, urinalysis, and 12-lead ECG. Blood and sputum cultures (Gram stain, culture, and sensitivity) may reveal infection. A CT scan or V/Q lung scan may be done if a pulmonary embolus is suspected. For the patient in severe ARF who needs mechanical ventilation, end-tidal CO_2 ($EtCO_2$) can assess trends in ventilation.[8]

❖ NURSING AND INTERPROFESSIONAL MANAGEMENT: ARF

Because many different problems cause ARF, initial management and specific care vary. Factors considered include patient age, underlying comorbidities, severity of onset, and suspected or most likely cause of the respiratory failure. We then tailor management strategies to what best meets the patient's unique needs. In acute care settings, collaboration among the health care team (e.g., nurses, physicians, respiratory therapists, pharmacists) is essential.

For mild to moderate ARF, O_2 administration via a high-flow O_2 delivery device (e.g., Optiflow) may be started. Non-invasive ventilation, such as bi-level positive airway pressure (Bi-PAP), may be an option for patients who are awake, alert, able to maintain a patent airway and clear their own secretions.

In severe ARF, the patient will receive care in an intensive care unit (ICU). ICU care will include mechanical ventilation. Continuous pulse oximetry and arterial BP monitoring will occur. ABGs will be performed often. Central or mixed venous O_2 saturation [$ScvO_2$ or SvO_2] data help determine the adequacy of tissue perfusion and the patient's response to treatment. Central venous pressure (CVP) monitoring may be ordered. The patient may need advanced hemodynamic monitoring to evaluate parameters such as ejection fraction, CO, and pulmonary capillary wedge pressure (PCWP).

◆ Assessment

Table 32.3 presents subjective and objective data that you should obtain from the patient with ARF. A thorough assessment may result in the early detection of respiratory insufficiency. This allows us to intervene sooner and may prevent worsening respiratory failure. Monitor patients with preexisting cardiac and/or respiratory disease closely. Any change in their overall condition may cause significant respiratory and hemodynamic decompensation.

The priority is immediately assessing the patient's ability to maintain a patent airway and breathe (ventilate). Observe trends in ABGs, pulse oximetry, and assessment findings. Remain alert to subtle changes that can occur in your patient's condition from hypoxemia or hypercarbia. Your ability to detect problems, notify the HCP, implement appropriate treatment, and evaluate response to therapy is essential.

◆ Clinical Problems

Clinical problems for the patient with ARF may include:

- Impaired respiratory system function
- Inadequate tissue perfusion
- Acid-base imbalance

Additional information on clinical problems and interventions for the patient with ARF is presented in eNursing Care Plan 32.1 (available on the website for this chapter).

◆ Planning

The overall goals for the patient with ARF include (1) independently maintain a patent airway, (2) absence of dyspnea or

TABLE 32.3 NURSING ASSESSMENT

ARF

Subjective Data

Important Health Information

Health history: Age, weight, level of consciousness, tobacco use, alcohol or drug use, hospitalizations related to lung disease, thoracic or spinal cord trauma, occupational exposures to lung toxins

Medications: Use of home O_2, inhalers (bronchodilators), home nebulization, immunosuppressant (e.g., corticosteroid) therapy, CNS depressants, illicit substances

Surgery or other treatments: Past intubation and mechanical ventilation, recent thoracic or abdominal surgery

Functional Health Patterns

Health perception–health management: Exercise, self-care activities, immunizations (flu, pneumonia, hepatitis)

Nutritional-metabolic: Eating habits; history of bloating, indigestion; recent weight gain or loss, change in appetite. Use of vitamins or herbal supplements

Activity-exercise: Fatigue, dizziness, dyspnea at rest or with activity, wheezing, cough (productive or nonproductive), sputum (volume, color, viscosity), palpitations, swollen feet, change in exercise tolerance

Sleep-rest: Changes in sleep pattern, use of CPAP

Cognitive-perceptual: Headache, chest pain or tightness, chronic pain

Coping–stress tolerance: Anxiety, depression, feelings of hopelessness. Risk for drug and/or alcohol use, nicotine withdrawal

Objective Data

Cardiovascular

Tachycardia progressing to bradycardia, dysrhythmias, extra heart sounds (S_3, S_4). Bounding pulse. Hypertension progressing to hypotension. Pulsus paradoxus, jugular venous distention, pedal edema

GI

Abdominal distention, ascites, epigastric tenderness, hepatojugular reflex

Neurologic

Somnolence, confusion, slurred speech, restlessness, delirium, agitation, tremors, seizures, coma, asterixis, ↓ deep tendon reflexes, papilledema

Respiratory

Increased respiratory rate (shallow, labored, increased WOB). Accessory muscle use with retractions, increased diaphragmatic excursion or asymmetric chest expansion, paradoxical chest and abdominal wall movement. Tactile fremitus, crepitus, or deviated trachea (late sign) on palpation. Absent, decreased, or adventitious breath sounds. Pleural friction rub. Bronchial or bronchovesicular sounds heard in other than normal location, inspiratory stridor

Skin

Pale, cool, clammy skin or warm, flushed skin. Peripheral and/or central cyanosis. Peripheral dependent edema

Possible Diagnostic Findings

↓/↑ pH, ↑/↓ $PaCO_2$, ↑/↓ bicarbonate, ↓ PaO_2, ↓ SaO_2, abnormal hemoglobin, ↑ WBC count, changes in serum electrolytes. Abnormal chest x-ray. Abnormal CVP or pulmonary artery pressures. Initially, CO may be ↑ due to the stress response. As hypoxemia, hypercapnia, and acidosis become more severe, CO will ↓.

recovery to baseline breathing patterns, (3) effectively cough and able to clear secretions, (4) normal ABG values or values within the patient's baseline, and (5) breath sounds within the patient's baseline.

Implementation

Prevention

For the patient at risk for ARF, prevention and early recognition of respiratory problems is important. This is especially important for patients with neuromuscular, cardiac, or respiratory problems (e.g., COPD). Do a thorough history and physical assessment to identify risk factors. Preventing atelectasis, pneumonia, and complications of immobility and optimizing hydration and nutrition can decrease the risk for ARF. Assess patients at high risk more often and implement preventive measures. Early strategies may include teaching patients about deep breathing and coughing, incentive spirometry, and early ambulation.

Acute Care

Interventions to improve the patient's oxygenation and ventilation status are essential to improving O_2 delivery and patient outcomes. The primary aim is to identify and treat the underlying cause of the ARF. Patients with V/Q mismatch, shunting, or diffusion impairment may be managed slightly differently, depending on the underlying cause. We monitor patients continuously for their response to therapy, including changes in respiratory status, trends in ABGs, and signs of clinical improvement.

Respiratory Therapy

The goals of respiratory care include maintaining adequate oxygenation and ventilation and correcting acid-base imbalance. Interventions include O_2 therapy, mobilizing secretions, and positive pressure ventilation (PPV) (Table 32.4).

Oxygen Therapy

The primary goal of O_2 therapy is to correct hypoxemia. This requires O_2 administration. Never withhold O_2 from a patient. Always administer O_2 at the lowest possible FIO_2 (O_2 concentration) needed to keep the PaO_2, SpO_2, and SaO_2 within patient-specific goals. Observe the patient's response to O_2 therapy. Closely monitor for changes in mental status, respiratory rate, and ABGs. A trend towards a normal PaO_2 level lets you know that the patient is responsive to O_2.

Several methods are available to provide O_2. Chapter 28 and Table 28.3 discuss O_2 delivery devices. The device selected depends upon the patient's overall condition, degree of respiratory failure, ability to maintain a patent airway, the amount of FIO_2 the device delivers, and the patient's ability to breathe spontaneously. The selected O_2 delivery device must help maintain PaO_2 at 60 mm Hg or higher and SaO_2 at 90% or higher.

The patient with hypoxemia is often agitated, disoriented, and restless. A face mask, though appropriate, may cause anxiety. Anxiety can cause dyspnea and increase O_2 consumption and CO_2 production. The patient may try to remove the mask. In this case, you need to explore other O_2 therapy options.

TABLE 32.4 Interprofessional Care

ARF

Diagnostic Assessment

- Vital signs with pulse oximetry (SpO_2)
- History and physical assessment
- Arterial blood gases (ABGs)
- Chest x-ray
- CBC with differential
- Serum electrolytes
- 12-Lead ECG
- Blood, sputum, and/or urine cultures (if indicated)
- Hemodynamic monitoring (if indicated)

Management

Respiratory Therapy

- O_2 therapy
- Mobilization of secretions
  - Positioning (unless contraindicated, head of bed elevated)
  - Effective coughing
  - Chest physiotherapy
  - Suctioning of the airway
  - Oral and/or IV hydration
  - Humidification (of O_2)
  - Ambulation (early mobility)
- Positive pressure ventilation (PPV)
  - Noninvasive positive pressure ventilation (e.g., BiPAP)
  - Intubation with positive pressure ventilation

Drug Therapy

- Reduce pain, anxiety, restlessness (e.g., fentanyl, morphine, hydromorphone, lorazepam)
- Relieve bronchospasm (e.g., albuterol)
- Reduce pulmonary congestion (e.g., furosemide, morphine)
- Treat pulmonary infections (e.g., antibiotics)
- Reduce airway inflammation (e.g., corticosteroids)

Supportive Therapy

- Manage the underlying cause of ARF
- Monitor hemodynamic status
- Optimize balance between activity and rest
- Monitor for deterioration in patient condition
- Be vigilant in avoiding and preventing complications

Breathing high O_2 concentrations for prolonged periods is not without potential adverse effects. Exposure to higher FIO_2 (greater than 60%) for longer than 48 hours poses a risk for O_2 *toxicity.* In this situation, oxygen-free radicals from the high O_2 levels cause inflammation and cell death by disrupting the alveolar-capillary membrane. *Absorption atelectasis* is another risk. O_2 can replace nitrogen and other gases normally present in the alveoli. Without nitrogen to help maintain the size and shape of the alveolus, structural support is lost, and the alveolus collapses. Other effects of prolonged exposure to high O_2 levels include increased pulmonary capillary permeability, decreased surfactant production, surfactant inactivation, and fibrotic changes in the alveoli.[9]

Another risk of O_2 therapy is specific to patients with chronic hypercapnia (e.g., patients with COPD). Chronic hypercapnia

blunts the response of chemoreceptors to high CO_2 levels as a respiratory stimulant. Initial O_2 therapy may be provided through a low-flow device, such as a nasal cannula at 1 to 2 L/min or a Venturi mask at 24% to 28%. Those who do not respond to O_2 therapy or other interventions may need mechanical ventilation with higher FIO_2.

Mobilizing Secretions

Retained pulmonary secretions may cause or worsen ARF. This occurs because the movement of O_2 into the alveoli and the removal of CO_2 is severely limited or blocked. Secretions can be mobilized by proper positioning, effective coughing, chest physiotherapy, suctioning, humidification, hydration, and, when possible, early ambulation.

Patient positioning. Position the patient with ARF upright. Elevate the head of the bed at least 30 degrees or use a reclining chair or chair bed. This helps maximize respiratory expansion, decrease dyspnea, and mobilize secretions. A sitting position improves pulmonary function by promoting the downward movement of the lungs. When lungs are upright, ventilation and perfusion are best in the lung bases. If there is a chance for aspiration, position the patient side-lying.

We may place a patient with a 1-sided lung problem in a lateral or side-lying position. This position, called *good lung down,* allows for improved V/Q matching in the affected lung. Pulmonary blood flow and ventilation are better in dependent lung areas. Secretions can drain out of the affected lung so they can be removed with suctioning. For example, place a patient with right-sided pneumonia on the left side. This will maximize ventilation and perfusion in the "good" lung and aid in secretion removal from the affected lung (postural drainage). Patients with ARF often have problems with both lungs. They may need repositioning at regular intervals on both sides to optimize air movement and drainage of secretions.

Effective coughing. When secretions are present, encourage the patient to cough. Unfortunately, not all patients will have enough strength or force to produce a cough that will clear the airway of secretions. *Augmented coughing (quad coughing)* may benefit some patients. To aid with augmented coughing, place 1 or both hands at the anterolateral base of the patient's lungs (Fig. 32.6). As you observe deep inspiration end and expiration begin, move your hands forcefully upward. This increases abdominal pressure and helps the patient cough. It increases expiratory flow and promotes secretion clearance.

Huff coughing is a series of coughs performed while saying the word "huff." This technique prevents the glottis from closing, forcing air and mucous from the airways.[10] The patient takes a deep breath, holds the breath for 2 or 3 seconds, and then forcefully exhales. COPD patients generate higher flow rates with a huff cough than a normal cough, which is less tiring.

The *staged cough* also helps clear secretions. To perform a staged cough, the patient assumes a sitting position. They breathe in and out 3 or 4 times through the mouth, then cough while bending forward and pressing a pillow inward against the diaphragm.

Chest physiotherapy. Chest physiotherapy is indicated for all patients producing sputum or have severe atelectasis or pulmonary infiltrates on chest x-ray. Postural drainage, percussion, and vibration to the affected lung segments help move secretions to the larger airways. Then, they can be removed by coughing or suctioning. Contraindications include TBI and increased intracranial pressure (ICP), unstable orthopedic injuries (e.g., spinal fractures, fractured ribs, fractured sternum), and recent hemoptysis.[11] See more about chest physiotherapy in Chapter 28.

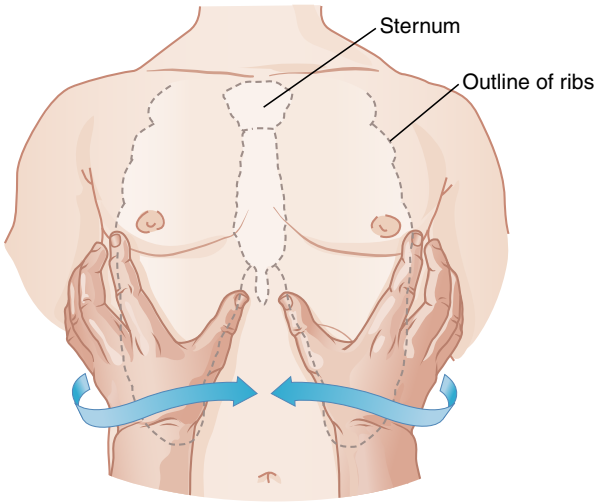

Fig. 32.6 Augmented coughing is performed by placing 1 or both hands on the anterolateral base of the lungs. After the patient takes a deep inspiration and at the beginning of expiration, move the hand(s) forcefully upward. This increases abdominal pressure and helps produce a forceful cough. (From American Association of Critical Care Nurses: *AACN advanced critical care nursing,* St Louis, 2009, Mosby.)

Suctioning. Suctioning may be needed if the patient is unable to expectorate secretions. Inserting a soft-tip suction catheter through a nasopharyngeal tube in the awake, non-intubated patient may help remove secretions at the back of the throat. Perform suctioning with caution, as stimulating the gag reflex may induce vomiting. We only suction through an artificial airway (e.g., endotracheal tube [ET], tracheostomy) as needed (see Chapter 28).

Humidification. Humidification is an adjunct in secretion management. We can thin secretions with aerosols of sterile normal saline or mucolytic drugs (e.g., acetylcysteine mixed with a bronchodilator) given by nebulizer. O_2 given by aerosol mask can thin secretions and promote their removal. Be aware that aerosol therapy may cause bronchospasm and severe coughing, causing a decrease in PaO_2. Frequent assessment of the patient's tolerance to therapy is critical.

Hydration. Thick, viscous secretions are hard to expel. Unless contraindicated, adequate fluid intake (2 to 3 L/day) keeps secretions thin and easier to remove. This may not be possible in the patient with ARF. The patient who is unable to take enough fluids orally needs IV hydration. Assess cardiac and renal status to determine whether the patient can tolerate the IV fluid volume and avoid HF and pulmonary edema. Regularly assess for signs of fluid overload (e.g., crackles, dyspnea, weight gain, increased CVP).

Fig. 32.7 Noninvasive BiPAP ventilation. A mask is placed over the nose or nose and mouth. Positive pressure from a mechanical ventilator aids the patient's breathing efforts, decreasing the work of breathing. (Courtesy Richard Arbour, RN, MSN, CCRN, CNRN, CCNS, FAAN, and Anna Kirk, RN, MSN.)

CHECK YOUR PRACTICE

You are caring for a 72-year-old male patient with hypoxemic ARF. He has a history of atrial flutter and COPD. A chest x-ray shows left-sided pneumonia. Your patient is awake but mildly confused. He has a productive cough with thick, yellow-green purulent sputum.

- What respiratory interventions would you expect to be ordered?

Positive Pressure Ventilation

If initial measures do not improve oxygenation and ventilation, the patient may need enhanced ventilatory assistance. Noninvasive positive pressure ventilation (NIPPV) is one option. With NIPPV, a mask is placed tightly over the patient's nose or nose and mouth (Fig. 32.7). When the patient breathes spontaneously, a mechanical ventilator or table-top unit delivers PPV to the patient. With NIPPV, it is possible to provide O_2 and decrease WOB, avoiding the need for intubation.

NIPPV is most useful in managing CRF in those with chest wall or neuromuscular problems. It may help patients with a chronic respiratory problem that is worse due to cardiac problems or infection. It is an option for patients who refuse intubation but still want some degree of ventilatory support (e.g., patients with end-stage COPD). NIPPV is not appropriate for patients with a decreased level of consciousness, high O_2 requirements, facial trauma, hemodynamic instability, or excessive secretions. NIPPV after extubation can help avoid reintubation.

There are 2 forms of NIPPV used for patients with ARF. Continuous positive airway pressure (CPAP) delivers 1 level of pressure—a constant pressure—to the patient's airway during inspiration and expiration. BiPAP uses 2 different levels of positive pressure (one on inspiration, another on expiration). With both CPAP and BiPAP, the patient must be awake and alert, have stable vital signs, and maintain spontaneous ventilation.

The most frequently used NIPPV for ARF is BiPAP.[12] BiPAP provides O_2 therapy and humidification, decreases WOB, and reduces respiratory muscle fatigue. It helps open collapsed airways and decrease shunt. If respiratory status worsens with NIPPV, PPV via mechanical ventilation with higher O_2 concentrations is needed. Chapter 28 discusses mechanical ventilation.

Drug Therapy

Drug therapy depends on several factors. These include the cause of ARF, the patient's comorbidities, and whether an infection is present. Goals of drug therapy include (1) reduce airway inflammation and bronchospasm, (2) relieve pulmonary congestion, (3) treat infection, and (4) reduce anxiety, pain, and restlessness.

Reduce Airway Inflammation and Bronchospasm

Relief of bronchospasm increases alveolar ventilation. In acute bronchospasm, short-acting bronchodilators (e.g., albuterol) may be given at 15- to 30-minute intervals until a response occurs. Give these drugs using a hand-held nebulizer or a metered-dose inhaler with a spacer. Side effects include tachycardia and hypertension. Prolonged use can increase the risk for dysrhythmias and cardiac ischemia. Monitor the patient's vital signs and ECG for any changes.

Corticosteroids (e.g., IV methylprednisolone) may be used in combination with other drugs, such as bronchodilators, to relieve inflammation and bronchospasm. It may take several hours to see their effects. Inhaled corticosteroids may take 4 to 5 days for optimum therapeutic effects, so they will not relieve dyspnea and increased WOB quickly.

DRUG ALERT

IV Corticosteroids

- Monitor potassium levels. Corticosteroids worsen hypokalemia caused by diuretics.
- Prolonged use causes adrenal insufficiency.
- Hyperglycemia, especially in those with diabetes, is common.

Relieve Pulmonary Congestion

Interstitial fluid can accumulate in the lungs because of injury to the alveolar capillary membrane from HF or fluid overload. IV diuretics (e.g., furosemide), morphine, or nitroglycerin can decrease pulmonary congestion caused by HF. Use caution when giving these drugs. Changes in heart rate and rhythm and significant decreases in BP are common.

Treat Infection

Lung infections (e.g., pneumonia, acute bronchitis) can result in excessive mucus production, fever, increased O_2 consumption, and inflamed, fluid-filled, and/or collapsed alveoli. Alveoli that are fluid filled or collapsed cannot take part in gas exchange. Consequently, pulmonary infections can either cause or worsen ARF. IV antibiotics are given to treat infection. Chest x-rays can show the location and extent of infection. Sputum cultures help identify the organisms causing the infection and their sensitivity to antimicrobial drugs.

Reduce Anxiety, Pain, and Restlessness

Anxiety, pain, and restlessness may result from hypoxemia and dyspnea. They increase O_2 consumption and CO_2 production (from an increased metabolic rate) and increase WOB. For the non-intubated patient, this may cause tachypnea and ineffective ventilation. They may cause ventilator dyssynchrony for the intubated patient and increase the risk for unplanned extubation (see Chapter 28).

We promote patient comfort in several ways. Frequently turn and reposition the patient. Provide reassurance and emotional support to the patient and caregiver. IV benzodiazepines (e.g., lorazepam, midazolam) and opioids (e.g., morphine, fentanyl) may decrease anxiety, restlessness, and pain. We should start these drugs at the lowest dose possible. Assess for treatable causes of restlessness (e.g., hypoxemia, pain, delirium) and manage as needed. Often, restlessness and mental status changes are the first signs of hypoxemia or patient-ventilator dyssynchrony. You should address the causes and not depend solely on the use of analgesics and sedatives.

! SAFETY ALERT

Managing Restlessness and Sedation

- Pain, hypoxemia, delirium, electrolyte imbalance, TBI, and drug reactions can cause restlessness.
- Assess and treat all reversible causes of restlessness.
- Monitor patients closely for CNS, cardiac, and respiratory depression when giving sedative and analgesic drugs, especially in the non-intubated patient.
- Sedative and analgesic drugs may have a prolonged effect in critically ill and older adult patients. This can delay weaning from mechanical ventilation and increase length of stay.

Nutrition Therapy

Maintaining protein and energy stores is especially important. The hypermetabolic state in critical illness increases the calories needed to maintain a stable body weight and muscle mass. Nutrition depletion causes a loss of muscle mass, including the respiratory muscles, which may delay recovery. The dietitian often determines the best method of feeding and optimal calorie and fluid requirements. Ideally, enteral nutrition (EN) should be started within 24 to 48 hours (see Chapter 44).

Evaluation

The expected outcomes are that the patient with ARF will

- Independently maintain a patent airway
- Maintain adequate oxygenation
- Have hemodynamic stability
- Achieve a return to baseline respiratory system function

Gerontologic Considerations: Acute Respiratory Failure

Many factors contribute to an increased risk for ARF in older adults. The reduced ventilatory capacity that accompanies aging increases the risk for ARF. Physiologic changes in the lungs include alveolar dilation, larger air spaces, and loss of surface area for gas exchange. Decreased elastic recoil within the airways, decreased chest wall compliance, and decreased respiratory muscle strength occur.[13]

In older adults, the PaO_2 falls further, and the $PaCO_2$ rises to a higher level before the respiratory system is stimulated to change the rate and depth of breathing. This delayed response contributes to the development of respiratory insufficiency. A history of tobacco use can accelerate age-related respiratory changes. Poor nutrition status and less physiologic reserve in the cardiopulmonary system increase the risk for further compromising respiratory function and ARF.

ACUTE RESPIRATORY DISTRESS SYNDROME

Acute respiratory distress syndrome (ARDS) is a sudden and progressive form of ARF in which the alveolar-capillary membrane becomes damaged and more permeable to intravascular fluid (Fig. 32.8). Next to septic shock, ARDS is one of the most common conditions seen in the adult ICU. ARDS accounts for about 10% of all adult ICU admissions.[14] The incidence of ARDS in the United States is more than 200,000 cases each year. Despite supportive therapy, the mortality rate is around 35%.[15]

Etiology

Table 32.5 lists conditions that predispose patients to ARDS. The most common cause is sepsis. ARDS may also develop because of multisystem organ dysfunction syndrome (MODS).

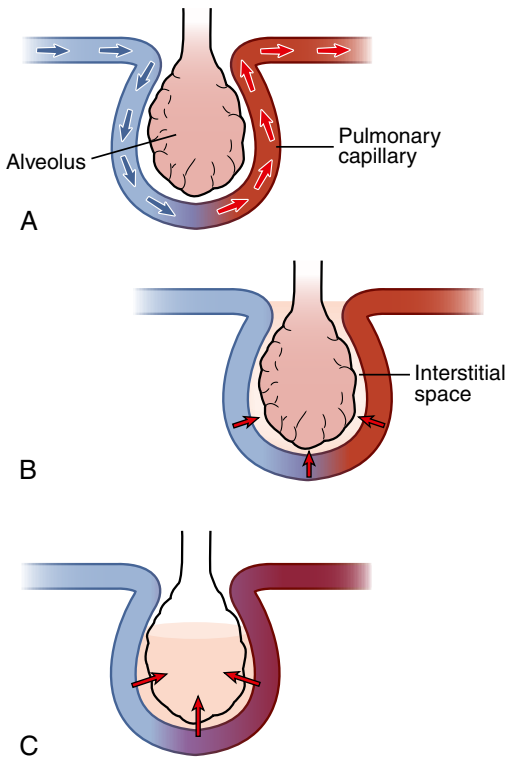

Fig. 32.8 Stages of edema formation in ARDS. (A) Normal alveolus and pulmonary capillary. (B) Interstitial edema occurs with accumulation of and increased flow of fluid into the interstitial space. (C) Alveolar edema occurs when the fluid crosses the alveolar-capillary membrane, causing severe impairment in gas exchange.

Patients with multiple risk factors are 3 or 4 times more likely to develop ARDS.

Either a direct or indirect lung injury causes ARDS. In direct lung injury, the pathogen comes into contact with the lung tissue. For example, aspiration of gastric contents into the lung immediately initiates the inflammatory response. In an indirect injury, ARDS develops due to a problem somewhere else in the body. For example, necrotizing pancreatitis or bowel obstruction with perforation causes widespread inflammation and infection. As a result, septic mediators gain entrance to the bloodstream and often move toward the lungs, which provide a favorable, dark, moist environment for their proliferation. This can be the beginning of ARF, which, left untreated, can progress to ARDS.

TABLE 32.5 Predisposing Conditions to ARDS

Direct Lung Injury	Indirect Lung Injury
Common Causes	
• Aspiration (gastric contents or other substances) • Bacterial or viral pneumonia • Sepsis	• Massive trauma • Sepsis and septic shock (especially gram-negative infection) • Severe TBI • Shock states (hypovolemic, cardiogenic)
Less Common Causes	
• Chest trauma (blunt or penetrating) • Embolism: fat, air, amniotic fluid, thrombus • Inhalation of toxic substances • Near-drowning • O_2 toxicity • Radiation pneumonitis	• Acute pancreatitis • Cardiopulmonary bypass • Disseminated intravascular coagulation • Opioid drug overdose • Transfusion-related acute lung injury (e.g., multiple blood transfusions) • Urosepsis

Pathophysiology

The pathophysiologic changes in ARDS are divided into 3 phases: (1) injury or exudative phase, (2) reparative or proliferative phase, and (3) fibrotic or fibroproliferative phase. The pathophysiology of ARDS is shown in Fig. 32.9.

Injury or Exudative Phase

The *injury or exudative phase* usually occurs 24 to 72 hours after the initial insult (direct or indirect).[16] It generally lasts 7 to 10 days. Engorgement of the peribronchial and perivascular interstitial space causes interstitial edema. Fluid in the parenchyma of the lung surrounding the alveoli crosses the alveolar membrane and enters the alveolar space. V/Q mismatch and shunt develop because the alveoli fill with fluid. Blood in the capillary network cannot be oxygenated.

We do not know the exact cause of the alveolar-capillary membrane damage. Some think it is caused by stimulation of the inflammatory and immune systems. This stimulation attracts neutrophils to the pulmonary interstitium. The neutrophils

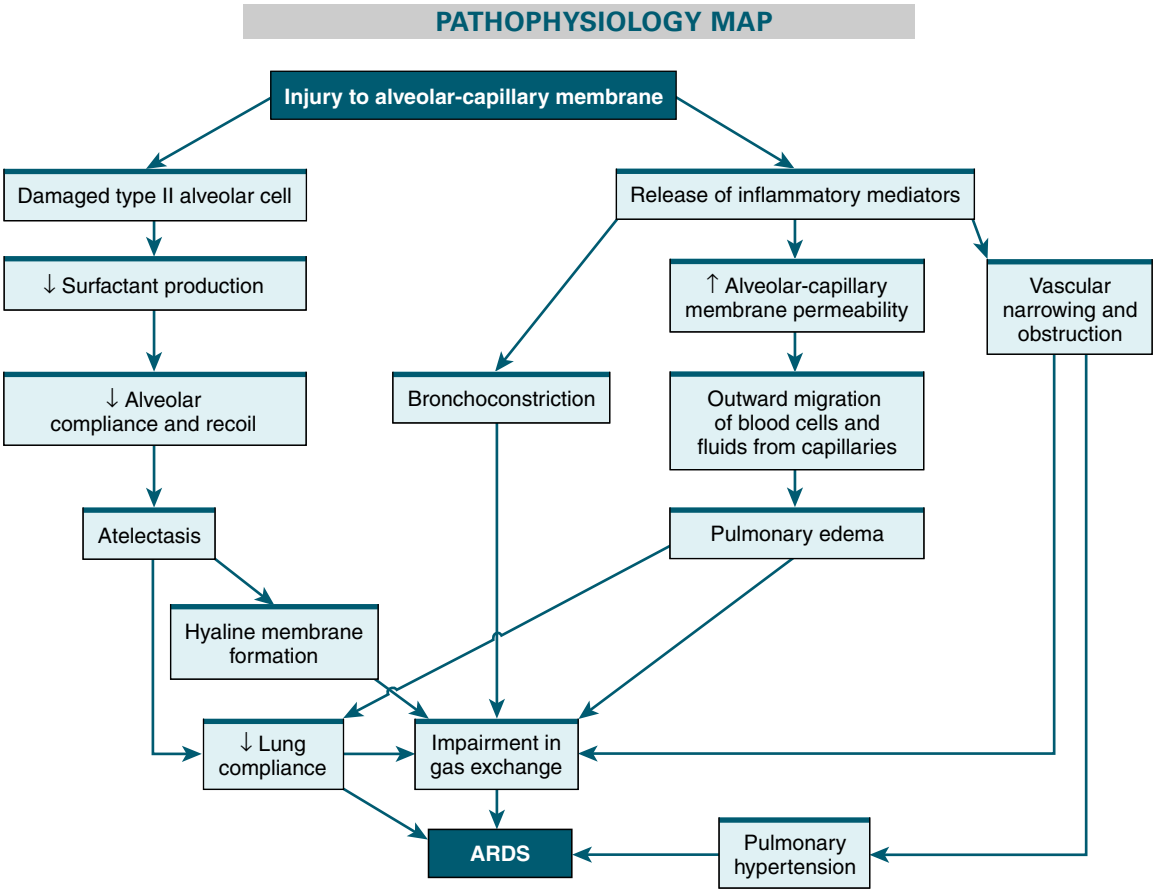

Fig. 32.9 Pathophysiology of ARDS.

release biochemical, humoral, and cellular mediators that produce changes in the lung. These changes include increased pulmonary capillary membrane permeability, destruction of collagen, formation of pulmonary microemboli, and pulmonary artery vasoconstriction.

Hypoxemia and the stimulation of juxtacapillary receptors in the parenchyma of the stiff lung *(J reflex)* initially cause an increase in respiratory rate and a decrease in tidal volume (V_T). This breathing pattern increases CO_2 removal, causing respiratory alkalosis. CO increases in response to hypoxemia, a compensatory effort to increase pulmonary blood flow. As atelectasis, pulmonary edema, and pulmonary shunt increase, compensation fails. Hypoventilation, decreased CO, and decreased tissue O_2 perfusion occur.

The changes caused by ARDS damage both alveolar type I cells and alveolar type II cells (which make surfactant). This damage, in addition to fluid and protein accumulation, results in surfactant dysfunction. The function of surfactant is to maintain alveolar stability and prevent alveolar collapse. When surfactant synthesis is decreased, or surfactant becomes inactivated, alveoli become unstable and collapse *(atelectasis)*. Widespread atelectasis further decreases lung compliance, compromises gas exchange, and contributes to hypoxemia.

Necrotic cells, protein, and fibrin form hyaline membranes that line the inside of each alveolus. In ARDS, the hyaline membrane thickens. This causes more atelectasis, further impairing gas exchange and reducing lung compliance.

Severe V/Q mismatch and shunting of pulmonary capillary blood result in hypoxemia unresponsive to increasing O_2 concentrations. This classic sign of ARDS is called **refractory hypoxemia**. In other words, despite receiving higher O_2 concentrations, the patient's condition continues to get worse. Diffusion impairment, caused by a thickened hyaline membrane, contributes to and worsens hypoxemia. As the lungs become less compliant because of decreased surfactant, pulmonary edema, and atelectasis, the patient must generate higher airway pressures to inflate "stiff" lungs. Reduced lung compliance increases the patient's WOB. At this point, the patient needs mechanical ventilation.

Reparative or Proliferative Phase

The *reparative* or *proliferative phase* of ARDS begins 1 to 2 weeks after the initial lung injury.[17] During this phase, there continues to be an influx of neutrophils, monocytes, lymphocytes, and fibroblasts as part of the inflammatory response. Increased pulmonary vascular resistance and pulmonary hypertension may occur because fibroblasts and inflammatory cells destroy the pulmonary vasculature. Lung compliance continues to decrease due to interstitial fibrosis. Hypoxemia continues because of the thickened alveolar membrane. This causes V/Q mismatch, diffusion limitation, and shunting. Fluid in the lungs and secretions in the airways increase airway resistance. The proliferative phase is complete when dense, fibrous tissue replaces the diseased lung. If the reparative phase persists, widespread fibrosis results. If the reparative phase stops, the lesions will often resolve.

Fibrotic or Fibroproliferative Phase

The *fibrotic phase* (*chronic* or *late phase*) of ARDS may start as early as 24 hours after the initial lung injury.[18] Not all patients who develop ARDS enter the fibrotic stage. For those who do, it is associated with a poorer prognosis. Collagenous and fibrous tissues remodel the lung. Diffuse scarring of the lungs, interstitial fibrosis, and alveolar duct fibrosis result in decreased lung compliance.[18] This reduces the surface area for gas exchange because the interstitium is fibrotic, and hypoxemia continues. Varying degrees of pulmonary hypertension may result from pulmonary vascular destruction and fibrosis.

Clinical Progression

Progression of ARDS varies among patients. Some survive the acute phase of lung injury. Pulmonary edema resolves, and complete recovery occurs within a week or so. The chance for survival is poorer in those who enter the fibrotic stage. Patients may need several weeks of long-term mechanical ventilation. It is not known why injured lungs repair and recover in some patients and worsen in others. Several factors are essential in determining the clinical course and outcome of ARDS. These include the nature of the initial injury, extent, and severity of comorbidities, how quickly the patient received medical care, and additional pulmonary complications (e.g., pneumothorax). Genetics may be a factor for a person's predisposition to developing ARDS.[19]

Clinical Manifestations and Diagnostic Studies

The initial presentation of ARDS is often subtle. At the time of the initial injury, and for the first 24 to 72 hours, the patient may not have respiratory symptoms or have only mild dyspnea, tachypnea, cough, and restlessness. Lung auscultation may be normal or reveal fine, scattered crackles. ABGs may show mild hypoxemia and respiratory alkalosis caused by hyperventilation. The chest x-ray may be normal or reveal diffusely scattered, but minimal interstitial infiltrates.

As ARDS evolves, symptoms worsen because of fluid in the lung parenchyma and alveoli and increased secretion accumulation in the airways. Respiratory distress becomes evident as WOB increases. Tachypnea and intercostal and suprasternal retractions may be present. Tachycardia, diaphoresis, mental status changes, cyanosis, and pallor may occur. Lung auscultation usually reveals scattered to diffuse crackles and coarse crackles on expiration. After 72 hours, the chest x-ray often shows diffuse and extensive bilateral interstitial and alveolar infiltrates (Fig. 32.10).

As ARDS progresses, ABGs reflect changes in oxygenation and ventilation. Refractory hypoxemia is the hallmark characteristic of ARDS. Hypercapnia often signifies that respiratory muscle fatigue and hypoventilation have severely affected gas exchange. Respiratory failure is imminent.

To help evaluate the severity of hypoxemia, we can calculate the **PaO2/FIO2** (P/F) ratio. This measure reflects the ratio of the patient's PaO_2 to the FIO_2 that the patient is receiving. Under normal circumstances (e.g., PaO_2 80 to 100 mm Hg; FIO_2 0.21 [room air]), the P/F ratio is greater than 400 (e.g., 95/0.21

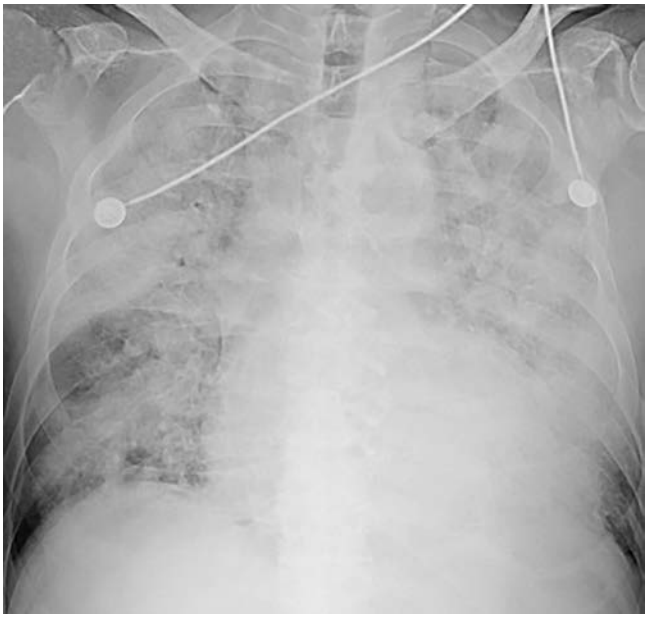

Fig. 32.10 Chest x-ray of a patient with ARDS. The x-ray shows extensive areas of consolidation. (From Walker CM, Chung JH: *Muller's imaging of the chest*, ed 2, St Louis, 2019, Elsevier.)

TABLE 32.6 Diagnostic Criteria

Berlin Definition of ARDS

Timing
Within 1 week of a known clinical insult or new or worsening respiratory symptoms

Chest X-Ray
Bilateral opacities: not fully explained by effusions, lobar/lung collapse, or nodules

Oxygenation
Mild ARDS: PaO_2/FIO_2 ratio ≥300 with PEEP or CPAP ≤5 cm H_2O
Moderate ARDS: PaO_2/FIO_2 ratio ≥200 with PEEP or CPAP ≤5 cm H_2O
Severe ARDS: PaO_2/FIO_2 ratio <100 with PEEP or CPAP ≤5 cm H_2O

Modified from Bellani G, Pham T, Laffey JG: Missed or delayed diagnosis of ARDS: A common and serious problem, *Intensive Care Med* 46:1180, 2020.

= 452). With the onset and progression of lung injury and impaired O_2 delivery through the alveolar-capillary membrane, the PaO_2 often remains lower than expected despite increased FIO_2. The P/F ratio distinguishes among mild (<300), moderate (<200), and severe (<100) ARDS (Table 32.6).

CHECK YOUR PRACTICE

You are caring for a 26-year-old woman with ARDS who experienced near-drowning 4 days ago. She is mechanically ventilated and receiving continuous IV sedation. The ventilator settings are full support (control mode), FIO_2 = 0.90 (90%), PEEP = +15 cm H_2O, V_T = 350 mL, respiratory rate 12 breaths/min (patient taking no breaths above the set rate on the ventilator), peak pressure = 35 cm H_2O. The patient's PaO_2 is 83 mm Hg.

- Calculate and interpret the PaO_2/FIO_2 (P/F) ratio.

TABLE 32.7 Complications of ARDS

Cardiovascular
- ↑ CO
- Dysrhythmias
- Hypotension

CNS and Psychologic
- Delirium
- PTSD

GI
- Hypermetabolic state, ↑ nutrient requirements
- Paralytic ileus
- Pneumoperitoneum
- Ulceration and GI bleeding

Hematologic
- Anemia
- Disseminated intravascular coagulation
- Thrombocytopenia
- VTE

Infection
- Catheter-related infection (e.g., central and peripheral IV catheters, urinary catheters)
- Sepsis

Renal
- AKI

Respiratory
- Pulmonary emboli
- Pulmonary fibrosis
- Ventilator-associated volutrauma, barotrauma
- Ventilator-associated pneumonia (VAP)

The decrease in lung compliance and increase in pulmonary resistance are associated with profound dyspnea, hypoxemia, increased WOB, and respiratory distress. We often refer to the chest x-ray as a "whiteout" because consolidation and infiltrates are widespread throughout the lungs, leaving few recognizable air spaces (Fig. 32.10). Pleural effusions may be present. Severe hypoxemia, hypercapnia, metabolic acidosis, and organ failure often accompany ARDS.

Complications

Complications may develop because of ARDS itself or its treatment (Table 32.7). Besides the lungs, the vital organs most often involved are the kidneys, liver, and heart. The main cause of death in ARDS is MODS, often accompanied by sepsis.

Abnormal Lung Function

Most patients will recover from ARDS within a year. Many will have normal to near normal lung function. However, not all patients regain normal lung function. Sometimes, abnormal lung function can persist for years or the rest of the patient's life. The severity of scarring and changes within the lungs are key factors. Mechanical ventilation, duration of time ventilated, and use of extracorporeal life support may be contributing factors.

Patients may report fatigue, chest pain, shortness of breath after minimal activity, and persistent dyspnea post-ARDS.

Ventilator-Associated Pneumonia

Risk factors for ventilator-associated pneumonia (VAP) include impaired host defenses, invasive monitoring devices, aspiration (e.g., patients receiving EN), and prolonged mechanical ventilation. Implementing a ventilator bundle protocol reduces the incidence of VAP in mechanically ventilated patients (Table 32.8).[20]

Barotrauma

Barotrauma occurs when fragile alveoli are overdistended with excess pressure during mechanical ventilation. The high peak airway pressures needed to ventilate the lungs predispose patients with ARDS to barotrauma. It results in alveolar air escaping from ruptured alveoli. This can lead to pulmonary interstitial emphysema, pneumothorax, subcutaneous emphysema, pneumopericardium, and tension pneumothorax. Providing ventilation with a smaller V_T (e.g., 4 to 8 mL/kg) and varying amounts of PEEP minimizes the risk for barotrauma.

GI Ulcers

Patients with ARF and ARDS are at high risk for GI ulcers because the blood is diverted from the GI to the respiratory system to help meet the body's demand for O_2. Management strategies include correcting predisposing conditions, such as hypotension, shock, and acidosis. Prophylactic management includes antiulcer drugs, such as proton pump inhibitors (e.g., pantoprazole) and mucosal-protecting drugs (e.g., sucralfate). Early EN helps prevent mucosal damage.

Venous Thromboembolism (VTE)

ARDS patients are susceptible to the effects of immobility and venous stasis. They are at risk for deep vein thrombosis (DVT) and pulmonary emboli. Prophylactic management may include intermittent pneumatic compression stockings, anticoagulation, and, when possible, early ambulation.

Acute Kidney Injury

AKI can occur from decreased renal perfusion and subsequent decreased O_2 delivery to the kidneys. This most often occurs because of hypotension in septic shock. It may also result from hypoxemia or nephrotoxic drugs (e.g., vancomycin) used to treat ARDS-related infections. Monitor intake and output, daily weight, and daily creatinine and urea levels.

Patients in ARDS often receive continuous renal replacement therapy (CRRT). They are frequently hemodynamically unstable and need vasopressors and/or inotropes to maintain heart rate and BP. They cannot tolerate the large volumes of fluid that traditional hemodialysis would remove. CRRT is slow, gentle, and continuous. The patient can receive CRRT 24 hours a day. The overall mortality rate for ARDS patients is higher in those who need CRRT.[21]

Psychological Issues

Recovery is far from complete for the patient who survives ARDS. Survivors may have anxiety, issues with memory and attention, inability to focus, nightmares, depression, and in some instances, various degrees of posttraumatic stress disorder (PTSD). PTSD can occur in ARDS survivors up to 5 years later.[22]

NURSING AND INTERPROFESSIONAL MANAGEMENT: ARDS

Management of a patient with ARF (Table 32.4) and the nursing care plan for ARF (eNursing Care Plan 32.1 available on the website for this chapter) apply to patients with ARDS. The next section discusses additional care for the patient with ARDS (Table 32.9).

TABLE 32.8 Components of a Ventilator Bundle

- Good handwashing before, during (as needed), and after delivery of patient care
- Elevate head of the bed 30–45 degrees
- Daily assessment of readiness for extubation (see Chapter 28)
- GI ulcer prophylaxis (see Chapter 46)
- VTE prophylaxis (see Chapter 41)
- Daily oral care with chlorhexidine (0.12%) solution
- Strict infection control measures

TABLE 32.9 Interprofessional Care

ARDS

General Care
- Hemodynamic monitoring
- Identify and treat underlying cause

Respiratory Therapy (see Chapter 28)
- O_2 administration
- Mechanical ventilation
  - Low V_T ventilation
  - Permissive hypercapnia
  - PEEP
- Positioning strategies (e.g., prone)
- Extracorporeal membrane oxygenation (ECMO)

Supportive Care
- Analgesia and sedation
- Neuromuscular blocking agents
- IV fluid administration (keep on the "dry" side)
- Inotropic and vasopressor drugs
  - norepinephrine
  - vasopressin
  - dopamine
  - dobutamine
- VAP prophylaxis
- Nutrition therapy
- VTE prophylaxis

Assessment

Because ARDS is the most severe form of ARF, the subjective and objective data you should obtain from someone with ARDS are the same as those for ARF (Table 32.3). Patient information may not be possible to obtain on admission due to the urgent need to protect the airway (intubation), initiate mechanical ventilation, monitor vital signs, and assist with urgent treatments and procedures (e.g., inserting an arterial and/or central line, initiating vasopressors to maintain BP).

Planning

With appropriate therapy, overall patient goals include a PaO_2 of 60 mm Hg or higher and adequate lung ventilation to help correct any acid-base imbalance. Longer-term goals include (1) PaO_2 within normal limits for age or at baseline on room air, (2) SaO_2 greater than 90%, (3) resolution of the cause(s), and (4) clear lungs on auscultation.

Implementation

Patients with moderate to severe ARDS receive care in an ICU. The entire health care team has important roles in the care of the patient with ARDS.

Even with appropriate therapy, the clinical course of ARDS is complex and unpredictable. Patients often need several days of mechanical ventilation to allow time for the overwhelming inflammation and fluid accumulation in the lungs to begin resolving. All mechanically ventilated patients with ARDS in the ICU will have continuous heart rate, respiratory rate, BP, and SpO_2 monitoring. $EtCO_2$ monitoring is standard. Best practices for care of the patient with ARDS include (1) O_2 administration, (2) mechanical ventilation, (3) low V_T ventilation, (4) permissive hypercapnia, (5) PEEP, (6) prone positioning, and (7) extracorporeal membrane oxygenation (ECMO).[23]

Respiratory Therapy

Oxygen Administration

The primary goal of O_2 therapy is to correct hypoxemia. Initially, using a high-flow system that delivers higher O_2 concentrations to maximize O_2 delivery may be all that is needed. Continuously monitor SpO_2 to assess the effectiveness of O_2 therapy. However, for most patients diagnosed with ARDS, high-flow O_2 delivery, including BiPAP, is temporary. As respiratory failure worsens, high-flow O_2 will not be able to keep the PaO_2 within acceptable ranges. Patients with moderate to severe ARDS and refractory hypoxemia need mechanical ventilation to maintain an acceptable PaO_2. Even with mechanical ventilation, the patient may need an FIO_2 of 70% or higher to keep the PaO_2 at least 60 mm Hg. Most HCPs agree that in the injury and reparative phases, they may have to accept a lower-than-normal PaO_2 (e.g., PaO_2 55 to 80 mm Hg) and SpO_2 (88% to 95%).

Mechanical Ventilation

Mechanical ventilation is required for the patient with moderate to severe ARDS. Pressure-control ventilation helps to keep the inspiratory and plateau pressures from becoming too high. This prevents alveolar overdistention and rupture. By reducing the amount of pressure going into the stiff, noncompliant lungs, we can help prevent further lung injury. However, no mode of mechanical ventilation is superior to the others.[23]

Low tidal volume (V_T) ventilation. Patients with ARDS are ventilated with a low V_T of 4 to 8 mL/kg.[24] Delivering a large V_T into stiff lungs can cause volutrauma and barotrauma. Volutrauma causes *alveolar fractures* (damage or tears in the alveolar capillary membrane) and the movement of fluids and protein into the alveolar spaces. Low V_T ventilation reduces mortality and the risk for volutrauma.

Permissive hypercapnia. As a result of delivering a lower-than-normal V_T to the patient with ARDS, the $PaCO_2$ level will slowly rise above normal limits. This is known as **permissive hypercapnia**. It is a consequence of low V_T ventilation, not a specific strategy. A $PaCO_2$ of up to 60 mm Hg is acceptable in the early phase of ARDS. The patient usually tolerates this rise in $PaCO_2$ if it is gradual, allowing the brain and systemic circulation to compensate. We do not use permissive hypercapnia with pregnant patients or those with TBI or increased ICP.

Frequent ABG samples are needed with careful monitoring of the pH, PaO_2, and $PaCO_2$ values. The pH is kept between 7.30 and 7.45. Acidosis and rising CO_2 levels are powerful stimulants to breathe. As a result, when permissive hypercapnia occurs, the patient usually receives continuous IV analgesia and sedation.

Positive end-expiratory pressure (PEEP). During PPV, it is common to apply PEEP at 5 cm H_2O to compensate for the loss of glottic function with an ET. PEEP increases functional residual capacity or the volume of air left in the lungs at the end of a normal expiration. PEEP helps open ("recruit") collapsed alveoli.

We typically apply PEEP in increments of 3 to 5 cm H_2O until oxygenation is adequate, with an FIO_2 of 60% or less (if possible). PEEP may improve ventilation in respiratory units that collapse at low airway pressures, thus allowing the FIO_2 to be lowered. Patients with ARDS may need higher levels of PEEP (e.g., 10 to 20 cm H_2O). There is no identified optimal level of PEEP for patients with ARDS.

PEEP is not without complications. The added intrathoracic and intrapulmonic pressures generated by positive pressure remaining in the lungs and transmitted to surrounding structures (e.g., inferior vena cava, heart) at end expiration can compromise venous return. This compromise can decrease the amount of blood returning to both the right and left sides of the heart. Dramatic reductions in preload, CO, and BP can occur. High levels of PEEP or excess inspiratory pressures can cause barotrauma and volutrauma.

Prone Positioning

Prone positioning is an option for patients with refractory hypoxemia and ARDS who do not respond to other strategies to increase PaO_2. By turning the patient prone, perfusion may be better matched to ventilation (Fig. 32.11). Air-filled alveoli in the anterior part of the lung become dependent. Alveoli in the posterior part of the lungs are "recruited" (given the opportunity to re-expand), improving oxygenation.

Placing a patient prone requires an ICU intensivist, respiratory therapist, and at least 3 nurses. Special attention must be given to securing and maintaining the airway before, during, and after proning. Once prone, the patient needs reattached to hemodynamic monitoring equipment and positioned in a side-lying position.

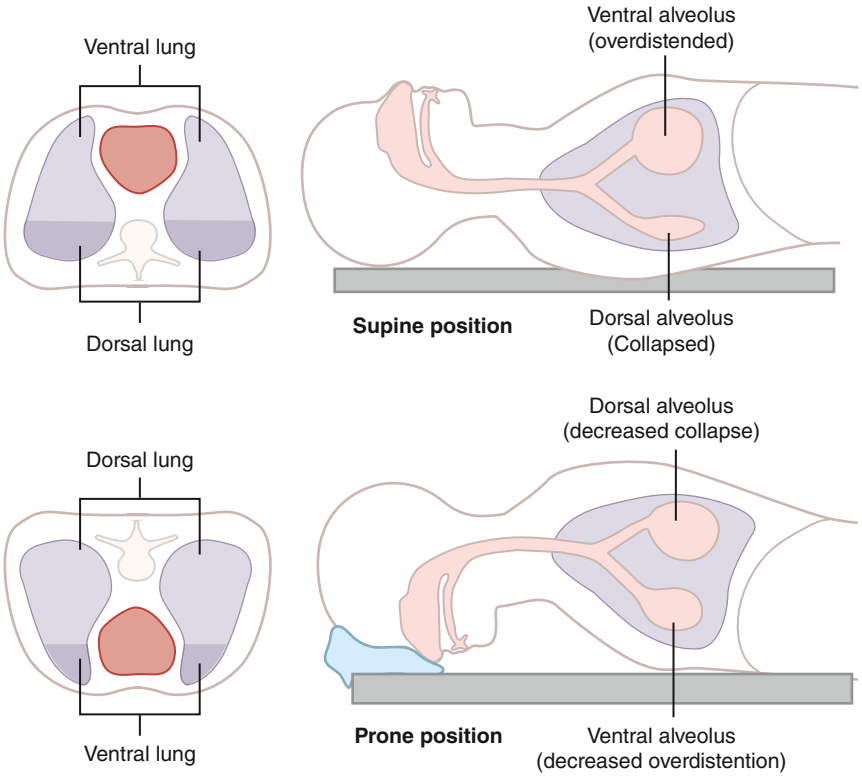

Fig. 32.11 Changes in the lung that occur because of prone positioning.

Some patients will have a big improvement in PaO_2 when prone. The improvement in oxygenation may be enough to allow a reduction in FIO_2 or PEEP. You may see hemodynamic instability (dysrhythmias, a decrease in BP) from fluid shifts while the patient is prone. There may be more need for airway suctioning as secretions are mobilized. Research suggests that patients be proned early in the course of ARDS. They can stay in the prone position for up to 16 hours per day.[25] We do not know the optimal length of time that a patient should be prone.

Alternatives to prone positioning include continuous lateral rotation therapy (CLRT) and kinetic therapy. CLRT provides continuous, slow, side-to-side turning by rotating the actual bed frame less than 40°. The bed moves laterally for 18 of every 24 hours to simulate postural drainage and help mobilize pulmonary secretions. Some beds have a vibration feature that provides chest physiotherapy. This assists with secretion mobilization and removal. Kinetic therapy is like CLRT, in that patients rotate side-to-side 40° or more. Obtain baseline assessments of the patient's pulmonary status (e.g., respiratory rate and rhythm, breath sounds, ABGs, SpO_2) and continue to monitor the patient throughout the therapy.

Extracorporeal Membrane Oxygenation (ECMO)

ECMO is used most often in specialized ICUs in major cities. Like hemodialysis, a large blood vessel is cannulated (most often the internal jugular, femoral artery, or femoral vein), and a catheter is inserted. Blood exits the body through the catheter and enters the ECMO unit. There, O_2 is delivered into the blood, and CO_2 is removed. Oxygenated blood is returned to the patient. $ECCO_2R$ is like ECMO. It does not require as high blood flow rates. It is only used to enhance oxygenation. Both ECMO and $ECCO_2R$ are expensive and require specially trained nurses and other personnel.

Supportive Therapy

Analgesia and Sedation

Analgesia and sedation, either by direct IV or continuous IV infusion, are essential. Analgesia and sedation decrease the discomfort from having an ET tube, help reduce WOB, and prevent ventilator dyssynchrony.

Patients who breathe asynchronously with mechanical ventilation may benefit from adjusting ventilator inspiratory flow rates or other settings. Patients who stay asynchronous with mechanical ventilation despite aggressive analgesia and sedation may need a neuromuscular blocking agent (NMBA). These drugs, such as vecuronium or pancuronium, relax skeletal muscles and promote synchrony with mechanical ventilation. Remember that a patient receiving neuromuscular blockade can appear to be asleep but still be awake and in pain. For this reason, simultaneous administration of analgesia and sedation with NMBAs is essential.

! SAFETY ALERT

Neuromuscular Blockade

- Always give concurrent analgesia and sedation to patients receiving an NMBA. This eliminates patient awareness, ensures patient comfort, and avoids the terrifying experience of being awake and in pain while paralyzed.
- Use an NMBA for the shortest duration and at the lowest dose possible to avoid complications.

Monitoring sedation levels in patients receiving NMBA is challenging. We monitor levels of drug paralysis through assessment. Note the respiratory rate and whether the patient is taking breaths above the set rate on the ventilator. Besides $ETCO_2$ monitoring, a peripheral nerve stimulator is an additional adjunct used in some settings to help assess the depth of paralysis in a patient receiving NMBA.

Promoting Tissue Perfusion

Patients with ARDS are at risk for hemodynamic compromise. Those on PPV and PEEP often have decreased CO. One cause is decreased venous return from the PEEP-induced increase in intrathoracic pressure. Dysrhythmias and decreased preload can decrease CO. Changes in intrathoracic or intrapulmonary pressures from PPV can also decrease CO.

Patients receiving PPV are at risk for alveolar hyperinflation, increased right ventricular afterload, and excess intrathoracic pressures. These changes can limit blood flow from the right side of the heart, through the pulmonary vasculature, to the left side of the heart and cause hemodynamic compromise (e.g., decreased CO). Blood return from the systemic circulation to the right side of the heart may be impaired, decreasing preload and CO.

Hemodynamic monitoring (e.g., ECG, arterial BP monitoring, SpO_2) is essential. BP and mean arterial pressure (MAP) are important indicators of the adequacy of CO. CVP may be ordered. Newer technologies permit us to monitor stroke volume variation, CO, and mixed venous oxygen saturation ($ScvO_2$ or SvO_2) non-invasively. Closely monitor BP and indicators of CO and tissue perfusion (SaO_2, mixed venous O_2 saturation) with the start of or changes in mechanical ventilation. A decrease in CO is treated with IV fluids, drugs, or both. Chapter 42 discusses drugs used to treat decreased CO and shock. Monitoring trends in hemodynamic status over time allows us to adjust therapy as needed.

Maintaining Fluid Balance and Nutrition

Maintaining fluid balance and nutrition is challenging. Increasing pulmonary capillary permeability results in fluid in the lungs and causes pulmonary edema. At the same time, the patient may be intravascularly volume depleted and at risk for hypotension and decreased CO (from mechanical ventilation and PEEP).

Monitor hemodynamic parameters, urine output, and daily weights to assess fluid volume status. Monitor intake and output hourly. Keep the ARDS patient on the "dry" side. In other words, avoid aggressive resuscitation with IV fluids. Since ARDS is an inflammatory process, diuretics play a minimal role. Dialysis therapy, such as CRRT, can help by removing small amounts of fluid hourly.

Maintaining protein and energy stores is important. Nutrition depletion causes a loss of muscle mass, including the respiratory muscles. This may prolong mechanical ventilation and delay recovery. Consult the dietician. We should start EN as soon as possible, ideally within 24 to 48 hours.[26]

Evaluation

The expected outcomes for the patient with ARDS are similar to those for a patient with ARF. The patient with ARDS should be able to maintain and sustain adequate oxygenation and ventilation with decreasing amounts of O_2, be hemodynamically stable, and be free of complications.

Case Study

Acute Respiratory Distress Syndrome

(© Thinkstock.)

Patient Profile

J.N., a 67-year-old male patient, was admitted 36 hours ago to the surgical ICU after emergent surgery for a small bowel obstruction, acute ischemic bowel, and perforated colon. He is intubated and mechanically ventilated.

Health History

- Mild obesity, hypertension, type 2 diabetes
- Lumbar spine surgery 5 years ago
- Chronic back pain controlled with ibuprofen 400 mg po q4–6hr as needed

Operative Procedure

- Surgery relieved small bowel obstruction, resected 2 feet of intestine, repaired the perforated colon, irrigated the abdominal cavity
- HR was 102 to 135, BP dropped to 70 mm Hg for 6 minutes, SpO_2 was greater than 90% for the duration of surgery
- Received 4 units of packed red blood cells and 5 L of 0.9% saline

Postoperative Status

J.N.'s condition worsened over the first 24 hours in the ICU. He became more tachycardic and hypotensive. J.N. continued to have declining SaO_2 levels, increased WOB, and worsening hemodynamic status. Despite direct IV analgesia and sedation, his respiratory rate increased. He was often "out-of-sync" with the ventilator and required progressively higher FIO_2. A chest x-ray showed bilateral pleural effusions and a right-sided pneumothorax, requiring chest tube placement. J.N. stayed dyssynchronous with the ventilator, so continuous IV analgesia and sedation infusions were ordered. NMBA was started to decrease his WOB and achieve ventilator synchrony.

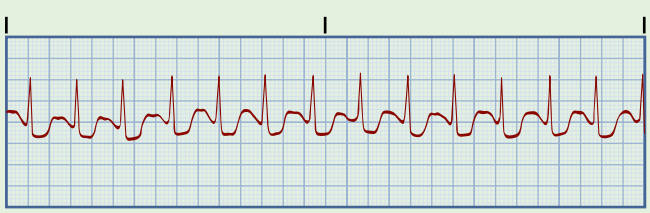
Current Status

J.N. remains hemodynamically unstable, requiring IV norepinephrine to support his BP. He is still mechanically ventilated and is receiving 100% FIO_2 with PEEP 15 cm H_2O. His oxygenation continues to worsen. Urine output has greatly decreased over the past 6 hours. He was diagnosed with AKI, and CRRT is being considered. His wife has brought in a copy of his advance directives. They state he does not want to be kept alive by artificial means. J.N.'s wife and adult children are at the bedside and voicing concerns about his condition.

Objective Data

Physical Assessment

- *CNS:* Sedated, paralyzed. Head of bed elevated 30 degrees. Temperature 101°F (38.3°C) rectally
- *Cardiovascular:* BP 96/54 mm Hg. 2+ carotid, radial, and femoral pulses; 1+ dorsalis pedis pulses. Skin cool, slow capillary refill. ECG shows:



- *Respiratory:* Intubated, mechanically ventilated. No accessory muscle use or retractions. Respiratory rate 18 breaths/min and in sync with ventilator. SpO_2 88%, coarse crackles bilaterally throughout all lung fields. Ventilator settings: V_T 350 mL, FIO_2 100%, rate 18/min, PEEP 15 cm H_2O, peak inspiratory pressure 35 cm H_2O

Case Study—cont'd

Acute Respiratory Distress Syndrome

- *GI:* Surgical dressing dry and intact; colostomy draining a moderate amount of serosanguineous drainage. NG tube draining a small amount of dark brown fluid. Receiving EN at 50 mL/hr via small-bore feeding tube.
- *Renal:* Indwelling bladder catheter draining concentrated, dark amber urine less than 30 mL/hr.

Diagnostic Findings

- Chest x-ray: Bilateral, scattered interstitial infiltrates compatible with ARDS
- Current ABG: pH 7.23, PaO_2 59 mm Hg, $PaCO_2$ 57 mm Hg, HCO_3 16 mEq/L, O_2 saturation 88%.
- Hemoglobin 6.9 g/dL (69 g/L), WBC 20.6/μL (20.6×10^9/L)
- Increased BUN and creatinine values

Discussion Questions

1. ***Recognize:*** What is the cause of ARDS for J.N? Is this a direct or indirect cause?
2. ***Recognize:*** How does the pathophysiology of ARDS predispose him to refractory hypoxemia?
3. ***Analyze:*** What manifestations does J.N. have that support a diagnosis of ARDS?
4. ***Analyze:*** Calculate the PaO_2/FIO_2 ratio. What does this value tell you about the seriousness of his condition?
5. ***Analyze:*** What other complications is J.N. at risk for developing from ARDS?
6. ***Plan:*** You are orienting a new nurse who asks you why you allowed J.N.'s family to stay at the bedside during your physical assessment and morning rounds with the ICU team. How would you respond?
7. ***Prioritize:*** What priority interventions should be implemented to improve J.N.'s respiratory status and hypoxemia?
8. ***Act:*** What information would you give to J.N.'s family about his status?
9. ***Act:*** Given the patient's advance directives, what ethical/legal issues could you encounter?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which signs and symptoms lead the nurse to suspect hypoxemic rather than hypercapnic respiratory failure? *(select all that apply)*
   - **a.** Cyanosis
   - **b.** Tachypnea
   - **c.** Morning headache
   - **d.** Paradoxical breathing
   - **e.** Use of pursed-lip breathing
2. An important consideration in selecting an O_2 delivery device for the patient with acute hypoxemic respiratory failure is to
   - **a.** always start with noninvasive positive pressure ventilation.
   - **b.** apply a low-flow device, such as a nasal cannula or face mask.
   - **c.** be able to correct the PaO_2 to a normal level as quickly as possible.
   - **d.** base the selection on the patient's condition and amount of FIO_2 needed.
3. The *most* common early manifestations of ARDS that the nurse may see are
   - **a.** dyspnea and tachypnea.
   - **b.** cyanosis and apprehension.
   - **c.** respiratory distress and frothy sputum.
   - **d.** bradycardia and increased work of breathing.
4. Interventions used in managing the patient with ARDS include *(select all that apply)*
   - **a.** prone positioning.
   - **b.** IV injection of surfactant.
   - **c.** low tidal volume ventilation.
   - **d.** aggressive IV fluid resuscitation.
   - **e.** positive end expiratory pressure (PEEP).
5. Which intervention is *most* likely to prevent or limit volutrauma in the patient with ARDS who is mechanically ventilated?
   - **a.** Increasing PEEP
   - **b.** Increasing the inspiratory flow rate
   - **c.** Use of low tidal volume ventilation
   - **d.** Suctioning the patient via endotracheal tube hourly

1. a, b, d; 2. d; 3. a; 4. a, c, e; 5. c.

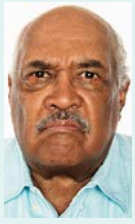
Case Study

Applying Clinical Judgment With Multiple Patients

You are assigned to care for the following 4 patients on a medical-surgical unit. You are sharing 1 AP with another RN.



(© Fuse/Thinkstock.)

F.T., a 70-year-old man with COPD, was admitted 2 days ago with bilateral lower lobe pneumonia. He is receiving IV antibiotics. Vital signs: 150/70, 94, RR 24, 99.4°F (37.4°C), O_2 saturation 96% on O_2 at 3 L/min via nasal cannula.

(© iStockphoto/Thinkstock.)

M.R., a 69-year-old man, is 6 days postoperative after a total laryngectomy with tracheostomy for laryngeal cancer. He developed pneumonia after surgery. He transferred from ICU at 0200 to accommodate a new patient. His last pain medication was 4 hours ago. He is awake, alert, but slightly confused. A tracheostomy tube is in place with O_2 via tracheal mask. Enteral feeding running at 30 mL/h via gastrostomy tube. Vital signs: 168/94, 84, RR 22, O_2 saturation 96%.

(© iStockphoto/Thinkstock.)

J.H. is a 52-year-old man with right lower lobe pneumonia and small cell lung cancer. He and his family are currently considering his treatment options. He is intermittently confused and anxious. Vital signs: 118/62, 106, RR 28 and shallow, 102.6°F (39.2°C), O_2 saturation 92% on O_2 at 4 L/min via nasal cannula.

(© iStockphoto/Thinkstock.)

H.M. is a 68-year-old woman admitted 6 days ago with a COPD exacerbation. She has not been able to ambulate much because of her shortness of breath. She is on oral prednisone and ipratropium. She is being discharged later today. She is starting Advair Diskus and O_2 therapy at home.

1. Highlight all the findings above that require your follow-up.
2. After receiving report, which patient should you see first?

Case Study—cont'd

3. Which morning tasks can you delegate to the AP? *(select all that apply)*
   a. Take vital signs and a pulse oximetry reading on F.T.
   b. Assess M.R.'s pain level and show him how to administer his feeding.
   c. Assist H.M. with AM care and gather belongings in anticipation of discharge.
   d. Provide coffee for J.H.'s family as they await a family meeting with the HCP.
   e. Teach F.T. how to do pursed-lip breathing and titrate O_2 to maintain saturation >95%.
4. While you are assessing J.H., the AP tells you that H.M. is reporting chest pain and worsening shortness of breath. M.R. is requesting pain medication. What should you do *first*?
   a. Ask the AP to get H.M.'s vital signs while you give M.R. pain medication.
   b. Ask the AP to increase H.M.'s O_2 to L/min while you assess M.R.'s pain.
   c. Ask the AP to obtain a stat 12-lead ECG on H.M. while you perform a focused cardiac and respiratory assessment.
   d. Ask the AP to have another RN give M.R. his pain medication while you go directly to H.M.'s room.

Case Study Progression

After assessing H.M., you notify her HCP. A stat 12-lead ECG is done, and a blood sample is drawn to check cardiac enzymes. H.M.'s chest pain is not relieved by sublingual nitroglycerin. You then give 1 mg IV morphine. H.M. states that her pain is "a little better" but continues to report dyspnea. The 12-lead ECG and cardiac enzyme results are all within normal limits.

5. Based on these findings, you recognize that H.M. may be experiencing _____**1**_____ and anticipate the HCP will order _____**2**_____ to determine the cause of her symptoms.

Options for 1	Options for 2
Acute heart failure	BNP and echocardiogram
Pneumothorax	D-dimer and spiral CT scan
Pulmonary embolism	ABGs and chest x-ray

6. While the transport nurse goes with H.M. to the radiology department, you turn your attention back to your remaining 3 patients. You see that you need to complete M.R.'s medication reconciliation after his transfer and prepare his morning medications. Choose the most likely options for the information missing from the table below by selecting from the lists of options provided.

Medication	Dose, Route, Frequency	Drug Class	Indication
acetaminophen	1	Analgesic; antipyretic	Reduce pain and fever
2	40 mg subcut daily	Anticoagulant	VTE prophylaxis
ceftriaxone	1 gram IV q12hr	Cephalosporin	3
albuterol nebulizer	2.5 mg q6hr as needed	4	Bronchodilation

Medication	Dose, Route, Frequency	Drug Class	Indication
Options for 1	***Options for 2***	***Options for 3***	***Options for 4***
325 mg rectal q 4 hr as needed 650 mg PEG q 6 hr as needed 1000 mg PEG q 6hr as needed	Enoxaparin Heparin Warfarin	Chemotherapy for laryngeal cancer Relieve dry mouth Treat postoperative pneumonia	β_2-adrenergic agonist Corticosteroid Leukotriene modifier

7. Before giving M.R.'s 0900 enteral feeding, you find his PEG tube clogged. Which action would you take *next*?
   a. Flush the tube with warm water, using a back-and-forth motion.
   b. Obtain an x-ray to confirm the tube is still placed in the stomach.
   c. Notify the HCP so that surgery to insert new tube can be scheduled.
   d. Instill 30 mL of cranberry juice into the tube and recheck in 1 hour.
8. You perform F.T.'s assessment and update his plan of care.
   For each assessment finding, use an X to indicate whether the interventions were Effective (helped to meet expected outcomes), Ineffective (did not help to meet expected outcomes), or Unrelated (not related to the expected outcomes).

Assessment Finding	Effective	Ineffective	Unrelated
Lungs have bibasilar coarse crackles			
Peripheral edema is 3+ bilaterally			
Can perform active range of motion without dyspnea			
Heart rate 80/min, regular			
Restlessness, slightly confused			
Afebrile			
Normal bowel sounds			
Clear sputum			

9. J.H.'s son calls you on the telephone to ask about his father's current condition and long-term prognosis. Which initial response would be most appropriate?
   a. Ask the person what the code word is to identify himself as family.
   b. Empathize with the son's need to know his father's long-term prognosis.
   c. Tell him you are not allowed to discuss any information over the telephone.
   d. Ask J.H.'s son what the HCP has told him to clarify his understanding of the situation.

Assessment: Hematologic System

Sandra Irene Rome

http: //evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Clotting
Functional Ability
Gas Exchange
Infection
Perfusion

LEARNING OUTCOMES

1. Describe the structures and functions of the hematologic system.
2. Distinguish between the different types of blood cells and their functions.
3. Explain the process of hemostasis.
4. Link the age-related changes in the hematologic system to differences in findings of hematologic studies.
5. Obtain subjective and objective assessment data related to the hematologic system from a patient.
6. Perform a physical assessment of the hematologic system using the appropriate techniques.
7. Distinguish normal from common abnormal findings of a physical assessment of the hematologic system.
8. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the hematologic system.

KEY TERMS

ecchymoses
erythropoiesis
fibrinolysis
hematopoiesis
hemolysis
leukopenia
neutropenia
pancytopenia
petechiae
reticulocyte
thrombocytopenia
thrombocytosis

Hematology is the study of blood and blood-forming tissues. This includes the bone marrow, blood, spleen, and lymph system. You need a basic knowledge of hematology to be able to evaluate several important concepts in the clinical setting. A functioning hematologic system supports our ability to transport oxygen (O_2), carbon dioxide (CO_2), nutrients, wastes, and electrolytes. It maintains intravascular volume, coagulates blood, and combats infections.[1]

STRUCTURES AND FUNCTIONS OF HEMATOLOGIC SYSTEM

Bone Marrow

Blood cell production (**hematopoiesis**) occurs within the bone marrow. *Bone marrow* is the soft material that fills the central core of bones. There are 2 types of bone marrow, yellow (adipose) and red (hematopoietic). Red marrow actively makes blood cells. In adults, we find red marrow mainly in the flat and irregular bones. These include the ends of long bones, pelvic bones, vertebrae, sacrum, sternum, ribs, flat cranial bones, and scapulae.

All 3 types of blood cells (red blood cells [RBCs], white blood cells [WBCs], platelets) develop from a common hematopoietic stem cell in the bone marrow. The hematopoietic *stem cell* is best described as an immature blood cell that can self-renew and differentiate into hematopoietic precursor cells. Several types of blood cells form as the cells mature and differentiate (Fig. 33.1).

The bone marrow responds by a negative feedback system to the need for specific blood cells by increasing that cell's

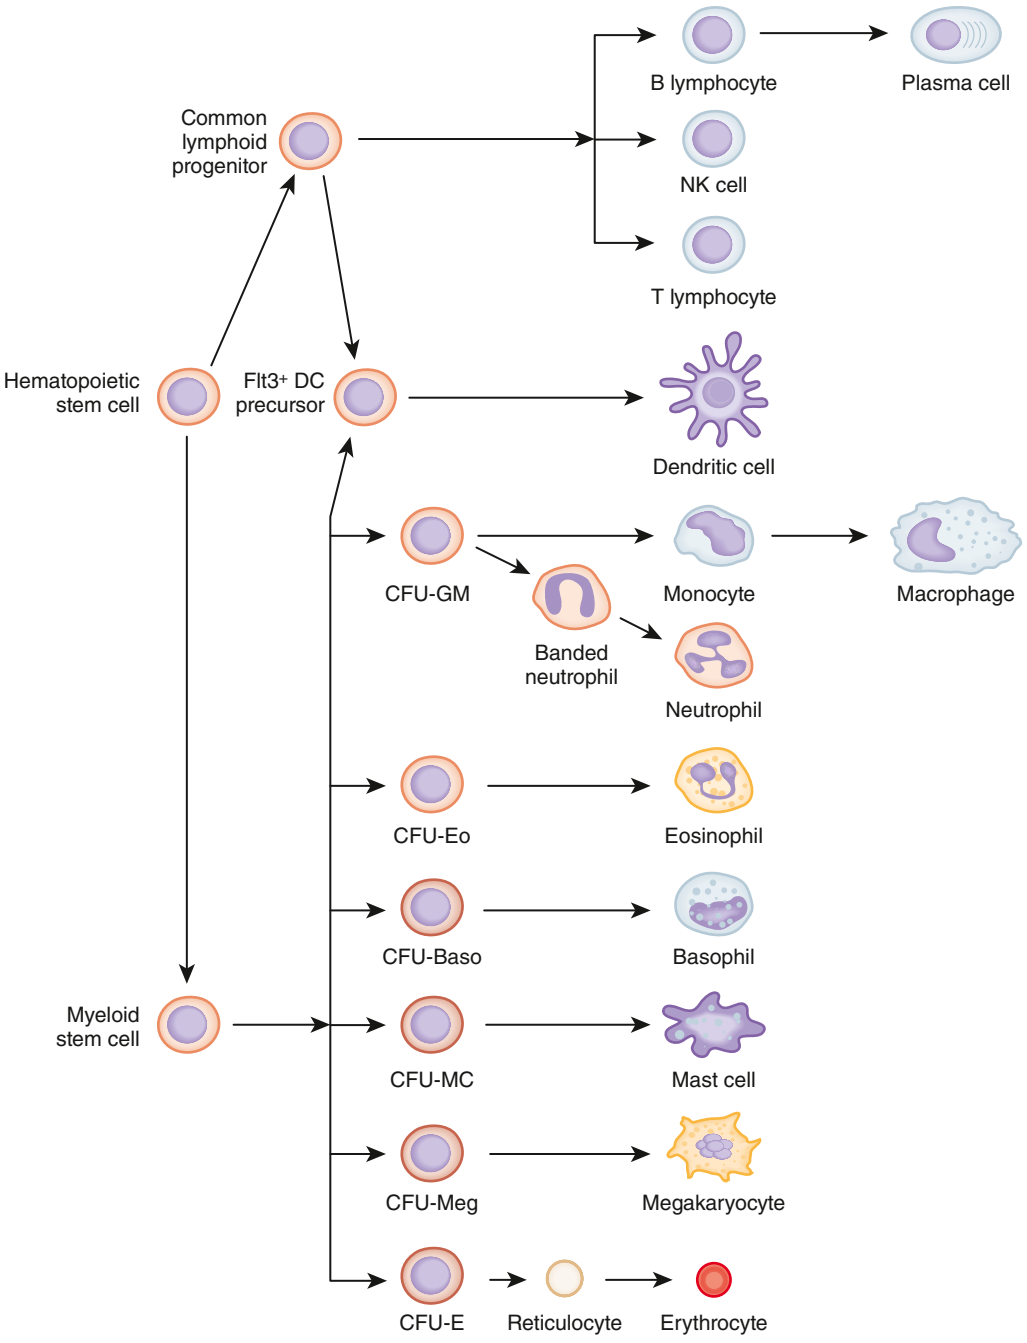

Fig. 33.1 Development of blood cells.

production. Various factors or cytokines (e.g., erythropoietin, granulocyte colony-stimulating factor [G-CSF], stem cell factor, thrombopoietin) stimulate the bone marrow. This results in stem cells differentiating into one of the committed hematopoietic cells (e.g., RBC). For example, when tissue hypoxia occurs, the kidney secretes erythropoietin. It circulates to the bone marrow and causes proerythroblasts to differentiate in the bone marrow.[1]

Blood

Blood is a type of connective tissue. It has 3 major functions: transportation, regulation, and protection (Table 33.1). Blood has 2 major components: plasma and blood cells. In an adult weighing between 150 and 180 lb, the volume of blood is between 4.7 and 5.5 L (5 to 6 quarts).

Plasma

About 55% of blood is plasma (Fig. 33.2).[1] Plasma is composed mainly of water. It also contains proteins, electrolytes, gases, nutrients (e.g., glucose, amino acids, lipids), and waste. The term *serum* refers to plasma minus its clotting factors. Plasma proteins include albumin, globulin, and clotting factors (mostly fibrinogen). Albumin is a protein that helps maintain oncotic pressure in the blood.[1] The liver makes most plasma proteins. The exception is antibodies (immunoglobulins). They are made by plasma cells.

Blood Cells

About 45% of the blood (Fig. 33.2) is composed of formed elements, or blood cells. The 3 types of blood cells are *erythrocytes* (RBCs), *leukocytes* (WBCs), and *thrombocytes* (platelets). The main function of RBCs is O_2 transportation. WBCs help protect the body from infection. Platelets promote blood coagulation.

Erythrocytes. The main functions of RBCs include transport of gases (both O_2 and CO_2) and assistance in maintaining acid-base balance. RBCs are flexible cells with a unique biconcave shape. This flexibility allows the cell to change its shape so that it can easily pass through tiny capillaries. The cell membrane is thin to promote diffusion of gases.

RBCs are mainly composed of a large molecule called *hemoglobin*. Hemoglobin is a complex protein-iron compound composed of heme (an iron compound) and globin (a simple protein). It binds with O_2 and CO_2. As RBCs circulate through the capillaries surrounding alveoli within the lung, O_2 attaches to iron on the hemoglobin. We refer to this O_2-bound hemoglobin as *oxyhemoglobin*. It gives arterial blood its bright red appearance. As RBCs flow to body tissues, O_2 detaches from the hemoglobin and diffuses from the capillary into tissue cells. CO_2 diffuses from tissue cells into the capillary, attaches to the globin part of hemoglobin, and is transported to the lungs for removal. Hemoglobin acts as a buffer and plays a role in maintaining acid-base balance. This buffering function is described in Chapter 17.

Erythropoiesis is the process of RBC production. It is regulated by cellular O_2 requirements and general metabolic activity. Erythropoiesis is stimulated by hypoxia and controlled by *erythropoietin*, a glycoprotein growth factor made and released mainly by the kidney. Erythropoietin stimulates the bone marrow to increase RBC production. We make about 2.5 million RBCs per second. The normal life span of RBCs is about 120 days. We need many essential nutrients for erythropoiesis.

TABLE 33.1 Functions of Blood

Function	Examples
Protection	• Homeostasis of blood coagulation • Combating invasion of pathogens and other foreign substances
Regulation	• Fluid and electrolyte balance • Acid-base balance • Body temperature • Intravascular oncotic pressure
Transportation	• O_2 from lungs to cells • Nutrients from GI tract to cells • Hormones from endocrine glands to tissues and cells • Metabolic waste products (e.g., CO_2, NH_3, urea) from cells to lungs, liver, kidneys

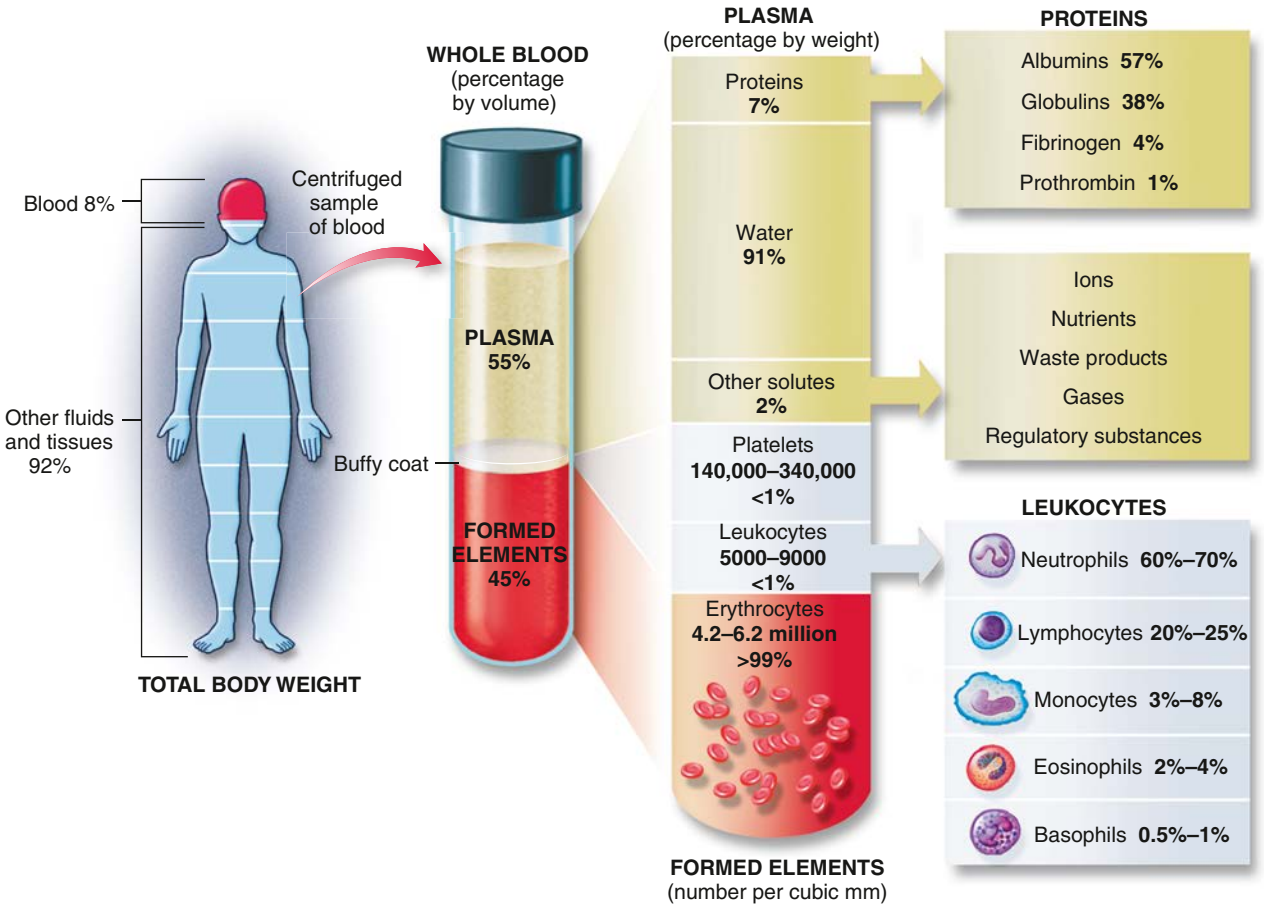

Fig. 33.2 Blood components in a healthy adult. Normally, 45% of the blood is composed of blood cells and 55% is composed of plasma. (From Patton KT, Thibodeau GA: *The human body in health and disease,* ed 7, St Louis, 2018, Mosby.)

These include protein, iron, folate (folic acid), cobalamin (vitamin B_{12}), riboflavin (vitamin B_2), pyridoxine (vitamin B_6), pantothenic acid, niacin, ascorbic acid (vitamin C), copper, and vitamin E. Endocrine hormones, such as thyroxine, corticosteroids, and testosterone, affect RBC production. For example, hypothyroidism may cause anemia.[2]

Several distinct cell types evolve during RBC maturation (Fig. 33.1). The **reticulocyte** is an immature RBC. Reticulocytes can develop into mature RBCs within 48 hours of release into the circulation. A mature RBC lacks a nucleus and cannot undergo mitotic division. Assessing the number of reticulocytes is a useful way to evaluate the rate and adequacy of RBC production.[1]

Hemolysis (destruction of RBCs) by monocytes and macrophages removes abnormal, defective, damaged, and old RBCs from circulation. Hemolysis normally occurs in the bone marrow, liver, and spleen. Because bilirubin is a component of RBCs, hemolysis results in increased bilirubin that our body must process. When hemolysis occurs by normal mechanisms, the liver conjugates and excretes all the bilirubin in bile.

Leukocytes. *Leukocytes* (WBCs) appear white when separated from blood. Like the RBCs, WBCs originate from stem cells within the bone marrow (Fig. 33.1). They may eventually reside in the thymus or secondary lymphoid tissues, such as the spleen, lymph nodes, and Peyer patches. There are several types of WBCs. Each has a different function. WBCs that have granules in the cytoplasm are *granulocytes* (or *polymorphonuclear leukocytes*). Granulocytes include neutrophils, basophils, and eosinophils.

WBCs that do not have granules in the cytoplasm are *agranulocytes.* They include lymphocytes, monocytes, and natural killer cells. Lymphocytes and monocytes are *mononuclear cells* because they have only one discrete nucleus. WBCs have a widely variable life span. Granulocytes may live for only hours. Some T lymphocytes may live for years.

Granulocytes. The main function of granulocytes is *phagocytosis.* This is the process by which WBCs engulf any unwanted organism and then digest and kill it. They can migrate through vessel walls and to the sites where they are needed. The *neutrophil* is the most common type of granulocyte, making up 65% to 75% of all WBCs. Neutrophils are the main phagocytic cells involved in acute inflammatory responses. Once they engulf a pathogen, the neutrophil dies in 1 to 2 days.[1] Hematopoietic growth factors (e.g., G-CSF, granulocyte-macrophage colony-stimulating factor [GM-CSF]) stimulate neutrophil production and maturation.

We call a mature neutrophil a *segmented neutrophil* ("seg," polysegmented neutrophil) because the nucleus is segmented into 2 to 5 lobes connected by strands. An immature neutrophil is a *band* (for the band appearance of the nucleus). Although band cells are sometimes found in the peripheral circulation of normal people and are capable of phagocytosis, the mature neutrophil is much more effective. An increase in neutrophils is a common sign of infection and tissue injury.

Eosinophils make up only 2% to 5% of all WBCs. They have a similar but reduced ability for phagocytosis. One of their main functions is to engulf antigen-antibody complexes formed during an allergic response. High eosinophil levels occur with some cancers, such as Hodgkin lymphoma, in parasitic infections, and in various skin diseases and connective tissue disorders.[1]

Basophils make up less than 1% of all WBCs. They have cytoplasmic granules that contain chemical mediators, such as heparin and histamine. A basophil responds to stimulation by an antigen or by tissue injury by releasing substances from the granules. This is part of the response seen in allergic and inflammatory reactions. *Mast cells* are like basophils, but they reside in connective tissues. They play a key role in inflammation, blood vessel permeability, and smooth muscle contraction.[1]

Lymphocytes. Lymphocytes make up 20% to 25% of the WBCs in the blood.[1] They form the basis of cellular and humoral immune responses. Two lymphocyte subtypes are B cells and T cells. T-cell precursors originate in the bone marrow. They migrate to the thymus gland for further differentiation into T cells. *Natural killer (NK) cells* are lymphocytes that kill virus-infected cells and activate T cells and phagocytes. They do not need prior exposure to antigens. Dendritic cells are the main phagocytic cells in the peripheral organs and skin. Most lymphocytes briefly circulate in the blood and reside in lymphoid and other tissues. See Chapter 14 for more about lymphocyte function.

Monocytes. Monocytes, the other type of agranular WBC, make up about 3% to 8% of the total WBCs.[1] They are potent phagocytic cells that ingest matter, such as bacteria, dead cells, tissue debris, and old or defective RBCs. These cells are present in the blood for only a brief time before they migrate into the tissues and become macrophages. In addition to macrophages that have differentiated from monocytes, tissues have resident macrophages. These resident macrophages have special names (e.g., Kupffer cells in the liver, osteoclasts in the bone, alveolar macrophages in the lung). They protect the body from pathogens at these entry points and are more phagocytic than monocytes. Macrophages interact with lymphocytes to promote humoral and cellular immune responses.

Thrombocytes. The main function of thrombocytes, or *platelets,* is to start the clotting process by producing an initial platelet plug at a site of injury. Platelets circulate suspended in plasma in an unactivated state. They must be available in enough numbers and be structurally and metabolically sound for blood clotting to occur. Platelet activation starts at the site of any capillary damage. Increasing numbers of platelets accumulate to form an initial platelet plug that is stabilized with clotting factors. We store about one-third of our platelets in the spleen.

Platelets originate from stem cells within the bone marrow (Fig. 33.1). The stem cell undergoes differentiation by transforming into a *megakaryocyte,* which fragments into platelets. Platelet production is partly regulated by *thrombopoietin* (TPO). TPO is a growth factor that acts on bone marrow to stimulate platelet production. It is mainly made in the liver. During inflammation, interleukin 6 (IL-6) causes us to make more TPO, which increases platelet production and potential thrombosis. Typically, platelets have a life span of only 8 to 11 days.

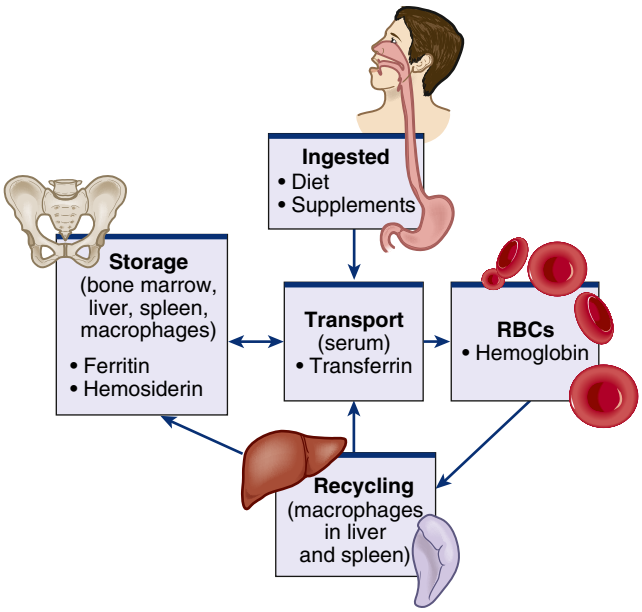

Fig. 33.3 Normal iron metabolism. Iron is ingested in the diet or from supplements. Macrophages break down ingested RBCs. Iron is returned to blood bound to transferrin or stored as ferritin or hemosiderin.

Normal Iron Metabolism

Our iron requirement is 25 mg daily. We get iron from food and supplements. Our body absorbs only 1 to 2 mg of iron from our diet. The rest comes from the continued recycling of iron from RBCs.[1] As part of normal iron metabolism, iron is recycled after macrophages in the liver and spleen phagocytize, or ingest and destroy, old and damaged RBCs.

After dietary iron is absorbed in the duodenum and proximal jejunum, transferrin transports it through the plasma (Fig. 33.3). Transferrin is made in the liver. How much iron is bound to transferrin is a reliable indicator of the iron supply for developing RBCs.

About two-thirds of total body iron is bound to heme in RBCs (hemoglobin) and muscle cells (myoglobin). We store the other one-third as ferritin and hemosiderin (degraded form of ferritin) in the bone marrow, spleen, liver, and macrophages (Fig. 33.3). When we do not replace stored iron, hemoglobin production is reduced. Normally, there is very little iron loss except from blood loss. We lose about 3% daily in urine, sweat, bile, and epithelial cells in the gastrointestinal (GI) tract.

Normal Clotting Mechanisms

Hemostasis describes the arrest of bleeding. This process is important in minimizing blood loss when body structures are injured. The sequence of events includes (1) vascular injury, vasoconstriction, and subendothelial exposure; (2) adhesion; (3) activation of the clotting cascade; (4) formation of a blood clot; and (5) clot retraction and dissolution.[1]

Vascular Injury, Vasoconstriction, and Subendothelial Exposure

When a blood vessel is injured, an immediate local vasoconstrictive response occurs. Vasoconstriction reduces blood leakage from the vessel by restricting the vessel size and pressing the endothelial surfaces together. The latter reaction enhances vessel wall stickiness and keeps the vessel closed after vasoconstriction subsides. Vascular spasm may last for 20 to 30 minutes. This allows time for the body to activate the platelet response and plasma clotting factors. The platelet response and plasma clotting factors are triggered by endothelial injury and the release of substances such as thromboxane A_2 (TXA_2) von Willebrand factor (vWF) and clotting factor VIII. Platelets begin to fill endothelial gaps.[1]

Adhesion

The loss of endothelial cells exposes adhesive glycoproteins, such as collagen and vWF, to which more platelets adhere. The stickiness is termed *adhesiveness*. The formation of clumps is termed *aggregation* or *agglutination*.

Clotting Cascade Activation

The interactions thus far cause the platelets to undergo an activation process. This leads to changes in platelet shape. The platelets then can bind adhesive proteins, including fibrinogen and vWF. Release of various platelet granules (including adenosine phosphate [ADP]) recruits and activates other platelets, clotting factors, and growth factors. As Fig. 33.4 shows, platelet lipoproteins stimulate necessary conversions in the clotting process.

Blood Clot Formation

Platelet aggregation is stimulated by TXA_2 and ADP, which induce fibrinogen receptors on the platelet. The formation of a visible fibrin clot on the platelet plug is the conclusion of a complex series of reactions involving different clotting (coagulation) factors. We label plasma clotting factors with both names and Roman numerals (Table 33.2).[3] Most are glycoproteins made in the liver. Monocytes, endothelial cells, and megakaryocytes make a few clotting factors. Some are enzymes that circulate in an inactive form (zymogens).[3]

Plasma proteins circulate in inactive forms until stimulated to start clotting through the intrinsic or extrinsic pathway (Fig. 33.4). The *intrinsic pathway* is activated by collagen exposure from endothelial injury when the blood vessel is damaged. The *extrinsic pathway* is activated when tissue factor or tissue thromboplastin is released from injured tissues.

Regardless of how we begin to clot, coagulation ultimately follows the same final common pathway of the clotting cascade. Thrombin, in the common pathway, is the most powerful enzyme in the coagulation process (Fig. 33.4). It converts fibrinogen to fibrin, which is an essential part of a blood clot. The final blood clot is a meshwork of protein strands that stabilizes the platelet plug and traps other cells, such as RBCs, phagocytes, and microorganisms.

Clot Retraction and Dissolution

Just as some blood elements foster coagulation *(procoagulants)*, others interfere with clotting *(anticoagulants)*. This counter mechanism to blood clotting keeps blood in its fluid state.

Antithrombin activity, vessel and platelet activity, and fibrinolysis contribute to anticoagulation. As the name implies, antithrombins keep blood in a fluid state by antagonizing thrombin,

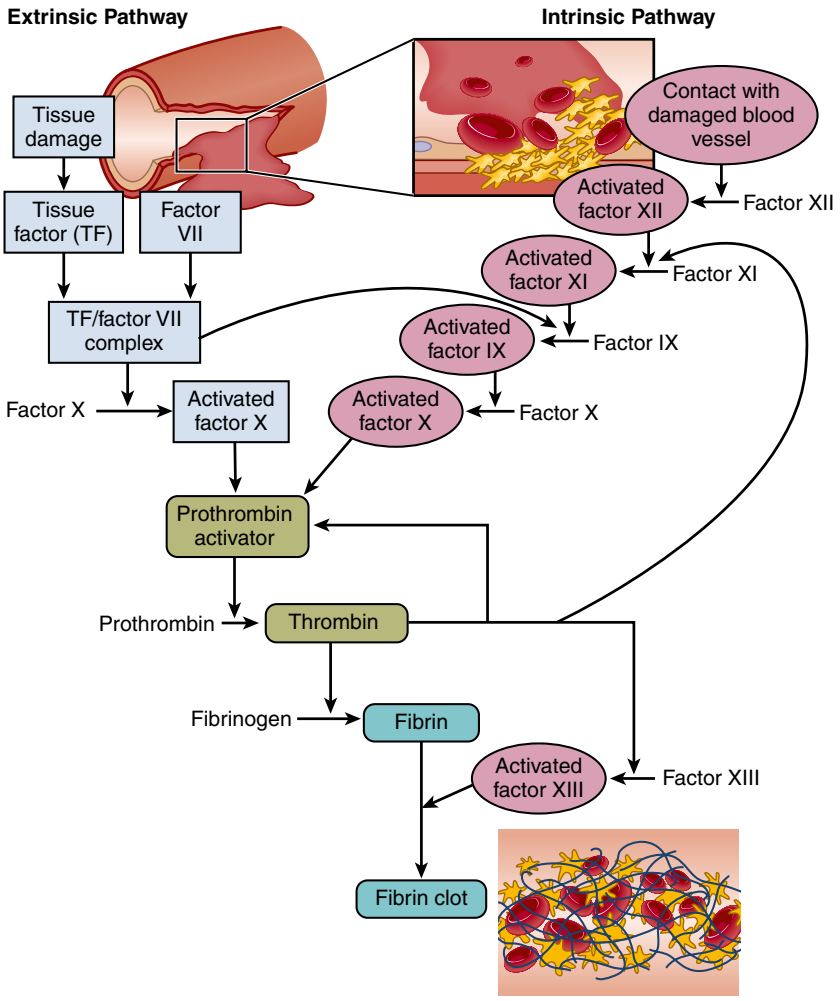

Fig. 33.4 Coagulation mechanism showing steps in the intrinsic pathway and extrinsic pathway as they would occur in the test tube.

a powerful coagulant. Endogenous heparin, antithrombin III, protein C, and protein S are examples of anticoagulants.

The second way we keep blood in its fluid form is **fibrinolysis**, a process resulting in the dissolution of the fibrin clot. The fibrinolytic system starts when plasminogen is activated by substances such as tissue plasminogen activator (t-PA) and urokinase-like plasminogen activator (u-PA) to plasmin (Fig. 33.5). Thrombin can activate the conversion of plasminogen to plasmin, promoting fibrinolysis. Plasmin attacks either fibrin or fibrinogen by splitting the molecules into smaller elements called *fibrin split products* (FSPs) or *fibrin degradation products* (FDPs). You can find more about FSPs in Table 33.8 and in the section on disseminated intravascular coagulation (DIC) in Chapter 34.

Excessive fibrinolysis predisposes the patient to bleeding. In this situation, bleeding results from the destruction of fibrin in platelet plugs or from the anticoagulation effects of increased FSPs. Increased FSPs lead to impaired platelet aggregation, reduced prothrombin, and an inability to stabilize fibrin.

Spleen

The spleen is the largest lymphoid organ. It is found in the upper left quadrant of the abdomen. The spleen has 4 major functions: hematopoietic, filtration, immunologic, and storage. The hematopoietic function is shown by the spleen's ability to make RBCs during fetal development. Through filtration, the mononuclear phagocyte system in the spleen removes old and defective RBCs from the circulation. The spleen can catabolize hemoglobin released by hemolysis and return the iron part of the hemoglobin to the bone marrow for reuse. The spleen filters circulating bacteria, especially encapsulated organisms such as gram-positive cocci. The spleen's rich supply of lymphocytes, monocytes, and stored immunoglobulins plays a role in immunologic function. The spleen is a storage site for RBCs and platelets. It can store more than 300 mL of blood. We store about one-third of platelets in the spleen.

Lymph System

The lymph system, consisting of lymph, lymphatic capillaries, ducts, and lymph nodes, carries fluid from the interstitial spaces to the blood. It is through the lymph that proteins and fat from the GI tract and certain hormones can return to the circulatory system. The lymph system also returns excess interstitial fluid to the blood.

Lymph is pale yellow interstitial fluid that has diffused through lymphatic capillary walls. The lymph vessels collect interstitial fluid from the tissues and transport it as lymph through vessels. Eventually, lymph enters the thoracic duct,

TABLE 33.2 Coagulation Factors

Coagulation Factor	Action
I Fibrinogen	Source of fibrin to form a clot
II Prothrombin	Converted to thrombin, which then activates fibrinogen into fibrin as well as factors V, VII, VIII, XI, XIII, protein C, for clot stabilization
III Tissue factor, tissue thromboplastin	Released from damaged endothelial cells and activates the extrinsic pathway by reacting with factor VII
IV Calcium	Required cofactor at several points in the coagulation cascade
V Proaccelerin (labile) factor	Binds with factor X to activate prothrombin
VII Stable factor, proconvertin	Forms a complex with factor III (tissue factor) and activates factors IX and X
VIII Antihemophilic factor	Works with factor IX and calcium to activate factor X
IX Christmas factor	Together with factor VIII, activates factor X
X Stuart factor	Activates conversion of factor II (prothrombin) to thrombin
XI Plasma thromboplastin antecedent	Activates factor IX when calcium is present
XII Hageman factor	Activates factor XI, which starts the intrinsic pathway
XIII Fibrin-stabilizing factor	Cross-links fibrin strands and stabilizes fibrin clot

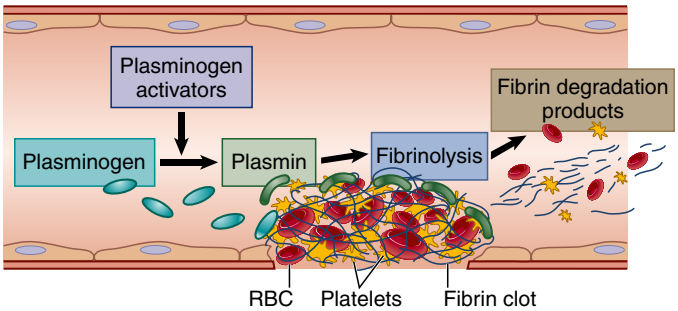

Fig. 33.5 Fibrinolytic system.

which drains into the superior vena cava. Lymph formation increases when interstitial fluid increases. This forces more fluid into the lymph system. When too much interstitial fluid develops or when something interferes with the reabsorption of lymph, *lymphedema* develops. Lymphedema may occur as a complication of mastectomy or lumpectomy with dissection of axillary nodes. In this case, lymphedema is caused by the obstruction of lymph flow from the removal of lymph nodes.

The lymphatic capillaries are thin-walled vessels that have an irregular diameter. They are larger than blood capillaries and do not have valves.

The *lymph nodes* are also part of the lymph system. Their main function is to filter pathogens and foreign particles that are carried by lymph to the nodes. They are round, oval, or bean shaped. Structurally, the nodes are small clumps of lymph tissue. They are found in groups along lymph vessels at various sites. There are more than 200 lymph nodes throughout the body. The greatest number is in the abdomen surrounding the GI tract. They vary in size according to their location. We have both superficial and deep lymph nodes. We can palpate superficial nodes. Evaluating deep nodes requires radiologic examination.[4]

Liver

The liver has metabolic, secretory, vascular, immune, and storage functions.[1,3] It makes all the procoagulants we need for hemostasis and blood coagulation and secretes bilirubin and bile. It stores iron that exceeds tissue needs, which can occur with blood transfusions or diseases that cause iron overload. *Hepcidin,* made by the liver, is a key regulator of iron balance. Iron overload or inflammation stimulates hepcidin synthesis. Hepcidin inhibits the release of stored iron from enterocytes (in the intestines) and macrophages. So, when iron is deficient, hepatocytes make less hepcidin. This results in the release of stored iron and an increase in dietary absorption. Other liver functions are described in Chapters 43 and 48.

Gerontologic Considerations: Effects of Aging on Hematologic System

Aging leads to a decrease in bone marrow mass and cellularity and an increase in bone marrow fat.[5] At birth, hematopoietic tissue occupies 80% to 100% of the marrow space. This is reduced to 50% at age 30 and 30% at age 70.[5] Although the older adult can still maintain adequate blood cell levels, the reduced reserve capacity leaves them more vulnerable to possible problems with clotting, transporting O_2, and fighting infection, especially during periods of increased demand. This contributes to their having a decreased ability to compensate for an acute or chronic illness.

Hemoglobin levels may begin to decrease in both men and women after middle age. Low-normal levels occur in most older people. Total serum iron, total iron-binding capacity, and intestinal iron absorption are all decreased. The RBC plasma membranes are more fragile. This may account for a slight increase in mean corpuscular volume (MCV) and a slight decrease in mean corpuscular hemoglobin concentration (MCHC) of RBCs in some older adults. While iron deficiency may cause low hemoglobin levels, other factors, such as GI bleeding, renal disease, testosterone deficiency, or bone marrow dysfunction, should be ruled out.[3] In 30% to 40% of cases, there is no specific cause of anemia. We call this "unexplained anemia."[6] Healthy older patients are not able to make reticulocytes in response to hemorrhage or hypoxemia as well as younger adults. This is likely due to a blunted response to erythropoietin.[3]

Aging generally does not affect the total WBC count and differential. There may be a slight increase in neutrophils and a decrease in lymphocytes. The function of lymphocytes decreases, blunting the response to infection.[3] During an infection, the older adult may have only a minimal elevation in the total WBC count. This suggests decreased bone marrow reserve of granulocytes and reflects possible impaired stimulation of hematopoiesis and neutrophil function.[3]

The number of platelets is unaffected by the aging process. Functionally, they may have increased adhesiveness. Clotting factors increase with age. Thus, aging is associated with an increased chance of clotting problems, such as venous thromboembolism.[3] Changes in vascular integrity related to aging can manifest as easy bruising.

Table 33.3 outlines the effects of aging on hematologic studies. Immune changes related to aging are detailed in Chapter 14.

ASSESSMENT OF HEMATOLOGIC SYSTEM

Much of the evaluation of the hematologic system is based on the health history and presenting signs and symptoms.

Case Study

Patient Introduction

(© Lisa F. Young/iStock.)

A.J. is a 63-year-old woman who presents to the emergency department with her husband. He came home from work and found his wife at home, weak and in bed after she work. She says she has been slowly getting more "cold and tired," but "that is what happens when you work at my age." Her husband states that she has become more tired over the last couple of weeks and "she looks pale." She has been having trouble working all day and even gets short of breath when doing simple errands. She recently had a "bad cold and sinus infection" that only improved after 2 courses of antibiotics. A.J. says, "I've noticed I've had a lot of bruising lately."

Discussion Questions

1. What are the possible causes of A.J.'s weakness, pallor, and shortness of breath?
2. Is her condition stable or an emergency?
3. What type of assessment is most appropriate for A.J.: comprehensive, focused, or emergency? On what basis did you make that decision?
4. What assessment questions would you ask A.J.?

You will learn more about A.J. and her condition as you read this chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

TABLE 33.3 GERONTOLOGIC ASSESSMENT DIFFERENCES

Effects of Aging on Hematologic Studies

Study	Changes
CBC Studies	
Hemoglobin (Hgb)	Usually normal in women; possibly slight ↓ in men
Mean corpuscular hemoglobin concentration (MCHC)	May be slightly ↓
Mean corpuscular volume (MCV)	May be slightly ↑
Platelets	May be slightly ↓; possible ↑ in adhesiveness
White blood cell (WBC) count	Decreased response to infection
Clotting Studies	
D-dimers	↑
Erythrocyte sedimentation rate (ESR)	↑ Significantly
Factors V, VII, IX	May be ↑
Fibrinogen	May be ↑
Partial thromboplastin time	May be ↓
Iron Studies	
Erythropoietin	May be ↑
Ferritin	↑
Serum iron	↓
Total iron-binding capacity	↓

Subjective Data

Important Health Information

Health history. Determine if the patient has had prior hematologic problems. Ask about anemia, bleeding problems, and blood disorders. Are there related medical conditions, such as malabsorption or liver (e.g., hepatitis, cirrhosis), kidney, or spleen problems? A solid organ transplant, loss of the spleen to traumatic injury, or a history of IV drug or alcohol use affects the risk for hematologic problems. A history of recent or recurrent infections or blood clotting problems is important to note.

Medications. A complete medication history is important. Ask about the use of vitamins, herbal products, or diet supplements. Many medications may interfere with normal hematologic function.[3] Those on long-term anticoagulant therapy, such as warfarin, are at risk for bleeding problems. Chemotherapy drugs and antiretroviral agents used to treat human immunodeficiency virus (HIV) infection may cause bone marrow depression. A patient previously treated with chemotherapy agents, particularly alkylating agents, has a higher risk for developing a secondary cancer of leukemia or lymphoma.

Surgery or other treatments. Obtain a surgical history. This includes splenectomy, tumor removal, prosthetic heart valve placement, and GI surgeries. A partial or total gastrectomy removes parietal cells, thus reducing intrinsic factor needed for the absorption of cobalamin (vitamin B_{12}). Duodenal excision (where iron absorption occurs), gastric bypass (the duodenum may be bypassed and parietal cell surface area decreased), and ileal resection (reduces area where cobalamin absorption takes place) can result in problems. Assess wound healing after surgery and if there were any bleeding problems. Discuss wound healing and bleeding as responses to injuries (including minor trauma) and dental extractions. Determine the number of previous blood transfusions and any complications. The risk for transfusion reactions and iron overload increases with the number of blood transfusions.

Functional Health Patterns

Key questions to ask a patient with a hematologic problem are outlined in Table 33.4.

Health perception–health management pattern. Ask the patient to describe the usual and present state of health. Gather demographic data, including age, gender, race, and ethnic background. Ask if there is any family history of hematologic problems (Box 33.1). Ask about anemia, cancer, RBC disorders, such as sickle cell disease, and bleeding disorders, such as hemophilia and clotting problems.

Assess risk factors, such as alcohol and cigarette use, which may disrupt the hematologic function. Alcohol is caustic to the GI mucosa and can cause damage that results in GI bleeding, esophageal varices, and decreased absorption of cobalamin and other nutrients.

Chronic alcohol users often have vitamin deficiencies. Alcohol exerts a damaging effect on platelet function and the liver, where we make clotting factors. Consequently, bleeding problems can develop and should be expected with chronic alcohol use. Illicit drug use is important to determine since many of these drugs may affect hematopoiesis.

Cigarette smoking increases low-density lipoprotein (LDL) cholesterol and levels of CO_2. This leads to hypoxia and

TABLE 33.4 HEALTH HISTORY

Hematologic System

Health Perception–Health Management
- Do you have any problem performing daily activities because of a lack of energy?*
- Do you smoke cigarettes or drink alcohol?[a]
- Do you take any prescribed or over-the-counter medications?[a]
- Are you taking any herbs?[a] Home remedies?[a]
- Have you in the past or are you currently consuming illegal drugs? What agents? What route? How often? When did you last use?
- Have you ever received a blood transfusion?[a]
- Is there any family history of anemia, cancer, bleeding, or clotting problems?[a]
- Have you had any surgeries?[a]

Nutritional-Metabolic
- Do you have any problems with eating, chewing, or swallowing?[a]
- Have you had any mouth sores, sore tongue, swollen or sore gums, oral bleeding?[a]
- What kind of diet do you follow? If a vegetarian, do you eat eggs, milk products, fish?
- How has your appetite been?
- Have you had any changes in your weight in the past year?[a]
- Do you take any vitamins, nutrition supplements, or iron?[a]
- Is nausea and vomiting a problem for you?[a]
- Have you ever had any unusual bleeding or bruising?[a]
- Have there been recent changes in the condition or color of your skin?[a]
- Have you had night sweats or cold intolerance?[a]
- Have you noticed any swelling in your armpits, neck, or groin?[a]

Elimination
- Have you had black or tarry stools?[a] Have you had light, clay-colored stools?[a]
- Have you noticed any blood or dark "tea color" in your urine?[a]
- Has your urine had a foul odor or cloudiness?
- Have you had any decrease in urine output?[a]
- Do you ever have diarrhea or change in bowel patterns?[a]

Activity-Exercise
- Do you have any shortness of breath at rest? With activity?[a]
- Do you have any limitations in joint motion?[a] Have any of your joints been swollen?[a]
- Do you have a problem with unsteady gait? Have you fallen recently?[a]
- Do you exercise regularly? What type and how often?[a]
- After activity, do you ever notice bleeding or bruising?[a]

Sleep-Rest
- Have you had excessive fatigue recently?[a]
- Are you more tired than usual?[a]
- Do you feel rested on awakening? If no, explain.

Cognitive-Perceptual
- Have you had any numbness or tingling?[a]
- Have you had any problems with your vision, hearing, or taste?[a]
- Have you noticed any changes in your mental function?[a]
- Do you have any pain, such as bone, joint, or abdominal pain, or abdominal fullness?[a]
- Do you have pain when moving your joints?[a]
- Have your muscles been sore or achy recently?[a]

Self-Perception–Self-Concept
- Does your health problem make you feel differently about yourself?[a]
- Do you have any physical changes that cause you distress?[a]

Role-Relationship
- Does your occupation bring you into contact with hazardous substances?[a]
- Has your present illness caused a change in your roles and relationships?[a]

Sexuality-Reproductive
- Has your problem caused any sexual or intimacy problems that concern you?[a]
- *Women:* When was your last menses? Do you consider your cycle normal? How long does your bleeding usually last? Have you had any increase in cramping or clotting?[a] Have there been any changes in the amount of flow?[a]
- *Men:* Do you ever have impotence?[a]
- Have you had unprotected sex in the past 6 months?[a] Was your partner someone new or a person with whom you have had a long-term sexual relationship?

Coping–Stress Tolerance
- Do you have a support system to help you when needed?
- What coping strategies do you use when your symptoms are worse?
- Do you have any specific symptoms when you feel stressed?[a]

Value-Belief
- Do you have any personal or religious objection to receiving blood or blood products?[a]
- Do you have any conflicts between your planned therapy and your value-belief system?[a]

[a]If yes, describe.

BOX 33.1 GENETIC RISK ALERT

- Hematologic problems with a strong genetic link include sickle cell anemia, hemophilia, thalassemia, and hemochromatosis.
- People with a family history of these problems have a greater risk for developing them.
- Leukemia, pernicious anemia, and clotting disorders may have a genetic predisposition.

changing the anticoagulant properties of the endothelium. Smoking increases platelet reactivity, plasma fibrinogen, hematocrit, and blood viscosity.

Nutritional-metabolic pattern. Determine if the patient has had anorexia, nausea, vomiting, or oral discomfort. A diet history may give clues about the cause of anemia. We need iron, cobalamin, and folic acid for RBC development. Iron and folic acid deficiencies are related to inadequate intake of foods such as meat, fish, eggs, leafy green vegetables, legumes, citrus fruits, and whole-grain and enriched breads, cereals, and rice.[7]

Hematemesis (bright red, brown, or black vomitus) is a manifestation of an underlying problem and always needs investigating. Peptic ulcer disease is a common cause of hematemesis.

Explore any changes in the skin's texture, color, or temperature. Ask about bleeding gum tissue or bleeding from anywhere on the body. Ask about any lumps or swelling in the neck, armpits, or groin. Specifically, ask what the lumps feel like (i.e., hard or soft, tender or nontender). Are they mobile or fixed? Primary lymph tumors are usually not painful. A nontender, consistently swollen lymph node may be a sign of a cancer, such as Hodgkin

or non-Hodgkin lymphoma. An acute infection may cause enlarged, tender lymph nodes.[4] Explore any reports of fever. Determine if the patient currently has a fever, recurring fevers, chills, or night sweats.

Ask patients if they have a history of heart or lung diseases. Cardiovascular problems, such as valvular disease or hypertension, may predispose patients to hemolysis. Many medications used to treat cardiovascular disease can cause problems with hematopoietic cell production or coagulation. Lung problems that lead to hypoxemia may cause chronic stimulation of erythropoietin and result in *polycythemia* (excess RBCs).

Elimination pattern. Ask if there has been blood in the urine or stool or if black, tarry stools have occurred. Ask the patient if they have had a recent stool tested for occult blood or colonoscopy.

Activity-exercise pattern. Because fatigue is a prominent symptom in many hematologic problems, ask about feelings of tiredness. Determine any weakness or feelings of heavy extremities. Assess for apathy, malaise, dyspnea, or palpitations. Note any change in the patient's ability to perform regular exercise and/or activities of daily living (ADLs), especially as they relate to a history of falling.

Sleep-rest pattern. Determine whether the patient feels rested after a night's sleep. Fatigue from a hematologic problem often does not resolve after sleep.

Cognitive-perceptual pattern. Assess for any joint pain that may be caused by a hematologic problem. Pain in the joint may occur with an autoimmune disorder, such as rheumatoid arthritis. It may occur with gout from increased uric acid production due to hematologic cancer or hemolytic anemia. Aching bones may result from pressure of expanding bone marrow with diseases such as leukemia. *Hemarthrosis* (blood in a joint) occurs in the patient with bleeding disorders and can be painful.

Note any paresthesias, numbness, and tingling as they may be related to a hematologic disorder. Assess for any changes in vision, hearing, taste, or mental status.

Self-perception–Self-concept pattern. Determine the effect of the health problem on the patient's perception of self and personal abilities. Assess the effect of certain problems, such as bruising, petechiae, and lymph node swelling, on the patient's personal appearance.

Role-relationship pattern. Ask the patient about any past or present occupational or household exposures to radiation or chemicals. If such exposure has occurred, determine the type, amount, and duration of the exposure. A person who was exposed to radiation, as a treatment modality or by accident, has a higher incidence of certain hematologic problems. The same is true of a person who was exposed to certain chemicals (e.g., benzene, vinyl chloride, pesticides). These chemicals are often used by mechanics and petroleum industry works, farmers, construction and transportation workers, or those in the military. Assess the effect of the present illness on the patient's usual roles and responsibilities.

Sexuality-reproductive pattern. Take a careful menstrual history from women. Include the age at which menarche and menopause began, duration and amount of bleeding, incidence of clotting and cramping, and any associated problems. Ask men if they have any erectile problems. Ask the patient about sexual behavior that may increase the risk for HIV infection.

Coping–stress tolerance pattern. The patient with a hematologic problem often needs help with ADLs. Ask the patient if adequate support is available to meet daily needs. Determine the patient's usual methods of handling stress. In the patient with platelet disorders or hemophilia, the potential for hemorrhage can be so frightening that usual life patterns may be drastically curtailed, affecting the person's quality of life.

Value-belief pattern. Treatment for some hematologic problems involves blood transfusions or a bone marrow transplant. Determine if these treatments conflict with the patient's value-belief system, including the patient's cultural and

Case Study

Subjective Data

(© Lisa F. Young/ iStock.)

A focused subjective assessment of A.J. revealed the following information:

Medical History: History of mild osteoarthritis. No surgical history. Prefers to take care of self with "natural therapy" and has not seen an HCP for 5 years, except for the recent sinus infection.

Medications: Metamucil 1 Tbsp/day PO; vitamins C, E, and D with calcium.

Health Perception–Health Management: Denies family or personal history of anemia, cancer, or bleeding disorders. Believes she comes from a family with great genes for longevity because they "eat organic foods." Drinks 1 glass of red wine with her evening meal "because it's good for your heart." Reporting a gradual increase in shortness of breath with exertion. Says she really cannot do anything anymore without having to stop and catch her breath. Says, "It's tough getting old."

Nutritional-Metabolic: Eat a lot of pasta "because it is cheap." Uses a lot of garlic for flavoring and the "health benefit of it." Although not a vegetarian, eats little meat.

Elimination: Denies black or tarry stool. Occasional constipation. No problems with urination. Urine without odor.

Activity-Exercise: Having a hard time performing ADLs without having to stop and catch her breath. Denies dyspnea at rest. States joints are stiff on arising in morning and after sitting but able to get around OK and work at her secretarial job. States her walking is steady but weak. No history of falling.

Sleep-Rest: Typically sleeps 8–9 hr per night with no trouble falling asleep. Still feels tired and needs to nap during her lunch break and during her days off.

Cognitive-Perceptual: Denies any numbness or tingling. Admits to being a little hard-of-hearing but can still see "pretty good."

Value-Belief: Prefers natural therapies over traditional medication.

Discussion Questions

1. What subjective assessment findings concern you most?
2. Based on these subjective assessment findings, what type of physical assessment should you perform?
3. What should you include in the physical assessment? For what would you be looking?
4. How will you individualize the physical assessment based on the information from A.J. and her husband?

You will learn more about the physical assessment of the hematologic system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

religious beliefs related to blood and blood transfusions. Notify the HCP if you identify any conflicts.

Objective Data

Physical Assessment

A complete physical assessment is needed to examine all systems that affect or are affected by the hematologic system. A patient's presenting symptoms may not immediately point to a hematologic problem (Table 33.5). For example, paresthesias of the lower extremities may not appear to be a hematologic problem. But when combined with other findings and risk factors, it may indicate cobalamin deficiency and resulting pernicious anemia. Certain aspects of the assessment are specifically relevant. These include skin, lymph nodes, spleen, and liver.

Lymph node assessment. Assess lymph nodes symmetrically. Note location, size (in centimeters), degree of fixation (e.g., movable, fixed), tenderness, and texture. Lightly palpate the superficial lymph nodes using the pads of the fingers (Fig. 33.6). Then gently roll the skin over the area and feel for lymph node enlargement. We cannot palpate deep lymph nodes. They are evaluated by radiologic examination.

Ordinarily, lymph nodes are not palpable in adults. If a node is palpable, it should be small (0.5 to 1 cm), mobile, firm, and nontender to be considered a normal finding. A node that is tender, hard, fixed, or enlarged (whether it is tender or not) is an abnormal finding and needs further investigation. Tender nodes are usually a result of inflammation. Hard or fixed nodes suggest cancer.[4]

TABLE 33.5 ASSESSMENT ABNORMALITIES

Hematologic System

Finding	Description	Possible Cause and Significance
Abdomen		
Distended abdomen	A larger than normal abdominal profile. May be soft or firm, tender or nontender, and accompanied by other symptoms, such as nausea, vomiting, or rebound tenderness	Lymphoma may manifest as abdominal adenopathy, mass(es), or bowel obstruction
Hepatomegaly	Palpable liver	Leukemia, cirrhosis, or fibrosis due to iron overload from sickle cell disease or thalassemia
Splenomegaly	Palpable spleen	Anemia, thrombocytopenia, leukemia, lymphomas, leukopenia, mononucleosis, malaria, cirrhosis, trauma, portal hypertension
Eyes		
Blurred vision, diplopia, visual field cuts	Decreased visual acuity or areas of blindness (field cuts)	Anemia, extreme leukocytosis, polycythemia, hyperviscosity may cause vision problems. Thrombocytopenia may cause intraocular hemorrhage with vision changes. Excessive clotting may cause thromboses in circulation to the brain that cause visual field cuts
Conjunctival pallor	Paleness. Decreased or absence of coloration in the conjunctiva	Low Hgb level (anemia)
Jaundiced sclera	Yellow appearance of sclera	Accumulation of bile pigment resulting from rapid or excessive hemolysis or liver disease or infiltration
Heart and Chest		
Altered blood pressure	*Hypertension:* >140/90 mm Hg *Hypotension:* <90 mm Hg systolic or >40 mm Hg drop from baseline *Orthostasis:* heart rate >20 beats/min increase or blood pressure >20 mm Hg decrease from baseline when moving from a lying position to either sitting or standing	May occur initially as a compensatory mechanism for anemia Infectious process, blood loss, compromised cardiovascular compensatory mechanisms Common with anemia, especially if also accompanied by low blood volume
Low O_2 saturation	O_2-carrying capacity as reflected by O_2 saturation by pulse oximetry	O_2 saturation may be decreased in cases of severe anemia
Palpitations	Feeling the heartbeat, flutter, or pound in chest	Anemia, fluid volume overload, hypotension with impending syncope, hypertension, dysrhythmias
Sternal tenderness	Abnormal sensitivity to touch or pressure on sternum	Leukemia resulting from increased bone marrow cellularity, causing increase in pressure and bone erosion. Multiple myeloma because of lytic bone lesions
Tachycardia	Heart rate >100 beats/min	Compensatory mechanism in anemia to increase cardiac output
Lymph Nodes		
Lymphadenopathy	Lymph nodes enlarged (>1 cm). May be tender to touch	Infection, foreign infiltrations, systemic disease such as leukemia, lymphoma, Hodgkin lymphoma, metastatic cancer
Mouth		
Gingival and mucous membrane changes	Pallor, gingival and mucosal ulceration or infection, swelling, or bleeding	Low Hgb level (anemia), neutropenia thrombocytopenia. Inability of impaired leukocytes to combat oral infections. Gingival hyperplasia may be present with some types of leukemia

Continued

TABLE 33.5 ASSESSMENT ABNORMALITIES—cont'd

Hematologic System

Finding	Description	Possible Cause and Significance
Smooth tongue	Tongue surface smooth and shiny. Mucosa thin and red from decreased papillae	Pernicious anemia, iron-deficiency anemia
Musculoskeletal System		
Arthralgia	Joint pain	Bleeding into joints from sickle cell disease, hemophilia
Bone pain	Pain in pelvis, ribs, spine, sternum	Multiple myeloma related to lytic bone lesions. Bone invasion by leukemia cells, bone demineralization resulting from various cancers, sickle cell disease
Joint swelling	Fluid-filled spaces surrounding joints	Occurs with hemophilia and sickle cell anemia as hemarthrosis causes inflammation
Nervous System		
Headache, nuchal rigidity	Pain in the cranium, potentially involving one area or extending from frontal area to back of neck	Generalized headache is a common manifestation of mild to moderate anemia. Severe headache with or without vision changes may signal intracranial hemorrhage due to thrombocytopenia. CNS disease with acute lymphoblastic leukemia, CNS lymphoma
Paresthesias of feet and hands, ataxia	Numbness sensation and extreme sensitivity in central and peripheral nerves. Impaired muscle movement	Cobalamin (vitamin B_{12}) deficiency or folate deficiency
Weakness	Lacking physical strength or energy	Low Hgb level (anemia)
Nose		
Nosebleeds	Spontaneous bleeding from nares	May occur with low platelet counts, especially if patient bends down for a long time, tries to lift a heavy item, or performs an intense Valsalva maneuver
Skin		
Chloroma	A tumor arising from myeloid tissue and containing a pale green pigment	Acute myelogenous leukemia that has infiltrated the skin, rare forms of lymphoma
Cyanosis	Bluish discoloration of skin and mucous membranes	Anemia, excess concentration of deoxyhemoglobin in blood
Excoriation	Scratch or abrasion of skin	Scratching from intense pruritus
Flushing	Transient, episodic redness of skin (usually around face and neck)	Increase in Hgb (polycythemia), congestion of capillaries. Flushing of palms of hands or soles of feet sign of anemia
Jaundice	Yellow appearance of skin and mucous membranes	Accumulation of bile pigment caused by rapid or excessive hemolysis or liver damage
Leg ulcers	Prominent on the malleoli on the ankles	Sickle cell disease
Pallor of skin or nail beds	Paleness. Decreased or absence of skin coloration	Low Hgb level (anemia)
Plasmacytoma	Tumor arising from abnormal plasma cells	Multiple myeloma that has infiltrated tissue
Pruritus	Unpleasant cutaneous sensation that provokes the desire to rub or scratch skin	Hodgkin lymphoma, cutaneous lymphomas, infiltrative leukemias, increased bilirubin

Develop a sequence when examining the lymph nodes. A convenient sequence is to start at the head and neck. First, palpate the preauricular, posterior auricular, occipital, tonsillar, submandibular, submental, superficial cervical, posterior cervical chain, deep cervical chain, and supraclavicular nodes. Next, palpate the axillary lymph nodes and pectoral, subscapular, and lateral groups of nodes. Then examine the epitrochlear nodes found in the antecubital fossa between the biceps and triceps muscles. Last, palpate the inguinal lymph nodes found in the groin.

Palpation of liver or spleen. The liver and spleen are normally not detectable by palpating the abdomen. An enlarged liver or spleen may be detectable by percussion or palpation. Measure the degree of liver enlargement by the number of fingerbreadths it extends below the rib border. The spleen may be harder to detect because of its deep location in the left abdomen. Techniques for palpating the liver and spleen are described in Chapter 43.

Skin assessment. Examine the skin over the entire body in a systematic manner. In patients with RBC disorders, the skin may be pale or pasty. It may have a cyanotic tinge in severe anemia. Erythrocytosis often causes small vessel occlusions, causing a purple, mottled appearance of the face, nose, fingers, or toes. You can best assess color changes in persons with dark skin in the sclera, conjunctiva, buccal mucosa, tongue, lips, nail beds, and palms.[4] *Clubbing of the fingers* (discussed in Chapter 27) can be seen with chronic anemia. Skin assessment is discussed in Chapter 24.

WBC disorders may cause infectious or cancerous skin lesions. These may occur anywhere and have a variable distribution pattern.

Look for findings that can indicate bleeding disorders. Assess for **petechiae** (small purplish red pinpoint lesions), **ecchymoses** (bruising), and *spider nevus* (a form of *telangiectasia*) (Table 33.6). The location of petechiae can indicate an accumulation of blood in the skin or mucous membranes. Small vessels leak

under pressure, and the platelet numbers are not enough to stop the bleeding. Petechiae are more likely to occur where clothing constricts the circulation. In general, skin and mucosal bleeding means a platelet disorder. Spontaneous bleeding into joints or muscles means a coagulation factor problem.

A *focused assessment* is used to assess the status of previously identified hematologic problems and to monitor for signs of new problems. A focused assessment of the hematologic system is shown in Box 33.2.

Case Study

Objective Data: Physical Assessment

(© Lisa F. Young/ iStock.)

Physical assessment findings of A.J. are as follows: BP 100/70 (lying), 88/60 (standing); apical pulse 110 (lying), 124 (standing), regular. Respiratory rate 26, temp 96.8°F (36°C), O_2 saturation 90% on room air. No jugular venous distention. Weight 106 lb (48 kg). Height 5 ft 1 in. Skin pale. 2 ecchymoses on her arms; 1 on the left lower leg. A few scattered petechiae on both ankles. No jaundice noted. Conjunctivae pale. Tongue smooth and shiny. Lungs clear with diminished breath sounds in the bases bilaterally. No visible bleeding. No enlarged lymph nodes, spleen, or liver noted. General weakness with dyspnea on exertion. No numbness or tingling or peripheral edema.

Discussion Questions

1. Which physical assessment findings are of most concern to you?
2. Based on the results of the assessment findings, what diagnostic studies do you think may be ordered for A.J.?

You will learn more about diagnostic studies in relation to the hematologic system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

DIAGNOSTIC STUDIES OF HEMATOLOGIC SYSTEM

The most direct means of evaluating the hematologic system is through laboratory analysis. Select studies are described in more detail here.

Laboratory Studies

Complete Blood Count

The complete blood count (CBC) involves several laboratory tests (Table 33.7). In addition to the CBC, a *peripheral smear* may be done. The smear is used to look at the *morphology* (shape and appearance) of the blood cells and may help with the diagnosis. For example, many immature blast WBCs may indicate acute leukemia. Diseases or treatments can disrupt the entire system. When the entire CBC is suppressed, a condition termed **pancytopenia** (marked decrease in the number of RBCs, WBCs, and platelets) exists.

Red blood cells. The total RBC count is reported as RBC × 10^6/μL. However, the total RBC count is not fully reliable in determining the adequacy of RBC function. We must evaluate other data, such as hemoglobin, hematocrit, and RBC indices. Normal values of some RBC tests are different for men and women because normal values are based on body mass. Men usually have a larger body mass than women.

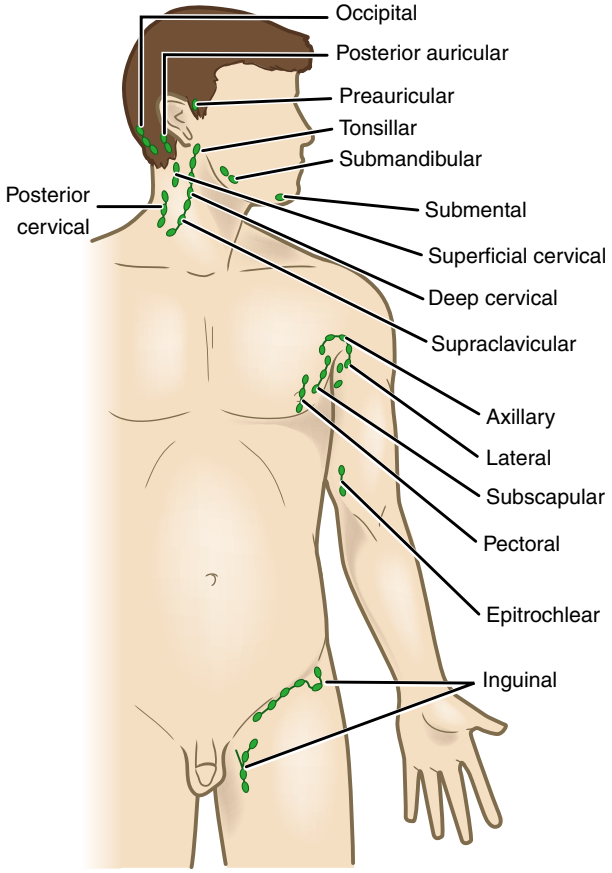

Fig. 33.6 Palpable superficial lymph nodes.

The *hemoglobin (Hgb) value* is reduced with anemia, hemorrhage, and hemodilution, such as that occurring with excess fluid volume. Increased hemoglobin occurs in polycythemia or hemoconcentration, which can develop from volume depletion (dehydration). Increases and decreases of the hematocrit value and RBC count occur with the same conditions that raise and lower the hemoglobin value.

The *hematocrit (Hct) value* is determined by spinning blood in a centrifuge. This causes RBCs and plasma to separate. The RBCs, being the heavier elements, settle to the bottom (Fig. 33.2). The hematocrit value is the percent of RBCs compared with the total blood volume. The hematocrit value generally is 3 times the hemoglobin value. *RBC indices* are special indicators that reflect RBC volume, color, and hemoglobin saturation (Table 33.7).[8] These parameters give insight into the cause of anemia.

White blood cells. The WBC count gives 2 sets of information. The first is a total count of WBCs in 1 μL of peripheral blood. A WBC count over 10,000/μL occurs with infection, inflammation, tissue injury or death, and cancer (e.g., leukemia, lymphoma). Although the degree of WBC elevation does not necessarily predict the severity of illness, it can give clues to the cause. Extremely high WBC counts (e.g., greater than 25,000/μL) occur with certain types of leukemia. A WBC count less than 5000/μL (**leukopenia**) occurs with bone marrow depression, severe or chronic illness, and other types of leukemia.

The second aspect of the WBC count, the *differential count,* measures the percent of each type of WBC. The WBC

TABLE 33.6 ASSESSMENT ABNORMALITIES

Vascular Skin Lesions

Finding	Description	Possible Cause and Significance
Angioma 	Benign tumor. Consists consisting of blood or lymph vessels	Most are congenital. May disappear spontaneously
Ecchymosis (bruise) 	Hemorrhagic spots of varied size. Flat. Round or irregular	Decreased platelets or clotting factors resulting in hemorrhage into skin. Vascular abnormalities. Break in blood vessel walls from trauma
Petechiae 	Pinpoint, flat, round area >2 mm. Purple, dark red, or brown	Same as above
Purpura 	Flat purple or reddish discoloration. <5 mm. Do not blanche.	Same as above
Spider nevus (spider angioma) 	Has a round, red, central part and branching radiations resembling a spider's web. Usually found on face, neck, or chest	High estrogen levels as in pregnancy or liver disease

TABLE 33.6 ASSESSMENT ABNORMALITIES—cont'd

Vascular Skin Lesions

Finding	Description	Possible Cause and Significance
Telangiectasia 	Fine, irregular red lines	Permanently dilated small blood vessels. Usually caused by sun damage or aging. May be seen with varicose veins, scleroderma, rosacea.

BOX 33.2 FOCUSED ASSESSMENT

Hematologic System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Unusual bleeding or bruising	Y	N
Black, tarry stool	Y	N
Blood in vomitus	Y	N
Swelling in neck, armpits, or groin	Y	N
Dark-colored or blood in urine	Y	N
Fatigue	Y	N
Heart palpitations	Y	N

Objective: Diagnostic

Check the following laboratory results for critical values.

CBC	✓
WBC count with differential	✓
Clotting: PT, INR, aPTT, platelets	✓
Hgb, Hct	✓

Objective: Physical Assessment

Inspect

Skin for lesions or color changes	✓

Auscultate

BP for change or orthostasis	✓

Palpate

Pulse for tachycardia	✓
Liver and spleen for enlargement	✓
Lymph nodes for lymphadenopathy	✓

differential gives valuable clues in determining the cause of illness. When infections are severe, we release more granulocytes from the bone marrow as a compensatory mechanism. To meet the increased demand, many young, immature polymorphonuclear neutrophils *(bands)* are released into circulation. More mature neutrophils are called *polymorphonuclear segmented neutrophils (segs)*. Together, bands and segs make up the *absolute neutrophil count* (ANC).

The WBC differential is very important because it is possible for the total WBC count to be essentially normal despite a marked change in one type of WBC. For example, a patient may have a normal WBC count of 8800/μL, but the differential count may show that the proportion of lymphocytes is only 10%. This is an abnormal finding that needs investigation.

When the bone marrow does not make enough neutrophils, neutropenia occurs. **Neutropenia** is a condition in which the ANC is less than 1000 cells/μL. You calculate the ANC by multiplying the total WBC count by the percentage of neutrophils. Neutropenia results from many disease processes, such as leukemia, or from bone marrow suppression. Severe neutropenia is associated with an ANC of less than 500 cells/μL. It is associated with a high risk for infection and death from sepsis.

Platelet count. The platelet count is the number of platelets per microliter of blood. Normal platelet counts are between 150,000 and 400,000/μL. Counts below 100,000/μL signify a condition termed **thrombocytopenia**. Bleeding may occur with thrombocytopenia. Spontaneous hemorrhage is possible once platelet counts fall below 10,000/μL, depending on the clinical situation.[6] A more extensive description of clotting studies is given in Table 33.8.[3,8]

Thrombocytosis is too many platelets. It occurs with inflammation and some cancers (see Chapter 34). The most likely complication of thrombocytosis is excessive clotting.

Blood Typing and Rh Factor

Blood group antigens (A and B) are found only on RBC membranes. They form the basis for the ABO blood typing system (Table 33.9). The presence or absence of 1 or both inherited antigens is the basis for the 4 blood groups: A, B, AB, and O. Blood group A has A antigens, group B has B antigens, group AB has both antigens, and group O has neither A nor B antigens. Each person has antibodies in the serum termed *anti-A* and *anti-B* that react with A or B antigens. These antibodies are

TABLE 33.7 Diagnostic Studies

CBC Studies

Study	Description and Purpose	Reference Intervals
Hemoglobin (Hgb)	Measures gas-carrying capacity of RBC	*Female:* 12–16 g/dL (120–160 g/L) *Male:* 14–18 g/dL (140–180 g/L)
Hematocrit (Hct)	Measures packed cell volume of RBCs. Expressed as a percentage of the total blood volume	*Female:* 37%–47% (0.37–0.47) *Male:* 42%–52% (0.42–0.52)
Platelet count	Number of circulating platelets	150,000–400,000 × 10^3/L (150–400 × 10^9/L)
Total RBC count (erythrocyte count)	Number of circulating RBCs per volume of blood	*Female:* 4.2–5.4 × 10^6/μL (4.2–5.4 × 10^{12}/L) *Male:* 4.7–6.1 × 10^6/μL (4.7–6.1 × 10^{12}/L)
Red cell indices		
Mean corpuscular volume (MCV) $MSV = \frac{Hct \times 10}{RBC \times 10^6}$	Determines relative size of RBCs. Low MCV reflection of microcytosis. High MCV reflection of macrocytosis	80–95 fL
Mean corpuscular hemoglobin (MCH) $MCH = \frac{Hgb \times 10}{RBC \times 10^6}$	Measures average weight of Hgb/RBCs. Low MCH indicates microcytosis or hypochromia. High MCH indicates macrocytosis	27–31 pg
Mean corpuscular hemoglobin concentration (MCHC) $MCHC = \frac{Hgb \times 100}{Hct}$	Evaluates RBC saturation with Hgb. Low MCHC indicates hypochromia. High MCHC occurs with spherocytosis	32%–36% (0.32–0.36)
RBC morphology	Examines shape and size of RBCs	No variation in RBC morphology
Reticulocyte count	Number of immature RBCs released from the bone marrow into the blood	0.5%–2.0% of RBC
WBC count	Total number of WBCs	5000–10,000/μL (5–10 × 10^9/L)
WBC differential	Determines whether each kind of WBC is present in proper proportion. Determines absolute value of each type of WBC by multiplying the percentage of cell type by total WBC count and dividing by 10	*Segmented neutrophils:* 55%–70% (0.55–0.70) *Banded neutrophils:* 0%–8% (0–0.08) *Eosinophils:* 1%–5% (0.01–0.04) *Basophils:* 0.5%–1% (0.005–0.01) *Lymphocytes:* 20%–40% (0.20–0.40) *Monocytes:* 2%–8% (0.02–0.08)

TABLE 33.8 Diagnostic Studies

Clotting Studies

Study	Description and Purpose	Reference Intervals
Activated clotting time (ACT)	Evaluates intrinsic coagulation status. More accurate than aPTT. Used during dialysis, coronary artery bypass procedure, arteriograms	70–120 s
Activated partial thromboplastin time (aPTT)	Assesses intrinsic coagulation by measuring factors I, II, V, VIII, IX, X, XI, XII. Higher in patients receiving heparin	30–40 s
Antithrombin (antithrombin III)	Naturally occurring protein made by liver that inhibits coagulation by inactivating thrombin and other factors. Lower in DIC and hypercoagulable disorders	17–30 mg/dL (170–300 mg/L) or 80%–120% of standard
Bleeding time	Duration of bleeding after a standardized superficial puncture wound of the skin. Measures the integrity of the platelet plug	1–9 min
D-dimer	Assay to measure a fragment of fibrin that forms because of fibrin degradation and clot lysis. Used as an adjunctive measure in diagnosis of hypercoagulable conditions (e.g., DIC, pulmonary embolism)	<250 ng/mL (<250 mcg/L)
Fibrin split products (FSPs) or fibrin degradation products (FDPs)	Reflects degree of fibrinolysis and predisposition to bleed (if present). Screening test for DIC. High levels occur with DIC, advanced cancer, severe inflammation	<10 mcg/mL (<10 mg/L)
Fibrinogen (factor I)	Reflects fibrinogen level. Increase is a possible sign of enhancement of fibrin formation, making patient hypercoagulable. Decrease means patient may be predisposed to bleeding.	200–400 mg/dL (2–4 g/L)
International normalized ratio (INR)	Standardized system of reporting prothrombin time (PT) based on a reference calibration model. Calculated by comparing patient's PT with a control value	0.8–1.1
Plasminogen	Assesses for plasminogen deficiency in patients who have multiple thromboembolic episodes	2.4–4.4 units/mL
Platelet count	Number of circulating platelets	150,000–400,000 × 10^3/L (150–400 × 10^9/L)
Prothrombin time (PT)	Assesses extrinsic coagulation by measuring factors I, II, V, VII, X	11–12.5 sec
Thrombin time	Reflects adequacy of thrombin and time to clot. Prolonged thrombin time means that coagulation is inadequate due to decreased thrombin activity	<21 sec

TABLE 33.9 ABO and Rh Blood Groups

	ANTIGENS PRESENT ON RBC		ANTIBODIES POSSIBLY PRESENT IN PLASMA		
Blood Type	**A or B**	**Rh (D)**	**A or B**	**Rh (D)**	**Percent of General Population**
O	—	—	A, B	Rh	7
O+	—	Rh	A, B	—	38
A	A	—	B	Rh	6
A+	A	Rh	B	—	34
B	B	—	A	Rh	2
B+	B	Rh	A	—	9
AB	A, B	—	—	Rh	1
AB+	A, B	Rh	—	—	3

found when the corresponding antigen is absent from the RBC surface. For example, there are B antibodies in the serum of people with blood group A.[8]

Blood reactions based on ABO incompatibilities result from RBC hemolysis. RBCs *agglutinate* (or clump) when a serum antibody is present to react with the antigens on the RBC membrane. For example, agglutination will occur in the blood of a person with type A blood if they receive blood transfused from a person with B antigens (i.e., type B or AB). The anti-B antibodies in the type A blood would react with the B antigens, starting the process that results in RBC hemolysis. Blood component compatibilities for transfusions are outlined in Table 34.33.

The *Rh system* is based on a third antigen, D. It is also on the RBC membrane. Rh-positive people have the D antigen, while Rh-negative people do not. Rh-positive blood is indicated with a "+" after the ABO group (e.g., AB+). Rh status is determined by a Coombs test (Table 33.10).

Because of transfusion therapy or during childbirth, a Rh-negative person may be exposed to Rh-positive blood. After exposure during childbirth, a Rh-negative mother forms an antibody, anti-D, which acts against Rh antigens (Rh-positive people normally have no anti-D). In future pregnancies, the mother's anti-D antibodies can cross the placenta and attack the RBCs of a Rh-positive fetus, causing hemolysis of the RBCs. A pregnant Rh-negative woman should receive Rho(D) immune globulin (RhoGAM) injections to prevent anti-D antibodies from forming.

Iron Metabolism

The laboratory tests used to evaluate iron metabolism include serum iron, transferrin saturation, serum ferritin, and total iron-binding capacity. We may do tests for nutrition deficiencies, leading to defective RBC production (Table 33.10).[8]

Serum iron is a measurement of the amount of protein-bound iron circulating in the serum. *Transferrin saturation* is a better indicator of iron available for erythropoiesis than serum iron. Unlike serum iron, the iron bound to transferrin is readily available for the body to use. You calculate transferrin saturation by dividing serum iron by total iron binding capacity (TIBC) and multiplying by 100. For example, a patient with a serum iron level of 100 mcg/dL and a TIBC of 300 mcg/dL would have a transferrin saturation of about 33%.

Under normal conditions, the serum ferritin concentration correlates closely with body iron stores. In normal patients, 1 ng/mL of ferritin corresponds to 8 to 10 mg of stored iron.

TIBC gives an indirect measure of all proteins that bind or transport iron between the tissues and bone marrow. However, it overestimates transferrin levels by 16% to 20% because it measures other proteins that can bind iron. These other proteins only bind iron when transferrin is more than half saturated. TIBC varies inversely with tissue iron stores. It is higher when iron stores are low and lower when iron stores are high.

Biopsies

Biopsy procedures specific to hematologic assessment are bone marrow examination and lymph node biopsy. A biopsy provides information needed for diagnosis and treatment planning. In general, these procedures are done when a peripheral blood smear is nonspecific.

Bone Marrow Examination

Bone marrow examination is important in evaluating many hematologic problems. It may involve aspiration only or aspiration with biopsy (Table 33.11).[8] The benefits gained from bone marrow examination are (1) a full evaluation of hematopoiesis and (2) the ability to get specimens for cytopathologic and chromosomal analysis. The preferred site for both aspiration and biopsy of bone marrow is the posterior iliac crest. A physician, nurse practitioner, or physician's assistant can perform the procedure. The patient may receive local anesthesia and sedation to minimize anxiety and pain.

For bone marrow aspiration, the skin over the puncture site is cleansed with a bactericidal agent. The skin, subcutaneous tissue, and periosteum are injected with a local anesthetic agent. Once the area is anesthetized, a bone marrow needle is inserted through the cortex of the bone (Fig. 33.7). The stylet of the needle is removed. The hub is attached to a 10-mL syringe, and 0.2 to 0.5 mL of the fluid marrow is aspirated. The patient will have pain when the periosteum is penetrated and with aspiration. Although the pain will last only a few seconds, it can be quite uncomfortable. After the marrow aspiration, the

TABLE 33.10 Diagnostic Studies

Miscellaneous Blood Studies

Study	Description and Purpose	Normal Values
Bilirubin	Measures degree of RBC hemolysis or liver's inability to excrete normal quantities of bilirubin. Increase in indirect bilirubin with hemolysis. Increase in direct bilirubin with obstructive problems (e.g., gallstones, liver tumor)	*Total:* 0.3–1.0 mg/dL (5.1–17.0 μmol/L) *Direct:* 0.1–0.3 mg/dL (1.7–5.1 μmol/L) *Indirect:* 0.2–0.8 mg/dL (3.4–12.0 μmol/L)
Blood smear (peripheral blood smear)	Reviews color, size, shape, quantity of cells in peripheral blood. Provides information about problems affecting RBCs, WBCs, or platelets	Normal quantity of each cell type, normal size, shape and color of RBCs, normal WBC differential count and platelets
Coombs test	Differentiates among types of hemolytic anemias. Detects immune antibodies and Rh factor	Negative
• Direct	Detects antibodies that are attached to RBCs	Negative
• Indirect	Detects circulating antibodies against red cells in serum	Negative
Cobalamin (vitamin B_{12})	Level of cobalamin available for production of new RBCs	160–950 pg/mL (118–701 pmol/L)
Erythrocyte sedimentation rate (ESR)	Measures sedimentation or settling of RBCs in 1 hr. Inflammatory process causes a change in plasma proteins, resulting in aggregation of RBCs and making them heavier. The faster the sedimentation rate, the higher the ESR	<20 mm/h (some gender variation)
Erythropoietin	Measures degree of hormonal stimulation to bone marrow to stimulate the release of RBCs	5–35 IU/mL (5–30 U/L)
Ferritin	Major iron storage protein. Is normally present in blood in concentrations directly related to iron storage	10–300 ng/mL (10–300 mcg/L)
Folic acid (folate)	Amount of folic acid (folate) available for RBC production	5–25 ng/mL (11–57 nmol/L)
Haptoglobin	A serum glycoprotein that binds to Hgb released into the bloodstream by hemolysis. Decreased with red cell hemolysis. Increased with infection, inflammation, cancer	50–220 mg/dL
Hemoglobin (Hgb) electrophoresis	Proteins involved in development of Hgb molecule have a definitive pattern of separation on electrophoresis. This pattern is changed with abnormal Hgb synthesis (e.g., thalassemia) or sickle cell anemia (where Hgb S is increased)	Normal Hb A1: >95% Hb A2: 2%–3% Hb F: 0.8%–2% Hb S: 0 Hb C: 0
Homocysteine	An intermediate amino acid formed during the metabolism of the essential amino acid methionine. Rapidly metabolized through pathways that require cobalamin (vitamin B_{12}) and folic acid. Increased in cobalamin and folic acid deficiency	*Normal:* 4–14 μmol/L
Iron		
• Iron total	Reflects amount of iron combined with proteins in serum. Indicates status of iron storage and use	*Male:* 80–180 mcg/dL (14–32 μmol/L) *Female:* 60–160 mcg/dL (11–29 μmol/L)
• (Total) iron-binding capacity (TIBC)	Measures all proteins available for binding iron. Transferrin represents the largest quantity of iron-binding proteins. Thus, TIBC is an indirect measure of transferrin, an evaluation of the amount of extra iron that can be carried	250–460 mcg/dL (45–82 μmol/L)
Lactic dehydrogenase (LDH)	Intracellular enzyme present in almost all body tissues. Levels rise in response to cell damage. Increased levels confirm diagnosis of injury or disease. Used as a nonspecific marker of hematologic cancer growth and response to treatment	100–190 U/L
Methylmalonic acid (MMA)	Indirect test for cobalamin (vitamin B_{12}). MMA metabolism requires cobalamin. Decreased levels with cobalamin deficiency. Helps distinguish cobalamin deficiency from folic acid deficiency	<3.6 μmol/mmol creatinine
Microglobulin (beta$_2$ microglobulin)	Protein found on the surface of all cells. Increased in cancers such as lymphoma, leukemia, or multiple myeloma. May be used as a tumor marker	*Blood:* 0.7–1.8 mcg/mL *Urine:* ≤300 mcg/L Spinal fluid: ≤2.4 mg/L
Serum protein electrophoresis (SPEP)	Separates proteins in blood on basis of electric charge. Helps detect hyperglobulinemic states, such as in multiple myeloma or some lymphomas	Normal banding pattern of albumin and globulins. Increase in any protein *(protein spike)* is abnormal
Transferrin	Largest of proteins that bind to iron. Increased in most people with iron-deficiency anemia	*Male:* 215–365 mg/dL (2.15–3.65 g/L) *Female:* 250–380 mg/dL (2.5–3.8 g/L)
Transferrin saturation (%)	Decreased in iron-deficiency anemia. Increased in hemolytic and megaloblastic anemia	*Male:* 20%–50% *Female:* 15%–50%

needle is removed. Pressure is applied over the aspiration site to ensure hemostasis. We then cover the site with a sterile pressure dressing.

Complications of bone marrow aspiration are minimal. There is a chance of damaging underlying structures. Other complications include infection if the patient is neutropenic. Hemorrhage may occur in the patient with severe thrombocytopenia.

Monitor the patient's vital signs until stable. Assess the site for excess drainage or bleeding. If bleeding is present, have the

TABLE 33.11 Diagnostic Studies

Hematologic System

Study	Description and Purpose	Nursing Responsibility
Molecular, Cytogenetic, and Gene Analysis Studies		
Cancer genomics (genotyping) **Cell surface immunophenotyping (flow cytometry)** **Chromosomal karyotyping, (PCR)** **Fluorescence in situ hybridization (FISH)**	Assesses for genetic or chromosomal abnormalities of cancer cells. Uses peripheral blood (e.g., leukemia), biopsy specimen (bone marrow, lymph node, tissue), or CSF. Used to confirm diagnosis and determine treatment, prognosis, and response to therapy	*Before:* Explain purpose of testing to patient. HCP will provide specific significance.
Procedures		
Bone marrow biopsy (Fig. 33.7)	Removal of bone marrow through a locally anesthetized site to evaluate status of blood-forming tissue. Used to diagnose and monitor aplastic anemia, multiple myeloma, myelodysplastic syndromes, leukemia, and some lymphomas	*Before*: Explain procedure to patient. Obtain signed consent form. Perform a surgical time-out before procedure. Analgesics may be given to enhance patient comfort and cooperation. *After:* Apply pressure dressing. Assess biopsy site for bleeding and apply pressure as needed. Tenderness at the puncture site for a few days may be normal. Assess for infection.
Lumbar puncture (LP)	Done to obtain CSF for testing for cancer, infection, and degenerative brain diseases. May be used to give chemotherapy to the central nervous system	*During:* Help position patient and provide support. *After*: Watch site for bleeding and signs of infection. Spinal headaches may occur. Follow postprocedure orders for how long the patient should lie flat. Encourage the patient to drink fluids.
Lymph node biopsy	Used to obtain lymph tissue for histologic examination to determine diagnosis and therapy	*Before:* Explain procedure to patient. Obtain signed consent form.
• Closed (needle) or fine needle	Done at the bedside or in an outpatient area. A very small needle is used to reduce risk for tracking cancer cells through normal subcutaneous tissue	*After:* Watch site for bleeding and monitor vital signs, especially if platelet count is low. Change sterile dressing as ordered. Inspect wound for healing and infection.
• Open	Done in operating room or procedure area using either local or general anesthesia. After making an incision, the lymph node and surrounding tissue are excised whenever possible	
Radioisotope Studies		
Bone scan	Radioactive isotope is injected IV and taken up by the bones. Uniform uptake is normal. Increased uptake seen in osteomyelitis, certain fractures, and bone cancer	*Before:* Patient may be asked to drink 4–6 glasses of water and then void before imaging (to see pelvic bones). Obtain IV access for injection of isotope.
SPECT scan (single-photon emission computed tomography)	Radioactive isotope is injected IV. Images from radioactive emissions used to evaluate the structures, such as spleen, liver, bone, and possible tumors. Patient is not a source of radioactivity	*Before:* Obtain IV access for injection of isotope. *After*: Have the patient drink fluids to aid in the excretion of the isotope.
Radiologic Studies		
Computed tomography (CT) scan	Noninvasive radiologic examination using computer-assisted x-ray evaluates the lymph nodes. Contrast medium used in abdominal studies of liver or spleen. Spiral (helical) CT scans used to evaluate lymph nodes	*Before:* Assess for iodine sensitivity if contrast medium used. IV and/or oral contrast may be given prior to procedure, depending on the area being studied. Patient may need to be NPO for 4 hr. *After:* Have patient drink fluids to avoid renal problems with any contrast.
Magnetic resonance imaging (MRI)	Noninvasive procedure produces sensitive images of soft tissue (central nervous system, neck and back, bones and joints, heart, breasts). An IV contrast agent (gadolinium) may be given. Provides a better contrast between normal tissue and pathologic tissue than CT.	*Before:* Oral and/or IV contrast injection may be used. Check for pregnancy, allergies, and renal function before test. Have patient remove all metal objects. Ask about any history of surgical insertion of staples, plates, dental bridges, or other metal appliances. Remove metallic foil patches. Patient may need to be fasting. Assess for claustrophobia and the need for antianxiety medication. *During*: Patient must lie completely still during scan.

Continued

TABLE 33.11 Diagnostic Studies—cont'd

Hematologic System

Study	Description and Purpose	Nursing Responsibility
Positron emission tomography (PET)	Glucose-containing nuclear tracer substance is injected and taken up by metabolically active cells. Follow-up scan shows different-colored tissues based on metabolic rate. Because cancer cells have an increased uptake of glucose, "hot spots" reflecting increased glucose consumption indicate the presence of active cancer. CT scanning may be done in conjunction or images fused.	*Before:* Obtain IV access to inject the tracer substance. Patients should be NPO, except for water and medications, for at least 4 hr prior. Hold glucose-containing IV solutions and change to normal saline. Check the blood glucose levels as high levels may interfere with test. May need bowel preparation depending on area being studied. *After:* Encourage fluids to excrete radioactive substance.
Skeletal x-ray	X-rays done to detect lytic lesions from multiple myeloma.	No specific nursing responsibilities.
Ultrasound (abdominal, liver, spleen)	Noninvasive probe is lubricated and slid across the abdomen to detect density and borders of the abdominal organs. Can detect irregular borders, masses, vascular structure, fluid collections, and biliary tree	*During:* Patients must be comfortable lying flat and having probe compress abdomen.
Urine Studies		
Bence Jones protein (free kappa and lambda light chains)	An electrophoretic measurement used to detect Bence Jones protein, which is found in most cases of multiple myeloma. May be present in some other hematologic disorders and metastatic cancers. Negative finding is normal.	*During:* Obtain random urine specimen early in the morning. If a 24-hr urine collection is done, discard first specimen, and collect all urine voided during the 24 hr, keeping on ice or refrigerated. Remind patient not to put toilet paper in urine collection container.

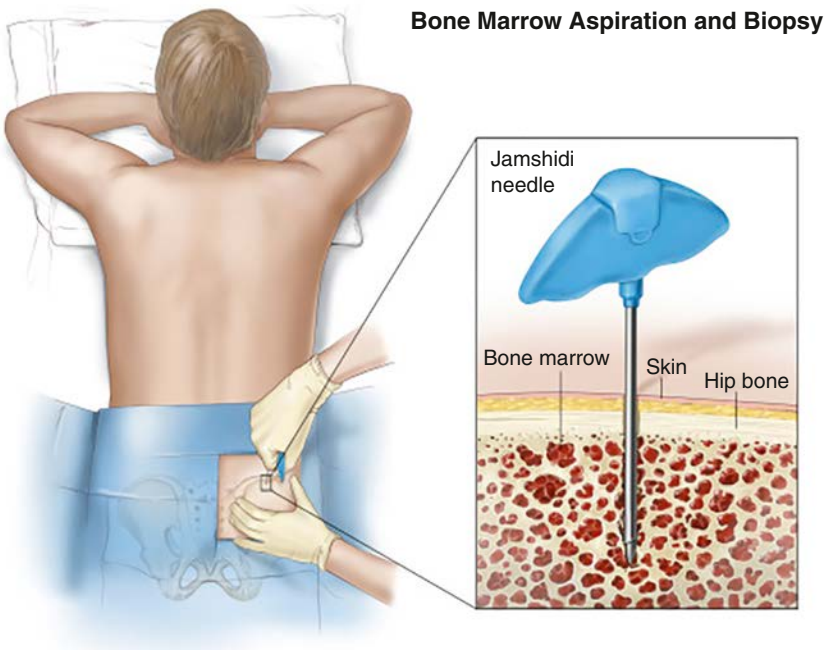

Fig. 33.7 Bone marrow aspiration from the posterior iliac crest.

patient lie supine for 30 to 60 minutes to keep pressure on the site. If the bed is too soft, have the patient lie on a rolled towel to provide more pressure. Notify the HCP if bleeding continues. You may give analgesics for postprocedure pain. Soreness over the puncture site for 3 to 4 days after the procedure is normal.

Lymph Node Biopsy

Lymph node biopsy involves obtaining lymph tissue for histologic examination to determine the diagnosis and help plan therapy. This may be done by either an open or a closed (needle) biopsy.

If the results from a needle biopsy are negative, it may only mean that the cancer cells were not part of the tissue in the biopsy specimen. However, a positive finding may be enough evidence to confirm a diagnosis. This technique is rarely used to confirm an initial diagnosis because larger specimens, such as excisional biopsies, are usually needed to perform cytopathologic tests.

Molecular Cytogenetics and Gene Analysis

Testing for specific chromosomal variations with hematologic problems is essential in diagnosis (Table 33.11). Results

determine treatment options, prognosis, and response to therapy. If a large number of abnormal cells are circulating in the blood, such as in acute leukemia, these tests may be done on peripheral blood. However, testing is usually done on samples from bone marrow, lymph node biopsies, and sometimes cerebrospinal fluid (CSF).[3,8]

There are a number of molecular tests. Flow cytometry can detect specific cell populations and their cell surface antigens.[3] Fluorescence in situ hybridization (FISH) identifies genetic defects using nucleic probes that are complementary to a targeted region of deoxyribonucleic acid (DNA). FISH can identify an abnormal extra chromosome 8, which is common in certain leukemias.[3] Reverse transcription polymerase chain reaction (PCR) is another way to detect specific mutations and amount. PCR can detect the Philadelphia chromosome translocation t(9;22) seen in chronic myeloid leukemia and some cases of acute lymphoblastic leukemia.[3]

Case Study

Objective Data: Diagnostic Studies

(© Lisa F. Young/ iStock.)

The HCP orders the following diagnostic studies for A.J.:

- CBC, basic metabolic panel (electrolytes, BUN, creatinine), PT/PTT
- Arterial blood gases
- Chest x-ray

A.J.'s CBC reveals an Hgb of 5.9 g/dL, Hct of 18.2%, WBC of 2600/μL (2.6×10^9/L), platelet count of 72,000/μL, PT = 18 seconds, aPTT = 37. Arterial blood gases and chest x-ray are normal. The HCP orders more blood work, including a WBC differential and RBC indices and admits her to the hospital for further evaluation and potential treatment.

Discussion Questions

1. Are these the diagnostic studies that you expected to be ordered?
2. Which diagnostic study results are abnormal?
3. Which diagnostic study results concern you most? What other studies may be ordered on admission?

This case study is continued in Chapter 34.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A person who lives at a high altitude may normally have an increased Hgb and RBC count because
- **a.** high altitudes cause vascular fluid loss, leading to hemoconcentration.
- **b.** hypoxia caused by decreased atmospheric O_2 stimulates erythropoiesis.
- **c.** the function of the spleen in removing old RBCs is impaired at high altitudes.
- **d.** impaired production of platelets leads to proportionally higher red cell counts.

2. A patient with cancer arising from granulocytic cells in the bone marrow will have
- **a.** a risk for bleeding.
- **b.** altered oxygenation.
- **c.** decreased production of antibodies.
- **d.** decreased phagocytosis of bacteria.

3. An anticoagulant such as warfarin that interferes with prothrombin production will alter the clotting mechanism during
- **a.** platelet aggregation.
- **b.** activation of thrombin.
- **c.** the release of tissue thromboplastin.
- **d.** stimulation of factor activation complex.

4. When reviewing laboratory results of an older patient with an infection, the nurse would expect to find
- **a.** mild leukocytosis.
- **b.** decreased platelet count.
- **c.** increased hemoglobin and hematocrit levels.
- **d.** decreased erythrocyte sedimentation rate (ESR).

5. Key information from the patient's health history that relates to the hematologic system includes
- **a.** jaundice.
- **b.** bladder surgery.
- **c.** early menopause.
- **d.** multiple pregnancies.

6. While assessing the lymph nodes, the nurse should
- **a.** apply gentle, firm pressure to deep lymph nodes.
- **b.** palpate the deep cervical and supraclavicular nodes last.
- **c.** lightly palpate superficial lymph nodes with the pads of the fingers.
- **d.** use the tips of the second, third, and fourth fingers to apply deep palpation.

7. If a lymph node is palpated, what is a normal finding?
- **a.** Hard, fixed nodes
- **b.** Firm, mobile nodes
- **c.** Enlarged, tender nodes
- **d.** Hard, nontender nodes

8. Nursing care for a patient after a bone marrow biopsy and aspiration includes *(select all that apply)*
- **a.** giving analgesics as needed.
- **b.** preparing to start a blood transfusion.
- **c.** keeping the sterile pressure dressing intact.
- **d.** giving preprocedure and postprocedure antibiotic medications.
- **e.** monitoring vital signs and assessing the site for excess drainage or bleeding.

1. b; 2. d; 3. b; 4. a; 5. a; 6. c; 7. b; 8. a; c, e.

Immunity
Infection
Pain
Perfusion

LEARNING OUTCOMES

1. Describe the general clinical manifestations and complications of anemia.
2. Distinguish the etiologies, clinical manifestations, diagnostic findings, and interprofessional and nursing management of iron deficiency, megaloblastic, and aplastic anemias.
3. Explain the nursing management of anemia from blood loss.
4. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of anemia from increased erythrocyte destruction.
5. Describe the pathophysiology and nursing and interprofessional management of polycythemia.
6. Explain the pathophysiology, clinical manifestations, and interprofessional and nursing management of various types of thrombocytopenia.
7. Describe the types, clinical manifestations, diagnostic findings, and interprofessional and nursing management of hemophilia and von Willebrand disease.
8. Explain the pathophysiology, diagnostic findings, and interprofessional and nursing management of disseminated intravascular coagulation.
9. Describe the etiology, clinical manifestations, and interprofessional and nursing management of neutropenia.
10. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of myelodysplastic syndromes.
11. Compare and contrast the clinical and laboratory findings of the major types of leukemia.
12. Explain the nursing and interprofessional management of acute and chronic leukemias.
13. Compare Hodgkin lymphoma and non-Hodgkin lymphomas in terms of clinical manifestations, staging, and interprofessional and nursing management.
14. Describe the pathophysiology, clinical manifestations, and interprofessional and nursing management of multiple myeloma.
15. Describe the spleen disorders and related interprofessional care.
16. Describe the nursing management of the patient receiving transfusions of blood and blood components.

KEY TERMS

anemia
aplastic anemia
disseminated intravascular coagulation (DIC)
hemochromatosis
hemolytic anemia
hemophilia
Hodgkin lymphoma
iron deficiency anemia
leukemia
lymphomas
megaloblastic anemias
multiple myeloma
myelodysplastic syndromes (MDS)
neutropenia
non-Hodgkin lymphomas (NHLs)
pernicious anemia
polycythemia
sickle cell disease (SCD)
thalassemia
thrombocytopenia

This chapter discusses common hematologic problems and their associated concepts.

There are a wide range of blood conditions and cancers. Because blood has so many essential functions, hematologic problems affect the patient in many ways. Patients with anemia and hematologic cancer may have to cope with fatigue. Compromised immunity and the risk for infection is a concern among patients with hematologic cancer and a common side effect of therapy. Pain is common with cancer and sickle cell disease (SCD). Clotting is an important protective mechanism that supports homeostasis when injury occurs. Excessive clotting can impair perfusion. Inadequate clotting can lead to blood loss and fluid volume deficit.

ANEMIA

Definition and Classification

Anemia is a deficiency in the number of erythrocytes (red blood cells [RBCs]), the quantity or quality of hemoglobin (Hgb), and/or volume of packed RBCs (hematocrit). It is not a specific disease. Anemia is a manifestation of a pathologic process. It is a common condition with many diverse causes. These include blood loss, impaired RBC production, or increased RBC destruction (Fig. 34.1). The diagnosis of anemia is based on a complete blood count (CBC), reticulocyte count, and peripheral blood smear. Once identified, further research is done to find the specific cause.[1]

Anemia can result from primary hematologic problems or develop because of diseases or disorders of other body systems. We classify the types of anemia by either *morphology* (cell characteristic) or *etiology* (cause). Morphologic classification is based on RBC size and color (Table 34.1). Etiologic classification is based on the clinical condition causing the anemia (Table 34.2).[1] Although the morphologic system is the most accurate way to classify anemia, it is easier to discuss patient care by focusing on the cause of the anemia.

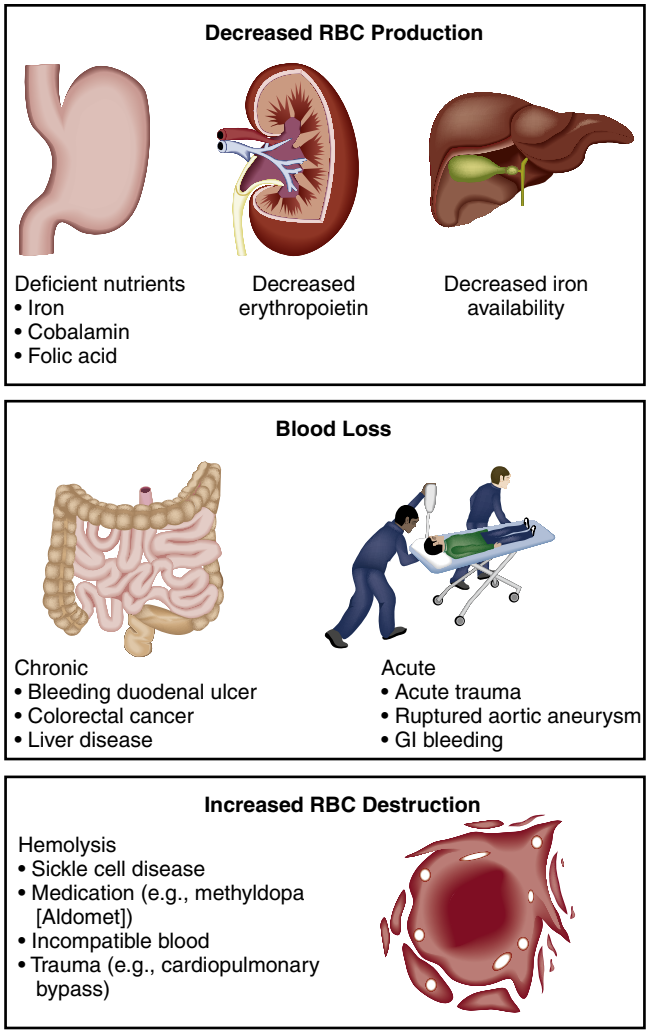

Fig. 34.1 Causes of anemia.

Clinical Manifestations

Because RBCs transport O_2, RBC disorders can lead to tissue hypoxia. The manifestations of anemia result from the body's response to the hypoxia. Specific manifestations vary depending on how fast the anemia has evolved, its severity, and any coexisting disease. We often use Hgb levels to determine the severity of anemia.

Mild anemia (Hgb 10 to 12 g/dL [100 to 120 g/L]) may exist without causing symptoms. If symptoms develop, it is because the patient has an underlying disease or has a compensatory response to heavy exercise. Symptoms include palpitations, dyspnea, and mild fatigue.

In moderate anemia (Hgb 6 to 10 g/dL [60 to 100 g/L]), there is an increase in cardiopulmonary symptoms. The patient may have them while resting as well as with activity.

In severe anemia (Hgb less than 6 g/dL [60 g/L]), the patient has many manifestations involving multiple body systems (Table 34.3).

Integumentary. Skin manifestations include pallor, jaundice, and itching. Pallor results from low Hgb levels and reduced blood flow to the skin. Jaundice occurs when RBC hemolysis increases the serum bilirubin concentration. Hemolysis also causes itching from the increased serum and skin bile concentrations.

Cardiopulmonary. Cardiopulmonary manifestations of severe anemia result from the heart and lungs trying

TABLE 34.1 Morphologic Classification of Anemia

Morphology	Etiology
Normocytic, normochromic (normal size and color) MCV 80–95 fL, MCH 27–31 pg	Acute blood loss, hemolysis, chronic kidney disease, chronic disease, cancer, endocrine problems, starvation, aplastic anemia, sickle cell anemia, pregnancy
Microcytic, hypochromic (small size, pale color) MCV <80 fL, MCH <27 pg	Iron deficiency anemia, vitamin B_6 deficiency, copper deficiency, thalassemia, lead poisoning
Macrocytic (megaloblastic), normochromic (large size, normal color) MCV >95 fL, MCH >31 pg	Cobalamin (vitamin B_{12}) deficiency, folic acid deficiency, liver disease (including effects of alcohol use)

MCH, Mean corpuscular hemoglobin; *MCV,* mean corpuscular volume.

TABLE 34.2 Etiologic Classification of Anemia

Decreased RBC Production

Decreased Hemoglobin Synthesis

- Iron deficiency
- Sideroblastic anemia (↓ porphyrin)
- Thalassemia (↓ globin synthesis)

Decreased Number of RBC Precursors

- Aplastic anemia and inherited disorders (e.g., Fanconi syndrome)
- Anemia of myeloproliferative diseases (e.g., leukemia) and myelodysplasia
- Chronic diseases or disorders
- Medications and chemicals (e.g., chemotherapy, lead)
- Radiation

Defective DNA Synthesis

- Cobalamin (vitamin B_{12}) deficiency
- Folic acid deficiency

Blood Loss

Acute

- Blood vessel rupture
- Splenic sequestration crisis
- Trauma

Chronic

- Gastritis
- Hemorrhoids
- Menstrual flow

Increased RBC Destruction (Hemolytic Anemias)

Acquired (Extrinsic)

- Antibodies against RBCs
- Cancer
- DIC
- Extracorporeal circulation
- HELLP syndrome (hemolysis, ↑ liver enzymes, ↓ platelets associated with pregnancy)
- Infectious agents (e.g., malaria) and toxins
- Physical destruction
- Prosthetic heart valves
- Thrombotic thrombocytopenic purpura (TTP)

Hereditary (Intrinsic)

- Abnormal hemoglobin (sickle cell disease)
- Enzyme deficiency (glucose-6-phosphate dehydrogenase [G6PD])
- Membrane abnormalities (paroxysmal nocturnal hemoglobinuria, hereditary spherocytosis)

to provide adequate amounts of O_2 to the tissues. Cardiac output is maintained by increasing the heart rate (HR) and stroke volume. The low blood viscosity contributes to systolic murmurs and bruits. In extreme cases or when heart disease is present, angina pectoris and myocardial infarction (MI) may occur if myocardial O_2 needs are not met. Heart failure (HF), cardiomegaly, pulmonary and systemic congestion, ascites, and peripheral edema may develop if the heart is overworked for an extended period.

NURSING AND INTERPROFESSIONAL MANAGEMENT: ANEMIA

This section discusses general management of anemia. Specific care for various types of anemia is discussed later in this chapter. More information on the nursing care of the patient with anemia is discussed in eNursing Care Plan 34.1.

Assessment

Table 34.4 outlines the subjective and objective data you should obtain from a patient with anemia. Assess the patient's knowledge about proper nutrition and adherence to safety precautions to prevent cardiopulmonary stress, falls, and injury.

Clinical Problems

Clinical problems for the patient with anemia include:

- Fatigue
- Nutritionally compromised
- Inadequate tissue perfusion

Planning

The overall goals are that the patient with anemia will (1) assume normal activities of daily living, (2) maintain adequate nutrition, and (3) develop no complications from anemia.

Implementation

Correcting the cause of the anemia is the goal of therapy. Implement nursing interventions specific to the patient's needs and type of anemia. Acute interventions may include blood transfusions, drug therapy (e.g., iron supplements), and O_2 therapy to stabilize the patient. Diet and lifestyle changes (described in sections on specific types of anemia) can reverse some anemias.

For the patient with fatigue, encourage alternate rest and activity periods. Help the patient to prioritize activities according to energy levels. Arrange activities (e.g., avoid activity right after meals) to reduce competition for O_2 supply to vital functions. Aid with regular activities (e.g., ambulation, transfers, personal care) to minimize fatigue and risk for injury from falls. Monitor the patient's cardiorespiratory response to activity (e.g., tachycardia, dysrhythmias, dyspnea, diaphoresis, pallor, tachypnea).

Collaborate with the dietitian to determine the number of calories and type of nutrients needed to meet nutrition requirements. Provide information about nutrient needs and how to increase intake of essential nutrients. Encourage increased intake of foods listed in Table 34.5 that are high in the nutrients needed for RBC production.[2]

Gerontologic Considerations: Anemia

Modest changes in RBC mass occur in older adults. Healthy older adults have a modest decline in Hgb of about 1 g/dL after age 70. This is partly due to the decreased production of testosterone in men and estrogen in women.[1]

Anemia is not a normal finding in older adults. For many, anemia is due to an underlying cause, such as iron deficiency, bleeding, chronic disease, renal problems, or a hematologic

TABLE 34.3 Manifestations of Anemia

Body System	SEVERITY OF ANEMIA: Mild (Hgb 10–12 g/dL [100–120 g/L])	Moderate (Hgb 6–10 g/dL [60–100 g/L])	Severe (Hgb <6 g/dL [<60 g/L])
Cardiovascular	Palpitations	↑ Palpitations, bounding pulse	↑ HR, ↑ pulse pressure, systolic murmurs, intermittent claudication, angina, HF, MI
Eyes	None	None	Icteric conjunctiva and sclera, retinal hemorrhage, blurred vision
GI	None	None	Anorexia, hepatomegaly, splenomegaly, problems swallowing, sore mouth
General	None or mild fatigue	Fatigue	Sensitivity to cold, weight loss, lethargy
Mouth	None	None	Glossitis, smooth tongue
Musculoskeletal	None	None	Bone pain
Pulmonary	Exertional dyspnea	Dyspnea	Tachypnea, orthopnea, dyspnea at rest
Neurologic	None	"Roaring in the ears"	Headache, vertigo, irritability, depression, impaired thought processes
Skin	None	None	Pallor, jaundice, itching

TABLE 34.4 NURSING ASSESSMENT

Anemia

Subjective Data

Important Health Information

Health history: Recent blood loss or trauma; chronic liver, endocrine, or renal disease (including dialysis); GI disease (malabsorption syndrome, ulcers, gastritis, hemorrhoids); inflammatory disorders (especially Crohn disease); smoking, exposure to radiation or chemical toxins (arsenic, lead, benzenes, copper); infectious diseases; recent travel with possible exposure to infection; angina, MI; history of falling

Medications: Use of vitamin and iron supplements; aspirin, anticoagulants, oral contraceptives, phenobarbital, penicillins, NSAIDs, omeprazole, phenytoin, sulfonamides, herbal products

Surgery or other treatments: Recent surgery, small bowel resection, gastrectomy, prosthetic heart valves, chemotherapy, radiation therapy

Diet history: General diet patterns, alcohol use

Functional Health Patterns

Health perception–health management: Family history of anemia; malaise

Nutritional-metabolic: Nausea, vomiting, anorexia, weight loss; dysphagia, dyspepsia, heartburn; night sweats, cold intolerance

Elimination: Hematuria, ↓ urine output; diarrhea, constipation, flatulence, tarry stools, bloody stools

Activity-exercise: Fatigue, muscle weakness, ↓ strength; dyspnea, orthopnea, cough, hemoptysis; palpitations; shortness of breath with activity

Cognitive-perceptual: Headache; abdominal, chest, and bone pain; painful tongue; paresthesias of feet and hands; itching; changes in vision, taste, or hearing; vertigo; hypersensitivity to cold; dizziness

Sexuality-reproductive: Menorrhagia, metrorrhagia; recent or current pregnancy; male impotence

Objective Data

General

Lethargy, apathy, general lymphadenopathy, fever

Cardiovascular

↑ HR, systolic murmur, dysrhythmias; postural hypotension, widened pulse pressure, bruits (especially carotid); intermittent claudication, ankle edema

GI

Hepatosplenomegaly; glossitis; beefy, red tongue; stomatitis; abdominal distention; anorexia

Neurologic

Headache, roaring in the ears, confusion, impaired judgment, irritability, ataxia, unsteady gait, paralysis, loss of vibration sense

Respiratory

Tachypnea

Skin

Pale skin and mucous membranes; blue, pale white, or icteric sclera; cheilitis (inflammation of the lips); poor skin turgor; brittle, spoon-shaped fingernails; jaundice; petechiae; bruising; nose or gingival bleeding; poor healing; dry, brittle, thinning hair

Possible Diagnostic Findings

↓ RBCs, ↓ Hgb; ↓ Hct; ↑ or ↓ reticulocytes, ↑ or ↓ MCV; possible ↓ serum iron, ferritin, folate, or cobalamin (vitamin B_{12}); heme-positive stools; ↓ serum EPO level; ↑ or ↓ LDH, bilirubin, transferrin (Table 34.6)

problem. For those with no identifiable cause, it may be due to cytokine dysregulation with aging.[1]

Manifestations of anemia in older adults may include pallor, confusion, ataxia, fatigue, and worsening cardiovascular and respiratory problems. Unfortunately, anemia may go unrecognized in older adults because we mistake the manifestations for normal aging changes or overlook them because of another health problem. By recognizing signs of anemia, you can play a key role in the care of older adults with anemia.

ANEMIA CAUSED BY DECREASED RBC PRODUCTION

Normally RBC production (termed *erythropoiesis*) is in equilibrium with RBC destruction and loss. This balance ensures that an adequate number of RBCs is always available. The normal life span of an RBC is 120 days. There are 3 problems that lead to decreased RBC production: (1) decreased Hgb synthesis from iron deficiency anemia,

TABLE 34.5 NUTRITION THERAPY

Nutrients for RBC Production

Role in RBC Production	Food Sources
Amino Acids (Protein)	
Heme and plasma membrane synthesis and structure	Eggs, meat, milk and milk products (cheese, ice cream), poultry, fish, legumes, nuts, soy
Cobalamin (Vitamin B_{12})	
Synthesis of DNA, RBC maturation, facilitates folate metabolism	Meat, eggs, enriched grain products, milk and dairy foods, fish (especially salmon)
Copper	
Mobilizes iron from tissues to plasma	Shellfish, whole grains, beans, nuts, potatoes, organ meats, dark leafy greens, dried fruits
Folic Acid	
Synthesis of DNA and RNA, RBC maturation	Green leafy vegetables, enriched grain products and breakfast cereals, orange juice, peanuts, avocado
Iron	
Hemoglobin synthesis	Lean beef, turkey, pork and chicken, fish, legumes, dark green leafy vegetables, whole-grain and enriched bread and cereals, beans
Niacin	
RBC maturation	Peanut butter, beef, poultry, fish, avocado; enriched and fortified grains
Pantothenic Acid (Vitamin B_5)	
Heme synthesis	Sweet potato, yogurt, avocado, cereal grains, legumes, eggs, milk
Pyridoxine (Vitamin B_6)	
Heme synthesis	Beef, pork, chicken, fish, fortified cereals, potatoes, bananas, nuts, beans
Riboflavin (Vitamin B_2)	
Oxidative reactions	Milk and dairy foods, enriched bread and other grain products, lean meats, eggs, green leafy vegetables
Vitamin C (Ascorbic Acid)	
Maintains iron in its ferrous form, aids in iron absorption	Citrus fruits, green leafy vegetables, strawberries, potatoes, kiwi fruit, tomatoes, green and red bell peppers
Vitamin E	
Heme synthesis. Protection against oxidative damage to RBCs	Vegetable oils, salad dressings, margarine, wheat germ, whole-grain products, seeds, nuts, peanut butter

thalassemia, and sideroblastic anemia; (2) defective deoxyribonucleic acid (DNA) synthesis in RBCs (e.g., cobalamin deficiency, folic acid deficiency) may lead to megaloblastic anemias; and (3) diminished availability of RBC precursors may result in aplastic anemia and anemia of chronic disease (Table 34.2).

IRON DEFICIENCY ANEMIA

Iron deficiency anemia is the most common nutrition disorder in the world. Those most susceptible to iron deficiency anemia are the very young, those on poor diets, and women in their reproductive years.[1] Normally, we lose 1 mg of iron daily in urine, bile, sweat, sloughing of epithelial cells from the skin and intestinal mucosa, and minor bleeding.[3]

Etiology

Iron deficiency anemia may develop from inadequate diet intake, malabsorption, blood loss, or hemolysis. Normal iron intake is usually enough to meet the needs of men and older women. It may be inadequate for people with higher iron needs (e.g., menstruating or pregnant women).

Iron malabsorption may occur after certain types of gastrointestinal (GI) surgery and in malabsorption syndromes. Iron absorption occurs in the duodenum. Thus malabsorption may occur after surgery that involves removal or bypass of the duodenum. It may occur if duodenal disease alters or destroys the absorption surface.

Blood loss is a major cause of iron deficiency in adults. The major sources of chronic blood loss are from the GI and genitourinary (GU) systems. GI bleeding is often not obvious. It may exist for a long time before the problem is found. Loss of 50 to 75 mL of blood from the upper GI tract is enough for stools to appear black *(melena)*. The black color results from the iron in the RBCs.

Common causes of GI blood loss are peptic ulcer, gastritis, esophagitis, diverticula, hemorrhoids, and cancer. GU blood loss occurs mainly from menstrual bleeding. Postmenopausal bleeding can contribute to anemia in susceptible older women. In addition to anemia of chronic kidney disease, dialysis treatment may cause iron deficiency anemia because of the blood lost in the dialysis equipment and frequent blood sampling.

Clinical Manifestations

In the early course of iron deficiency anemia, the patient may not have any symptoms. As the disease becomes chronic, any of the general manifestations of anemia may develop (Table 34.3). Specific manifestations may occur with iron deficiency anemia. Pallor is the most common finding. *Glossitis* (inflammation of the tongue) is the second most common. Another finding is *cheilitis* (inflammation of the lips). The patient may report headache, paresthesias, and a burning sensation of the tongue.

Diagnostic Studies

Laboratory values seen with iron deficiency anemia are shown in Table 34.6.[1,6] Other diagnostic studies (e.g., stool occult blood test) are done to find the cause of the iron deficiency. Endoscopy and colonoscopy may detect GI bleeding. A bone marrow biopsy may be done if other tests are inconclusive.

Interprofessional and Nursing Management

The main goal is to treat the underlying problem that is causing iron loss, reduced intake (e.g., malnutrition, alcohol use), or poor iron absorption. We also direct efforts toward replacing iron (Table

TABLE 34.6 Laboratory Results in Anemia

Etiology of Anemia	Hgb/Hct	MCV	Reticulocytes	Serum Iron	TIBC	Transferrin	Ferritin	Bilirubin	Serum B_{12}	Folate

TABLE 34.7 Interprofessional Care

Iron Deficiency Anemia

Diagnostic Assessment

- History and physical assessment
- Hgb and Hct (hematocrit) levels
- RBC count, including morphology
- Reticulocyte count
- Serum iron
- Serum ferritin
- Serum transferrin
- Total iron-binding capacity (TIBC)
- Stool examination for occult blood

Management

- Identify and treat underlying cause
- Drug therapy
  - Oral: ferrous sulfate or ferrous gluconate
  - IM or IV: iron dextran, sodium ferrous gluconate, iron sucrose
- Nutrition therapy (Table 34.5)
- Packed RBC transfusion

34.7). Teach the patient which foods are good sources of iron (Table 34.5). If nutrition is already adequate, increasing iron intake through diet may not be enough. The patient may need oral, or occasionally, IV iron supplements. If the iron deficiency is from acute blood loss, the patient may need a packed RBC transfusion.

Drug Therapy

Many oral iron preparations are available. When giving iron, consider the following factors:

1. Iron is absorbed best from the duodenum and proximal jejunum. Enteric coated or sustained-release capsules, which release iron farther down in the GI tract, are counterproductive and expensive.
2. The daily dose should provide 100 to 200 mg of elemental iron. This can be taken in 3 or 4 daily doses, with each tablet or capsule containing 60 to 70 mg of iron.[2]
3. Iron is best absorbed in an acidic environment. For this reason and to avoid binding the iron with food, iron should be taken an hour before meals, when the duodenal mucosa is most acidic. Taking iron with vitamin C (ascorbic acid) or orange juice enhances iron absorption. Iron may be taken with meals if absolutely needed to decrease GI side effects.
4. Undiluted liquid iron may stain the teeth. Dilute liquid iron, and have the patient drink it through a straw.
5. GI side effects may occur, including heartburn, constipation, and diarrhea. Have the patient stay upright for 30 minutes after taking oral forms. If side effects develop, the dose and type of supplement may need adjusted. For example, someone may not be able to tolerate ferrous sulfate because of the effects of the sulfate base. Ferrous gluconate may be a better for them. Tell patients that iron will cause their stools to become black because the GI tract excretes excess iron. Constipation is common. The patient should start on stool softeners and laxatives, if needed, when started on iron.

DRUG ALERT

Iron

- Some IV and IM iron preparations have a risk for an allergic reaction, so monitor the patient accordingly.
- Oral iron should be taken 1 hour before meals.
- Vitamin C (ascorbic acid) enhances iron absorption.

In some situations, we many need to give iron parenterally. Parenteral iron is indicated for malabsorption, intolerance of oral iron, a need for iron beyond oral limits, or poor patient adherence in taking oral iron. Parenteral iron can be given IM or IV. We give a test dose of IV iron dextran then observe the patient for 1 hour before giving the rest of dose so we can monitor for anaphylaxis.[4,5]

Because IM iron solutions may stain the skin, use separate needles for withdrawing the solution and injecting the medication. Use a Z-track injection technique.

Assess the Hgb and RBC count to evaluate the response to therapy. Stress adherence with diet and drug therapy. To replenish the body's iron stores, the patient needs to take iron therapy for 2 to 3 months after the Hgb level returns to normal. Monitor patients who need lifelong iron therapy for potential liver problems from the iron storage.

THALASSEMIA

Etiology

Thalassemia is a group of diseases involving inadequate production of normal Hgb, which decreases RBC production. Thalassemia

is due to an absent or reduced globulin protein. α-Globin chains are absent or reduced in α-thalassemia. β-Globin chains are absent or reduced in β-thalassemia. Hemolysis occurs as mononuclear phagocytes in the marrow destroy most erythroblasts. Those released into the blood are rapidly destroyed by macrophages in the spleen.[1] Thalassemia is commonly found in persons whose ethnic origins are near the Mediterranean Sea and equatorial or near-equatorial regions of Southeastern Asia, the Middle East, India, Pakistan, China, Southern Russia, and Africa.[1]

Genetic Link

Thalassemia has an autosomal recessive genetic basis (see Fig. 13.4 and Table 13.2). A person with thalassemia may have a heterozygous or homozygous form of the disease. A person who is heterozygous has 1 thalassemic gene and 1 normal gene. They have *thalassemia minor* (or thalassemic trait), which is a mild form of the disease. A homozygous person has 2 thalassemic genes. This causes the more severe form known as *thalassemia major.*[1]

Clinical Manifestations and Diagnostic Studies

The patient with thalassemia minor is often asymptomatic. They have mild to moderate anemia with *microcytosis* (small cells) and *hypochromia* (pale cells), mild splenomegaly, bronzed skin color, and bone marrow hyperplasia.[3]

Thalassemia major is a life-threatening disease. Symptoms develop in childhood by age 2 and can cause growth and development deficits. The person is pale and has other general symptoms of anemia (Table 34.3). Jaundice from RBC hemolysis is prominent. There is pronounced splenomegaly because the spleen continuously tries to remove the damaged RBCs. Hepatomegaly and cardiomyopathy occur from iron deposition.

The bone marrow responds to the reduced O_2-carrying capacity of the blood by increasing RBC production. The marrow becomes packed with immature erythroid precursors that die. This stimulates further RBC production, leading to chronic bone marrow hyperplasia and expansion of the marrow space. This may cause thickening of the cranium and maxillary cavity. Thrombocytosis after spleen dysfunction and/or removal may occur.

Cardiac complications from iron overload, lung disease, and hypertension also contribute to early death. Endocrine problems (diabetes, growth retardation, hypogonadism), osteoporosis, pulmonary hypertension, and thrombosis may occur.[1,2]

Laboratory values seen with thalassemia major are shown in Table 34.6.

Interprofessional Care

Thalassemia minor does not need treatment because the body adapts to the reduction of normal Hgb. Treatment of thalassemia major includes blood transfusions or exchange transfusions in conjunction with chelating agents that bind to iron. Transfusions are generally given when the Hgb drops to less than 7 g/dL (100 g/L), depending on the manifestations.[1] Chelating agents reduce the iron overloading that occurs with chronic transfusion therapy. Drugs used include oral deferasirox (Exjade, JadeNu) or deferiprone (Ferriprox), or IV or subcutaneous deferoxamine (Desferal).[1] A new therapy, luspatercept-aamt (Reblozyl), may be given subcutaneously every 21 days. It improves Hgb levels and reduces transfusion needs. It blocks inhibitors of late-stage RBC production.[6]

Because an enlarged spleen sequesters RBCs, the patient may need a splenectomy. Monitor liver, heart, and lung function and provide treatment as needed.

Hematopoietic stem cell transplantation (HSCT) is the only cure for thalassemia. However, the risks of this procedure may outweigh its benefits. With iron chelation therapy, patients are living longer. We are researching gene transfer therapy to correct the globin gene expression.

TABLE 34.8 Causes of Megaloblastic Anemia

Cobalamin (Vitamin B_{12}) Deficiency
- Chronic alcohol use
- Diet deficiency
- Deficiency of gastric intrinsic factor
  - Celiac disease
  - Gastrectomy
  - Gastric bypass
  - *Helicobacter pylori*
  - Pernicious anemia
- Increased requirement (pregnancy)
- Intestinal malabsorption

Folic Acid Deficiency
- Chronic alcohol use
- Chronic hemodialysis (folic acid lost during dialysis)
- Diet deficiency (e.g., leafy green vegetables, citrus fruits)
- Drugs interfering with absorption or use of folic acid (e.g., metformin phenytoin)
- Increased requirement (pregnancy)
- Malabsorption syndromes
  - Celiac disease
  - Crohn disease
  - Small bowel resection

Drug-Induced Suppression of DNA Synthesis
- Alkylating agents
- Folate antagonists
- Metabolic inhibitors

Inherited Defects
- Defective folate metabolism
- Defective transport of cobalamin

Myelodysplastic Syndromes

MEGALOBLASTIC ANEMIAS

Megaloblastic anemias are characterized by the presence of abnormally large *(macrocytic)* RBCs. We call them *megaloblasts.* Macrocytic RBCs are easily destroyed because they have fragile cell membranes. Megaloblastic anemias are caused by impaired DNA synthesis, which results in defective RBC maturation. Most result from cobalamin (vitamin B_{12}) and folic acid deficiencies. They can also occur with congenital disorders, suppression of DNA synthesis by drugs, inborn errors of cobalamin and folic acid metabolism, and *erythroleukemia* (malignant

blood disorder characterized by a proliferation of erythropoietic cells in bone marrow) (Table 34.8).[1]

COBALAMIN DEFICIENCY

The most common cause of cobalamin deficiency is **pernicious anemia**. It is caused by an absence of *intrinsic factor* (IF). Pernicious anemia is a disease of insidious onset. It begins in middle age or later (usually after age 40), with 60 years being the most common age at diagnosis. Pernicious anemia occurs most often in persons of Northern European descent (especially Scandinavians) and Blacks.[1,4]

Etiology

Normally, the parietal cells of the gastric mucosa secrete IF. IF is required for cobalamin (extrinsic factor) absorption. We absorb cobalamin in the distal ileum. Without IF, we do not absorb cobalamin. In pernicious anemia, the gastric mucosa does not secrete IF because of either gastric mucosal atrophy or autoimmune destruction of parietal cells. In the autoimmune process, antibodies are directed against the gastric parietal cells and/or IF itself. Because parietal cells also secrete hydrochloric acid (HCl), in pernicious anemia there is a decrease in HCl in the stomach. An acid environment in the stomach is needed for IF secretion.

Cobalamin deficiency can occur in patients who had GI surgery (e.g., gastrectomy, gastric bypass) or a small bowel resection involving the ileum. Others at risk include those with Crohn disease, ileitis, celiac disease, diverticula of the small intestine, or chronic atrophic gastritis (see Table 34.8). In these cases, cobalamin deficiency results from the loss of IF-secreting gastric mucosal cells or impaired absorption of cobalamin in the distal ileum. Cobalamin deficiency also occurs with excess alcohol or hot tea ingestion, smoking, long-term users of H_2-histamine receptor blockers and proton pump inhibitors, and those who are strict vegetarians.[1]

There is a familial predisposition for pernicious anemia. Assess patients who have a positive family history of pernicious anemia for symptoms. Although the disease cannot be prevented, early detection and treatment can lead to reversal of symptoms.

Clinical Manifestations

General manifestations of anemia due to cobalamin deficiency develop due to tissue hypoxia (Table 34.3). GI manifestations include a sore, red, beefy, and shiny tongue; anorexia, nausea, and vomiting; and abdominal pain. Typical neuromuscular manifestations include weakness, paresthesias of the feet and hands, reduced vibratory and position senses, ataxia, muscle weakness, and impaired cognition. Because cobalamin deficiency–related anemia has an insidious onset, it may take several months or years for manifestations to develop.[1]

Diagnostic Studies

Laboratory data reflective of cobalamin deficiency anemia are shown in Table 34.6. The RBCs appear large (macrocytic) and have abnormal shapes. This structure contributes to RBC destruction because the cell membrane is fragile. Serum cobalamin levels are low.

Normal serum folate levels and low cobalamin levels suggest megaloblastic anemia due to cobalamin deficiency. A serum test for anti-IF antibodies is specific for pernicious anemia. Patients with pernicious anemia have an increased risk for gastric cancer. They may have an upper GI endoscopy and biopsy of the gastric mucosa at the time of diagnosis and at appropriate intervals afterward.

Serum methylmalonic acid (MMA) (high in cobalamin deficiency) and serum homocysteine (high in both cobalamin and folic acid deficiencies) help determine the cause of the anemia.

❖ Interprofessional and Nursing Management

Without cobalamin administration, the patient will die in 1 to 3 years. Most patients need parenteral vitamin B_{12} (cyanocobalamin, hydroxocobalamin) or intranasal cyanocobalamin (Nascobal). A typical treatment schedule consists of 1000 mcg/day of cobalamin IM for 2 weeks, then weekly until the Hgb is normal, and then monthly for life.

The nursing measures discussed in eNursing Care Plan 34.1 for the patient with anemia are appropriate for the patient with cobalamin deficiency anemia. In addition to these measures, assess for neurologic problems that are not corrected by replacement therapy. Implement measures to reduce the risk for injury from the decreased sensitivity to heat and pain. Protect the patient from falling, burns, and trauma. In some people, the neuromuscular problems may not be reversible. They may need physical therapy.

FOLIC ACID DEFICIENCY

Folic acid (folate) deficiency can cause megaloblastic anemia. Folic acid is needed for DNA synthesis leading to RBC formation and maturation. Common causes of folic acid deficiency are shown in Table 34.8.

The manifestations of folic acid deficiency are similar to cobalamin deficiency. It develops insidiously. Symptoms may be attributed to other coexisting problems (e.g., cirrhosis, esophageal varices). GI problems may include stomatitis, cheilosis, dysphagia, flatulence, and diarrhea. Thiamine deficiency, which is often present with folate deficiency, can cause neurologic symptoms.[3]

The diagnostic findings for folic acid deficiency are shown in Table 34.6. The serum folate level is low (normal is 5 to 25 ng/mL [11 to 57 nmol/L]), with a normal serum cobalamin level.

We treat folic acid deficiency with replacement therapy. The usual dosage is 1 to 5 mg/day by mouth.[2,4] The duration of treatment depends on the reason for the deficiency. Teach the patient to eat foods high in folic acid (Table 34.5). The nursing measures discussed in eNursing Care Plan 34.1 for the patient with anemia are appropriate for the patient with folic acid deficiency anemia.

ANEMIA OF CHRONIC DISEASE

Anemia of chronic disease (also called *anemia of inflammation*) usually develops after 1 to 2 months of disease activity. Causes include cancer, autoimmune and infectious disorders (human immunodeficiency virus [HIV], hepatitis, malaria), HF, or chronic inflammation. Bleeding episodes can contribute to anemia of chronic disease.

TABLE 34.9 Causes of Aplastic Anemia

- Chemical agents and toxins (e.g., benzene, insecticides)
- Drugs (e.g., alkylating agents, antiseizure drugs, antimetabolites, antimicrobials, gold, NSAIDs, antithyroid medications, allopurinol)
- Immune suppression of stem cells by autoreactive T lymphocytes
- Inherited stem cell defect (e.g., Fanconi anemia)
- Radiation
- Toxic injury to bone marrow stem cells
- Viral and bacterial infections

Anemia of chronic disease is associated with an underproduction of RBCs and mild shortening of RBC survival. The RBCs are usually normocytic, normochromic, and hypoproliferative. The anemia is usually mild. It can become more severe if the underlying disorder is not treated.

This type of anemia has an immune basis. The cytokines released in these problems, especially interleukin-6 (IL-6), cause an increased uptake and retention of iron within macrophages (see Fig. 33.3). This leads to a diversion of iron from circulation into storage sites, limiting the iron available for RBC production. There is reduced RBC life span, decreased erythropoietin (EPO) production, and an ineffective bone marrow response to EPO.

Anemia of chronic disease must be recognized and distinguished from anemia of other causes. High serum ferritin and increased iron stores distinguish it from iron deficiency anemia. Unlike megaloblastic anemia, there are normal folate and cobalamin blood levels.

The best treatment is to correct the underlying problem. If the anemia is severe, blood transfusions may be needed. They are not recommended for long-term treatment. EPO therapy is used for anemia from renal disease (see Chapter 51) and cancer and its therapies (see Chapter 16). Its use is limited because of the increased risk for thromboembolism and death in some patients.

APLASTIC ANEMIA

Aplastic anemia is a disease in which the patient has peripheral blood *pancytopenia* (decrease of all blood cell types—RBCs, white blood cells [WBCs], platelets) and hypocellular bone marrow. The spectrum can range from a moderate condition managed with EPO or blood transfusions to very severe with potentially fatal bleeding and sepsis. The incidence of aplastic anemia is rare, with an annual rate of 2 new cases per million people in the United States per year.[7]

Etiology

About 70% of aplastic anemias are due to autoimmune activity by autoreactive T lymphocytes.[1] The cytotoxic T cells target and destroy the patient's own hematopoietic stem cells. Other causes include toxic injury to bone marrow stem cells or an inherited stem cell defect (Table 34.9).

Clinical Manifestations

Aplastic anemia can manifest abruptly (over days) or insidiously over weeks to months. It can vary from mild to very severe. The patient may have symptoms caused by suppression of any or all bone marrow elements. General manifestations of anemia, such as fatigue and dyspnea, as well as cardiovascular and cerebral responses, may occur (Table 34.3). The patient with neutropenia (low neutrophil count) is susceptible to infection. They are at risk for septic shock and death. Thrombocytopenia can lead to bleeding (e.g., petechiae, bruising, nosebleeds).

Diagnostic Studies

Laboratory studies confirm the diagnosis. Because aplastic anemia affects all marrow elements, Hgb, WBC, and platelet values are decreased. Other RBC indices are generally normal (Table 34.6). Thus we classify the condition as a normocytic, normochromic anemia. The reticulocyte count is low. Serum iron and total iron-binding capacity (TIBC) may be high as initial signs of decreased RBC production. Bone marrow biopsy, aspiration, and pathologic examination will be done to confirm the laboratory findings. The marrow in aplastic anemia is hypocellular with increased yellow marrow (fat content).

❖ Interprofessional and Nursing Management

Management is based on identifying and removing the causative agent (when possible) and providing supportive care until the pancytopenia resolves. Nursing interventions appropriate for the patient with pancytopenia from aplastic anemia are discussed in eNursing Care Plan 34.1 for anemia, eNursing Care Plan 34.2 for thrombocytopenia, and eNursing Care Plan 34.3 for neutropenia (available on the website for this chapter). Nursing actions are aimed at preventing complications from infection and bleeding.

The prognosis of severe untreated aplastic anemia is poor. Early consideration of an HSCT is critical. The best treatment outcomes for those who receive an HSCT occur in younger patients who have had limited blood transfusions. Prior transfusions increase the risk for HSCT graft rejection. HSCT is discussed in Chapter 16.

Those in the interim or ineligible for HSCT may receive immunosuppressive therapy with antithymocyte globulin (ATG) and cyclosporine.[1] Eltrombopag (Promacta), an oral thrombopoietin receptor agonist, can increase platelet counts. High-dose cyclophosphamide, alemtuzumab, or androgens may be helpful in select patients who do not respond to other treatments.[4] Non-HSCT patients who need ongoing supportive blood transfusion should receive an iron-binding agent to prevent iron overload.

ANEMIA CAUSED BY BLOOD LOSS

An acute or chronic problem can cause anemia from blood loss.

ACUTE BLOOD LOSS

Acute blood loss occurs with sudden bleeding. Causes of acute blood loss include trauma, surgery complications, and problems that disrupt vascular integrity. There are 2 clinical concerns in such situations. First, a sudden reduction in the total blood volume can lead to hypovolemic shock. Second, if the acute loss is

TABLE 34.10 Manifestations of Acute Blood Loss

VOLUME LOST[a]		
%	mL	Manifestations
10	500	None or rare vasovagal syncope
20	1000	No detectable signs or symptoms at rest. ↑ HR with exercise and slight postural hypotension
30	1500	Normal supine BP and pulse at rest. Postural hypotension and ↑ HR with exercise
40	2000	BP, central venous pressure, and cardiac output below normal at rest; air hunger; rapid, thready pulse and cold, clammy skin
50	2500	Shock, lactic acidosis, and potential death

[a]Based on an adult with a total blood volume of 5 L.

more gradual, the body maintains its blood volume by slowly increasing the plasma volume. While this preserves circulating fluid volume, the number of RBCs available to carry O_2 is significantly decreased.

Clinical Manifestations

The manifestations of anemia from acute blood loss are caused by the body's attempts to maintain an adequate blood volume and meet O_2 requirements. Table 34.10 outlines the manifestations of patients with varying degrees of blood volume loss. The signs and symptoms the patient has are more important than the laboratory values. For example, an adult with a bleeding peptic ulcer who had a 750-mL hematemesis (15% of a normal total blood volume) within the past 30 minutes may have postural hypotension and normal Hgb and hematocrit values. Over the next 36 to 48 hours, fluid moving from the extravascular into the intravascular space will replace most of the blood volume deficit. Only then will the Hgb and hematocrit reflect the blood loss.

Assess the patient for pain. Internal bleeding may cause pain due to tissue distention, organ displacement, and nerve compression. Pain may be localized or referred. In the case of retroperitoneal bleeding, the patient may not have abdominal pain. Instead, there may be numbness and pain in a lower extremity from compression of the lateral cutaneous nerve (in the region of the 1st to 3rd lumbar vertebrae). The major complication is shock (see Chapter 42).

Diagnostic Studies

When blood volume loss is sudden, plasma volume has not yet had a chance to increase. Laboratory data do not reflect the RBC loss. Values may seem normal or high for 2 to 3 days. However, once the plasma volume is replaced, the RBC mass is less concentrated. Then, RBC, Hgb, and hematocrit levels are low and reflect the actual blood loss.

❖ Interprofessional and Nursing Management

Interprofessional care is initially concerned with (1) replacing blood volume to prevent shock; (2) promoting coagulation to prevent further bleeding; and (3) finding the source of the bleeding and stopping the blood loss. Blood transfusions (packed RBCs) can be used depending on the volume lost. If a large volume of blood is lost, whole blood, platelets, plasma, and cryoprecipitate may be given because large volumes of RBCs dilute the coagulation system. IV fluids used in emergencies include volume replacement fluids (e.g., 0.9% NaCl, lactated Ringer) or colloids that pull fluids into the vascular space (e.g., dextran, hetastarch, albumin).[8] The amount of infusion varies with the solution used.

The body needs 2 to 5 days to make more RBCs in response to increased EPO. The patient may need iron supplements because iron availability affects the marrow production of RBCs. When anemia exists after acute blood loss, diet iron may not be enough to maintain iron stores. We may need to give oral or parenteral iron preparations.

In the case of trauma, it may be impossible to prevent blood loss. For the postoperative patient, carefully monitor the blood loss from various drainage tubes and dressings and implement appropriate actions.

The anemia should begin to correct itself once we find the source of bleeding, control the blood loss, and replace fluid and blood volumes. There should be no need for long-term treatment of this type of anemia.

CHRONIC BLOOD LOSS

The sources of chronic blood loss are similar to those of iron deficiency anemia (e.g., bleeding ulcer, hemorrhoids, menstrual and postmenopausal blood loss). The effects of chronic blood loss are usually due to depleted iron stores. We consider it an iron deficiency anemia. Management of chronic blood loss anemia involves identifying the source and stopping the bleeding. The patient may need iron supplements.

ANEMIA CAUSED BY INCREASED RBC DESTRUCTION

The third major cause of anemia is **hemolytic anemia.** It is a condition caused by the destruction or hemolysis of RBCs at a rate that exceeds production. Hemolysis can occur with problems intrinsic or extrinsic to the RBCs. *Intrinsic hemolytic anemias,* which are usually hereditary, result from defects in the RBCs themselves (Table 34.2).

More common are the *acquired hemolytic anemias*. In this type of anemia, the RBCs are normal but external factors are causing damage (Table 34.2). Macrophages, particularly those in the spleen, liver, and bone marrow, destroy RBCs that are old, defective, or moderately damaged. Fig. 34.2 shows the sequence of events involved in extravascular hemolysis.

The patient with hemolytic anemia has the general manifestations of anemia with some specific manifestations (Table 34.3). Jaundice occurs because the increased RBC destruction causes increased bilirubin levels. The spleen and liver may enlarge from hyperactivity, which is due to macrophage phagocytosis of the defective RBCs.

A major focus of treatment is to maintain renal function. When RBCs are hemolyzed, the Hgb molecule is released and filtered by the kidneys. The accumulation of Hgb molecules can

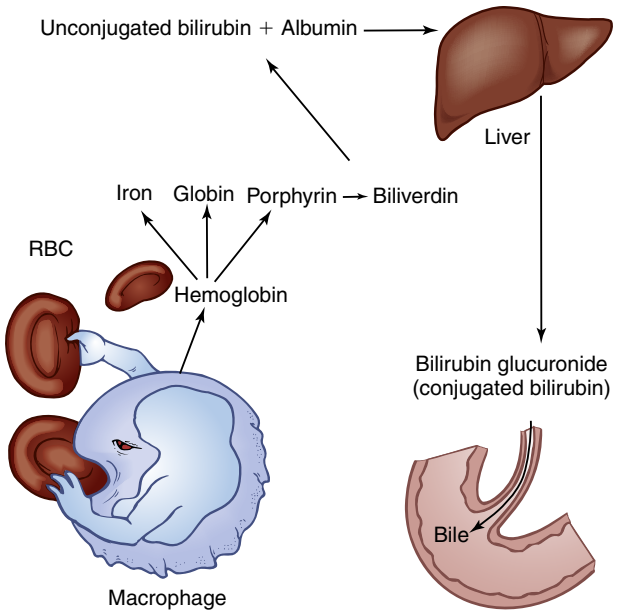

Fig. 34.2 Sequence of events in extravascular hemolysis.

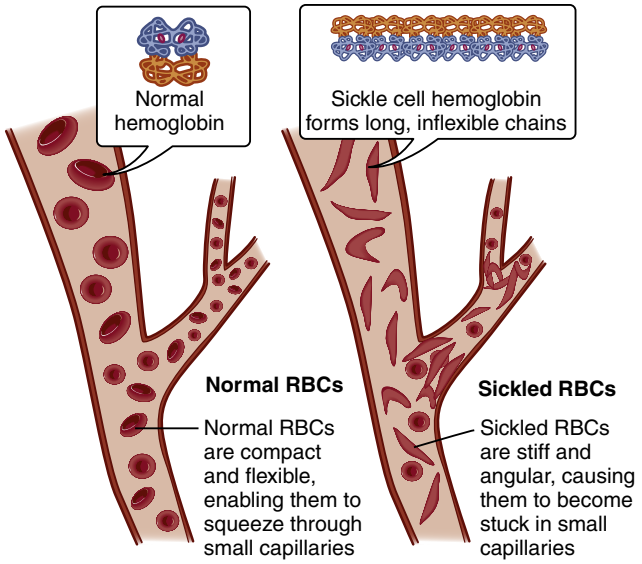

Fig. 34.3 In sickle cell, the hemoglobin forms long inflexible chains and alters the shape of the red blood cells *(RBCs)*. The sickled RBCs can become stuck in the capillaries and occlude the blood flow.

obstruct the renal tubules and lead to acute tubular necrosis (see Chapter 51).

SICKLE CELL DISEASE

Sickle cell disease (SCD) is a group of inherited, autosomal recessive disorders characterized by an abnormal form of Hgb in the RBC. Because this is a genetic disorder, SCD is usually found during routine neonatal screening. Although median survival can now exceed 50 years old, SCD often results in irreversible damage of the lungs, kidneys, brain, retina, or bones that significantly affects patients' quality of life.[1]

Etiology and Pathophysiology

Genetic Link

In SCD, the abnormal Hgb, *hemoglobin S* (Hgb S), results from the substitution of valine for glutamic acid on the β-globin chain of Hgb (see Fig. 13.3). Hgb S causes the RBC to stiffen and elongate, taking on a sickle shape in response to low O_2 levels (Fig. 34.3).

Types of SCD disorders include sickle cell anemia, sickle cell–thalassemia, sickle cell Hgb C disease, and sickle cell trait (Box 34.1).[9] *Sickle cell anemia* is the most severe of the SCD syndromes. It occurs when a person is homozygous for hemoglobin S (Hgb SS), meaning the person has inherited Hgb S from both parents. *Sickle cell–thalassemia* and *sickle cell Hgb C* occur when a person inherits Hgb S from 1 parent and another type of abnormal Hgb (e.g., thalassemia or Hgb C) from the other parent. Both these forms of SCD are less common and less severe than sickle cell anemia. *Sickle cell trait* occurs when a person is heterozygous for hemoglobin S (Hgb AS). This means the person has inherited Hgb S from 1 parent and normal hemoglobin (Hgb A) from the other parent. Sickle cell trait is typically a mild to asymptomatic condition.

BOX 34.1 GENETICS IN CLINICAL PRACTICE

Sickle Cell Disease

Genetic Basis
- Autosomal recessive disorder
- Mutation in β-globin *(HBB)* gene found on chromosome 11
- Various versions of β-globin result from different mutations in the *HBB* gene
- Hgb S variant involves substitution of valine for glutamic acid in the β-globin gene

Incidence
- Most common inherited blood disorder in the United States
- Affects around 100,000 Americans
- Occurs in about 1 of every 365 African American births
- Occurs in about 1 of every 16,300 Hispanic American births
- Affects people of Mediterranean, Caribbean, Arabian, and East Indian descent
- 1 in 13 African American babies is born with sickle cell trait

Genetic Testing
- DNA testing is available
- Electrophoresis of hemoglobin and sickling screening test are common

Clinical Implications
- Sickle cell trait is the carrier state for sickle cell disease (SCD) and is a mild type of SCD
- If both parents have the trait, there is a 1 in 4 chance that their baby will have SCD
- Genetic counseling is recommended for people with a family history of SCD so they can understand the risks for transmitting the genetic mutation

Sickling Episodes

The major pathophysiologic event of SCD is the sickling of RBCs (Fig. 34.3). The main trigger of sickling episodes is low O_2 tension in the blood. Infection is the most common cause of hypoxia or deoxygenation of the RBCs. Other causes include

high altitude, emotional or physical stress, surgery, and blood loss. Events that can trigger or sustain a sickling episode include dehydration, increased hydrogen ion concentration (acidosis), increased plasma osmolality, decreased plasma volume, and low body temperature. A sickling episode can also occur without an obvious cause.

Sickled RBCs become rigid and take on an elongated, crescent shape (Fig. 34.3). Sickled cells cannot easily pass through capillaries or other small vessels and can cause vascular occlusion, leading to acute or chronic tissue injury. The resulting hemostasis promotes a self-perpetuating cycle of local hypoxia, deoxygenation of more RBCs, and more sickling. Circulating sickled cells are hemolyzed by the spleen, leading to anemia. At first, sickling is reversible with reoxygenation. It eventually becomes irreversible because of cell membrane damage from recurrent sickling. Vasoocclusive phenomena and hemolysis are the clinical hallmarks of SCD.

Sickle cell crisis is a severe, painful, acute exacerbation of RBC sickling, causing a vasoocclusive crisis. As sickled cells impair blood flow, vasospasm occurs, further restricting blood flow. Severe capillary hypoxia causes changes in membrane permeability, leading to plasma loss, hemoconcentration, thrombi, and further circulatory stagnation. Tissue ischemia, infarction, and necrosis eventually occur from lack of O_2. Shock is a possible life-threatening consequence because of severe O_2 depletion of the tissues and decreased circulating fluid volume. Sickle cell crisis can begin suddenly and persist for days to weeks.

The frequency, extent, and severity of sickling episodes are highly variable and unpredictable. They depend on the percent of Hgb S present. People with sickle cell anemia have the most severe form because the RBCs have a high percentage of Hgb S.

Clinical Manifestations

The effects of SCD vary from person to person. The severity may be due to genetic variants. Many people with sickle cell anemia are in fairly good health most of the time. However, they may have chronic health problems and pain from organ tissue hypoxia and damage (e.g., involving the kidneys or liver).

The typical patient is anemic but asymptomatic except during sickling episodes. Because most people with sickle cell anemia have dark skin, pallor is easier to detect by examining the mucous membranes. The skin may have a grayish cast. Because of the hemolysis, jaundice is common. Patients are prone to gallstones.

The main symptom associated with sickling is pain. The pain severity can range from minor to excruciating. During sickle cell crisis, the pain is severe because of tissue ischemia. The episodes can affect any area of the body or several sites simultaneously. The back, chest, extremities, and abdomen are affected most often. Pain episodes are often accompanied by other manifestations, such as fever, tachypnea, hypertension, nausea, and vomiting.

Complications

With repeated episodes of sickling, there is gradual involvement of all body systems, especially the spleen, lungs, kidneys, and brain. Organs that need large amounts of O_2 are most often affected and form the basis for many of the complications of SCD (Fig. 34.4). Infection is a major cause of mortality. One reason for this is the spleen does not phagocytize foreign substances as it becomes infarcted and dysfunctional (usually by 2 to 4 years of age) from the sickled RBCs. The spleen becomes small from the repeated scarring, termed *autosplenectomy.*

Pneumonia is the most common infection. It often is of pneumococcal origin. Infections can be so severe that they cause an aplastic and hemolytic crisis and gallstones. *Aplastic crisis* can be so severe that it causes a temporary shutdown of RBC production in the bone marrow.

Acute chest syndrome is a term used to describe acute pulmonary complications that include pneumonia, tissue infarction, and fat embolism. There may be fever, chest pain, cough, lung infiltrates, and dyspnea. Pulmonary infarctions may cause pulmonary hypertension, MI, and cor pulmonale. The heart may become ischemic and enlarged, leading to HF. Retinal vessel obstruction may result in bleeding, scarring, retinal detachment, and blindness. The increased blood viscosity and the lack of O_2 can injure the kidneys. Renal failure may occur. Pulmonary embolism or stroke can result from thrombosis and infarction of cerebral blood vessels. Bone changes may include osteoporosis and osteosclerosis after infarction. Chronic leg ulcers can result from the hypoxia and are especially prevalent around the ankles. *Priapism* (persistent penile erection) may occur if penile veins become occluded.

Diagnostic Studies

A peripheral blood smear may reveal sickled cells and increased, abnormal reticulocytes. Hgb electrophoresis can determine the amount of Hgb S and SCD from other variants.

The accelerated RBC breakdown gives the patient the characteristic findings of hemolysis (jaundice, high serum bilirubin levels) and abnormal laboratory test results (Table 34.6). Skeletal x-rays show bone and joint deformities and flattening. MRI can diagnose a stroke caused by blocked cerebral vessels from sickled cells. Doppler studies can assess for deep vein thromboses (DVTs). A chest x-ray can diagnose infection.

❖ Interprofessional and Nursing Management

Goals of interprofessional care include (1) preventing sequelae from SCD; (2) alleviating the manifestations from complications of SCD; (3) minimizing end-organ damage; and (4) continuously assessing for and promptly treating serious sequelae, such as acute chest syndrome, which can lead to immediate death.[1]

A patient in sickle cell crisis may need to be hospitalized. O_2 therapy treats hypoxia and controls sickling. Assess for any changes in respiratory status. Encourage incentive spirometry. Rest can reduce metabolic requirements. Provide DVT prophylaxis. Fluids will reduce blood viscosity and maintain renal function. Priapism is managed with pain medication and fluids. If it does not resolve within a few hours, a urologist may be called.[2]

Transfusion therapy is needed with an aplastic crisis. Patients who have frequent crises or serious complications, such as acute chest syndrome, may need aggressive RBC exchange transfusion

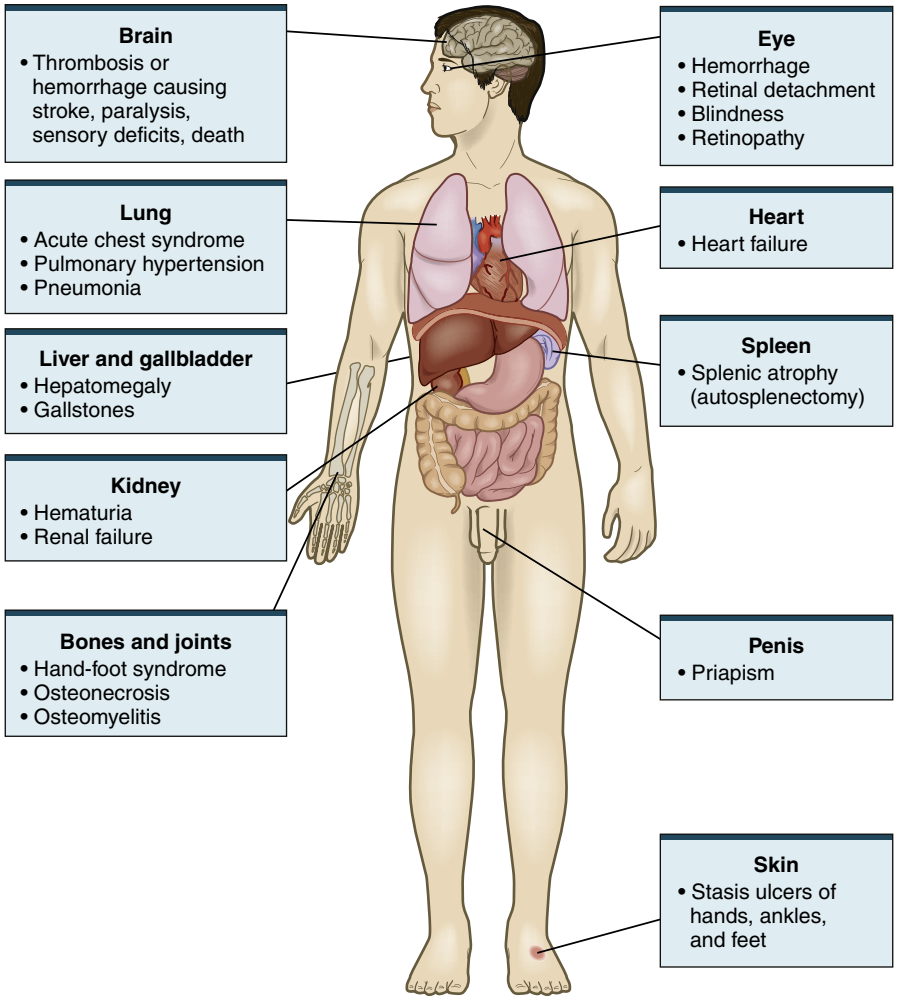

Fig. 34.4 Clinical manifestations and complications of sickle cell disease. (Modified from Huether SE, McCance KL, Brashers VL: *Understanding pathophysiology*, ed 7, St Louis, 2020, Elsevier.)

programs. These patients, like those with thalassemia major, may need iron chelation therapy to reduce transfusion-produced iron overload.

CHECK YOUR PRACTICE

A 21-year-old Black woman presents to the emergency department (ED) after a ski trip to Colorado. She is in excruciating pain in her chest and abdomen. She is short of breath, and her O_2 saturation is 86%. Vital signs show her heart rate is 110 beats/min and respiratory rate 28/min. She has crackles in the lungs. You note 6 previous ED admissions for sickle cell crises.

- What are your priorities for her nursing care?

Use a holistic approach to address the pain and its impact on the patient's quality of life (see Chapter 9).[1] Patients may have different types and sites of pain, as well as acute and chronic pain. Undertreatment of sickle cell pain is a major problem (Box 34.2). SCD patients may develop tolerance. They may need larger doses of pain medication to reduce pain to an acceptable level. Pain can cause patients to have central sensitization, hyperalgesia, and altered opioid metabolism. This can cause mood and emotional problems.

During an acute crisis, optimal pain control usually includes large doses of continuous opioid analgesics, along with breakthrough analgesia, often in the form of patient-controlled analgesia (PCA). Adjunctive measures include nonsteroidal antiinflammatory drugs (NSAIDs), antineuropathic pain drugs (e.g., antidepressants, antiseizure drugs), local anesthetics, or nerve blocks. Occupational and physical therapy can optimize functioning. Social and chaplain services can help to address social, emotional, and spiritual needs.

Infection is a frequent complication. Any febrile illness in a patient with SCD is an emergency. Wound infections, such as chronic leg ulcers, may be treated with rest, antibiotics, and proper wound care (see Chapter 12). Patients with acute chest syndrome receive broad-spectrum antibiotics, O_2 therapy, fluid therapy, and exchange transfusion. Blood transfusions are done sparingly between crises because patients develop antibodies to RBCs and iron overload. Because chronic hemolysis results decreased folic acid stores, the patient should take an oral folic acid supplement.

Various drugs can reduce sickling episodes.[10] Hydroxyurea (Hydrea) increases the production of Hgb F (fetal hemoglobin) and alters the adhesion of sickled RBCs to the endothelium. The increase in Hgb F is accompanied by a reduction in hemolysis, an increase in Hgb concentration, and a decrease

BOX 34.2 ETHICAL/LEGAL DILEMMAS

Pain Management

Situation

N.C., a 21-year-old African American man in the emergency department (ED) in sickle cell crisis, reports excruciating pain. He is known to several of the staff members in the ED. A nurse remarks to you that it must be time for his "fix" of pain drugs.

Ethical/Legal Points for Consideration

- The standard of care for pain management requires that (1) a pain assessment is done based on the patient's self-report, (2) the patient receives the best possible pain relief under the circumstances, and (3) we provide competent and compassionate care to all patients.
- The pain assessment includes reviewing the patient's medical record to see if there are health care issues or conditions that may affect the patient's response to pain and pain management.
- Document patient behaviors related to pain management. Be objective (factual observations) rather than subjective, such as labeling ("the patient is in withdrawal").
- When pain relief is inadequate, you must notify the HCP. Make sure the HCP has assessed the patient and based the plan of care on that assessment.

Discussion Questions

1. How can you teach your peers about pain assessment and management?
2. What factors do you need to include in your assessment and management of N.C.?

in sickled cells and painful crises. Adakveo (crizanlizumab) reduces sickle cell and blood vessel adhesion. Voxelotor (Oxbryta) stabilizes an oxygenated Hgb cell, reducing sickling. Oral glutamine, an amino acid, decreases endothelial adhesion and can reduce the number and frequency of pain crises and hospitalizations.[10]

HSCT is the only available treatment that can cure some patients with SCD. It is not widely available. The selection of appropriate recipients, scarcity of appropriate donors, risk, and cost-effectiveness limit its use. We are researching gene therapy.[10]

Patient teaching and support are important in the long-term care of the patient with SCD. The patient and caregiver must understand the basis of SCD and the reasons for supportive care and ongoing screening tailored to SCD manifestations. Teach the patient ways to avoid crises. Review steps to avoid dehydration and hypoxia, such as avoiding high altitudes and seeking medical attention quickly to counteract problems, such as upper respiratory tract infections. Teach patients to maintain adequate fluid intake. Encourage routine immunizations, such as pneumococcal, influenza, and hepatitis. Screening for retinopathy should begin at age 10. Each person with SCD should have a reproductive life plan.[1] Provide teaching about pain control because the pain during a crisis may be severe and often requires considerable analgesia. Minor pain episodes that are not associated with infection or other symptoms that need medical attention can sometimes be managed at home.

ACQUIRED HEMOLYTIC ANEMIA

Acquired hemolytic anemia results from hemolysis of RBCs from extrinsic factors. These factors include (1) physical destruction, (2) antibody reactions, and (3) infectious agents and toxins (Table 34.2).[1]

Physical destruction of RBCs results from the exertion of extreme force on the cells. Traumatic events that disrupt the RBC membrane include hemodialysis, extracorporeal circulation used in cardiopulmonary bypass, and prosthetic heart valves. The force needed to push blood through abnormal vessels, such as those that have been burned, irradiated, or affected by vascular disease (e.g., diabetes), may physically damage RBCs.

RBCs can be fragmented and destroyed as they try to pass through abnormal arterial or venous microcirculation. The RBCs are sheared as they try to pass by excess platelet aggregation and/or fibrin polymer formation, such as is seen in thrombotic thrombocytopenic purpura (TTP) and disseminated intravascular coagulation (DIC).

Antibodies may destroy RBCs by the mechanisms involved in antigen-antibody reactions. In blood transfusion reactions, the recipient's antibodies attack and hemolyze donor cells. Autoimmune antibody reactions occur when people develop antibodies against their own RBCs. This can be an idiopathic (no prior hemolytic history) or from other autoimmune diseases (e.g., systemic lupus erythematosus [SLE]) or medications (aspirin, clopidogrel, tacrolimus).[2,6]

Infectious agents cause hemolysis in 3 ways: (1) invading the RBC and destroying its contents (e.g., parasites, such as in malaria), (2) releasing hemolytic substances (e.g., *Clostridium perfringens*), and (3) generating an antigen-antibody reaction (e.g., *Mycoplasma pneumoniae*). Various agents may be toxic to RBCs and cause hemolysis. Hemolytic toxins include chemicals, such as oxidative drugs, arsenic, lead, copper, and bee stings or spider bites.

Laboratory findings in hemolytic anemia are shown in Table 34.6. Treatment and management involve general supportive care until the causative agent can be eliminated or at least made less injurious to the RBCs. Because a hemolytic crisis is a potential consequence, be ready to institute appropriate emergency therapy. This includes aggressive hydration and electrolyte replacement to reduce the risk for kidney injury caused by Hgb (from RBC lysis) clogging the kidney tubules and subsequent shock. Supportive care may include giving corticosteroids and blood products or removing the spleen.

The patient with chronic hemolytic anemia may need folate replacement. To suppress the RBC destruction, immunosuppressive agents may be used, such as glucocorticoids or rituximab (Rituxan), a monoclonal antibody to B-cell CD20. For severe cases associated with hemolysis, thrombocytopenia, and acute kidney injury, additional immunosuppressants (e.g., cyclosporine) may be used. Plasma exchange and eculizumab (Soliris), a monoclonal antibody to complement protein C5, are options.[2,4]

OTHER RED BLOOD CELL DISORDERS

HEMOCHROMATOSIS

Hemochromatosis is an iron overload disorder characterized by increased intestinal iron absorption. A genetic defect is the

BOX 34.3 GENETICS IN CLINICAL PRACTICE

Hemochromatosis

Genetic Basis

- Autosomal recessive disorder
- Caused by mutations in the *HFE (C282Y or H63D), HAMP, SLC40A1, FTH1,* and *TFR2* genes
- These genes play a key role in regulating iron absorption, transport, and storage
- Mutations in these genes impair the control of iron absorption during digestion and change iron distribution to other parts of the body, causing iron accumulation in tissues and organs

Incidence

- Most common genetic disease in people of European ancestry
- The C282Y mutation of the *HFE* gene is the most common
- About 1 in 15 people of Northern European ancestry have at least 1 copy of the *C282Y* mutation in the *HFE* gene
- Affects 1 in 300 non-Hispanic whites in the United States

Genetic Testing

- DNA testing is available and recommended for all first-degree relatives of people with the disease
- American Hemochromatosis Society recommends genetic testing regardless of family history

Clinical Implications

- Many people who have the gene mutation do not know it until diseases becomes apparent
- Clinical expression is variable and depends on diet iron, blood loss, and other modifying factors
- Early treatment can prevent serious complications

most common cause (Box 34.3).[11] It may occur with diseases such as sideroblastic anemia and liver disease, and the chronic blood transfusions used to treat thalassemia and SCD.

The normal range for total body iron is 40 mg/kg in women and 50 mg/kg in men. People with hemochromatosis accumulate iron at an increased rate. They may exceed total iron concentrations of 50 g.[2]

Symptoms usually do not develop until after age 40 years in men and after 50 years in women.[11] Early symptoms are nonspecific. They include fatigue, arthralgia, impotence, abdominal pain, and weight loss. Later, the excess iron accumulates in the liver and causes liver enlargement and cirrhosis. Excess iron deposits in the liver, pancreas, heart, joints, and endocrine glands cause diabetes, skin pigment changes (bronzing), heart problems (e.g., cardiomyopathy), arthritis, and testicular atrophy. There may be an enlarged liver and spleen and skin pigmentation changes.

Laboratory values show a high serum iron, TIBC, and serum ferritin. Testing for known genetic mutations confirms the diagnosis. MRI can measure liver and cardiac iron.[4] Liver biopsy can quantify the amount of iron and establish the degree of organ damage.

The goal of treatment is to remove excess iron from the body and minimize any symptoms the patient may have. Iron removal is achieved by removing 500 mL of blood each week until the iron stores are depleted. Then blood is removed less often to maintain iron levels within normal limits.

Iron-chelating drugs may be used. They form a complex with iron and promote its excretion from the body.[4] Deferoxamine chelates and removes iron via the kidneys. It is given IV or subcutaneously. Deferasirox and deferiprone are oral drugs. Diet changes include avoiding vitamin C and iron supplements, uncooked seafood, and iron-rich foods.

We manage problems from organ involvement (e.g., diabetes, HF) with the usual treatment for these problems. The most common causes of death are cirrhosis, liver failure, liver cancer, and HF. With early diagnosis and treatment, life expectancy is normal. However, many cases go undetected and untreated.

POLYCYTHEMIA

Polycythemia is the production and presence of increased numbers of RBCs. The increase in RBCs can be so great that blood circulation is impaired because of the increased blood viscosity *(hyperviscosity)* and volume *(hypervolemia)*.

Etiology and Pathophysiology

The 2 types of polycythemia are primary polycythemia, or polycythemia vera, and secondary polycythemia (Fig. 34.5). Their causes and pathogenesis differ, although their complications and manifestations are similar.

Primary Polycythemia

Polycythemia vera is a chronic myeloproliferative disorder. It involves increased production not only of RBCs but also WBCs and platelets. This leads to enhanced blood viscosity and blood volume and congestion of organs and tissues with blood. Splenomegaly and hepatomegaly are common. Patients have hypercoagulopathies that predispose them to clotting. The disease develops insidiously and follows a chronic, vacillating course. The median age at diagnosis is 60 years old, with a slight male predominance.[1]

Genetic Link

Polycythemia vera begins with 1 or more DNA mutations of a single hematopoietic stem cell. Most cases are not inherited, but a familial predisposition may exist.[1] It is associated with mutations in the Janus kinase-2 *(JAK2)* gene. The *JAK2* gene provides instructions for making a protein that promotes cell proliferation, especially blood cells from hematopoietic stem cells.

Secondary Polycythemia

Secondary polycythemia can be either hypoxia driven or hypoxia independent. In hypoxia-driven secondary polycythemia, hypoxia stimulates the kidneys to make EPO, which stimulates RBC production. The need for O_2 may result from high altitude, lung disease, cardiovascular disease, alveolar hypoventilation, defective O_2 transport, or tissue hypoxia.

EPO levels may return to normal once the Hgb stabilizes at a higher level. In this situation, secondary polycythemia is a physiologic response in which the body tries to compensate

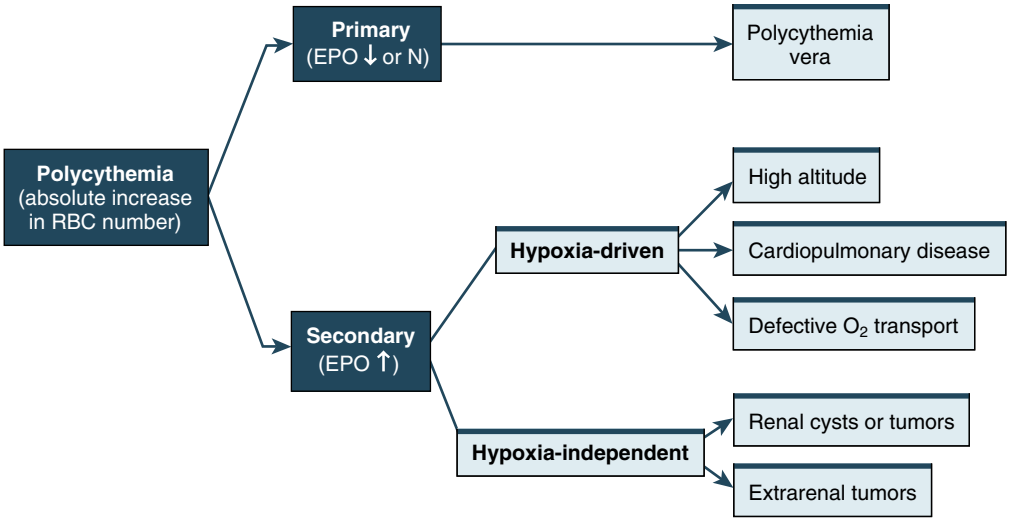

Fig. 34.5 Differentiating between primary and secondary polycythemia. *EPO,* Erythropoietin; *N,* normal.

for a problem, rather than a pathologic response. Chapter 31 discusses hypoxia-driven secondary polycythemia in COPD.

In hypoxia-independent secondary polycythemia, cancer or benign tumor tissue makes EPO. Serum EPO levels often stay increased in these situations. Splenomegaly does not occur with secondary polycythemia.

Clinical Manifestations and Complications

Circulatory manifestations occur due to the hypertension caused by hypervolemia and hyperviscosity. They are often the first manifestations and include headache, vertigo, dizziness, tinnitus, and visual changes. Generalized itching (often exacerbated by a hot bath) may be a striking symptom. It is related to histamine release from an increased number of basophils. Paresthesias and *erythromelalgia* (painful burning and redness of the hands and feet) may be present. The patient may have angina, HF, intermittent claudication, and thrombophlebitis, which may be complicated by embolization. These manifestations are caused by blood vessel distention, impaired blood flow, circulatory stasis, thrombosis, and tissue hypoxia from the hypervolemia and hyperviscosity. The most common acute complication and major cause of mortality is stroke from a thrombosis.

Hemorrhagic phenomena caused by either vessel rupture from overdistention or inadequate platelet function may result in petechiae, bruising, nosebleeds, or GI bleeding. Bleeding can be acute and catastrophic. Hepatomegaly and splenomegaly from organ engorgement may contribute to satiety and fullness. The patient may have pain from peptic ulcers caused either by increased gastric secretions or liver and spleen engorgement. *Plethora* (ruddy complexion) may be present. Uric acid is 1 of the products of RBC destruction. As RBC destruction increases, uric acid production increases. This leads to hyperuricemia and gout.

Although the incidence is low, myelofibrosis and leukemia develop in some patients with polycythemia vera. These disorders may be caused by the chemotherapy drugs used to treat the disease or by a disorder in the stem cells that progresses to erythroleukemia.

Diagnostic Studies

The major diagnostic criteria for polycythemia vera include (1) high Hgb, hematocrit, and RBC mass; (2) bone marrow examination showing hypercellularity of RBCs, WBCs, and platelets; and (3) presence of *JAK2* V617F or *JAK2* exon 12 mutation.[12] Other studies show low EPO level (secondary polycythemia has a high level); (3) high WBC count with basophilia and neutrophilia; (4) high platelet count and platelet dysfunction; and (5) normal or high leukocyte alkaline phosphatase, uric acid, and cobalamin levels.

❖ Interprofessional and Nursing Management

Treatment aims to reduce blood volume and viscosity and bone marrow activity. Phlebotomy is the mainstay of treatment. The aim of phlebotomy is to reduce the hematocrit and keep it less than 45%.[13] At the time of diagnosis, 300 to 500 mL of blood may be removed every few days until the hematocrit is reduced to acceptable levels.[13] Phlebotomy then may be needed every 2 to 3 months, reducing the blood volume by about 500 mL each time. A person managed with repeated phlebotomies eventually becomes iron deficient, although they are rarely symptomatic. Hydration therapy can reduce the blood's viscosity. Low-dose aspirin can prevent clotting.[13]

Myelosuppressive agents, such as hydroxyurea, or busulfan (Myleran), may be given.[13] Ruxolitinib (Jakafi), which inhibits expression of the *JAK2* mutation, is given to those who do not respond to hydroxyurea. α-Interferon (α-IFN)-2b and pegylated IFN alfa-2a are options for women of childbearing age or those with intractable itching.[13]

When acute exacerbations of polycythemia vera develop, you have several nursing responsibilities. Depending on your agency, you may either assist with or perform the phlebotomy. Assess intake and output during hydration therapy to avoid fluid overload (which worsens circulatory congestion) or fluid deficit (which makes the blood more viscous). Give myelosuppressive agents as ordered. Observe the patient and teach them about drug side effects.

Assess the patient's nutrition status. Inadequate food intake can result from GI symptoms of fullness, pain, and dyspepsia.

TABLE 34.11 Causes of Acquired Thrombocytopenia

Impaired Platelet Production

- Cancers and other disorders
  - Aplastic anemia
  - Leukemia, lymphoma, myeloma, myelodysplastic disorders
  - Marrow metastases by solid tumors
- Drugs (chemotherapy, others)
- Immune thrombocytopenia (ITP)
- Infections, bacterial, fungal, viral (hepatitis C virus, HIV, cytomegalovirus)
- Nutrition deficiencies, alcohol use
- Radiation

Increased Platelet Destruction

- Artificial surfaces (e.g., cardiopulmonary bypass, hemodialysis)
- Disseminated intravascular coagulation (DIC)
- Heparin-induced thrombocytopenia (HIT)
- Pregnancy-related
- Thrombotic microangiopathy
  - Atypical hemolytic uremic syndromes (aHUSs)
  - Thrombotic thrombocytopenic purpura (TTP)

Abnormal Platelet Distribution

- Dilution (massive blood transfusion, fluids)
- Splenic sequestration

Begin activities and any drug therapy to decrease thrombus formation.

Because of its chronic nature, polycythemia vera requires ongoing evaluation. Assess the patient for complications with each encounter.

PROBLEMS OF HEMOSTASIS

Hemostasis involves the vascular endothelium, platelets, and coagulation factors. They normally work together to stop bleeding and repair vascular injury. These mechanisms are described in Chapter 33. Disruption in any component may result in bleeding or thrombotic disorders.

Three major disorders of hemostasis discussed in this section are (1) thrombocytopenia (low platelet count), (2) hemophilia and von Willebrand disease (inherited disorders of specific clotting factors), and (3) DIC.

THROMBOCYTOPENIA

Etiology and Pathophysiology

Thrombocytopenia is a reduction of platelets to less than 150,000/μL (150×10^9/L). Acute, severe, or prolonged decreases from normal can result in abnormal hemostasis that presents as prolonged bleeding from minor trauma or spontaneous bleeding without injury.

Platelet disorders occur from impaired production, increased destruction, or abnormal distribution (Table 34.11).[1] While they can be inherited (e.g., Wiskott-Aldrich syndrome), most are acquired. Drugs are a common cause of acquired disorders.[1] Although some drugs are directly myelosuppressive (e.g., chemotherapy, ganciclovir), the usual mechanism of drug-related thrombocytopenia is accelerated platelet destruction caused by antibodies. Antibodies attack the platelets when the drug binds to the platelet surface.

Some drugs affect platelet aggregation. Aspirin doses as low as 81 mg can alter platelet aggregation. Normal function is restored when new platelets are made.

Immune Thrombocytopenia

The most common acquired thrombocytopenia is *immune thrombocytopenia* (ITP). ITP is an acquired immune disorder where there is abnormal platelet destruction. In general, ITP presents as an acute condition in children and a chronic condition in adults.

Thrombocytopenia results from antiplatelet antibodies, impaired platelet production, and T cell–mediated destruction of platelets.[1] In ITP, antibodies coat the platelets. These platelets function normally. When they reach the spleen, these antibody-coated platelets are mistaken as foreign and destroyed by macrophages. Decreased platelet production contributes to ITP. Sometimes autoimmune disease (e.g., SLE) or infection, such as *Helicobacter pylori* or viral infection (HIV), contributes to ITP.[1,14] Platelets normally survive 8 to 10 days. However, in ITP, platelet survival is shortened.

Thrombotic Thrombocytopenic Purpura

TTP is an uncommon syndrome characterized by microangiopathic hemolytic anemia (MAHA), thrombocytopenia, neurologic changes, fever (in the absence of infection), and renal problemss.[1] Not all features are present in all patients. Because it is almost always associated with hemolytic-uremic syndrome (HUS), TTP is often referred to as *TTP-HUS*. The disease is associated with enhanced platelet aggregation, which form microthrombi that deposit in arterioles and capillaries.

In most cases, TTP is caused by the deficiency of a plasma enzyme (ADAMTS13) that breaks down the von Willebrand clotting factor (von Willebrand factor [vWF]) into normal size. vWF is the most important factor that mediates platelet adhesion to damaged endothelial cells. Without the enzyme, unusually large amounts of vWF attach to activated platelets, promoting platelet aggregation. TTP is a medical emergency because bleeding and clotting occur at the same time.

TTP occurs mainly in previously healthy adults, with a slight female predominance. The syndrome may be idiopathic (thought to be due to an autoimmune disorder against ADAMTS13). It may occur due to certain drug toxicities (e.g., chemotherapy, cyclosporine, oral contraceptives, valacyclovir, clopidogrel) pregnancy or preeclampsia, infection, or a known autoimmune disorder, such as SLE or scleroderma.[1]

Heparin-Induced Thrombocytopenia

One of the risks associated with heparin is the life-threatening condition called *heparin-induced thrombocytopenia* (HIT), or *heparin-induced thrombocytopenia and thrombosis syndrome* (HITTS). Typically, patients develop thrombocytopenia 5 to 14 days after the onset of heparin therapy. We suspect HIT if the platelet count decreases by more than 50% or is less than

Fig. 34.6 Acute immune thrombocytopenic purpura often presents with purpuric lesions. (From Howard MH, Hamilton PJ: *Hematology,* ed 4, London, 2013, Mosby.)

150,000/μL. As many as 5% of patients on IV heparin therapy develop HIT.[14]

In HIT, platelet destruction and vascular endothelial injury are the 2 major responses to an immune-mediated response to heparin. Platelet factor 4 (PF4) (a protein made and released by platelets) binds to heparin. This PF4-heparin complex then binds to the platelet surface, leading to further platelet activation and release of more PF4, thus creating a positive feedback loop. The body makes antibodies against the PF4-heparin-platelet complex. They are removed prematurely from circulation, leading to thrombocytopenia and platelet-fibrin thrombi.

Although the major problem of HIT is venous thrombosis, arterial thrombosis can occur. DVT and pulmonary emboli most often result as a complication of the thromboses. Other complications include arterial vascular infarcts, causing skin necrosis, stroke, and end-organ damage (e.g., kidneys). Bleeding symptoms are unusual because the platelet count is rarely less than 20,000/μL.

Clinical Manifestations

Many patients with thrombocytopenia are asymptomatic. The most common symptom is bleeding, usually mucosal or cutaneous. Mucosal bleeding may manifest as nosebleeds and gingival bleeding. Large bullous hemorrhages may appear on the buccal mucosa due to the lack of vessel protection by the submucosal tissue. Bleeding into the skin is seen as petechiae, purpura, or bruising. *Petechiae* are small, flat, red or reddish brown microhemorrhages (see Table 33.6). When the platelet count is low, RBCs may leak out of the blood vessels and into the skin to cause petechiae. When there are many petechiae, we call the resulting reddish skin *purpura* (Fig. 34.6). Pain and tenderness are sometimes present.

The major complication of thrombocytopenia is bleeding. Bleeding may be insidious or acute and internal or external. It may occur in any area of the body, including the joints, retina, and brain. Prolonged bleeding from trauma or injury does not usually occur until platelet counts are under 50,000/μL (50 × 10^9/L).[1] When the count is under 20,000/μL (20 × 10^9/L), spontaneous, life-threatening bleeding (e.g., intracranial bleeding) can occur.

TABLE 34.12 Laboratory Results in Thrombocytopenia and DIC

Laboratory Test	ITP	TTP	HIT	DIC
Platelets	↓↓↓	↓↓↓	↓↓	↓↓↓

Haptoglobin	N	↓	N	↓
Hgb	N	↓↓	N	N or ↓
Indirect bilirubin	N	↑	N	N or ↑
LDH	N	↑↑↑	N	↑
Reticulocytes	N	↑	N	N or ↑
Schistocytes	N	↑↑↑	N or ↑	N or ↑
Coagulopathy				
PT	N	N	N	Prolonged
aPTT	N	N	N	Prolonged
D dimer	N	N or ↑	↑	↑↑
Other tests	ITP IgG assay, platelet activation/function assay, *Helicobacter pylori,* hepatitis C, HIV, bone marrow biopsy	ADAMTS13 Urinalysis (for proteinuria, hematuria), Creatinine	Platelet activation/function assay, PF4-heparin complex (antigen assay)	Fibrin split products (FSPs)

Insidious bleeding may be first detected by discovering the anemia from the blood loss. Be aware of manifestations of internal blood loss, including weakness, fainting, dizziness, tachycardia, abdominal pain, and hypotension. Prolonged bleeding after routine procedures, such as venipuncture or IM injection, may indicate thrombocytopenia.

Because vascular thromboses may occur with thrombocytopenia (e.g., TTP, HIT), assess for signs and symptoms of vascular ischemic problems (see Chapter 41).

Diagnostic Studies

Thrombocytopenia exists when the platelet count is under 150,000/μL (150 × 10^9/L). The patient's history and assessment, along with laboratory studies, help to determine the cause of the thrombocytopenia. Table 34.12 compares results for types of thrombocytopenia.

Laboratory tests that assess secondary hemostasis or coagulation, such as the prothrombin time (PT) and activated partial thromboplastin time (aPTT), can be normal even in severe thrombocytopenia. If they are increased, this may point toward DIC.

Specific assays, such as ITP antigen-specific assay, platelet activation/function assay, or PF4-heparin complex for HIT, can help with the diagnosis. In TTP, testing for ADAMTS13 deficiency is not always diagnostic. Thrombocytopenia may be severe in TTP, but coagulation studies are normal. Lactate

dehydrogenase (LDH) may be increased. With TTP, altered RBC morphology, including *spherocytes* (small, globular, completely hemoglobinated RBCs), fragmented cells (schistocytes), and pronounced reticulocytosis, may be present. These findings are partially a result of intravascular fibrin deposition causing a "slicing" of RBCs.

Bone marrow examination may be done to see if production problems (e.g., leukemia, aplastic anemia, other myeloproliferative disorders) are the cause of thrombocytopenia or when other tests are inconclusive. When destruction of circulating platelets is the cause, bone marrow analysis shows *megakaryocytes* (precursors of platelets) to be normal or increased, even though circulating platelets are reduced. The absence or decreased number of megakaryocytes on bone marrow biopsy is consistent with thrombocytopenia caused by decreased bone marrow production (e.g., aplastic anemia).

Interprofessional Care

Interprofessional care of thrombocytopenia differs based on the cause. Removal or treatment of the underlying cause is sometimes sufficient. The patient with thrombocytopenia should avoid aspirin and other drugs that affect platelet function or production. The following sections discuss management strategies for the different causes of thrombocytopenia (Table 34.13).

Immune Thrombocytopenic Purpura

Multiple therapies are part of managing the patient with ITP. If the patient is asymptomatic, they may not be treated unless the platelet count is under 30,000/μL.[14] Corticosteroids are used initially to treat ITP because they suppress the phagocytic response of splenic macrophages. [14] This alters the spleen's recognition of platelets and increases the platelets' life span. Corticosteroids depress antibody formation and reduce capillary leakage.

Romiplostim (Nplate) and eltrombopag (Promacta) are used for patients with chronic ITP who have an insufficient response to steroids. These drugs are thrombopoietin receptor agonists that increase platelet production. [14] Rituximab (Rituxan) lyses activated B cells, thus reducing the immune recognition of platelets. High doses of IV immunoglobulin (IVIG) and a component of IVIG, anti-Rh_o(D) (anti-D, WinRho), may be given to a patient who does not respond to other treatments. These agents compete with antiplatelet antibodies for macrophage receptors in the spleen.

Immunosuppressive therapy (e.g., azathioprine, cyclosporine A) may be used in refractory cases (Table 34.13).[14] Platelet transfusions can increase platelet counts in cases of life-threatening bleeding, a platelet count less than 10,000/μL, or with bleeding before a procedure.[15] Platelets should not be given prophylactically because of the risk for antibody formation.

The patient may need a splenectomy if they do not respond to treatment. The effectiveness of splenectomy is based on 4 factors. First, the spleen has an abundance of the macrophages that sequester and destroy platelets. Second, structural features of the spleen enhance the interaction between antibody-coated platelets and macrophages. Third, some antibody synthesis occurs in the spleen, so antiplatelet antibodies decrease after splenectomy. Fourth, the spleen normally sequesters about one third of the platelets, so its removal increases the number of platelets in circulation.

TABLE 34.13 Interprofessional Care

Thrombocytopenia

Diagnostic Assessment

- History and physical assessment
- Bone marrow aspiration and biopsy
- CBC, including platelet count
- Specific laboratory studies (Table 34.12)

Management

Immune Thrombocytopenic Purpura

- Corticosteroids
- Romiplostim (Nplate)
- Eltrombopag (Promacta)
- Rituximab (Rituxan)
- Splenectomy
- IV immunoglobulin (IVIG)
- Anti-Rh_o(D)
- Immunosuppressives (e.g., Azathioprine, cyclophosphamide)

Thrombotic Thrombocytopenic Purpura

- Identify and treat or remove of cause
- Plasmapheresis (plasma exchange)
- Corticosteroids
- Rituximab (Rituxan)
- Caplacizumab
- Immunosuppressives (e.g., cyclophosphamide, cyclosporine)
- Splenectomy

Heparin-Induced Thrombocytopenia

- Direct thrombin inhibitor (argatroban [Acova])
- Indirect thrombin inhibitor (fondaparinux [Arixtra])
- Synthetic thrombin inhibitor (bivalirudin)
- Plasmapheresis (plasma exchange)
- Warfarin (Coumadin)
- Direct oral anticoagulants (e.g., apixaban, rivaroxaban)
- Thrombolytic agents

Decreased Platelet Production

- Identify and treat or remove of cause
- Immune therapies (corticosteroids, danazol, cyclosporine)
- Avatrombopag
- Platelet transfusions

Thrombotic Thrombocytopenic Purpura

We treat TTP in a variety of ways. The first step is to treat the underlying disorder or remove the causative agent, if known. If untreated, TTP usually results in irreversible renal failure and death. Plasma exchange (plasmapheresis) (see Chapter 14) can reverse platelet consumption by supplying the right vWF and enzyme (ADAMTS13) and removing the large vWF molecules that bind with platelets. Treatment should continue daily until the patient's platelet counts normalize and hemolysis has ceased. Corticosteroids are used with this treatment.[16]

Rituximab is given to patients who are refractory to plasma exchange. It decreases the level of inhibitory ADAMTS13 immunoglobulin G (IgG) antibodies. Caplacizumab, an anti-VWF

antibody, blocks VWF binding to platelets. This can reduce platelet aggregation and thrombosis and normalize the platelet count.[16] Other immunosuppressants, such as cyclosporine or cyclophosphamide, are options. Splenectomy is an option in patients who are refractory to plasma exchange or immunosuppression. Platelet administration is contraindicated because this may lead to new vWF-platelet complexes and increased clotting.[4]

Heparin-Induced Thrombocytopenia

We stop all forms of heparin when HIT is present. This includes heparin flushes for vascular catheters. To maintain anticoagulation, the patient should receive a direct thrombin inhibitor, such as argatroban. Other options are fondaparinux (Arixtra), a factor Xa inhibitor (indirect thrombin inhibitor), or bivalirudin (a synthetic thrombin inhibitor).[17] Warfarin should be started only when the platelet count reaches 150,000/μL. If clotting is severe, the most common treatments are plasmapheresis to clear the platelet-aggregating IgG from the blood, thrombolytic agents to treat the thromboembolic events, and surgery to remove clots. Platelet transfusions are not given because they may enhance thromboembolic events.

Patients who have had HIT should never receive heparin or low-molecular-weight heparin (LMWH) again. This should be noted in the patient's medical record.

Thrombocytopenia From Decreased Platelet Production

The management of acquired thrombocytopenia is based on finding the cause and treating the disease or removing the causative agent. Platelet transfusions are given if life-threatening bleeding develops. Platelet transfusions are generally not done unless the count is under 10,000/μL (10×10^9/L) or the patient is actively bleeding, has an active infection, or is having an invasive procedure.[6]

Acquired thrombocytopenia is often caused by another underlying condition (e.g., aplastic anemia, leukemia) or therapy used to treat another problem.[1,6] For example, in acute leukemia all blood cell types may be depressed. Plus, the patient may receive chemotherapy drugs that cause bone marrow suppression. If the patient can be supported throughout the course of chemotherapy-induced thrombocytopenia, the thrombocytopenia will resolve. If we do not find a cause, we may try immune therapies.[4]

❖ NURSING MANAGEMENT: THROMBOCYTOPENIA

◆ Assessment

Subjective and objective data that you should obtain from a patient with thrombocytopenia are outlined in Table 34.14.

◆ Clinical Problems

The main clinical problem for the patient with thrombocytopenia is impaired tissue perfusion.

◆ Planning

The overall goals are that the patient with thrombocytopenia will (1) have no bleeding, (2) maintain vascular integrity, and (3) manage self-care related to an increased risk for bleeding.

TABLE 34.14 NURSING ASSESSMENT

Thrombocytopenia

Subjective Data

Important Health Information

Health history: Recent or excessive bleeding; viral illness; HIV infection; cancer (especially leukemia or lymphoma); aplastic anemia; SLE; cirrhosis; exposure to radiation or toxic chemicals; DIC

Medications: Many medications, including chemotherapy agents, valproic acid (Depakote), furosemide, gold, NSAIDs, penicillin

Functional Health Patterns

Health perception–health management: Family history of bleeding problems; malaise

Nutritional-metabolic: Bleeding gingiva; coffee-ground or bloody vomitus; easy bruising

Elimination: Hematuria, dark or bloody stools

Activity-exercise: Fatigue, weakness, fainting; nosebleeds, hemoptysis; dyspnea

Cognitive-perceptual: Pain and tenderness in bleeding areas (e.g., abdomen, head, extremities); headache

Sexuality-reproductive: Menorrhagia, metrorrhagia

Objective Data

General

Fever, lethargy

GI

Splenomegaly, abdominal distention; heme-positive stools

Skin

Petechiae, bruising, purpura

Possible Diagnostic Findings

Platelet count <150,000/μL (150×10^9/L), prolonged bleeding time, ↓ Hgb and Hct; normal or ↑ megakaryocytes in bone marrow examination

◆ Implementation

◆ Health Promotion

Discourage using over-the-counter (OTC) medications known to be causes of acquired thrombocytopenia and reduced platelet function. Some have aspirin as an ingredient. Aspirin reduces platelet adhesiveness, thus contributing to bleeding.

Encourage persons to seek care if manifestations of bleeding (e.g., prolonged nosebleeds, petechiae) develop. Observe for early signs of thrombocytopenia in the patient receiving chemotherapy drugs.

◆ Acute Care

The goal during acute episodes of thrombocytopenia is to prevent or control bleeding (see eNursing Care Plan 34.2 on the website for this chapter). Bleeding is usually from superficial sites. Deep bleeding (into muscles, joints, and abdomen) usually occurs only when clotting factors are decreased. Stress that a minor nosebleed or new petechiae may indicate potential bleeding and to notify the HCP.

Bleeding from the posterior nasopharynx may be hard to detect because the person swallows the blood. If you cannot avoid a subcutaneous injection, use a small-gauge needle. Apply direct pressure for at least 5 to 10 minutes after the injection. An

TABLE 34.15 PATIENT & CAREGIVER TEACHING

Thrombocytopenia

Include the following instructions when teaching a patient or caregiver the precautions to take when the platelet count is low:

1. Notify your HCP of any symptoms of bleeding. These include:
   - Black, tarry, or bloody bowel movements
   - Black or bloody vomit, sputum, or urine
   - Bleeding from the mouth or anywhere in the body
   - Bruising or small red or purple spots on the skin
   - Difficulty talking, sudden weakness of an arm or leg, confusion
   - Headache or changes in how well you can see
2. Ask your HCP about restrictions in your normal activities, such as vigorous exercise or lifting weights. In general, walking is safe. Wear sturdy shoes or slippers. If you are weak and at risk for falling, get help or supervision when getting out of bed or chair.
3. Do not blow your nose forcefully; gently pat it with a tissue if needed. For a nosebleed, keep your head up and apply firm pressure to the nostrils and bridge of your nose. If bleeding continues, place an ice bag over the bridge of your nose and the nape of your neck. If you are unable to stop a nosebleed after 10 min, call your HCP.
4. Do not bend down with your head lower than your waist.
5. Prevent constipation by drinking plenty of fluids. Do not strain when having a bowel movement. Your HCP may prescribe a stool softener. Do not use a suppository, an enema, or a rectal thermometer without the permission of your HCP.
6. Shave only with an electric razor. Do not use blades.
7. Do not tweeze your eyebrows or other body hair.
8. Do not puncture your skin, such as getting tattoos or body piercing.
9. Do not use any medication that can prolong bleeding, such as aspirin. If you are unsure about a medication, ask your HCP or pharmacist about it in relation to your thrombocytopenia.
10. Use a soft-bristle toothbrush to prevent injuring the gums. Flossing is usually safe if done gently using the thin tape floss. Do not use alcohol-based mouthwashes because they can dry your gums and increase bleeding.
11. Women who are menstruating should keep track of the number of pads used per day. When you start using more pads per day than usual or bleed more days, notify your HCP. Do not use tampons; only use sanitary pads.
12. Ask your HCP before you have any invasive procedures done, such as a dental cleaning, manicure, or pedicure.

ice pack may be helpful. Avoid IM injections. Help the patient to understand the importance of adhering to self-care measures that reduce the risk for bleeding (Table 34.15).

Note that many of these disorders may be accompanied by vascular clotting, and appropriate assessment and management should be taken. As bleeding occurs, RBCs and coagulation factors are consumed along with platelets. Monitor all blood cell and coagulation studies. In a woman with thrombocytopenia, menstrual blood loss may exceed the usual amount and duration. Suppressing menses with hormonal agents may be needed during predictable periods of thrombocytopenia (e.g., during chemotherapy and HSCT) to reduce menstrual blood loss. Administering platelet transfusions is an important nursing role.

TABLE 34.16 Types of Hemophilia

Type	Inheritance Pattern
Hemophilia A	
Factor VIII	Recessive sex-linked (transmitted by female carriers, occurs almost exclusively in men)
Hemophilia B	
Factor IX	Recessive sex-linked (transmitted by female carriers, occurs almost exclusively in men)
von Willebrand Disease	
vWF, variable factor VIII deficiencies and platelet dysfunction	Autosomal dominant, seen in both genders Recessive (in severe forms of the disease)

Ambulatory Care

Monitor the patient with ITP who is receiving treatment for their response to therapy. Teach the person with acquired thrombocytopenia to avoid causative agents when possible (Table 34.11). If the patient cannot avoid causative agents (e.g., chemotherapy), teach them to avoid injury or trauma during these periods and the signs and symptoms of bleeding (Table 34.15).

Patients with either ITP or acquired thrombocytopenia should have planned periodic medical evaluations to assess and treat situations in which exacerbations and bleeding are likely to occur. Address the impact of the condition on the patient's quality of life.

Evaluation

The expected outcomes are that the patient with thrombocytopenia will

- Have no evidence of bleeding or bruising
- State needed knowledge and skills to manage disease process

HEMOPHILIA AND VON WILLEBRAND DISEASE

Hemophilia is an X-linked recessive genetic disorder caused by a defective or deficient coagulation factor. The 2 major types of hemophilia: *hemophilia A* (classic hemophilia, factor VIII deficiency) and *hemophilia B* (Christmas disease, factor IX deficiency). *von Willebrand disease* is a related disorder involving a deficiency of the von Willebrand coagulation protein. Factor VIII is made in the liver and circulates as a complex with vWF.

Hemophilia A is 4 times as common as hemophilia B.[18] Although rare, there are cases of *acquired hemophilia A* that are due to the body developing antibodies against its own factor VIII. von Willebrand disease is the most common congenital bleeding disorder.

Genetic Link

The inheritance patterns of hemophilia and von Willebrand disease are discussed in Table 34.16 and Box 34.4.

Clinical Manifestations and Complications

The manifestations of hemophilia A and B are similar. All manifestations relate to bleeding. Any bleeding episode in persons with hemophilia may be life threatening. Manifestations

BOX 34.4 GENETICS IN CLINICAL PRACTICE

Hemophilia A and B

Genetic Basis

- X-linked recessive disorder
- *Hemophilia A:* Caused by mutations in the *F8* gene that provides instructions for making coagulation factor VIII
- *Hemophilia B:* Caused by mutations in the *F9* gene that provides instructions for making coagulation factor IX
- Mutations in the *F8* or *F9* gene lead to the production of an abnormal version or reduced amounts of coagulation factors

Incidence

- *Hemophilia A:* 1 in 5,600 male births
- *Hemophilia B:* 1 in 1,400 male births

Genetic Testing

- DNA testing is available

Clinical Implications

- Female carriers transmit the genetic defect to 50% of their sons, 50% of their daughters are carriers
- Males with hemophilia do not transmit the genetic defect to their sons, but all their daughters are carriers
- While rare, female hemophilia can occur if a male with hemophilia mates with a female carrier

include (1) slow, persistent, prolonged bleeding from minor trauma and small cuts; (2) delayed bleeding after minor injuries (the delay may be several hours or days); (3) uncontrollable bleeding after dental extractions or gingival irritation with a hard-bristle toothbrush; (4) nosebleeds, especially after a blow to the face; (5) GI bleeding from ulcers and gastritis; (6) hematuria and potential renal failure from GU trauma; (7) splenic rupture from falls or abdominal trauma; (8) bruising and subcutaneous hematomas (Fig. 34.7) and possible compartment syndrome; (9) neurologic signs, such as pain, anesthesia, and paralysis, which may develop from nerve compression caused by hematoma formation; and (10) hemarthrosis (bleeding into the joints) (Fig. 34.8), which may lead to joint injury and deformity severe enough to cause crippling.[1]

In children, these manifestations may lead to the diagnosis. In adults, these may be the first sign of a mild form of the disease that escaped detection through a childhood free of major injuries, dental procedures, or surgeries.

Diagnostic Studies

Laboratory studies determine the type of hemophilia present. Any factor deficiency within the intrinsic system (factor VIII, IX, XI, or XII or vWF) will yield the laboratory results outlined in Table 34.17.

Interprofessional Care

The goals of interprofessional care are to prevent and treat bleeding. Care for persons with hemophilia or von Willebrand disease requires (1) preventive care, (2) replacement therapy during acute bleeding episodes and as prophylaxis, and (3) treating

Fig. 34.7 Severe bruising in a person with hemophilia after a fall. (Courtesy Peter Bonner.)

Fig. 34.8 Acute hemarthrosis of the knee is a common complication of hemophilia. (From Lissauer T, Carroll W: *Illustrated textbook of pediatrics,* ed 5, London, 2018, Mosby.)

TABLE 34.17 Laboratory Results in Hemophilia

Test	Results
Bleeding time	Prolonged in von Willebrand disease due to structurally defective platelets. Normal in hemophilia A and B because platelets not affected
Factor assays	Reductions of factor VIII in hemophilia A, factor IX in hemophilia B, vWF in von Willebrand disease
Partial thromboplastin time	Prolonged due to deficiency in intrinsic clotting system factor
Platelet count	Normal. Adequate platelet production
Prothrombin time	Normal. No involvement of extrinsic system
Thrombin time	Normal. No impairment of thrombin-fibrinogen reaction

complications of the disease and its therapy. Most patients can expect almost normal life spans free of bloodborne illnesses because of improvements in the blood donation process and the use of recombinant replacement factors. Designated treatment

centers provide interprofessional care of hemophilia and related disorders.

Replacement of deficient clotting factors is the primary means of supporting a patient with hemophilia. Regular prophylaxis is preferred over on-demand treatment. The most common problem with acute management is starting factor replacement therapy too late and stopping it too soon. Minor bleeding episodes should be treated for at least 72 hours. Surgery and traumatic injuries may need longer therapy. The patient may need prophylactic replacement therapy before surgery and dental care. Table 34.18 lists examples of replacement therapy.[18]

For mild hemophilia A and certain subtypes of von Willebrand disease, desmopressin acetate (DDAVP), a synthetic analog of vasopressin, can stimulate an increase in factor VIII and vWF.[19] This drug acts on platelets and endothelial cells to cause the release of vWF. vWF then binds with factor VIII, thus increasing its concentration. DDAVP can be given IV, subcutaneously, or by intranasal spray. Beneficial effects (e.g., decreased bleeding time) are seen within 30 minutes when given IV and can last for more than 12 hours. Because the drug's effect is short lived, the patient must be closely monitored. They may need repeated doses. It is an appropriate therapy for minor bleeding episodes and dental procedures. The intranasal form may be used as home therapy for some patients with mild to moderate forms of the disease.

Antifibrinolytic therapy (tranexamic acid [Cyklokapron]) reduces fibrinolysis by inhibiting plasminogen activation in the fibrin clot, thus enhancing clot stability.[19] These agents stabilize clots in areas of increased fibrinolysis, such as the oral cavity, and in patients with difficult episodes of nosebleeds and menorrhagia. Topical thrombin and fibrin sealants can treat mucosal bleeding.

Complications of hemophilia treatment include development of inhibitors to factors VIII or IX, allergic reactions, and thrombotic complications with using factor IX because it contains activated coagulation factors. Patients with vWF may develop antibodies against vWF concentrates, the infusion of which could cause life-threatening anaphylaxis. Thus replacement factors for these patients should not contain vWF. Chronically, the development of inhibitors to the factor products can occur and needs expert management. Emicizumab is an option to address the problem of inhibitors for hemophilia A. It is a monoclonal antibody that binds factors IX and X, causing activation of factor X. This leads to thrombin generation, bypassing the need for Factor VIII.[1,4] Gene transfer therapy is an experimental treatment.

NURSING MANAGEMENT: HEMOPHILIA

Implementation

Health Promotion

Because of the hereditary nature of hemophilia, refer affected persons for genetic counseling before reproduction. This is especially important because many persons with hemophilia live into adulthood. Include reproductive concerns and long-term effects in the care plan.

Acute Care

We implement measures to control bleeding. They include the following:

1. Stop the topical bleeding as quickly as possible. Apply direct pressure or ice, pack the area with Gelfoam or fibrin foam, and apply topical hemostatic agents, such as thrombin.
2. Give the specific coagulation factor to raise the level of the deficient coagulation factor. Monitor the patient for signs and symptoms, such as hypersensitivity.
3. When joint bleeding occurs, in addition to giving replacement factors, use the "RICE" protocol: Rest the involved joint to prevent crippling deformities from hemarthrosis, ice the joint for 20 minutes every 3 to 4 hours, compress/wrap the joint, and elevate.[2] Give analgesics to reduce severe pain. Do not use aspirin and aspirin-containing compounds. As soon as bleeding stops, encourage mobilization of the affected area through range of motion exercises and physical therapy. Avoid weight bearing until all swelling has resolved and muscle strength has returned. Orthotics may be prescribed.
4. Manage any life-threatening complications that may develop from bleeding or side effects from coagulation factors. Examples include measures to prevent or treat airway obstruction from bleeding into the neck and pharynx, recognizing compartment syndrome in an extremity, and early assessment and treatment of intracranial bleeding.

Ambulatory Care

Home management is a primary consideration because the disease follows a progressive, chronic course. The patient's knowledge of the illness and how to live with it influences their quality

BOX 34.5 EVIDENCE-BASED PRACTICE

Depression in Patients With Hemophilia

K.S. is a 47-year-old female admitted with hematuria and hypertension. She was diagnosed with hemophilia A as an infant. She describes a history of chronic joint disease and pain from bleeding into joints. You note in her health record that she has been identified as an "inhibitor." In discussion with the clinical nurse specialist, you learn that inhibitors are people with hemophilia A who develop antibodies to attack clotting factors provided in disease treatment. Their management becomes more complex because their immune system resists standard treatments. When you perform your admission interview, you identify behaviors suggesting anxiety and depression. K.S. seems apathetic, responding briefly to questions about her history and symptoms. Then she unexpectedly asks, "Do we have to do this again? After all these trips to the hospital, I've had it with all these questions."

Making Clinical Decisions

Synthesis of Best Available Evidence

Persons with hemophilia often experience pain and impaired function, leading to a decreased quality of life and depression. Anxiety also can be related to the risk of bleeding.

Clinician Expertise

You realize an appropriate approach to the admission interview is to slow the interaction with the patient, speak in a low tone and demonstrate empathy about the repeated hospitalizations. If she continues to show irritability or expresses anger, you will remain calm and supportive. Assure K.S. you are interested in understanding her health concerns so you can provide the best possible care and support her in her disease management efforts. Encourage K. S. to share her feelings about the chronic nature of hemophilia and the years of living with its uncertainty. Ask questions about pain management, disability, and social support with empathy. Allow K. S. to steer the conversation as much as possible.

Patient Preferences and Values

K. S. expresses concern about past failed treatments and tells you she will soon begin treatment with emicizumab.

Implications for Nursing Practice

1. How should you discuss treatment with emicizumab with K.S.?
2. What else would you want to know about her depression and anxiety?
3. What strategies can you suggest to improve her quality of life?

Reference for Evidence

Batt K, Boggio L, Neff A, et al.: Patient-reported outcomes and joint status across subgroups of US adults with hemophilia with varying characteristics: results from the Pain, Functional Impairment, and Quality of Life (P-FiQ) study, *European Journal of Haematology* 100:12, 2018.

and length of life (Box 34.5). Refer the patient and caregiver to a local chapter of the National Hemophilia Foundation to encourage networking with others who are dealing with hemophilia.[18] Provide ongoing assessment of the patient's adaptation to the illness. Psychosocial support and assistance should be readily available as needed.

Most of the long-term care measures are related to patient teaching. Teach the patient to recognize disease-related problems and which problems can be treated at home and which require hospitalization. Immediate medical attention is needed for severe pain or swelling of a muscle or joint that restricts movement or inhibits sleep and for a head injury, swelling in the neck or mouth, abdominal pain, hematuria, melena, and skin wounds in need of suturing.

Teach the patient to perform daily oral hygiene without causing trauma. Understanding how to prevent injuries is another consideration. Teach the patient to take part only in noncontact sports (e.g., golf) and to wear gloves when doing household chores to prevent cuts or abrasions from knives, hammers, and other tools. The patient should wear a Medic Alert tag to ensure that HCPs know about the hemophilia in case of an accident. You can teach many patients or caregivers to self-administer the factor replacement therapies at home.

◆ Evaluation

The overall expected outcomes are similar to those for the patient with thrombocytopenia.

DISSEMINATED INTRAVASCULAR COAGULATION

Disseminated intravascular coagulation (DIC) is a serious bleeding and thrombotic disorder that results from abnormally initiated and accelerated clotting. Subsequent decreases in clotting factors and platelets ensue, which may lead to uncontrollable bleeding. The term DIC can be misleading because it suggests that blood is only clotting. However, there is profuse bleeding that results from the aggregation of platelets and clotting factors. DIC is not a disease. It is always caused by an underlying disease or condition. That underlying problem must be treated for DIC to resolve.

Etiology and Pathophysiology

DIC is an abnormal response of the normal clotting cascade stimulated by a disease process or disorder.[3] Table 34.19 lists diseases and disorders known to predispose a patient to DIC. DIC can occur as an acute, catastrophic condition, or it may exist at a subacute or chronic level. Chronic and subacute DIC is most often seen in patients with long-standing illnesses, such as cancer or autoimmune disease. Occasionally these patients have subclinical disease manifested only by laboratory abnormalities.

Each condition may have 1 or multiple triggering mechanisms to start the clotting cascade. For example, tumors and traumatized or necrotic tissue release tissue factors into circulation. Endotoxin from gram-negative bacteria activates several steps in the coagulation cascade.

The manifestations of DIC result from consumption and depletion of platelets and coagulation factors, as well as clot lysis and formation of fibrin split products (FSPs) that have anticoagulant properties (Fig. 34.9). Tissue factor is released at the site of tissue injury and by some cancers, such as leukemia. It enhances normal coagulation mechanisms. Abundant intravascular thrombin, the most powerful coagulant, is made. It speeds the conversion of fibrinogen to fibrin and enhances platelet aggregation. There is widespread fibrin and platelet deposition in capillaries and arterioles, causing thrombosis. This process can lead to multiorgan failure.

Clotting inhibitory mechanisms, such as antithrombin III (AT III) and protein C, are depressed. Excess clotting activates

the fibrinolytic system, which in turn breaks down the newly formed clot, creating FSPs. FSPs have anticoagulant properties. They inhibit normal blood clotting by (1) coating the platelets and interfering with platelet function; (2) interfering with thrombin and thus disrupting coagulation; and (3) attaching to fibrinogen, which interferes with the process needed to form a stable clot. As FSPs accumulate and clotting factors are depleted, the blood loses its ability to clot. A stable clot cannot form at injury sites, which predisposes the patient to bleeding.

TABLE 34.19 Risk Factors for DIC

Acute DIC

Cancers
Acute leukemia
Metastatic solid tumors

Hemolytic Processes
Acute hemolysis from infection or immunologic disorders
Transfusion of mismatched blood

Obstetric Conditions
Abruptio placentae
Amniotic fluid embolism
HELLP syndrome (hemolysis, ↑ liver enzymes, ↓ platelets associated with pregnancy)
Septic abortion or pregnancy

Septicemia (Bacterial, Viral, Fungal, Parasitic)
Shock
Anaphylactic
Cardiogenic
Hemorrhagic

Tissue Damage
Acute anoxia (e.g., after cardiac arrest)
Extensive burns and trauma
Heatstroke
Hepatitis
Postoperative damage, especially after extracorporeal membrane oxygenation
Prosthetic devices
Severe head injury
Snakebites
Transplant rejections
Vascular disorders (e.g., aortic aneurism)

Subacute DIC

Cancer
Metastatic cancer
Myeloproliferative/lymphoproliferative cancers

Obstetric
Retained dead fetus

Chronic DIC
- Cancer
- Liver disease
- SLE

Clinical Manifestations

DIC has both bleeding and thrombotic manifestations. Question bleeding in a person with no history or obvious cause because it may be 1 of the first manifestations of acute DIC.

Bleeding manifestations include manifestations in the (1) skin, such as pallor, petechiae, purpura, oozing blood, venipuncture site bleeding, hematomas, and occult bleeding; (2) respiratory system (e.g., tachypnea, hemoptysis); (3) cardiovascular system, such as tachycardia and hypotension; (4) GI tract, such as upper and lower GI bleeding, abdominal distention, bloody stools; (5) GU tract (e.g., hematuria); (6) neurologic system, such as vision changes, dizziness, headache, and mental status changes; and (7) musculoskeletal system (e.g., bone and joint pain).

Thrombotic manifestations are a result of fibrin or platelet deposition in the microvasculature (Fig. 34.9). These manifestations affect the (1) skin (e.g., cyanosis, ischemic tissue necrosis, hemorrhagic necrosis) (Fig. 34.10); (2) respiratory system (e.g., tachypnea, dyspnea, pulmonary emboli); (3) cardiovascular system (e.g., ECG changes, venous distention); (4) GI tract (e.g., abdominal pain, paralytic ileus); (5) kidney damage and oliguria, leading to failure; and (6) neurologic (e.g., delirium, coma).

Diagnostic Studies

Table 34.20 lists tests used to diagnose acute DIC. D dimer, a polymer resulting from the breakdown of fibrin, is a specific marker for the degree of fibrinolysis. In general, tests that measure raw materials needed for coagulation (e.g., platelets, fibrinogen) are reduced and values that measure clotting times are prolonged. Fragmented RBCs (schistocytes), indicative of partial occlusion of small vessels by fibrin thrombi, may be found on blood smears.

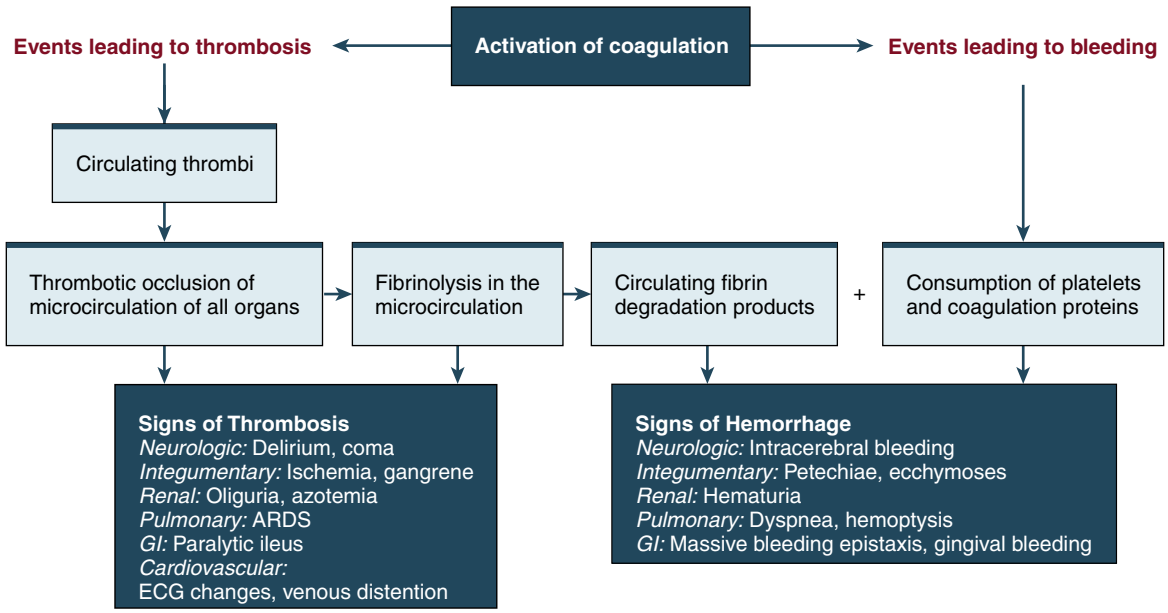

Fig. 34.9 Sequence of events that occur during DIC.

Interprofessional Care

It is important to diagnose DIC quickly, stabilize the patient (e.g., oxygenation, volume replacement), treat the underlying causative disease or problem, and control the ongoing thrombosis and bleeding. Depending on its severity, we use a variety of measures to manage DIC (Fig. 34.11). First, if chronic DIC is diagnosed in a patient who is not bleeding, no treatment for DIC is needed. Treating the underlying disease may be enough

Fig. 34.10 Gangrene from severe DIC. (From Howard MR, Hamilton PJ: *Haematology: an illustrated colour atlas,* ed 4, London, 2013, Churchill Livingstone.)

TABLE 34.20 Laboratory Results in Acute DIC

Test	Finding in Acute DIC
Screening Tests	
Prothrombin time (PT)	Prolonged
Partial thromboplastin time (PTT)	Prolonged
Activated partial thromboplastin time (aPTT)	Prolonged
Fibrinogen	↓
Platelets	↓
Thrombin time	Prolonged
Special Tests	
Antithrombin III (AT III)	↓
D dimers (cross-linked fibrin fragments)	↑
Factor assays (prothrombin and factors V, VIII, X, XIII)	↓ but may be misleading because V and VIII ↑ with inflammation
Fibrin split products (FSPs)	↑
Peripheral blood smear	Schistocytes present
Plasminogen, tissue plasminogen activator	↓
Proteins C and S	↓

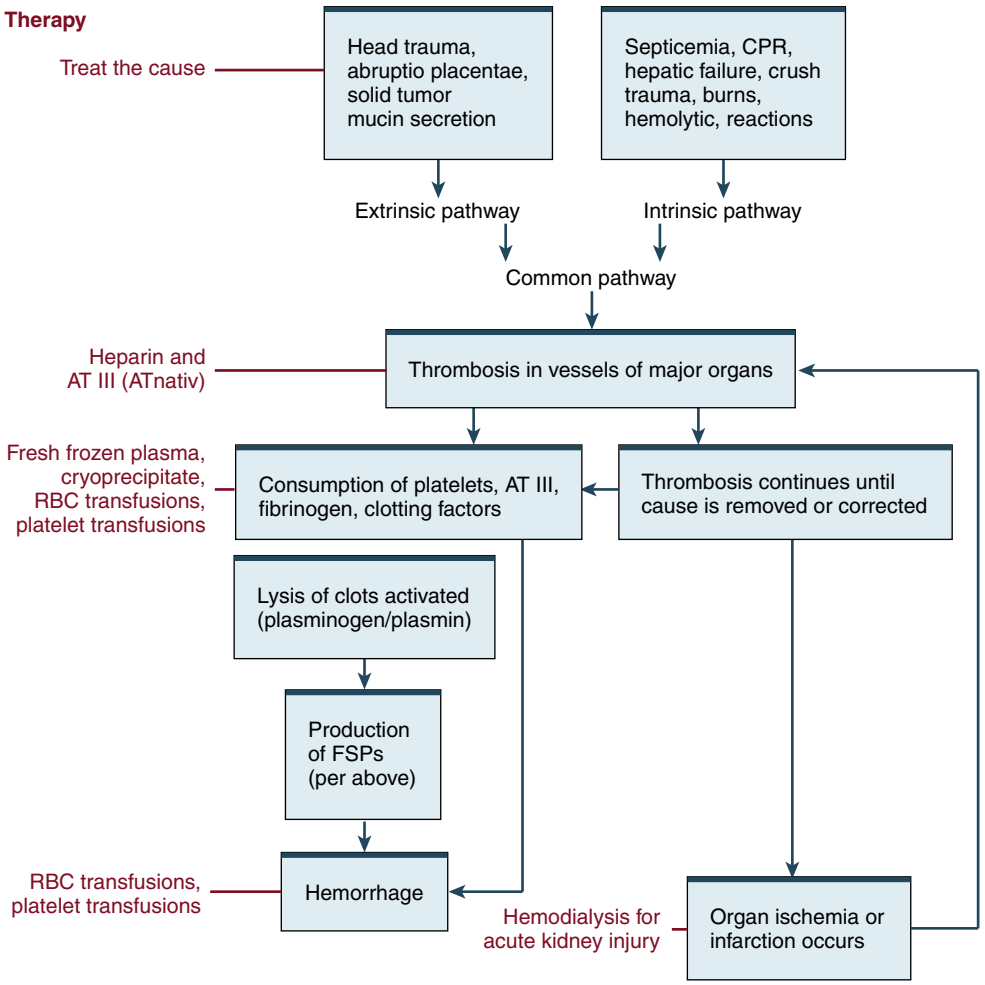

Fig. 34.11 Sites of action for therapies in DIC. *AT III,* Antithrombin III; *FSP,* fibrin split product.

to reverse the DIC (e.g., chemotherapy with DIC caused by cancer). Second, when the patient with DIC is bleeding, therapy is directed toward providing support with needed blood products while treating the primary disorder.

Blood products are given cautiously based on specific component deficiencies to patients who have serious bleeding, are at high risk for bleeding (e.g., surgery), or require invasive procedures. Blood product support with platelets, cryoprecipitate, and fresh frozen plasma (FFP) is usually reserved for a patient with life-threatening bleeding.[1] Therapy stabilizes a patient, prevents severe blood loss or massive thrombosis, and gives time to treat the underlying cause. Cryoprecipitate replaces factor VIII and fibrinogen. It may be given if the fibrinogen level is low and there is potentially dangerous or active bleeding.[4] FFP is given only to patients with significant bleeding and a prolonged PT and aPTT. It replaces all clotting factors except platelets and is a source of antithrombin.

A patient with thrombosis is often treated by anticoagulation with heparin or LMWH. Heparin is used to treat DIC only when the benefit (reduce clotting) outweighs the risk (further bleeding). AT III (ATnativ) may be useful in severe DIC, although it increases the risk for bleeding. Chronic DIC does not respond to oral anticoagulants. It is controlled with long-term use of heparin.

❖ NURSING MANAGEMENT: DISSEMINATED INTRAVASCULAR COAGULATION

Be alert to the development of DIC, especially with the risk factors listed in Table 34.19. Early detection of bleeding and clotting, both occult and overt, must be a primary goal. Assess for signs of external bleeding (e.g., petechiae, oozing at IV or injection sites), signs of internal bleeding (e.g., increased heart rate, changes in mental status, increasing abdominal girth, pain), and any signs that microthrombi may be causing clinically significant organ damage (e.g., decreased renal output).

Remember that because DIC is caused by an underlying disease, that problem must be managed while providing supportive care for the manifestations of DIC. Minimize tissue damage and protect the patient from sources of bleeding. Prompt administration of prescribed therapies is crucial. Give blood products and medications correctly. Table 34.14 and eNursing Care Plan 34.2 provide assessments and interventions appropriate for the patient with DIC.

NEUTROPENIA

Leukopenia refers to a decrease in the total WBC count (granulocytes, monocytes, and lymphocytes). *Granulocytopenia* is a deficiency of granulocytes, which include neutrophils, eosinophils, and basophils. Neutrophilic granulocytes (neutrophils) play a key role in phagocytizing pathogenic microbes. They are closely monitored in clinical practice as an indicator of a patient's risk for infection. A reduction in neutrophils is termed **neutropenia**. Some clinicians use the terms granulocytopenia and neutropenia interchangeably because the largest constituency of granulocytes is the neutrophils.

TABLE 34.21 Common Causes of Neutropenia

Autoimmune Disorders
- Felty syndrome
- SLE

Drugs
- Anticancer agents (busulfan, methotrexate, mercaptopurine, cytarabine, combination therapies)
- Antiinflammatory drugs (indomethacin)
- Antimicrobial agents (ganciclovir, penicillin G, trimethoprim/sulfamethoxazole)
- Cardiovascular drugs (captopril, procainamide)
- Diuretics (hydrochlorothiazide)
- Miscellaneous (ticlopidine, amitriptyline)

Hematologic Disorders
- Addison disease
- Aplastic anemia
- Congenital (cyclic neutropenia)
- Idiopathic neutropenia
- Leukemia
- Myelodysplastic syndrome

Infections
- Fulminant bacterial infection (e.g., typhoid fever, miliary tuberculosis)
- Parasitic
- Rickettsial
- Viral (e.g., hepatitis, influenza, HIV, measles)

Others
- Bone marrow infiltration (e.g., cancer, tuberculosis, lymphoma)
- Hemodialysis
- Hypersplenism (e.g., portal hypertension, storage diseases [e.g., Gaucher disease])
- Nutrition deficiencies (cobalamin, folic acid)
- Severe sepsis

Normally, neutrophils range from 2500 to 8000 cells/μL. Calculate the *absolute neutrophil count* (ANC) by multiplying the total WBC count by the percent of neutrophils (segmented and banded). *Neutropenia* is defined as ANC less than 1000 cells/μL (1×10^9/L). *Severe neutropenia* is an ANC less than 500 cells/μL.[12]

In considering the clinical significance of neutropenia, it is important to know whether the decrease in the neutrophil count was gradual or rapid, the degree of neutropenia, and the duration. The faster the drop and the longer the duration, the greater the chance of life-threatening infection, sepsis, and death. The patient with an ANC between 500 and 1000/μL is at moderate risk for a bacterial infection. Severe neutropenia places the patient at severe risk. Other factors and comorbid conditions can increase the risk of life-threatening consequences. These include immune disorders or treatments (e.g., SLE, steroids), being older than age 60, having an existing infection or previous fungal infection, dehydration, and having COPD.[20]

Neutropenia is a clinical consequence of several conditions or diseases (Table 34.21). It can be an expected effect, a side effect, or an unintentional effect of certain drugs. The most common cause

of neutropenia is chemotherapy and immunosuppressive therapy for the treatment of cancer and autoimmune disease. A term we use to describe the lowest point of neutropenia (and other blood cells) in a patient treated with chemotherapy is *nadir.*

Clinical Manifestations

The patient with neutropenia is predisposed to infection with opportunistic pathogens and nonpathogenic organisms from the normal body flora. When the WBC count is low or immature WBCs are present, normal phagocytic mechanisms are impaired. The classic manifestations of inflammation—redness, heat, and swelling—may not occur. WBCs are the major component of pus. Therefore, in the patient with neutropenia, pus formation (e.g., as a visible skin lesion or as lung infiltrates on a chest x-ray) is absent.

! SAFETY ALERT

Neutropenia

- A low-grade fever in neutropenic patients is of great significance. It may indicate infection and lead to septic shock and death unless treated promptly.
- Neutropenic fever (≥100.4°F [38°C] and/or new signs or symptoms suggesting infection and a neutrophil count <500/μL) is a medical emergency.
- Blood cultures should be drawn STAT (within 1 hr) and antibiotics started within 1 hr.

Assume that fever in a neutropenic patient is caused by infection. It requires immediate attention. The immunocompromised, neutropenic patient has little or no ability to fight infection. A minor infection can lead rapidly to sepsis and death. The mucous membranes of the throat and mouth, skin, perineal area, and pulmonary system are common entry points for pathogenic organisms in susceptible hosts.

Manifestations related to infection at these sites include sore throat and dysphagia, ulcerative lesions of the pharyngeal and buccal mucosa, diarrhea, rectal tenderness, vaginal itching or discharge, shortness of breath, and nonproductive cough. Any report of minor pain or any other symptom by the patient may be significant and should be reported to the HCP at once. Minor problems can progress to fever, chills, sepsis, septic shock, and death if not recognized and treated early.

Systemic infections caused by bacterial, fungal, and viral organisms are common in patients with neutropenia. The patient's own flora (normally nonpathogenic) contributes significantly to life-threatening infections. Organisms known to be common sources of infection include gram-positive coagulase-negative *Staphylococcus* and *Staphylococcus aureus,* viridans streptococci and gram-negative *Escherichia coli, Klebsiella, Enterobacter,* and *Pseudomonas aeruginosa.*[20] Fungi involved include *Candida* (usually *C. albicans*) and *Aspergillus* organisms. Viral infections caused by reactivation of herpes simplex and zoster are common after prolonged periods of neutropenia, such as in HSCT patients.[20]

Diagnostic Studies

The primary diagnostic tests for assessing neutropenia are the peripheral WBC count and bone marrow aspiration and biopsy (Table 34.22). A total WBC count of less than 4000/μL (4×10^9/L) reflects leukopenia. However, only a differential count can confirm the presence of neutropenia (neutrophil count less than 1000/μL [1×10^9/L]). Patients with acute leukemia who present with a high WBC may in fact have neutropenia, because most of the WBCs are ineffective leukemia blasts cells.

A peripheral blood smear assesses for immature forms of WBCs (e.g., bands). The hematocrit level, reticulocyte count, and platelet count are done to evaluate bone marrow function. Review the patient's recent past and current drug history. If the cause of neutropenia is unknown, a bone marrow aspiration and biopsy is done to examine cell numbers and morphology. Other studies assess spleen and liver function.

TABLE 34.22 Interprofessional Care

Neutropenia

Diagnostic Assessment

- History and physical assessment
- Risk assessment for severity and duration of neutropenia
- WBC count with differential count
- WBC morphology
- Hgb and Hct
- Reticulocyte and platelet count
- Bone marrow aspiration and biopsy
- Cultures of nose, throat, sputum, urine, stool, obvious lesions, blood (as indicated)
- Chest x-ray, liver function tests, and other diagnostic tests

Management

- Identify and remove cause of neutropenia (if possible)
- Identification of site of infection (if present) and causative organism
- Blood cultures drawn STAT, before antibiotics
- Antimicrobial therapy STAT (within 1 hr)
- Prophylactic hematopoietic myeloid growth factors after myelosuppressive chemotherapy
- Strict hand hygiene
- Single-patient room, positive-pressure or high-efficiency particulate air (HEPA) filtration, depending on risk
- Community isolation and home precautions (if outpatient)
- Safe activity and ambulation to maintain physical and pulmonary function

G-CSF, Granulocyte colony-stimulating factor; *GM-CSF,* granulocyte-macrophage colony-stimulating factor.

❖ Interprofessional and Nursing Management

The nursing and interprofessional care of neutropenia includes (1) determining the cause of the neutropenia, (2) instituting antibiotic therapy promptly, (3) identifying the offending organisms if an infection has developed, (4) giving hematopoietic growth factors prophylactically after chemotherapy, and (5) implementing protective practices (e.g., strict hand washing, skin and oral hygiene) (Tables 34.22 and 34.23).[21] Often patients can be managed on an outpatient basis if the patient and caregiver can monitor for fever and other signs of infection and seek care promptly if needed (Table 34.24).

Sometimes, the cause of the neutropenia can be easily treated (e.g., nutrition deficiencies). However, neutropenia can be a side effect that must be tolerated as a necessary step in therapy (e.g.,

TABLE 34.23 NURSING MANAGEMENT

Caring for the Patient With Neutropenia

- Make sure that hand hygiene is done before, during, and after patient care by everyone caring for the patient.
- Assess patient for signs and symptoms of infection.
- Screen visitors for infectious diseases.
- Place the patient on a diet that observes food safety guidelines (well washed fruits and vegetables; keep hot foods hot and cold foods cold, no undercooked eggs, meats) to protect them from bacteria found in some foods.
- Obtain cultures of sputum, throat, lesions, wounds, urine, and feces.
- Give antibiotics and hematopoietic growth factors.
- Implement measures to manage fever (see Table 12.5).
- Provide daily skin care and frequent oral hygiene.
- Teach patient and caregivers about
  - Hand hygiene.
  - How to avoid infection, including the need for skin care and oral hygiene (Table 34.24).
  - Signs and symptoms of infection and what to do if they occur.

TABLE 34.24 PATIENT & CAREGIVER TEACHING

Neutropenia

Include the following instructions when teaching a patient or caregiver the precautions to take when the neutrophil count is low:

1. Clean your hands often with soap and water. Make sure those around you wash their hands often, especially if they help with your care. You may also use an antibacterial hand gel.
2. Notify your nurse or HCP if you have any of the following:
   Fever ≥100.4°F (38°C)[a]
   Chills or feeling hot
   Redness, swelling, discharge, or new pain on or in your body
   Changes in urination or bowel movements
   Cough, sore throat, mouth sores, or blisters
3. If you are at home, take your temperature as directed and follow instructions on what to do if you have a fever.
4. Avoid crowds and people with colds, flu, or infections. If you are in a public area, wear a mask and use hand sanitizing gel frequently.
5. Avoid uncooked meats, seafood, or eggs and unwashed fruits and vegetables. Ask your HCP about your specific diet guidelines.
6. Avoid prolonged contact with soil, such as gardening, and household renovation.
7. Bathe or shower daily. Use a moisturizer to prevent skin from drying and cracking.
8. Maintain some daily activity as instructed by your health care team. This may include walking and moderate exercise while avoiding crowds.
9. Brush your teeth with a soft toothbrush 4 times daily. You may floss once daily if it does not cause excessive pain or bleeding. Avoid alcohol-based mouthwashes.
10. Do not clean up after pets. You may feed and pet your dog or cat if you wash your hands well after handling.

[a]Confirm the cut-off temperature with the HCP.

chemotherapy, radiation therapy). In some situations, the neutropenia resolves when the primary problem is treated (Table 34.21). Myeloid growth factors (see Table 16.15) can be used to prevent neutropenia or to reduce its severity and duration.[5] Once neutropenia has occurred, these agents are generally not as effective.

Ongoing monitoring is essential. Early identification and appropriate management can prevent death from sepsis.[3] Monitor the neutropenic patient for signs and symptoms of infection (e.g., any fever 100.4°F [38°C] or greater) and early septic shock. Frequent vital signs (e.g., every 15 minutes to 1 hour) and assessing mental status are essential. See Chapter 42 for more information on signs of septic shock. Identifying the infective organism depends on obtaining cultures from various sites. Serial blood cultures (at least 2) or 1 from a peripheral site and 1 from a venous access device should be done promptly and antibiotics started within 1 hour.

Prophylactic antibiotic, antiviral, and antifungal medications may be started, then switched to treatment doses depending on the risk of specific infections and diagnostic results.[20] We usually give broad-spectrum antibiotics by the IV route because of the rapidly lethal effects of infection. However, some oral antibiotics are highly effective. We may give them to patients who do not have a severe or prolonged neutropenia.[20] Using a third- or fourth-generation cephalosporin with broad microorganism coverage (e.g., cefepime, ceftazidime) or a carbapenem (e.g., imipenem/cilastatin) depends on the patient's response and diagnostic tests.

Begin therapy promptly and observe for side effects of antimicrobial agents. Ongoing febrile episodes or a change in the patient's assessment requires a call to the HCP for assessment, or more cultures, diagnostic tests, or antimicrobial therapies. The longer the neutropenia, the greater the risk is for a fungal infection. Antifungal therapy is started whenever a culture is positive or in patients who do not become afebrile with broad-spectrum antibiotic coverage.

Sputum, throat, lesions, wounds, urine, and fecal cultures may be part of surveillance. Depending on the clinical situation, the patient may need CT scans, bronchoscopy with bronchial brushings, or lung biopsy to diagnose the cause of pneumonic infiltrates. Invasive diagnostic studies are often contraindicated because of the concern of introducing infection and the fact that patients are often thrombocytopenic. Despite these many tests, we find the causative organism in only 40% to 50% of neutropenic patients. Thus the priority is to obtain the blood cultures and begin the antibiotic at once.

Keep the following principles in mind: (1) the patient's normal flora is the most common source of microbial colonization and infection; (2) transmission of organisms from humans most often occurs by direct contact with the hands; (3) air, food, water, and equipment provide opportunities for infection transmission; and (4) HCPs, visitors, and other patients with infections can be sources of infection transmission under certain conditions.

Hand hygiene is the single most important preventive measure to minimize the risk for infection in the neutropenic patient. Strict hand hygiene by staff and visitors using an antiseptic hand wash or sanitizing gel before and after contact is the major method to prevent transmission of harmful pathogens.

Separate immunocompromised patients from those who are infected or have conditions that increase the probability of transmitting infections (e.g., respiratory infections). Place the

hospitalized patient in a private room. High-efficiency particulate air (HEPA) filtration is an air-handling method with a high-flow filtering system that can reduce or eliminate the number of aerosolized pathogens (especially molds) in the environment for those with prolonged neutropenia.[20] Teach the patient and caregiver to avoid potentially hazardous foods, such as raw and undercooked meats and eggs, and to make sure fruits and vegetables are well-washed before eating.

The nursing measures discussed in eNursing Care Plan 34.3 (available on the website for this chapter) are important in treating the patient with neutropenia. Do not overlook quality-of-life issues for the patient with neutropenia. Fatigue, malaise, a decrease in functioning, and social isolation require coaching on safe activity.

MYELODYSPLASTIC SYNDROME

Myelodysplastic syndrome (MDS) is a group of hematopoietic stem cell disorders that results in peripheral blood cytopenia, abnormal cell morphology in 1 or more cell lines, and increased risk of acute myeloid leukemia (AML).[22] The incidence is 4.5 per 100,000 people per year in the United States. Although it can occur in all age-groups, the highest prevalence is in people older than 80 years of age, at which point the rate increases to 55.4 per 100,000.[23]

Etiology and Pathophysiology

The cause of MDS is unknown. Persons at risk are those who had radiation therapy, had chemotherapy with alkylating agents (e.g., chlorambucil, cyclophosphamide, melphalan), or were exposed to industrial solvents (e.g., benzene, vinyl chloride). Around 50% of MDS patients have an acquired chromosome abndormality.[4] Rarely, genetic disorders cause the disease.

We refer to MDS as a *clonal disorder* because some bone marrow stem cells continue to function normally, while others do not. The abnormal clone of the stem cells is usually found in the bone marrow. Eventually, it may be found in the circulation.

Sometimes, 1 type of MDS transforms into another. Depending on the subtype, MDS may progress to AML.[23] In contrast to AML, in which the leukemic cells show little normal maturation, the clonal cells in MDS always have some degree of maturity. Disease progression is slower than in AML, and sometimes treatment is not needed.

Clinical Manifestations

Manifestations result from neoplastic transformation of the immature hematopoietic stem cells in the bone marrow. MDS often presents as infection and bleeding caused by inadequate numbers of ineffectively functioning circulating granulocytes or platelets. It may be found in the older adult during testing for the symptoms of anemia, thrombocytopenia, or neutropenia. It may be diagnosed incidentally from a routine CBC. During the advanced stage of MDS, life-threatening anemia, thrombocytopenia, and neutropenia occur.

Diagnostic Studies

Bone marrow biopsy with aspirate analysis is essential for both the diagnosis and classification of the specific type of MDS. The patient has peripheral cytopenia and changes in the bone marrow (hypocellular or hypercellular). Laboratory data and bone marrow studies rule out other causes of the dysplasia, such as nonmalignant disorders, cobalamin and folate deficiencies, and infection.

❖ Interprofessional and Nursing Management

Treatment of MDS is based on the premise that treatment aggressiveness of treatment should match disease aggressiveness. This is based on the amount and type of dysplasia in the bone marrow, specific genetic mutations, anticipated patient tolerance, and patient preference.[23] Supportive treatment consists of hematologic monitoring (serial bone marrow and peripheral blood examinations), antibiotic therapy, or transfusions with blood products along with chelators to prevent iron overload. Aminocaproic acid or other antifibrinolytic drugs may be used for patients who are refractory to platelet transfusions.[23]

Low-risk patients may be treated with EPO, myeloid growth factors, thrombopoietin-receptor agonists, or lenalidomide.[23] Azacitidine (Vidaza) and decitabine (Dacogen) are drugs that help to restore normal growth control and differentiation of hematopoietic cells. They reduce the frequency of transformation of MDS to acute leukemia. Side effects include myelosuppression, nausea, vomiting, constipation or diarrhea, and renal problems.

Other treatments for MDS include cytarabine with or without antitumor antibiotics (anthracyclines), ATG, and cyclosporine.[23] Chemotherapy and allogeneic HSCT are used in appropriate patients to treat bone marrow dysfunction of MDS and restore it with normal hematopoiesis.

Nursing care of a patient with MDS is like that of a patient with manifestations of anemia, thrombocytopenia, and neutropenia. See eNursing Care Plan 34.1 for the patient with anemia, eNursing Care Plan 34.2 for the patient with thrombocytopenia, and eNursing Care Plan 34.3 for the patient with neutropenia. The eNursing Care Plans are available on the website for this chapter.

LEUKEMIA

Leukemia is the general term used to describe a group of cancers affecting the blood and blood-forming tissues of the bone marrow, lymph system, and spleen. Leukemia occurs in all age-groups. It results in an accumulation of dysfunctional cells because of a loss of regulation in cell division. An estimated 60,530 new cases are diagnosed each year. Leukemias account for 28% of all childhood cancers. Of those, 75% are lymphoid leukemias.[24] Leukemia follows a progressive course that is eventually fatal if untreated. However, progress in successful cancer treatments has been rapid for hematopoietic and lymphoid cancers in the past 30 years.[24]

Etiology and Pathophysiology

Leukemia has no single cause. All cancers, including leukemia, begin as a mutation in the DNA of certain cells. Most leukemias result from a combination of factors, including genetic and environmental influences. Abnormal genes *(oncogenes)* can cause

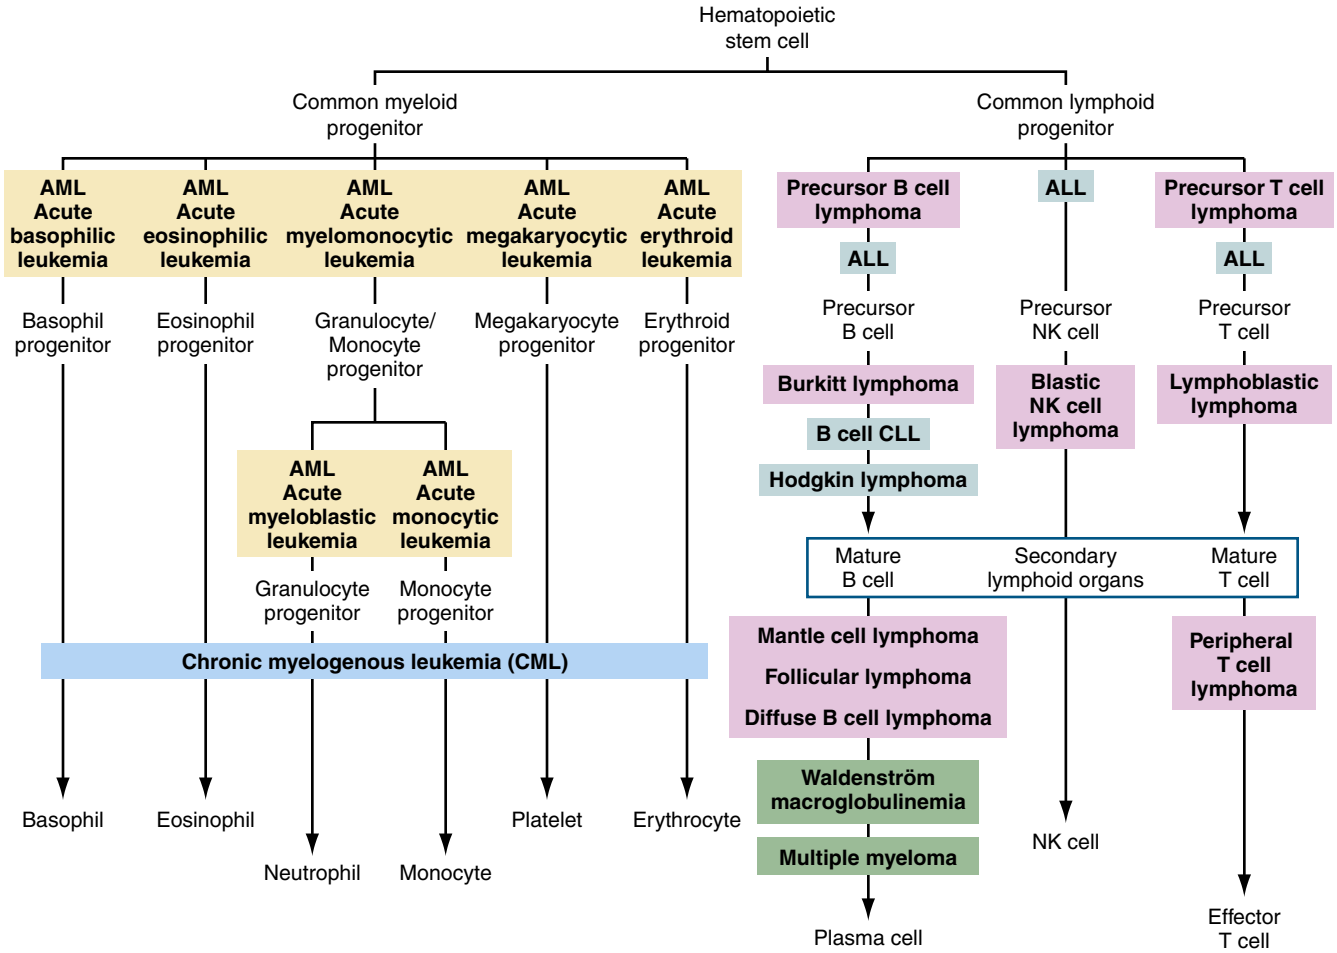

Fig. 34.12 Origins of leukemias, lymphomas, and myeloma. Differentiation pathways of blood-forming cells and the point at which the malignant clone originates. *AML,* Acute myeloid leukemia; *CLL,* chronic lymphocytic leukemia; *NK,* natural killer. (Modified from Huether SE, McCance KL, editors: *Understanding pathophysiology,* ed 7, St Louis, 2017, Elsevier.)

leukemia (see Chapter 16). Chemical agents (e.g., benzene), chemotherapy drugs (e.g., alkylating agents, topoisomerase II inhibitors), viruses, radiation, and immunologic deficiencies increase the risk of leukemia. Depending on the type of leukemia, other potential causes are exposure to pesticides (farmworkers) and smoking. Leukemia occurs more often in those with certain congenital or inherited abnormalities (e.g., Down syndrome).[2]

Classification

We classify leukemia based on acute versus chronic disease and the type of WBC involved. The terms *acute* and *chronic* refer to cell maturity and nature of disease onset. With acute leukemia, there is clonal proliferation of immature hematopoietic cells. The leukemia develops after malignant transformation of a single type of immature hematopoietic cell, followed by cellular replication and expansion of that malignant clone (Fig. 34.12). Chronic leukemias involve more mature forms of the WBC. The disease onset is more gradual.

Leukemia classified by the type of leukocyte involved is either myelogenous or lymphocytic origin. By combining the acute and chronic categories with the cell type involved, 1 can identify 4 major types of leukemia: acute lymphocytic leukemia (ALL), AML, chronic myelogenous (granulocytic) leukemia (CML), and chronic lymphocytic leukemia (CLL). Table 34.25 shows other defining features of these subtypes.

Acute Myeloid Leukemia

AML represents about one third of all leukemias. It makes up about 80% of the acute leukemias in adults.[24] With AML there is uncontrolled proliferation of myeloblasts, the precursors of granulocytes. There is hyperplasia of the bone marrow. The manifestations are usually related to replacement of normal hematopoietic cells in the marrow by leukemic myeloblasts and, to a lesser extent, to infiltration of other organs and tissue (Table 34.25). Its onset is often abrupt and dramatic. A patient may have serious infections and abnormal bleeding from the onset of the disease.

Acute Lymphocytic Leukemia

ALL is the most common type of leukemia in children. It accounts for around 20% of acute leukemia cases in adults.[24] In ALL, immature small lymphocytes proliferate in the bone marrow. Most are of B-cell origin. Most patients have fever

TABLE 34.25 Types of Leukemia

Age of Onset	Clinical Manifestations	Diagnostic Findings
Acute Myeloid Leukemia (AML)		
Accounts for 80% of acute leukemias in adults. Increase in incidence with advancing age after 60 years.	Fatigue and weakness, headache, mouth sores, anemia, bleeding, fever, infection; gingival hyperplasia, mild splenomegaly in some patients	↓ RBC count, Hgb, Hct, platelet count. ↓ to ↑ WBC count with myeloblasts. ↑ LDH. Hypercellular bone marrow with myeloblasts.
Acute Lymphocytic Leukemia (ALL)		
Accounts for 20% of acute leukemias in adults. Most adult patients older than 50 years of age.	Fever, pallor, bleeding, anorexia, fatigue, and weakness. Bone, joint, and abdominal pain. Generalized lymphadenopathy, infections, weight loss, hepatosplenomegaly, headache, mouth sores, neurologic manifestations: CNS involvement, ↑ intracranial pressure (nausea, vomiting, lethargy, cranial nerve dysfunction) from meningeal infiltration. Men may have painless enlargement of the scrotum.	↓ RBC, Hgb, Hct, platelet count. ↓, normal, or ↑ WBC count. ↑ LDH. Hypercellular bone marrow with lymphoblasts. Lymphoblasts may be in cerebrospinal fluid. Presence of Philadelphia chromosome (up to 25% of patients).
Chronic Myelogenous Leukemia (CML)		
Increase in incidence with advancing age. Median age at diagnosis of 67. Rare in children.	No symptoms early in disease. Fatigue and weakness, fever, night sweats, sternal tenderness, weight loss, joint pain, bone pain, massive splenomegaly.	↓ RBC count, Hgb, Hct. ↑ platelet count early, ↓ count later. ↑ WBCs, including a wide variety of myeloid cells and basophils. Nucleated RBCs common. Philadelphia chromosome present in ≈98% of patients.
Chronic Lymphocytic Leukemia (CLL)		
Most common form of leukemia in adults. Increase in incidence with advancing age. Average onset is 72 years of age, with predominance in men.	Frequently no symptoms. Detection of disease often during examination for unrelated condition, chronic fatigue, anorexia, splenomegaly and lymphadenopathy, hepatomegaly. May progress to fever, night sweats, weight loss, fatigue, and frequent infections.	Mild anemia and thrombocytopenia with disease progression. Total WBC count >100,000/μL. ↑ in peripheral lymphocytes and lymphocytes in bone marrow. May have autoimmune hemolytic anemia, idiopathic thrombocytopenic purpura, hypogammaglobulinemia.

at the time of diagnosis. Signs and symptoms may appear abruptly with bleeding or fever, or they may be insidious with progressive weakness, fatigue, bone and/or joint pain, and bleeding. Central nervous system (CNS) infiltration is especially common. Infiltration into other tissues and lymph nodes can occur.[1]

Chronic Myelogenous Leukemia

CML is caused by excessive development of neoplastic granulocytes in the bone marrow. These granulocytes are in all stages of development. They move into the peripheral blood in massive numbers and infiltrate the liver and spleen.[1]

The natural history of CML is a chronic stable phase followed by a more acute, aggressive phase called the *blastic phase*. The chronic phase of CML can last for several years with current therapies. Once CML transforms to an acute or blastic phase, it must be treated more aggressively, similar to an acute leukemia. For younger patients and those that stop responding to maintenance therapies, an HSCT is done.[4]

Genetic Link

The *Philadelphia chromosome* originates from the translocation between the *BCR* gene on chromosome 22 and the *ABL* gene on chromosome 9. The protein that is encoded by the newly created *BCR-ABL* gene on the Philadelphia chromosome interferes with normal cell cycle events, such as the regulation of cell proliferation.

The Philadelphia chromosome is present in about 98% or more of patients with CML. It is a diagnostic hallmark of CML and an important indicator of residual disease or relapse after treatment. However, the presence of the Philadelphia chromosome is not specific to diagnose CML. It is also found in ALL and occasionally in AML.

Chronic Lymphocytic Leukemia

CLL is the most common leukemia in adults in the United States.[24] With CLL there is production and accumulation of functionally inactive but long-lived, small, mature-appearing lymphocytes. B cells are usually involved. The lymphocytes infiltrate the bone marrow, spleen, and liver. Lymph node enlargement (lymphadenopathy) is present throughout the body.

Complications are rare in early-stage CLL but may develop as the disease advances. Pressure on nerves from enlarged lymph nodes causes pain and even paralysis. Mediastinal node enlargement leads to pulmonary symptoms. Because CLL is usually a disease of older adults, treatment decisions must consider disease progression and treatment side effects. Many patients in the early stages of CLL do not need treatment. Others are followed closely and receive treatment only when the disease progresses.

Other Leukemias

Occasionally we cannot determine the subtype of leukemia. The leukemic cells may have lymphoid, myeloid, or mixed characteristics. Often these patients do not respond to treatment and

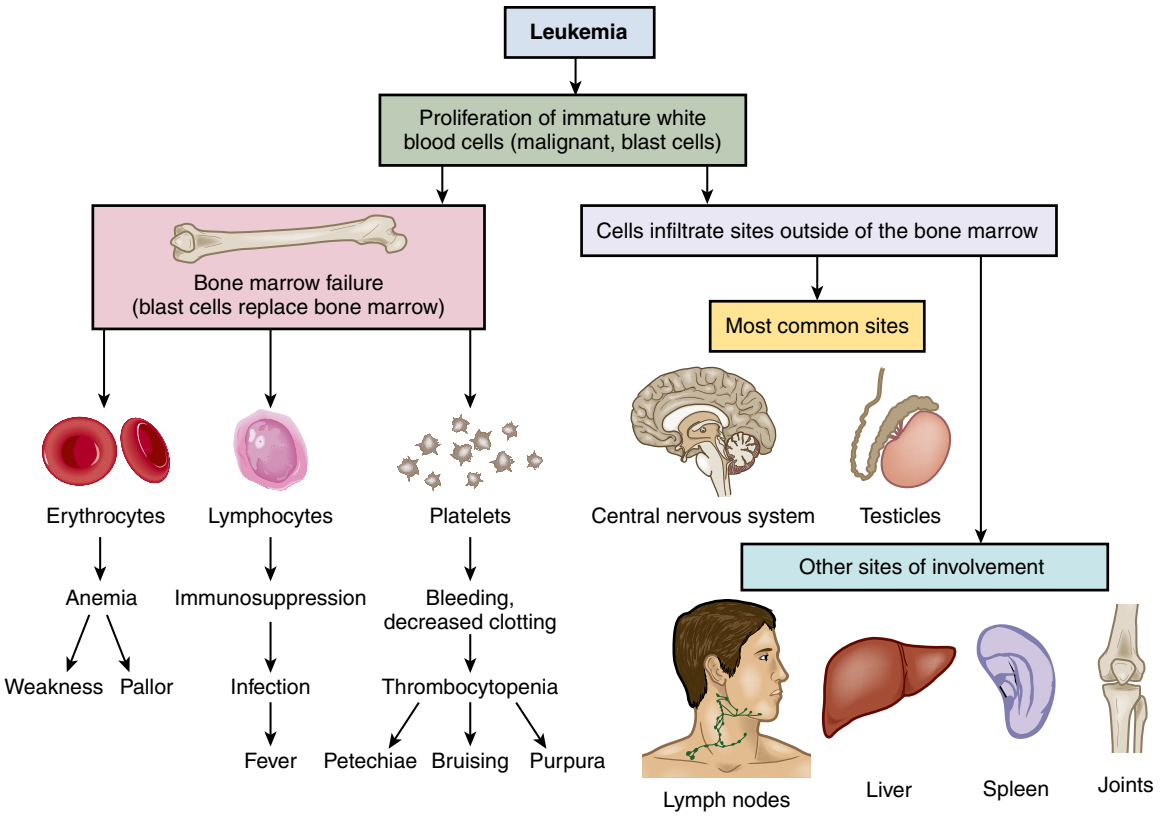

Fig. 34.13 Pathophysiology of leukemia. (Modified from McKinney ES, James SR, Murray SS, et al.: *Maternal-child nursing,* Philadelphia, 2000, Saunders.)

have a poor prognosis. Other rare types include hairy cell and biphenotypic (both abnormal myeloid and lymphoid clones) leukemias.

Overlap Between Leukemia and Lymphoma

Overlap exists between leukemia and non-Hodgkin lymphoma (NHL) because both involve proliferation of lymphocytes or their precursors (Fig. 34.12). A leukemia-like picture with peripheral lymphocytosis and bone marrow involvement may be present in some types of NHL.[1] Patients with more extensive nodal involvement (especially mediastinal), fewer circulating abnormal cells, and fewer blast forms in the marrow are considered to have lymphoma.

Clinical Manifestations

The manifestations of leukemia vary (Table 34.25). They relate to problems caused by bone marrow failure and, sometimes, leukemic infiltrates in tissues (Fig. 34.13). Bone marrow failure results from (1) bone marrow overcrowding by abnormal cells and (2) inadequate production of normal marrow elements. The patient is predisposed to anemia, thrombocytopenia, and decreased number and function of WBCs.

As leukemia progresses, the body makes fewer normal blood cells. The abnormal WBCs continue to accumulate because they do not go through the normal cell life cycle to death *(apoptosis).* The leukemic cells may infiltrate the patient's organs, leading to splenomegaly, hepatomegaly, lymphadenopathy, bone pain, meningeal irritation, and oral lesions. Solid masses from collections of leukemic cells, called *chloromas,* can occur. A high leukemic white count in the peripheral blood (more than 100,000 cells/μL) can cause the blood to thicken and potentially block circulatory pathways. This is called *leukostasis.* It can be life threatening.

Diagnostic Studies

Peripheral blood evaluation and bone marrow examination are the primary methods used to diagnose and classify the type of leukemia. We use various morphologic, histochemical, immunologic, and cytogenetic methods to identify leukemic cell types, stage of development, and genetic mutations. Knowing the type of leukemia is important because each type has a different prognosis and treatment options. For example, in CML, the finding of the Philadelphia chromosome is an important diagnostic indicator. It is also sometimes present in ALL and affects the treatment.[25,26] Other studies, such as lumbar puncture and PET/CT scans, can detect leukemic cells outside of the blood and bone marrow.

Interprofessional Care

For some patients, cure is a realistic goal. For others, the goal is to attain remission or disease control. In *complete remission,* there is no evidence of disease on physical assessment, the bone marrow and peripheral blood appear normal, and molecular analysis shows no residual problems.[1] *Minimal residual disease* is when tumor cells cannot be detected by morphologic examination but can be identified by molecular testing. With *partial*

remission, there is a lack of symptoms and a normal peripheral blood smear, but there is still evidence of disease in the bone marrow. *Molecular remission* means that all molecular studies are negative for residual leukemia.

The patient's prognosis is directly related to the ability to maintain remission. The prognosis becomes more unfavorable with each relapse. After each relapse, the succeeding remission may be harder to achieve and shorter in duration.

Age and cytogenetic analysis are part of treatment decisions. Because chemotherapy is the mainstay of the treatment, you need to understand the principles of cancer chemotherapy (see Chapter 16). Radiation and biologic therapies may be used. Sometimes patients have such a high WBC count (e.g., 100,000 cells/μL or more) that initial emergent treatment may include leukapheresis and hydroxyurea. The purpose of these treatments is to reduce the WBC count and risk for leukemia cell–induced thrombosis. In some cases, such as nonsymptomatic patients with CLL, watchful waiting with active supportive care may be appropriate.

Chemotherapy Stages

We often think about chemotherapy as 3 stages: induction, postinduction or postremission (consolidation), and maintenance.

Induction therapy. The first stage, *induction therapy,* is the attempt to bring about a remission. Induction is aggressive treatment that seeks to destroy leukemic cells in the tissues, peripheral blood, and bone marrow to eventually restore normal hematopoiesis on bone marrow recovery. During induction therapy, a patient may become critically ill because the bone marrow is severely depressed by the chemotherapy. Nursing interventions focus on neutropenia, thrombocytopenia, and anemia. Common chemotherapy drugs for induction of AML include cytarabine and an antitumor antibiotic (anthracycline), such as daunorubicin or idarubicin.[27] After 1 course of induction therapy, around 70% of newly diagnosed patients younger than age 50 achieve complete remission. We assume that leukemic cells persist undetected after induction therapy. This could lead to relapse within a few months without further therapy.[27]

Postinduction or postremission therapy. Terms used to describe postinduction or postremission chemotherapy include *intensification* and *consolidation. Intensification therapy,* or high-dose therapy, may start immediately after induction therapy and last for several months. Other drugs that target the cell in a different way than those given during induction may be added.

Consolidation therapy is started after a remission is achieved. It may consist of 1 or 2 more courses of the same drugs given during induction or involve high-dose therapy (intensive consolidation). The purpose of consolidation therapy is to eliminate remaining leukemic cells that may not be clinically or pathologically evident.

Maintenance therapy. The goal of maintenance therapy is to keep the body free of leukemic cells. It may also be used for acute leukemia, depending on the presence of specific cytogenetic markers and therapies that can target them.[25,27]

Drug Therapy Regimens

Combination drug therapy is the mainstay of treatment for leukemia. The 3 purposes for using multiple drugs are to (1) decrease drug resistance, (2) minimize the drug toxicity by using multiple drugs with varying toxicities, and (3) interrupt cell growth at multiple points in the cell cycle. The drugs used vary. Table 34.26 gives examples of treatment regimens used in various types of leukemia.

TABLE 34.26 Drug Therapy

Leukemia

Drug Therapy	Other Therapy
Acute Myeloid Leukemia (AML)	
arsenic trioxide, azacitidine, cytarabine, daunorubicin, decitabine, enasidenib, etoposide, fludarabine, gemtuzumab ozogamicin, gilteritinib, glasdegib, idarubicin, ivosidenib, midostaurin, mitoxantrone, sorafenib, tretinoin, venetoclax Combination chemotherapy of cytarabine and antitumor antibiotic (most common initial therapy)	Allogeneic hematopoietic stem cell transplant (HSCT) (see Chapter 16)
Acute Lymphocytic Leukemia (ALL)	
asparaginase, blinatumomab, bosutinib, clofarabine, cyclophosphamide, cytarabine, dasatinib, daunorubicin, dexamethasone, doxorubicin, etoposide, fludarabine, imatinib, inotuzumab ozogamicin, 6-mercaptopurine, methotrexate, nelarabine, nilotinib, pegaspargase, ponatinib, prednisone, rituximab, vincristine Combination chemotherapy of several agents is common over a prolonged time	Cranial radiation therapy, intrathecal methotrexate or cytarabine, allogeneic HSCT, Tisagenlecleucel (CAR-T cell therapy) (see Chapter 16)
Chronic Myelogenous Leukemia	
bosutinib, dasatinib, imatinib, nilotinib, omacetaxine, ponatinib Combination chemotherapy for progression to acute phase as per either AML or ALL therapy	HSCT, α-interferon, leukapheresis
Chronic Lymphocytic Leukemia	
Acalabrutinib, alemtuzumab, chlorambucil, bendamustine, cyclophosphamide, duvelisib, fludarabine, ibrutinib, idelalisib, lenalidomide, obinutuzumab, ofatumumab, prednisone, rituximab, venetoclax, zanubrutinib	Radiation, splenectomy, colony-stimulating factors, allogeneic HSCT

Some drugs target small molecules that promote the growth and differentiation of leukemic cells. For example, all-*trans* retinoic acid is used to treat acute promyelocytic leukemia (a type of AML). It causes normal differentiation of the promyelocytes, which has arrested in this type of leukemia by the translocation of the *PML* gene on chromosome 15 to the *RARA* gene on chromosome 17 (t15;17).[27] Midostaurin, a multikinase inhibitor, inhibits this growth pathway in AML patients with the *FLT3* mutation.[27] Imatinib (Gleevec) and other tyrosine-kinase inhibitors target the BCR-ABL protein that is present in nearly

all patients with CML and some patients with ALL.[26] This drug kills only cancer cells, leaving healthy cells alone.

Specific targeted therapy in the form of monoclonal antibodies is an important treatment for hematopoietic cancers. However, cures with these therapies alone are rare. Rituximab binds to the B-cell antigen (CD20) and is a treatment for ALL and CLL.[28] Alemtuzumab (Campath), a treatment for CLL, binds to CD52, a panlymphocyte antigen present on both T and B cells.[28]

Other Treatments

In addition to chemotherapy, corticosteroids and radiation therapy have a role in treating the patient with leukemia. Total body radiation can prepare a patient for bone marrow transplantation. Radiation may be restricted to certain areas, such as the liver and spleen, or other organs affected by infiltrates. In ALL, prophylactic intrathecal methotrexate or cytarabine is given to decrease the CNS involvement which is common in this type of leukemia. When CNS leukemia does occur, cranial radiation is an option. Immunotherapy and targeted therapy, such as monoclonal antibodies and chimeric antigen receptor (CAR) T cells, may be indicated for specific leukemias. These therapies are discussed in Chapter 16.

Hematopoietic Stem Cell Transplantation

HSCT is another option for treating leukemia. The goal of HSCT is to eliminate all leukemic cells from the body using combinations of chemotherapy with or without total body irradiation. This treatment eradicates the patient's hematopoietic stem cells, which are then replaced with those of an HLA-matched sibling, HLA-half-matched relative, volunteer donor *(allogeneic),* or identical twin *(syngeneic)*. HSCT is discussed in Chapter 16.

The primary complications for patients with allogeneic HSCT are graft-versus-host disease (GVHD), relapse of leukemia, and infection and sepsis. Because HSCT has serious associated risks, the patient must weigh the significant risks for treatment-related death or treatment failure (relapse) with the hope of cure.

❖ NURSING MANAGEMENT: LEUKEMIA

◆ Assessment

Subjective and objective data that you should obtain from a patient with leukemia are outlined in Table 34.27.

◆ Clinical Problems

Clinical problems for the patient with leukemia include those for anemia, thrombocytopenia, and neutropenia (see eNursing Care Plan 34.3, available on the website).

◆ Planning

The overall goals are that the patient with leukemia will (1) understand and adhere to the treatment plan; (2) have minimal side effects and complications associated with both the disease and its treatment; and (3) establish realistic hope and goals, feeling supported during periods of treatment, relapse, or remission.

TABLE 34.27 NURSING ASSESSMENT

Leukemia

Subjective Data

Important Health Information

Health history: Exposure to chemical toxins (e.g., benzene, arsenic), radiation, or viruses (HTLV-1); chromosome abnormalities (Down syndrome, Klinefelter syndrome, Fanconi syndrome), immunologic deficiencies; organ transplantation; frequent infections; bleeding tendencies

Medications: Chemotherapy

Surgery or other treatments: Radiation exposure; prior radiation and chemotherapy for cancer

Functional Health Patterns

Health perception–health management: Family history of leukemia; malaise

Nutritional-metabolic: Mouth sores, weight loss; chills, night sweats; nausea, vomiting, anorexia, dysphagia, early satiety; easy bruising

Elimination: Hematuria, ↓ urine output; diarrhea, dark or bloody stools

Activity-exercise: Fatigue with progressive weakness; dyspnea, nosebleeds, cough

Cognitive-perceptual: Headache; muscle cramps; sore throat; generalized sternal tenderness, bone, joint, abdominal pain; paresthesias, numbness, tingling, visual changes

Sexuality-reproductive: Prolonged menses, menorrhagia, metrorrhagia, impotence

Objective Data

General

Fever, generalized lymphadenopathy, lethargy

Cardiovascular

↑ HR, systolic murmurs

GI

Gingival bleeding and hyperplasia; oral ulcerations, herpes and *Candida* infections; perirectal irritation and infection; hepatomegaly, splenomegaly

Musculoskeletal

Muscle wasting, bone pain, joint pain

Neurologic

Seizures, disorientation, confusion, impaired coordination, cranial nerve palsies, papilledema

Skin

Pallor or jaundice; petechiae, bruising, purpura, reddish brown to purple cutaneous infiltrates, macules, and papules

Possible Diagnostic Findings

↓, normal, or ↑ WBC count with shift to the left (↑ blast cells) and neutropenia; anemia, ↓ hematocrit and hemoglobin, thrombocytopenia, specific chromosome abnormalities; hypercellular bone marrow aspirate or biopsy with myeloblasts, lymphoblasts, and markedly ↓ normal cells

◆ Implementation

◆ Acute Care

The nursing role during acute phases of leukemia is challenging because the patient has many physical and psychosocial needs. As with other forms of cancer, the diagnosis of leukemia can evoke great fear and be equated with death. It may be viewed as a hopeless, horrible disease with many painful and undesirable consequences. The treatment and prognosis are driven by many factors, such as age and type of leukemia. You must understand the patient's type of leukemia, prognosis, treatment plan, and goals. By doing this, you can help the patient to realize that,

although the future may be uncertain, one can have a meaningful quality of life while in remission or with disease control and that, in some cases, there is reasonable hope for cure.

The family needs help adjusting to the stress of this abrupt onset of serious illness and the losses imposed by the sick role (e.g., dependence, withdrawal, changes in role responsibilities, changes in body image). The diagnosis of leukemia often brings with it the need to make difficult decisions at a time of profound stress for the patient and family.

Patients may have comorbid conditions that affect treatment decisions. Important nursing interventions include (1) maximizing the patient's physical functioning, (2) teaching patients that acute side effects of treatment are usually temporary, and (3) encouraging patients to discuss their quality-of-life issues.

You are an important advocate in helping the patient and family understand the complexities of treatment decisions and manage the side effects and toxicities. This may include making sure the HCP addresses fertility concerns. A patient may need a long hospitalization or to temporarily relocate to an appropriate treatment center. This can lead a patient to feeling deserted and isolated at a time when support is most needed. You can help to reverse feelings of abandonment and loneliness by balancing the demanding technical needs with a humanistic, caring approach. The patient's needs are best met by care from an interprofessional team (e.g., psychiatric and oncology clinical nurse specialists, case managers, dietitians, chaplains, and social workers).

Quality nursing care significantly affects patient survival and comfort during aggressive chemotherapy. You need to make astute assessments and plan care to help the patient manage the severe side effects. Life-threatening results of bone marrow suppression (neutropenia, thrombocytopenia, and anemia) require prompt nursing interventions. Other critical aspects of care include anticipating, monitoring for, and helping to treat emergencies, such as DIC, tumor lysis syndrome, and leukostasis. Complications of chemotherapy may affect the patient's GI tract, nutrition status, skin and mucosa, cardiopulmonary status, liver, kidneys, and neurologic system. Nursing interventions related to chemotherapy are discussed in Chapter 16.

Review all drugs being given, including the mechanism of action, purpose, routes of administration, doses, potential side effects, safe handling considerations, and toxic effects. Assess laboratory data reflecting drug effects and sequelae of the disease. Unlike treatments for solid tumors, patients with leukemia receive chemotherapy even if they have severe myelosuppression since the underlying disorder is causing the problem and will not resolve unless treated.

Ambulatory Care

Ongoing care is needed to monitor for signs and symptoms of disease control or relapse. For a patient receiving long-term or maintenance chemotherapy, the fatigue of long-term chronic disease management can become discouraging. Teach the patient and caregiver the importance of continued diligence in disease management and the need for follow-up care. Review drug information, self-care measures, and when to seek medical care.

TABLE 34.28 Comparison of Hodgkin and Non-Hodgkin Lymphoma

	Hodgkin Lymphoma	Non-Hodgkin Lymphoma
Cellular origin	B lymphocytes	B lymphocytes (85%) T or natural killer lymphocytes (15%)
Extent of disease	Localized to regional but may be more widespread. Spreads to adjacent tissues	Disseminated, can spread to other areas of the body
B symptoms (fever, drenching night sweats, weight loss)	Common	Uncommon
Extranodal involvement	Rare	Common

The goals of rehabilitation for long-term survivors of leukemia are to manage the physical, psychologic, social, and spiritual consequences and delayed effects from the disease and its treatment. Involving the patient in survivor networks and support groups or services may help the patient to adapt to living after a life-threatening illness. Exploring national and community resources (e.g., American Cancer Society, Leukemia & Lymphoma Society) may reduce the financial burden and the feelings of dependence. Provide resources for spiritual support.

Vigilant follow-up care helps to ensure that we recognize and treat the survivor's unique needs. Often these needs may need a referral or consultation. For example, physical therapy personnel may develop an exercise program to address posttreatment deficits from drug-induced peripheral neuropathy. Patients should follow the advice of their HCP about receiving vaccines.

Evaluation

The expected outcomes are that the patient with leukemia will

- Cope effectively with the diagnosis, treatment regimen, and prognosis
- Have no complications related to the disease or treatment
- Feel supported throughout treatment

LYMPHOMAS

Lymphomas are cancers originating in the bone marrow and lymphatic structures resulting in the proliferation of lymphocytes. Lymphomas make up 4% to 5% of all cancers in the United States.[24] Two major types of lymphoma are Hodgkin lymphoma and NHL. A comparison of these 2 types of lymphoma is shown in Table 34.28.[4]

HODGKIN LYMPHOMA

Hodgkin lymphoma, or *Hodgkin disease,* makes up about 10% of all lymphomas. There is a proliferation of abnormal giant, multinucleated cells, called *Reed-Sternberg cells,* or its variant, *Hodgkin cells* (mononucleated), which proliferate in the lymph nodes.[4] The disease has a bimodal age-specific incidence, occurring most frequently in persons from 15 to 30 years of age and

Fig. 34.14 Enlarged cervical lymph node in the neck of a man with Hodgkin lymphoma. (From Howard MR, Hamilton PJ: *Haematology: an illustrated colour atlas,* ed 4, London, 2013, Churchill Livingston.)

older than 55 years of age.[29] Males are affected almost twice as often as females.[4] Each year, about 8480 new cases of Hodgkin's lymphoma are diagnosed, with around 970 deaths.[24] About 85% of all patients are cured.[4]

Etiology and Pathophysiology

Although the cause of Hodgkin lymphoma is unknown, several key factors play a role in its development. The main interacting factors include infection with Epstein-Barr virus (EBV), genetic predisposition, and exposure to occupational toxins. The incidence of Hodgkin lymphoma is increased in those with HIV infection.[29]

The disease likely starts in a single location and then spreads along adjacent lymphatics. However, in recurrent disease, it may spread more diffusely. It eventually infiltrates other organs, especially lungs, spleen, and liver. When the disease begins above the diaphragm, it stays confined to lymph nodes for a variable time. Disease originating below the diaphragm often spreads to extra lymphoid sites, such as the liver. There are 5 histologic subtypes. Nodular sclerosis is the most common.

Clinical Manifestations

The onset of symptoms is usually gradual. The initial sign is often enlargement of cervical, axillary, or inguinal lymph nodes (Fig. 34.14). Subsequent lymph node involvement is generally by spread to adjacent lymph nodes. The nodes are movable and nontender. Enlarged nodes are not painful unless they exert pressure on adjacent nerves.

The patient may have weight loss, fatigue, weakness, fever, chills, tachycardia, or night sweats. A group of initial findings, including fever (>100.4°F [38°C]), drenching night sweats, and weight loss (exceeding 10% in 6 months), are termed *B symptoms*. They correlate with a worse prognosis. After having even small amounts of alcohol, patients with Hodgkin lymphoma may have a rapid onset of pain at the site of disease. The cause for the alcohol-induced pain is unknown. Generalized itching without skin lesions may develop. Cough, dyspnea, stridor, and dysphagia may occur with mediastinal node involvement.

In more advanced disease, there may be hepatomegaly and splenomegaly. Anemia results from increased destruction and decreased production of RBCs. Other signs vary depending on the site of disease. For example, intrathoracic involvement may lead to superior vena cava syndrome. Enlarged retroperitoneal nodes may cause palpable abdominal masses or interfere with renal function. Jaundice may occur from liver involvement. Spinal cord compression leading to paraplegia may occur with extradural involvement. Bone pain occurs from bone involvement.

Diagnostic and Staging Studies

Peripheral blood analysis, lymph node biopsy, bone marrow examination, and radiologic studies are important in evaluating Hodgkin lymphoma. Abnormalities in the CBC, such as a microcytic hypochromic anemia, are variable and not diagnostic. Leukopenia and thrombocytopenia may develop, but they are usually a consequence of treatment, advanced disease, or hypersplenism. Other blood studies may show increased erythrocyte sedimentation rate and LDH, high leukocyte alkaline phosphatase from liver and bone involvement, hypercalcemia from bone involvement, and hypoalbuminemia from liver involvement.

Radiologic evaluation can help define all sites and determine the clinical stage of the disease. PET and CT scans are used to stage and then assess the response to therapy and to distinguish residual tumor from fibrotic masses after treatment. Scans can show masses, such as renal displacement caused by retroperitoneal node enlargement, abdominal or mediastinal lymph node enlargement, and liver, spleen, bone, and brain infiltration.

Using all the information from the various diagnostic studies, HCPs determine a clinical stage of disease (Fig. 34.15). The final staging is based on the clinical stage (extent of the disease), presence of B symptoms, and other unfavorable prognostic features. The terms used in staging involve an A or B classification, depending on whether systemic symptoms are present at diagnosis, and a Roman numeral (I to IV) that reflects the location and extent of the disease.[29]

❖ Interprofessional and Nursing Management

Treatment depends on the nature and extent of the disease. Combination chemotherapy works well because, as in leukemia, the drugs used have an additive antitumor effect without increasing side effects. As with leukemia, therapy must be aggressive. The standard for chemotherapy is the ABVD regimen: doxorubicin (**A**driamycin), **b**leomycin, **v**inblastine, and **d**acarbazine. Patients with favorable early-stage disease receive 2 to 4 cycles of chemotherapy.[29] Patients with early-stage disease but unfavorable prognostic features (e.g., B symptoms) or intermediate-stage disease receive 4 to 6 cycles of chemotherapy. Advanced-stage Hodgkin lymphoma is treated more aggressively using 6 to 8 cycles of chemotherapy. A common regimen is BEACOPP (**b**leomycin, **e**toposide, doxorubicin [**A**driamycin], **c**yclophosphamide, vincristine [**O**ncovin], **p**rocarbazine, and **p**rednisone).[29]

The role of involved-site radiation as a supplement to chemotherapy varies depending on the extent of disease and the presence of resistant disease after chemotherapy. Response to therapy is determined by PET and CT scans and other diagnostic tests (e.g., bone marrow biopsy).

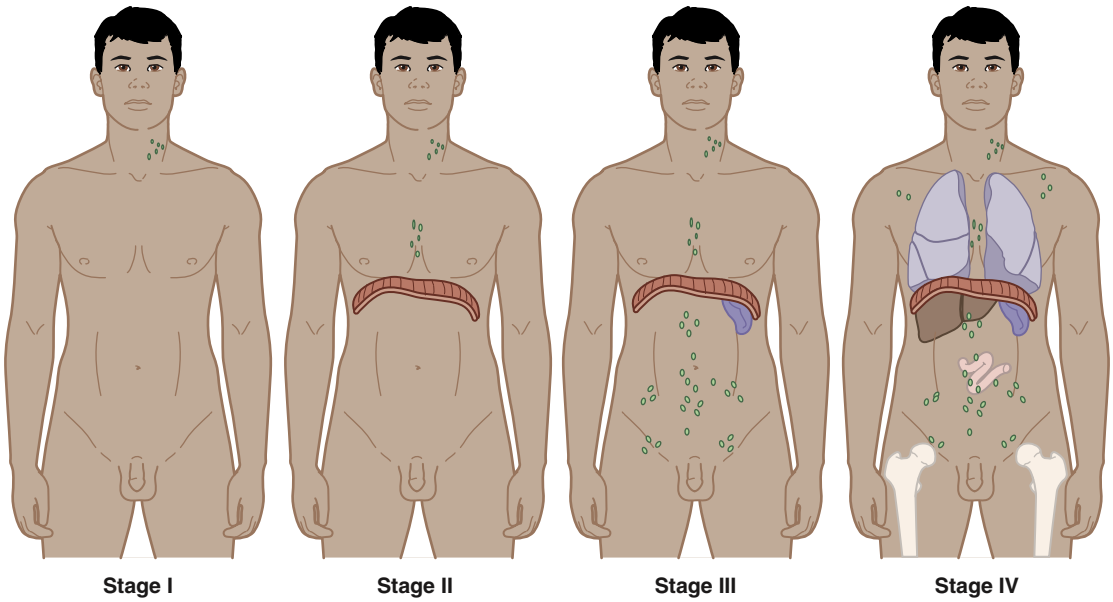

Fig. 34.15 Staging system for Hodgkin lymphoma and non-Hodgkin lymphoma. *Stage I,* Involvement of single lymph node (e.g., cervical node). *Stage II,* Involvement of 2 or more lymph nodes on 1 side of diaphragm. *Stage III,* Lymph node involvement above and below the diaphragm. *Stage IV,* Involvement outside of diaphragm (e.g., liver, bone marrow). The stage is followed by the letter *A* (absence) or *B* (presence) to indicate significant systemic symptoms (e.g., fever, night sweats, weight loss).

A variety of chemotherapy regimens and newer agents, such as brentuximab vedotin, nivolumab, bendamustine, everolimus, or pembrolizumab, are options for patients who have relapsed or refractory disease. Sometimes we give a single drug palliatively to someone who cannot tolerate intensive combination therapy. Ideally, once in remission, a curative option may be intensive chemotherapy with autologous or allogeneic HSCT.[29] HSCT has allowed patients to receive higher, potentially curative doses of chemotherapy while reducing life-threatening leukopenia. Maintenance chemotherapy does not contribute to increased survival after achieving complete remission.

A serious consequence of treatment is the later development of secondary cancers and potential long-term treatment toxicities, such as endocrine, heart, and lung problems. Secondary solid tumor cancers may occur 10 years after ending treatment. The most common secondary cancers are lung and breast cancer, especially with radiation therapy. Patients should have close follow-up and screening for early detection of these problems.

Nursing care focuses on managing problems related to the disease (e.g., pain caused by a tumor, superior vena cava syndrome), pancytopenia, and other side effects of therapy. Because patient survival depends on their response to treatment, supporting the patient through the consequences of treatment is important.

Psychosocial considerations are as important as they are with leukemia. However, the prognosis for Hodgkin lymphoma is better than that for many forms of cancer. Address the physical and spiritual consequences. Fertility issues may be of concern because this disease occurs in adolescents and young adults. Help to ensure that these issues are addressed soon after diagnosis.

NON-HODGKIN LYMPHOMA

Non-Hodgkin lymphomas (NHLs) are a broad group of cancers of primarily B, T, and natural killer (NK) cells. They affect persons of all ages. There are more than 75 types. We classify NHL by the level of differentiation (maturity), cell of origin, immunophenotype (cell surface antigens, CD20, CD52), and genetic and clinical features.[30] The most common subtypes are diffuse large B-cell lymphoma and follicular lymphoma.[4] Burkitt lymphoma is the most aggressive form. A simplified example of the classification system is shown in Table 34.29.[30,31]

A variety of presentations and courses occur, from indolent (slowly developing) to rapidly progressive disease. NHL is the

TABLE 34.29 Classification of Non-Hodgkin Lymphoma[a]

B-Cell Lymphomas
- Burkitt lymphoma
- Diffuse large B-cell lymphoma (DLBCL)
- Follicular lymphoma
- Mantle cell lymphoma
- Marginal zone B-cell lymphoma (MALT)
- Plasmablastic lymphoma
- Small lymphocytic lymphoma/chronic lymphocytic leukemia

T-Cell and Natural Killer (NK)-Cell Lymphomas
- Anaplastic large T-cell lymphoma
- Extranodal NK/T cell lymphoma
- Mycosis fungoides and Sézary syndrome
- Peripheral T-cell lymphoma, not otherwise specified (NOS)

Posttransplant Lymphoproliferative Disorders (PTLD)
- Infectious mononucleosis-like PTLD

Histiocytic and Dendritic Cell Tumors
- Langerhans cell histiocytosis

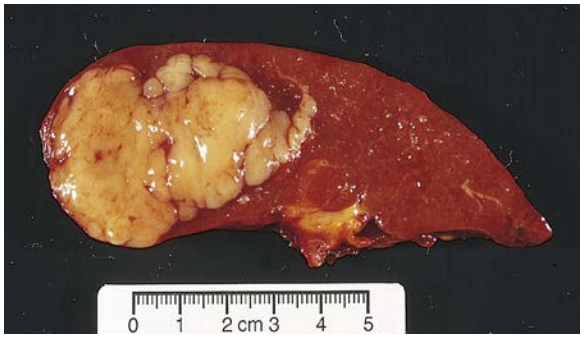

Fig. 34.16 Non-Hodgkin lymphoma involving the spleen. The presence of an isolated mass is typical. (From Cotran RS, Kumar V, Abbas AK: *Robbins pathologic basis of disease,* ed 6, Philadelphia, 1999, Saunders.)

most common hematologic cancer. Each year about 77,240 new cases of NHL are diagnosed and 19,940 deaths occur.[24]

Etiology and Pathophysiology

The cause of NHL is usually unknown. NHLs may result from chromosomal translocations, infections, environmental factors, and immunodeficiency states. Chromosomal translocations have a key role in the pathogenesis of many NHLs. Viruses and bacteria implicated in the pathogenesis of NHL include human T-cell leukemia virus, type 1 (HTLV-1), EBV, human herpesvirus 8, hepatitis C, *H. pylori,* and *Chlamydia trachomatisi.*[4] Chemicals linked to NHL include pesticides, herbicides, solvents, and organic chemicals. NHL is more common in people who have inherited immunodeficiency syndromes, have used immunosuppressive agents (e.g., to prevent rejection after an organ transplant or to treat autoimmune disorders), or received chemotherapy or radiation therapy.

NHL does not have a hallmark feature that parallels the Hodgkin or Reed-Sternberg cell of Hodgkin lymphoma. All NHLs involve lymphocytes arrested in various stages of development and may mimic a leukemia. For example, small lymphocytic lymphoma (SLL) and CLL result from malignant proliferation of small B lymphocytes, with most CLL disease within the bone marrow versus the lymph nodes. Some NHLs can begin outside the lymph nodes. Diffuse large B-cell lymphoma, the most common aggressive lymphoma, is usually found in lymph nodes in the neck or abdomen.

Clinical Manifestations

The method of spread can be unpredictable. Most patients have widespread disease at the time of diagnosis (Fig. 34.16). The primary manifestation is painless lymph node enlargement. The lymphadenopathy can wax and wane in indolent disease. Because the disease has usually spread, other symptoms are present depending on where the disease is present (e.g., hepatomegaly with liver involvement, neurologic symptoms with CNS disease). NHL can manifest in nonspecific ways, such as an airway obstruction, hyperuricemia and renal failure from tumor lysis syndrome, pericardial tamponade, and GI symptoms. Patients with high-grade lymphomas may have lymphadenopathy and B symptoms, such as fever, night sweats, and weight loss.

Diagnostic and Staging Studies

Diagnostic studies used for NHL resemble those used for Hodgkin lymphoma. However, because NHL is more often in extranodal sites, more diagnostic studies may be done. These include an MRI or lumbar puncture to rule out CNS disease, a bone marrow biopsy to determine bone marrow infiltration, or a barium enema or upper endoscopy to look for GI involvement. In early NHL, the CBC may be normal, but some lymphomas manifest in a "leukemic" phase.

Clinical staging, as described for Hodgkin lymphoma, helps to guide therapy (Fig. 34.15). Establishing the precise histologic subtype through biopsy is important. Treatment is guided by the cell type, cytogenetic studies, and clinical behavior: *indolent* (low grade), aggressive (high grade), or *highly aggressive* (very high grade). Other factors, known as the International Prognostic Index (IPI), may be considered for each subtype. These include the clinical stage, number of extranodal sites, serum LDH, WBC count, and patient's age and performance status.[30,31] Immunologic, cytogenetic, and molecular studies are used for making therapeutic decisions and assessing prognosis. Other studies might include blood tests for tumor lysis; screening for hepatitis, HIV, and other infections; skin biopsies; bone marrow biopsies; and lumbar punctures. The prognosis for NHL is based on the histopathology.

❖ Interprofessional and Nursing Management

Treatment involves chemotherapy, biotherapy, radiation, and sometimes phototherapy and topical therapy (Table 34.30).[30,31] More aggressive lymphomas (diffuse large B cell) are generally more responsive to treatment. In contrast, indolent lymphomas (e.g., follicular lymphomas) have a naturally long course but are hard to effectively treat.[30]

Patients with low-grade (indolent) lymphoma may live 10 years or more without treatment. However, some early therapies can be well tolerated and may reduce the time to progression of the disease. Those that have an infectious basis, such as *H. pylori* gastric lymphomas, may be treated with antibiotic or antiviral therapy. HSCT may help in certain subtypes of aggressive or refractory lymphomas. CAR T-cell immunotherapy may be used.

Rituximab, a monoclonal antibody against the CD20 antigen on the surface of normal and malignant B cells, treats NHL in combination with other agents. Once bound to the cells, rituximab causes lysis and cell death. Numerous chemotherapy combinations are used to try to overcome the resistant nature of this disease. Targeted therapies are becoming more prevalent (Table 34.30).

DRUG ALERT

Rituximab (Rituxan)

- Monitor for signs of severe hypersensitivity infusion reactions, especially with first infusion.
- Manifestations may include hypotension, bronchospasm, dysrhythmias, angioedema, and cardiogenic shock.
- Screen for history of hepatitis because the drug may reactivate hepatitis.

TABLE 34.30 Treatment of Non-Hodgkin Lymphoma[a]

Recommended Therapies	Common Chemotherapy Combinations
Indolent (Low-Grade) Follicular Lymphoma, Marginal Zone B-Cell Lymphoma, Mucosa-Associated Lymphoid Tissue (MALT)	
• External beam irradiation for local, limited disease • Single-agent rituximab, obinutuzumab • Rituximab or obinutuzumab with another agent (bendamustine, chlorambucil, cyclophosphamide, lenalidomide) • Combination chemotherapy (R-CHOP or other) • Targeted therapies (duvelisib, tazemetostat) • Radioimmunotherapy • Hematopoietic stem cell transplant (HSCT) • Anti-CD19 CAR-T cell therapy	**R-CHOP: r**ituximab, **c**yclophosphamide, doxorubicin **h**ydrochloride, vincristine (**O**ncovin), **p**rednisone **R-CVP: r**ituximab, **c**yclophosphamide, **v**incristine, **p**rednisone
Aggressive (Intermediate- or High-Grade) Mantle Cell, Diffuse Large B-Cell, T-Cell, Natural Killer–Cell Lymphomas	
• Combination chemotherapy with localized radiation if needed • Aggressive combination chemotherapy for 3–8 cycles with local radiation if needed • Intrathecal chemotherapy if needed • Single agent or other combination treatment, depending on subtype and response (e.g., acalabrutinib, alemtuzumab, asparaginase, belinostat, bendamustine, bortezomib, brentuximab vedotin, gemcitabine, ibrutinib, lenalidomide, nivolumab, oxaliplatin, pembrolizumab, polatuzumab vedotin, romidepsin, venetoclax, vinorelbine, zanubrutinib) • HSCT (autologous or allogeneic) • Anti-CD19 CAR T-cell therapy	**CHOP** ± rituximab (see above) **ICE** ± rituximab: **i**fosfamide, **c**yclophosphamide, **e**toposide **R-EPOCH: r**ituximab, **e**toposide, **p**rednisone, vincristine (**O**ncovin), **c**yclophosphamide, doxorubicin **h**ydrochloride **ESHAP** ± **R: e**toposide, methylprednisolone (**S**olu-Medrol), **h**igh-dose cytarabine (**A**ra-C), cisplatin (**P**latinol), with or without **r**ituximab **Hyper-CVAD** ± **R:** hyperfractionated **c**yclophosphamide, **v**incristine, doxorubicin (**A**driamycin), **d**examethasone alternating with high-dose methotrexate and cytarabine with or without rituximab **DHAP** ± **R: d**examethasone, **h**igh-dose cytarabine (**A**ra-C), cisplatin (**P**latinol), with or without **r**ituximab
Highly Aggressive (e.g., Burkitt Lymphoma)	
• Aggressive combination chemotherapy for 3–8 cycles • HSCT	**R-EPOCH: r**ituximab, **e**toposide, **p**rednisone, vincristine (**O**ncovin), **c**yclophosphamide, doxorubicin **h**ydrochloride **Hyper-CVAD** ± **R** (see above) **CODOX-M: c**yclophosphamide, vincristine (**O**ncovin), **dox**orubicin, high-dose **m**ethotrexate, with or without rituximab (includes intrathecal methotrexate) **ICE** ± rituximab (see above)

[a]The acronym for some drug regimens use the trade name of chemotherapy drugs. In some cases, the trade name drug has been discontinued, and the drug currently used is the generic version.

Another therapy for some types of NHL is the monoclonal antibody ibritumomab tiuxetan (Zevalin). It contains a radioactive particle that can kill cancer cells. The therapy targets the CD20 antigen, which is on the surface of mature B cells and B-cell tumors. Targeting allows for the delivery of the radiation directly to the cancer cells. Side effects include pancytopenia. Use radiation precautions in caring for these patients. Teach patients about safety issues and how to minimize the risk for radiation exposure to staff and others.

In general, T-cell lymphomas are harder to cure. We treat them aggressively up front, often followed by an HSCT. Treatment of cutaneous T-cell lymphomas includes topical corticosteroids or topical chemotherapy for limited-stage disease. For more diffuse disease, treatment may include more aggressive combination therapies.[31]

The nursing care for NHL is similar to that for Hodgkin lymphoma. It is based on managing problems related to the disease (e.g., pain caused by the tumor, spinal cord compression, tumor lysis syndrome), pancytopenia, and other side effects of therapy. However, because NHL can be more extensive and involve specific organs (e.g., CNS, spleen, liver, GI tract, bone marrow), it is important to understand the subtype and extent of the disease. For example, a patient with colon involvement may have acute abdominal pain, guarding, and an enlarged abdomen. A patient with a Burkitt NHL beginning chemotherapy is at high risk for tumor lysis syndrome and needs frequent laboratory monitoring. See Chapter 16 for more on cancer therapies and their effects.

The patient undergoing external beam radiation therapy has special nursing needs. The skin in the radiation field needs special care. Concepts related to safety issues with radiation therapy are important to include in the plan of care (see Chapter 16).

Psychosocial considerations are important. Help the patient and family to understand the disease, treatment, and expected and potential side effects. Some aggressive treatments need close follow-up and even inpatient admission. Fertility issues may be of concern in young patients. As in Hodgkin lymphoma, evaluating patients with NHL for long-term effects of therapy is important because the delayed consequences of disease and treatment may not become apparent for many years.

MULTIPLE MYELOMA

Multiple myeloma, or *plasma cell myeloma,* is a condition in which cancerous plasma cells proliferate in the bone marrow and destroy bone. Multiple myeloma accounts for about 1.8%

of all cancers and 18% of hematologic cancers.[32] The disease is more common in men and in Blacks.[1,4] It generally occurs between the ages of 65 and 74 years old, with an average onset age of 69 years.[32] Most patients need therapy off and on during the course of the disease. About 10% of patients who undergo stem cell transplant may be cured.

Etiology and Pathophysiology

The cause of multiple myeloma is unknown. It is possible that exposure to organic chemicals (e.g., benzene), herbicides, and insecticides plays a role. Viral infections, such as HIV, may increase the risk.

The disease process involves excess production of plasma cells. Normal plasma cells are activated B cells, which make immunoglobulins (antibodies) that protect the body. In multiple myeloma, instead of a variety of plasma cells making antibodies to fight different infections, myeloma tumors make monoclonal antibodies. *Monoclonal* means they are all of 1 kind, making them ineffective and even harmful. Not only do they not fight infections, but they infiltrate the bone marrow. These monoclonal proteins (called *M proteins*) are made up of 2 light chains and 2 heavy chains. *Bence Jones proteins* are the light chain part of these monoclonal antibodies. They may show up in the urine in many patients with multiple myeloma.

The cancerous plasma cells build up in the bone marrow. They produce nuclear factor-κβ (NF- κβ) ligand (RANKL), which binds to RANK receptors on the osteoclast surface, causing activation and osteolytic lesions.[4] As myeloma protein increases, normal plasma cells are reduced. This further compromises the body's normal immune response. Proliferation of cancerous plasma cells and the overproduction of immunoglobulin and proteins may result in the end-organ effects of myeloma on the bone marrow, bone, and kidneys and possibly the spleen, lymph nodes, liver, and heart.

Clinical Manifestations

Multiple myeloma develops slowly and insidiously. The patient often does not have symptoms until the disease is advanced. Skeletal pain is the major manifestation. Pain in the pelvis, spine, and ribs is common and triggered by movement. Diffuse osteoporosis develops as the myeloma protein destroys bone. Osteolytic lesions occur in the skull, vertebrae, long bones, and ribs. Vertebral destruction can lead to vertebral collapse of vertebrae with spinal cord compression. Loss of bone integrity can lead to pathologic fractures.

Bony degeneration causes calcium loss from bones, eventually causing hypercalcemia. Hypercalcemia may cause renal, GI, or neurologic problems, such as polyuria, anorexia, confusion, and heart problems. A serum *hyperviscosity syndrome* leading to cerebral, lung, renal, and other organ dysfunction can occur in some patients. High protein levels caused by the myeloma protein can result in renal tubular obstruction, interstitial nephritis, and renal failure. The patient may have anemia, thrombocytopenia, neutropenia, and immune dysfunction from the replacement of normal bone marrow with plasma cells. Neurologic problems may be caused by regional myeloma cell growth compressing the spinal cord or cranial nerves or by perineuronal or perivascular deposition of the abnormal protein.[4]

Diagnostic Studies

Evaluating multiple myeloma involves laboratory, radiologic, and bone marrow examination. M protein is often found in the blood and urine. Possible findings include pancytopenia, hypercalcemia, Bence Jones protein in the urine, and a high serum creatinine. Bone marrow analysis shows significantly increased numbers of plasma cells in the bone marrow. Skeletal bone surveys, MRI, and/or PET and CT scans show distinct areas of destroyed bone; generalized thinning of the bones; or fractures, especially in the vertebrae, ribs, pelvis, and bones of the thigh and upper arms.

The simplest measure of staging and prognosis in multiple myeloma is based on blood levels of 2 markers: β_2-microglobulin and albumin. Higher levels of β_2-microglobulin and lower levels of albumin are associated with a poorer prognosis.[32] Cytogenetic studies of the bone marrow also play a role in prognostic stratification. For example, deletion of chromosome 17p13 is a high-risk (poor prognostic) feature.

❖ Interprofessional and Nursing Management

Interprofessional care involves managing both the disease and its symptoms. The current treatment options include corticosteroids, chemotherapy, immunotherapy, targeted therapy, and HSCT.[32] Multiple myeloma is seldom cured. Treatment can relieve symptoms, produce remission, and prolong life. Pain control of pain and preventing pathologic fractures are goals of management.

Zoledronic acid and denosumab inhibit bone breakdown. They are given for skeletal pain and hypercalcemia. They inhibit bone resorption without inhibiting bone formation and mineralization. A major focus of nursing care relates to patient safety due to the bone involvement and sequelae from bone breakdown. Because of the potential for pathologic fractures, use caution when moving and ambulating the patient. A slight twist or strain in the wrong area (e.g., a weak area in the patient's bones) may cause a fracture.

DRUG ALERT

Zoledronic Acid (Zometa)

- Make sure the patient is hydrated before giving drug.
- Renal toxicity may occur if IV infusion is given in less than 15 min.
- Patients should have a dental exam prior to first dose and ongoing monitoring for osteonecrosis of the jaw.

Kyphoplasty may be used to control spine vertebral disease. It is a minimally invasive procedure in which cement is injected to stabilize the vertebral compression.

Chemotherapy includes a corticosteroid plus 2 chemotherapy agents, such as bortezomib and lenalidomide or bortezomib and cyclophosphamide. The goal is to reduce the number of plasma cells. Initial treatment depends on whether the patient is a future stem cell transplant candidate and predicted tolerance of therapy. High-dose chemotherapy followed by HSCT has evolved as the standard of care in eligible patients.[32]

Immunotherapy and targeted therapy are options. Immunomodulator drugs (described in Chapter 16) include

thalidomide, lenalidomide, and pomalidomide. Proteosome inhibitors include bortezomib, carfilzomib, and ixazomib. Panobinostat is a drug that affects enzymes that promote cancer cell growth. Daratumumab is a monoclonal antibody against CD38, a protein found on the surface of myeloma cells.

Other drugs can treat some complications of multiple myeloma. For example, IV furosemide promotes renal excretion of calcium. Although tumor lysis is rare, once chemotherapy is started, allopurinol may be given to prevent any renal damage from uric acid accumulation (from cell breakdown). Because of the myeloma proteins, the patient is at risk for renal problems and electrolyte and fluid imbalances.

Ambulation and adequate hydration are used to treat hypercalcemia, dehydration, and potential renal damage. Weight bearing helps the bones resorb some calcium. Maintaining adequate hydration helps minimize problems from hypercalcemia and prevent protein precipitates from causing renal tubular obstruction. IV fluids are given to maintain a urine output of 1.5 to 2 L/day if the patient does not already have renal compromise.

In some patients, the levels of plasma proteins are so high that it causes a hyperviscosity of the blood leading to neurologic changes, renal insufficiency, and other problems related to lack of blood flow. In this instance, plasmapheresis is used.

As in any pain management situation, assess the patient and implement measures to control pain (see Chapter 9). Analgesics, such as NSAIDs, acetaminophen, or an acetaminophen/opioid combination, may be more effective than opioids alone in diminishing bone pain. Braces, especially for the spine, may help control pain. Peripheral neuropathy is common with several therapies for multiple myeloma. It contributes to discomfort, the inability to do basic activities of daily living, and the risk for injury from falling.

Patients are at risk for DVT related to chemotherapy and immobility and should receive preventive measures unless their platelet count is low.[32]

Assessment and prompt treatment of infection are important. Recurrent infections may be due to a decrease in the production of normal immunoglobulins, the ineffectiveness of the overproduced and abnormal immunoglobulins, corticosteroids, and/or neutropenia from bone marrow infiltration or side effects of treatment.

The patient's psychosocial needs require sensitive, skilled management. Help the patient and significant others adapt to changes fostered by chronic illness and adjust to the losses related to the disease process, while helping to maximize functioning and quality of life. The patient may have remissions and exacerbations. Patients may be on dialysis because of myeloma-induced renal failure. Acute care is needed at various times during the illness.

The final, acute phase is unresponsive to treatment and usually short in duration. Help the patient and family navigate needed resources, such as palliative or hospice care, social services, and spiritual care, as appropriate.

DISORDERS OF THE SPLEEN

Many illnesses can affect the spleen. Most can cause some degree of *splenomegaly* (enlarged spleen) (Table 34.31). However, an enlarged spleen may be present in some people without any evidence of disease. The term *hypersplenism* refers to the presence of splenomegaly and peripheral cytopenias (anemia, leukopenia, thrombocytopenia) with normal bone marrow. The degree of splenic enlargement varies with the disease. For example, massive splenic enlargement may occur with mononucleosis, chronic myelogenous leukemia, and thalassemia major. Mild splenic enlargement occurs with HF and SLE.

TABLE 34.31 Common Causes of Splenomegaly

Congestion
- Acquired hemolytic anemia
- Cirrhosis of the liver
- HF (portal hypertension)
- Portal or splenic vein thrombosis
- Sickle cell disease
- Thalassemia

Infections and Inflammation
- Autoimmune diseases: SLE, rheumatoid arthritis
- Bacterial infections: brucellosis, endocarditis, salmonella, syphilis, tuberculosis, typhoid fever
- Fungal infections: histoplasmosis, systemic candidiasis
- Parasitic infections: malaria, schistosomiasis, leishmaniasis
- Viral infections: cytomegalovirus, hepatitis, mononucleosis

Infiltrative Diseases and Tumors or Cysts
- Acute and chronic leukemia
- Amyloidosis
- Gaucher disease
- Lymphomas
- Polycythemia vera
- Other primary or secondary tumors and cysts
- Sarcoidosis

The normal spleen holds 350 mL of blood. It stores about one third of our platelet mass. When the spleen enlarges, its normal filtering and storage capacity increases. Consequently, there is often a reduction in the number of circulating blood cells as they engorge the spleen. In addition, there are unusual findings in the peripheral smear. These include abnormally shaped RBCs, Howell-Jolly bodies (a dark purple granule in the RBC), and siderotic granules (Pappenheimer bodies) clustering near the edge of the RBC.[1,4] These findings aid in diagnosing a malfunctioning spleen. A slight to moderate enlargement of the spleen is usually asymptomatic and found during routine abdominal assessment. While massive splenomegaly can be well tolerated, the patient may have abdominal discomfort and early satiety. Other ways we assess the size of the spleen include ultrasound, CT or PET scan, MRI, and liver/spleen nuclear scan.

Sometimes a splenectomy is part of the evaluation or treatment of splenomegaly. Another major reason for splenectomy is splenic rupture. The spleen may rupture from trauma; inadvertent tearing during another surgery; and diseases, such as mononucleosis, malaria, and lymphoid tumors. After a splenectomy, there can be a dramatic increase in peripheral RBC, WBC, and platelet counts.

BOX 34.6 ETHICAL/LEGAL DILEMMAS

Religious Beliefs

Situation

W.D., an 81-year-old woman with dementia, comes to the hospital from long-term care with lower gastrointestinal (GI) bleeding. During colonoscopy, the HCP cauterized the source of the bleed; however, her Hgb is 5.4 g/dL. Her family tells you that she is a Jehovah's Witness and must not receive blood products. If she does not have transfusions, her HCP is concerned she will have cardiopulmonary failure.

Ethical/Legal Points for Consideration

- Competent adults have the right to make health care decisions, including the right to refuse treatment, based on their religious beliefs.
- If the patient is determined to be incompetent and a guardian is appointed, the guardian has the legal right to make the consent or refusal.
- If the HCP believes that the treatment is essential to preserve life and health and there is no legal decision maker, a request is made for a legal determination of whether the patient is incapable of consent or refusal. If the judge agrees, the patient is made a ward of the court for this issue. Usually, the HCP is directed to make a decision based on the patient's best interests.

Discussion Questions

1. What resources do you have available to consult about religious practices?
2. How could you determine if the family were acting in W.D.'s best interest or their own?
3. What nonblood alternatives are available for Jehovah's Witnesses?

Nursing responsibilities for patients with spleen disorders vary depending on the problem. Splenomegaly may be painful. The patient may need analgesics; care in moving, turning, and positioning; and evaluation of lung expansion because spleen enlargement may impair diaphragmatic expansion. If anemia, thrombocytopenia, or leukopenia develops from splenic enlargement, institute nursing measures to support the patient and prevent life-threatening complications.

After a splenectomy, observe the patient for bleeding and shock. Immune deficiencies may develop, such as low IgG levels. Patients have a lifelong risk for infection, especially from encapsulated organisms, such as *Pneumococcus* species. Pneumococcal vaccination reduces this risk.

BLOOD COMPONENT THERAPY

Blood component therapy is often used to manage hematologic diseases. Many therapeutic and surgical procedures depend on blood product support. However, blood component therapy only temporarily supports the patient until the underlying problem is resolved. Because transfusions are not free from hazards, they should be used only if needed. Make sure that the HCP has discussed the risks, benefits, and alternatives with the patient and that this is recorded in the medical record (Box 34.6).

Traditionally, the term *blood transfusion* meant the administration of whole blood. Blood transfusion now has a broader meaning because of the ability to give specific components of blood, such as platelets, packed RBCs, or plasma. Usually, a specific component is ordered. Whole blood may be used in cases of massive bleeding, severe coagulopathy, or shock or in military settings (Table 34.32).[4]

Administration Procedure

In general, we use 18- to 20-gauge IV catheters to give blood components to adults. Smaller gauges, such as 25 gauge, may be used in neonates.[15] Larger sizes (e.g., 16 or 18 gauge) in adults may be preferred when giving rapid transfusions or if the infusion is sluggish. Smaller needles can be used for platelets, albumin, and clotting factor replacement. In emergencies when we cannot establish IV access, we may use the intraosseous route. [15] Verify the patency of the access before requesting the blood component from the blood bank. Most blood product administration tubing is of a "Y type" with a macroaggregate filter (170 to 260 μm; filters out particulate). One arm of the Y is for the isotonic saline solution, and the other arm of the Y for the blood product. You may use infusion pumps or syringes approved for blood administration by your agency. [15]

! SAFETY ALERT

Blood Transfusions

- Do not use dextrose solutions, lactated Ringer solution, or any other solution other than 0.9% sodium chloride for giving blood because they will cause RBC hemolysis.
- Exceptions to these restrictions may be appropriate, such as in trauma situations. These solutions include ABO-compatible plasma and 5% albumin. Follow agency policy.[15]
- Do not give any additives, including medications, in the same tubing as the blood unless you first clear the tubing with saline solution.

After obtaining the blood or blood components from the blood bank, make a positive identification of the blood product and recipient. Improper product-to-patient identification is the most common cause of hemolytic transfusion reactions. This places a great responsibility on nurses to conduct the identification procedure appropriately. Follow the procedures at your agency. Most have a dual-checking system with 2 licensed persons checking the patient identification with the labeled blood component and/or a bar-code scanning system. The blood bank does the typing and crossmatching the donor's blood with the recipient's blood. The result of any needed compatibility testing should be on the product bag or tag.

Table 34.33 outlines blood component compatibilities for transfusions. ABO compatibility is not a prerequisite for platelet transfusions. However, after multiple platelet transfusions, a patient may develop anti-HLA antibodies to the transfused platelets. With the use of lymphocyte typing to match HLA types of the donor and recipient, multiple platelet transfusions can be given with fewer complications to those who develop antibodies to platelets. The patient may be premedicated with an antihistamine and hydrocortisone to decrease the chance of reacting to platelet transfusions if there is a history of reactions.[15]

Take the patient's vital signs before beginning the transfusion so that you have a baseline in case an acute reaction occurs (Table 34.34). If the patient has abnormal vital signs (e.g., high fever), call the HCP to clarify if you should give the blood component. Start the blood as soon as you have it.

TABLE 34.32 Common Blood Products

Description	Special Considerations	Indications for Use
Albumin		
Prepared from plasma. Can be stored for 5 years. Available in 5% or 25% solution. Heat treated. Does not transmit viruses.	Albumin 25% expands the blood volume by ≈3.5 times, Hyperosmolar solution acts by moving water from extravascular to intravascular space.	Hypovolemic shock, hypoalbuminemia, after large-volume paracentesis, replacement in plasmapheresis.
Cryoprecipitates and Commercial Concentrates		
Prepared from fresh frozen plasma. 10–15 mL/bag. Can be stored for 1 year. Once thawed, must be used within 4–6 hr.	See also Table 34.18.	Replacement for fibrinogen deficiency, usually due to DIC, severe liver disease, or massive transfusion. Has other clotting factors, especially factor VIII, factor XIII, and von Willebrand factor.
Fresh Frozen Plasma		
Liquid part of whole blood is separated from cells and frozen. 1 unit is ≈250 mL. Rich in clotting factors but has no platelets. Can be stored for up to 1 year, depending on storage. Must be used within 24 hr after thawing.	Use in treating hemorrhagic shock is being replaced by pure preparations, such as albumin and plasma expanders.	Bleeding caused by deficiency in clotting factors (e.g., DIC, bleeding, massive transfusion, liver disease, vitamin K deficiency, excess warfarin).
Frozen RBCs		
Prepared from RBCs using glycerol for protection and frozen. Can be stored for up to 10 years.	Successive washings with saline solution remove most WBCs and plasma proteins.	Autotransfusion. Stockpiling or rare donors for patients with alloantibodies.
Packed RBCs		
Prepared from whole blood by sedimentation or centrifugation. 1 unit is 250–350 mL. Can be stored up to 42 days depending on processing (anticoagulants and preservatives).	Use of RBCs for treatment allows remaining components of blood (e.g., platelets, albumin, plasma) to be used for other purposes. Less risk of fluid overload. Preferred RBC source because they are more component specific. Leukocyte depletion (leukoreduction) by filtration, washing is frequently used. Decreases non-hemolytic febrile or mild allergic reactions in patients who receive frequent transfusions. Reduces transmission of viruses. Irradiation prevents graft-versus-host disease in immunocompromised patients.	Severe or symptomatic anemia, acute blood loss. 1 unit of RBCs can be expected to ↑ Hgb by 1 g/dL or Hct by 3% in a typical adult. 1 unit can replace a blood loss of 500 mL.
Platelets		
Prepared from fresh whole blood. An apheresed single donation is usually 200–400 mL in volume. May be pooled from multiple donors.	Can obtain multiple units from 1 donor by plateletpheresis. Can be kept at room temperature in the blood bank under gentle agitation for 1–5 days depending on type of collection and storage. For patients who receive frequent transfusions and become refractory, may give leukocyte reduced, HLA, or type specific to prevent alloimmunization to HLA antigens.	Bleeding caused by thrombocytopenia. May be contraindicated in TTP and HITT except in life-threatening hemorrhage. Average corrected count increment is 10×10^9/L. Failure to have an increase may be due to fever, sepsis, splenomegaly, or DIC or development of antibodies *(refractory)*.

TABLE 34.33 Blood Component Compatibilities for Transfusions

	DONOR PRODUCT			
Recipient's Type	**Packed Red Blood Cells**	**Plasma**	**Platelets**	**Cryoprecipitate**
O+	O+, O–	All groups	O, B, A, AB	Any group is safe to transfuse
O–	O–

A–	A–, O–			
B+	B+, B–, O+, O–	B, AB	B, AB, A, O	
B–	B–, O–			
AB+	All groups	Only AB	Any group	
AB–	AB–, B–, A–, O–			

TABLE 34.34 NURSING MANAGEMENT

Blood Transfusions

- Complete a baseline physical assessment as a basis to assess changes during and after the transfusion.
- Ensure that the IV line is appropriate and patent.
- Double-check patient identification and blood product identification data with another licensed nurse (consider state nurse practice act and agency policy).
- Adjust the transfusion rate according to the HCP orders and agency policy.
- Assess for signs of transfusion reactions.
- Delegate AP to take vital signs as directed.
- Evaluate for therapeutic effect of blood product (improvement in CBC, ↑ BP, ↓ bleeding).
- Monitor for circulatory overload (e.g., shortness of breath) if the transfusion is given rapidly.

Collaborate With Other Team Members

Blood Bank Personnel

- Perform type and crossmatch of the donor's blood with the recipient's blood.
- Note the result of the compatibility testing on the product bag or tag.
- When handing off the blood or blood component to nursing personnel, ensure that a positive identification is made with product and patient's information.
- Assist the HCP in evaluation of transfusion reactions.

Do not refrigerate it on the nursing unit. If you do not start the blood within 30 minutes, return it to the blood bank for storage. During the first 15 minutes or 50 mL of blood infusion, stay with the patient. Reactions are most likely to occur during this time. The infusion rate during this period should be no more than 2 mL/min. Do not infuse packed RBCs quickly except in an emergency. Rapid infusion of cold blood may cause the patient to become chilled. If rapid replacement of large amounts of blood is needed, you might use a blood-warming device. Other blood components, such as FFP and platelets, may be given over 15 to 30 minutes. Refer to your agency's policy and the HCPs orders.

After the first 15 minutes, retake vital signs to assess patient tolerance. The rate of the rest of the infusion is determined by the HCP's orders, the patient's clinical condition, and the product being infused. Observe the patient periodically throughout the transfusion (e.g., every 30 minutes) and up to 1 hour after the transfusion. Most patients not at risk of fluid overload can tolerate the infusion of 1 unit of packed RBCs over 2 hours. The transfusion should not take more than 4 hours to give because of the increased risk for bacterial growth in the product once it is out of refrigeration.

Blood Transfusion Reactions

A *blood transfusion reaction* is an adverse reaction to blood transfusion therapy. It can range in severity from mild symptoms to a life-threatening condition. Because reactions can be significant, perform a careful patient assessment. Common signs and symptoms are associated with more than 1 type of adverse reaction. We describe blood transfusion reactions as acute or delayed (Tables 34.35 and 34.36).[4,15] The HCP and blood bank HCPs are responsible for identifying the type of reaction. A transfusion reaction is a *serious reportable event* (SRE) and a *sentinel event* (see Chapter 1).

Acute Transfusion Reactions

The most common cause of hemolytic reactions is transfusion of ABO-incompatible blood (Table 34.35). This is an example of a type II cytotoxic hypersensitivity reaction (see Chapter 14). Severe hemolytic reactions are rare. Mislabeling specimens and giving blood to the wrong person cause most acute hemolytic reactions. This points to the importance of using proper patient identifiers when drawing blood samples and when giving medications and blood products.

! SAFETY ALERT

Transfusion Reaction

If a transfusion reaction occurs, take the following steps:

1. Stop the transfusion and stay with the patient.
2. Maintain a patent IV line with saline solution.
3. Notify the blood bank and the HCP.
4. Recheck identifying tags and numbers.
5. Monitor vital signs and urine output.
6. Treat symptoms per HCP order.
7. Save the blood bag and tubing and send them to the blood bank.
8. Collect required blood and other specimens as ordered to evaluate for the reaction.
9. Document according to agency policy.

Delayed Transfusion Reactions

Delayed transfusion reactions include delayed hemolytic reactions, infections, GVHD, and iron overload (Table 34.36).

CHECK YOUR PRACTICE

Your 82-year-old male patient with severe iron deficiency anemia is receiving his second unit of packed RBCs. He received the first transfusion without any problems. He is now reporting chills and feels like his heart is racing.

- What should you do?

Autotransfusion

Autotransfusion, or autologous transfusion, involves removing whole blood from a person and transfusing that blood back into the same person. This avoids problems of incompatibility, allergic reactions, and disease transmission. Methods of autotransfusion include:

- *Autologous donation* or *elective phlebotomy* (predeposit transfusion). A person donates blood before a planned surgery. The blood can be frozen and stored for up to 10 years. Usually, the blood is stored without being frozen and given to the person within a few weeks of donation. This technique is beneficial to the patient with a rare blood type or for any patient who may need limited blood product support during a major surgery (e.g., elective orthopedic surgery).
- *Autotransfusion.* A method for replacing blood volume that involves safely and aseptically collecting, filtering, and returning the patient's own blood lost during a major surgery or from a traumatic injury. Autotransfusion collection devices are most often used in surgery. Some allow blood to be automatically and continuously reinfused. Others require collecting the blood for a time (usually no longer than 4 hours) and then reinfusing it. Drainage after the first 24 hours or drainage that may contain pathogens is generally not reinfused. Anticoagulants may be added before reinfusion.

TABLE 34.35 Acute Transfusion Reactions

Cause	Manifestations	Management	Prevention
Acute Hemolytic Reaction			
Infusion of ABO-incompatible whole blood, RBCs, or components containing as little as 10 mL of RBCs. Antibodies in the recipient's plasma attach to antigens on transfused RBCs, causing RBC destruction.	Reactions usually develop in first 15 min. May occur up to 2 hr after. Fever with or without chills; back, abdominal, chest, or flank pain; infusion site pain, ↑ HR, dyspnea, tachypnea, ↓ BP, hemoglobinuria, acute jaundice, dark urine, bleeding, acute kidney injury, shock, cardiac arrest, DIC, death.	• Monitor and maintain BP with IV fluids as ordered. • Treat shock and DIC if present. • Draw blood samples for serologic testing slowly to avoid hemolysis from the procedure. Send other specimens as ordered. • Give diuretics as prescribed to maintain urine flow. • Insert indwelling urinary catheter or measure voided amounts to monitor hourly urine output. Dialysis may be needed if renal failure occurs. • Do not transfuse more RBC-containing components until blood bank has provided newly crossmatched units.	Verify and document patient identification from sample collection to component infusion (e.g., visually compare label on sample collection and blood component with patient identification).
Allergic Reaction (Mild)			
Sensitivity to foreign plasma proteins. More common in people with history of allergies.	Flushing, itching, hives.	• Give antihistamine, corticosteroid, epinephrine, as ordered. • If symptoms are mild and transient, transfusion may be restarted slowly with HCP's order. • Do not restart transfusion if fever or pulmonary symptoms develop.	Treat prophylactically with antihistamines or steroids. Consider washed RBCs and platelets.
Anaphylactic and Severe Allergic Reaction			
Sensitivity to donor plasma proteins. Infusion of IgA proteins to IgA-deficient recipient who has developed IgA antibody.	Anxiety, abdominal pain, hives, dyspnea, wheezing, progressing to bronchospasm, ↓ BP, shock, and possible cardiac arrest.	• Monitor VS frequently. • Start CPR, if indicated. • Administer O_2. • Have epinephrine ready for injection. • Antihistamines, corticosteroids, β_2-agonists may be given. • Do not restart transfusion.	Transfuse extensively washed RBC products from which all plasma has been removed. Use blood from IgA-deficient donor. Use autologous components.
Circulatory Overload Reaction			
Fluid given faster than the circulation can accommodate. People with cardiac or renal disease at risk.	Cough, dyspnea, pulmonary congestion, adventitious breath sounds, headache, hypertension, ↑ HR, distended neck veins.	• Monitor VS. • Place patient upright with feet in dependent position. • Obtain chest x-ray if ordered. • Administer prescribed diuretics, O_2.	Adjust transfusion volume and flow rate based on patient size and clinical status. Have blood bank divide future units into smaller aliquots for better spacing of fluid infused.
Febrile, Nonhemolytic Reaction			
Sensitization to donor WBCs (most common), platelets, or plasma proteins.	Sudden chills, rigors, and fever (rise in temperature of >1°C), headache, vomiting.	Give antipyretics as prescribed (acetaminophen). Do not restart transfusion unless HCP orders.	Consider leukocyte-reduced blood products. Give acetaminophen or diphenhydramine 30 min before transfusion.
Massive Blood Transfusion Reaction			
Can occur with replacement of 10 or more RBC units within 24 hr. RBC transfusions do not contain clotting factors, albumin, and platelets.	Hypothermia and dysrhythmias (from rapid infusion of large quantities of cold blood). Citrate toxicity and hypocalcemia (from the citrate, a storage solution). Hypocalcemia (citrate binds calcium). Hyperkalemia or hypokalemia.	Monitor the patient with frequent vital signs. Draw labs to monitor clotting status and electrolyte levels. Monitor ECG for changes from electrolyte problems	Use blood-warming equipment. Infuse 10% calcium gluconate as ordered. Adjust infusion rate as ordered. Because of dilution effect on coagulation due to massive RBC transfusion, platelets and plasma will also be given.

TABLE 34.35 Acute Transfusion Reactions—cont'd

Cause	Manifestations	Management	Prevention
Sepsis			
Transfusion of bacterially infected blood components.	Rapid onset of chills, rigors, fever, vomiting, diarrhea, marked ↓ BP, shock.	• Monitor VS. • Obtain culture of patient's blood. Other tests may be ordered to discern from a hemolytic reaction. • Treat septicemia as directed—antibiotics, IV fluids, vasopressors,	Collect, process, store, and transfuse blood products according to blood banking standards and complete the transfusion within 4 hr of starting time.
Transfusion-Related Acute Lung Injury (TRALI) Reaction			
Reaction between transfused antileukocyte antibodies and recipient's leukocytes, causing pulmonary inflammation and capillary leak.	Fever, chills, hypotension, tachypnea, frothy sputum, dyspnea, hypoxemia, respiratory failure. Noncardiogenic pulmonary edema. Leading cause of transfusion-related deaths. Arises within 1–6 hr of transfusion.	• Monitor VS frequently • Provide O_2 and administer corticosteroids as ordered. • Start CPR if needed and provide ventilatory and BP support if needed. • Draw blood for arterial blood gases and HLA or antileukocyte antibodies and other tests to discern from hemolysis or circulatory overload. • Obtain chest x-ray.	Provide leukocyte-reduced products. Blood bank personnel will identify donors who are implicated in TRALI reactions and will not allow them to donate.

TABLE 34.36 Delayed Transfusion Reactions

Manifestations	Prevention and Management
Delayed Hemolytic	
Fever, mild jaundice, ↓ hemoglobin. Occurs as early as 3 days or as late as several months posttransfusion as the result of destruction of transfused RBCs by alloantibodies not detected during crossmatch.	Monitor patients with supportive care. Hemolysis may be severe enough to warrant further transfusions with antigen-negative RBCs. Eculizumab may be beneficial.
Graft-Versus-Host Disease	
Rash, diarrhea, hepatitis, fever	Irradiation of blood products to reduce the risk of donor lymphocytes attacking an immunocompromised patient
Infection	
Specific product testing has greatly reduced the risk of infection Potential risk of infection includes: *Babesia* species (babesiosis), Creutzfeldt-Jakob disease ("mad cow disease"), Cytomegalovirus (CMV), dengue fever virus, hepatitis B and C, herpesvirus type 6 (HSV-6), HIV, human herpesvirus 8 (KS virus), Epstein-Barr virus (EBV), HTLV-I/II, malaria, *Trypanosoma cruzi* (Chagas' disease), West Nile virus, Zika virus,	Treatment based on the cause. Ways of detecting some infectious agents prior to product release are now used, such as surface antigen testing and nucleic acid tests for Babesia, hepatitis, HIV, HTLV, treponema pallidum, and *T. cruzi*. West Nile virus, and Zika virus, Donor screening is the only available method to reduce the risk for donor-contaminated blood for malaria and Creutzfeldt-Jakob disease. Leukocyte-reduced components or processing may reduce virus transmission. Patients may be monitored serologically (e.g., CMV titers after allogeneic stem cell transplant).
Iron Overload	
Excess iron is deposited in heart, liver, pancreas, and joints, causing dysfunction. HF, dysrhythmias, impaired thyroid and gonadal function, diabetes, arthritis, cirrhosis. Occurs in patients receiving ≥20 units for chronic anemia (e.g., sickle cell anemia, β-thalassemia) over time.	May be prevented by deferoxamine, which chelates and removes accumulated iron via the kidneys, given IV or subcutaneously. Deferasirox and deferiprone, oral agents that chelate iron, may be used. Phlebotomy may be used.

Case Study

Leukemia

(© Lisa F. Young/iStock.)

Patient Profile

A.J. is a 63-year-old woman who is brought to the ED by her husband (see the Chapter 33 case study). She has become progressively weaker and was admitted for further evaluation.

Subjective Data

- Progressive weakness over the last couple of weeks
- Had a recent sinus infection that resolved after 2 courses of antibiotics
- Reports periodic shortness of breath
- Has noticed a lot of bruising lately

Objective Data

Physical Assessment

- Scattered petechiae on both ankles and 2 bruises on her arms and 3 on her left lower leg
- Skin is very pale
- BP 100/70 (lying), 88/60 (standing), temperature 96.8°F (36°C), respiratory rate 26/min, apical pulse 110/min (lying), 124/min (standing), O_2 saturation 90% on room air

Laboratory Results

- Hct 18.2%
- Hgb 5.9 g/dL, WBC count 2600/μL (2.6×10^9/L)
- Platelet count 72,000/μL (72×10^9/L)
- Peripheral blood smear shows that 80% of the WBCs are blasts
- PT 18 s, aPTT 37 s
- LDH 560 units/L

Bone Marrow Biopsy

- Multiple myeloblasts (>50%)

Interprofessional Care

- Consultation with a hematologist-oncologist
- 2 units of packed red blood cells
- *Diagnosis:* acute myeloid leukemia (AML)

Discussion Questions

1. ***Recognize***: What laboratory and bone marrow biopsy results suggest AML?
2. ***Recognize***: How is AML treated?
3. ***Analyze***: What is A.J.'s prognosis?
4. ***Plan***: What life-threatening problems can with AML and its treatment? How can you anticipate and assess for these problems?
5. ***Prioritize:*** Based on the assessment data presented, what are the priority clinical problems?
6. ***Prioritize:*** What are the priority nursing interventions for A.J.?
7. ***Prioritize:*** What are the patient teaching priorities for an adult newly diagnosed with AML?
8. ***Act***: What interprofessional team members are likely to be involved in A.J.'s care?
9. ***Act:*** A.J. becomes fatigued after starting chemotherapy. She wants to know if she can still work and do household chores even if she is so fatigued. What is your best advice for her?
10. Develop a conceptual care map for A.J.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. In a severely anemic patient, the nurse would expect to find
   - **a.** cyanosis and hypertension.
   - **b.** pulmonary edema and fibrosis.
   - **c.** dyspnea and increased heart rate.
   - **d.** dysrhythmias and expiratory wheezing.
2. When obtaining assessment data from a patient with a microcytic, hypochromic anemia, the nurse would ask the patient about
   - **a.** folic acid intake.
   - **b.** diet intake of iron.
   - **c.** a history of gastric surgery.
   - **d.** a history of sickle cell anemia.
3. Nursing interventions for a patient with severe anemia from peptic ulcer disease include *(select all that apply)*
   - **a.** instructions for high-iron diet.
   - **b.** taking vital signs every 8 hours.
   - **c.** monitoring stools for occult blood.
   - **d.** teaching self-injection of erythropoietin.
   - **e.** administration of cobalamin (vitamin B_{12}) injections.
4. The nursing management of a patient in sickle cell crisis includes *(select all that apply)*
   - **a.** monitoring CBC.
   - **b.** optimal pain management and O_2 therapy.
   - **c.** blood transfusions if needed and iron chelation.
   - **d.** rest as needed and deep vein thrombosis prophylaxis.
   - **e.** administration of IV iron and diet high in iron content.
5. A complication of the hyperviscosity of polycythemia is
   - **a.** thrombosis.
   - **b.** cardiomyopathy.
   - **c.** pulmonary edema.
   - **d.** disseminated intravascular coagulation (DIC).
6. When caring for a patient with thrombocytopenia, the nurse instructs the patient to
   - **a.** dab their nose instead of blowing.
   - **b.** be careful when shaving with a safety razor.
   - **c.** continue with physical activities to stimulate thrombopoiesis.
   - **d.** avoid aspirin because it may mask the fever that occurs with thrombocytopenia.
7. The nurse would expect that a patient with von Willebrand disease undergoing surgery would be treated with administration of vWF and
   - **a.** thrombin.
   - **b.** factor VI.
   - **c.** factor VII.
   - **d.** factor VIII.

8. A patient with a head injury develops petechiae across the chest and abdomen and oozing from venipuncture sites. Which measures would the nurse include in the patient's care?
   a. Avoid other venipunctures.
   b. Apply dressings to the sites.
   c. Use an electric razor for shaving.
   d. Provide oral care with glycerin swabs.
   e. Administer warfarin sodium as ordered.
9. Priority nursing actions when caring for a hospitalized patient with a new-onset temperature of 102.2°F (39°C) and severe neutropenia include *(select all that apply)*
   a. starting the prescribed antibiotic STAT.
   b. drawing peripheral and central line blood cultures.
   c. ongoing monitoring of the patient's vital signs for septic shock.
   d. taking a full set of vital signs and notifying the physician immediately.
   e. administering transfusions of WBCs treated to decrease immunogenicity.
10. Because myelodysplastic syndrome arises from immature hematopoietic stem cells in the bone marrow, laboratory results the nurse would expect to find include a(n)
    a. excess of T cells.
    b. excess of platelets.
    c. deficiency of granulocytes.
    d. deficiency of all cellular blood components.
11. Which laboratory findings support the patient's new diagnosis of acute myelocytic leukemia?
    a. Increased WBC, RBC, and LDH
    b. Increased LDH and platelet count
    c. Decreased RBC, hemoglobin, and hematocrit
    d. Decreased RBC, presence of Philadelphia chromosome
12. Multiple drugs are often used in combination to treat leukemia and lymphoma because
    a. there are fewer toxic and side effects.
    b. the chance that 1 drug will be effective is increased.
    c. the drugs are more effective without causing side effects.
    d. the drugs work by different mechanisms to maximize killing of cancer cells.
13. The nurse is aware that a major difference between Hodgkin lymphoma and non-Hodgkin's lymphoma is that
    a. Hodgkin lymphoma occurs only in young adults.
    b. Hodgkin lymphoma is considered potentially curable.
    c. non-Hodgkin's lymphoma can manifest in multiple areas.
    d. non-Hodgkin's lymphoma is treated only with radiation therapy.
14. A patient with multiple myeloma becomes confused with an increased urine output. The laboratory finding that may explain these findings is:
    a. hyperkalemia.
    b. hyperuricemia.
    c. hypercalcemia.
    d. hypocalcemia.
15. When reviewing a patient's hematologic laboratory values after a splenectomy, the nurse would expect to find
    a. RBC abnormalities.
    b. increased WBC count.
    c. decreased hemoglobin.
    d. decreased platelet count.
16. Transfusion complications that can be decreased with leukocyte depletion or reduction of RBC transfusion are
    a. chills and hemolysis.
    b. leukostasis and neutrophilia.
    c. fluid overload and pulmonary edema.
    d. transmission of cytomegalovirus and fever.

1. c; 2. b; 3. a; 4. a, b, c, d; 5. a; 6. a; 7. d; 8. a, b, c; 9. a, b, c, d; 10. d; 11. c; 12. d; 13. c; 14. c; 15. b; 16. d.

Case Study

Applying Clinical Judgment With Multiple Patients

You are working on the oncology unit and have been assigned to care for the following 4 patients. You have 1 AP who is assigned to help you, and there are 2 other RNs on your clinical unit.

(© Lisa F. Young/iStock.)

A.J. is a 63-year-old woman admitted with severe anemia (Hgb 5.9 g/dL and Hct 18.2%) and acute myelocytic leukemia (AML). Her WBC count is 2600/μL, and platelet count is 72,000/μL. A.J. has dyspnea on exertion. She received 2 units of RBCs. Vital signs: 102/60, 100, RR 22, temp 96.8°F (36°C), O_2 saturation 94% with O_2 2 L/min via nasal cannula. She starts chemotherapy tomorrow.

(© g-stockstudio/iStock/Thinkstock.)

J.J. is a 52-year-old white man newly diagnosed with acute lymphocytic leukemia (ALL). Laboratory results reveal Hgb 6.9 g/dL, Hct 20%, WBC count 120,000/μL (120×10^9/L), and platelet count 9,000/μL (25×10^9/L). Vital signs: 100/70, 110, RR 26, temperature 102.2°F (39°C). He is having a port placed today after he receives platelet transfusions.

(© Studio Grand Ouest/iStock/Thinkstock.)

P.H. is a 45-year-old woman who is receiving chemotherapy for ovarian cancer. She was admitted with fever and chills. Her WBC count is 2200/μL (2.2×10^9/L), with an absolute neutrophil count (ANC) of 400/μL (0.4×10^9/L). She will begin IV antibiotic therapy. Vital signs: 118/60, 98, RR 20, temperature 99.2°F (37.3°C).

(© Ridofranz/iStock.)

G.L. is a 67-year-old man who came to the ED yesterday with abdominal pain. A CT scan of the abdomen showed several lymphatic masses. The HCP suspects non-Hodgkin lymphoma and admits him for a diagnostic workup. He currently rates his pain as a 3 on a scale of 0 to 10.

1. Highlight all the findings above that require your follow-up.
2. After receiving report, which patient should you see first?
3. Which tasks could you delegate to the AP *(select all that apply)*?

Case Study—cont'd

a. Assist A.J. to a chair after completing her AM care.
b. Obtain the first unit of platelets for J.J. from the blood bank.
c. Explain the importance of isolation to P.H. and her family.
d. Ask A.J. why she has not received regular medical care for 5 years.
e. Assess G.L. for other clinical manifestations of non-Hodgkin lymphoma.

4. When you enter J.J.'s room, you find him somewhat confused and lethargic. His family states he had just had a severe coughing episode.

Use an X for the following nursing actions that are Indicated (appropriate or necessary), Contraindicated (could be harmful), or Nonessential (makes no difference or not necessary) for J.J. at this time.

Nursing Action	Indicated	Contraindicated	Nonessential
Perform a focused neurologic assessment.			
Direct the AP to stay with J.J. while you contact the HCP.			
Ask family members for a copy of his living will.			
Call respiratory therapy to give him a breathing treatment.			
Place him flat, in a side-lying position.			
Obtain vital signs with O_2 saturation.			
Initiate NPO status.			

Case Study Progression

J.J.'s HCP orders a repeat CBC and an emergency CT scan of the head. Your supervisor arranges for another RN to accompany J.J. to the CT scan while you prepare to administer his platelets.

5. Based on P.H.'s condition, the priority need will be prevention of _____**1**_____. To reduce this risk, the most important intervention is to _____**2**_____.

Options for 1	Options for 2
Bleeding	encourage ambulation as tolerated
Infection	initiate bleeding precautions
VTE	perform hand hygiene
	wear a mask in the patient's room

6. While waiting for J.J.'s platelets, you complete A.J.'s assessment and begin to develop her plan of care. Indicate which nursing action listed in the far-left column is appropriate for each potential complication. Note that not all actions will be used.

Nursing Action	Complication	Appropriate Nursing Action for Each Complication
a. Implement neutropenic precautions	Anemia	
b. Administer ferrous sulfate 325 mg TID.	Dehydration	
c. Provide a nutrition supplement with each meal.	Fatigue	
d. Administer O_2 therapy.	Inadequate tissue perfusion	
e. Initiate daily weights.	Infection	
f. Reposition every 2 hours while in bed.		
g. Alternate rest and activity periods.		
h. Monitor laboratory results as available.		

7. An RN from the float pool arrives to accompany J.J. to CT scan at the same time the AP arrives with the platelets. Which intervention would be *most* appropriate?
   a. Put the unit platelets in the refrigerator to start when J.J. returns to the floor.
   b. Ask the RN to verify the correct unit of platelets with you and start the infusion.
   c. Give the RN an SBAR report and ask her to start the platelets on the way to CT scan.
   d. Ask the RN if she would prefer to give the platelets or hold it for J.J.'s return to the unit.
8. G.L. asks you to explain the diagnostic testing he can expect to undergo related to the suspected lymphoma. Which tests will you explain to him? *(select all that apply)*
   a. PET scan
   b. Bone marrow biopsy
   c. Peripheral blood smear
   d. Excisional lymph node biopsy
   e. Lymphangiography of internal lymph nodes
9. The HCP orders ferrous sulfate 325 mg TID for A.J. You teach A.J. to take her iron *(select all that apply)*
   a. at breakfast time in the morning.
   b. with orange juice to increase absorption.
   c. 1 hour before meals to facilitate absorption.
   d. 2 hours after eating to minimize side effects.
   e. whenever she feels tired or is short of breath with activity.

Assessment: Cardiovascular System

Debra Hagler and Diana Rabbani Hagler

http://evolve.elsevier.com/Lewis/medsurg/

CONCEPTUAL FOCUS

Health Promotion
Nutrition
Perfusion

LEARNING OUTCOMES

1. Discern the anatomic location and function of the pericardial layers, atria, ventricles, and valves.
2. Relate the coronary circulation to the areas of heart muscle supplied by the major coronary arteries.
3. Distinguish the structure and function of arteries, veins, capillaries, and endothelium.
4. Describe the mechanisms involved in the regulation of blood pressure.
5. Relate the various waveforms on a normal electrocardiogram to the associated cardiac events.
6. Obtain significant subjective and objective assessment data related to the cardiovascular system from a patient and/or caregiver.
7. Perform a physical assessment of the cardiovascular system using the appropriate techniques.
8. Distinguish normal from abnormal findings of a physical assessment of the cardiovascular system.
9. Link the age-related changes of the cardiovascular system to the differences in assessment findings.
10. Apply the principles of hemodynamic monitoring to the nursing and interprofessional management of patients.
11. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the cardiovascular system.

KEY TERMS

action potential
afterload

STRUCTURES AND FUNCTIONS OF CARDIOVASCULAR SYSTEM

Heart

Structure

The heart is a 4-chambered hollow muscular organ normally about the size of a fist. It lies within the thorax, in the mediastinal space that separates the right and left pleural cavities. The heart is composed of 3 layers: a thin inner lining, the *endocardium;* a layer of muscle, the *myocardium;* and an outer layer, the *epicardium.* A fibroserous sac called the *pericardium* covers the heart. The pericardium consists of 2 layers: the inner *(visceral)* layer (part of the epicardium) and the outer *(parietal)* layer. A small amount of pericardial fluid (around 10 to 15 mL) lubricates the space between the pericardial layers *(pericardial space)* and prevents friction between the surfaces as the heart contracts.

The septum vertically divides the heart. The interatrial septum creates a right and left atrium. The interventricular septum creates a right and left ventricle. The wall thickness of each heart chamber is different. The atrial myocardium is thinner than that of the ventricles. The left ventricular wall is 2 to 3 times thicker than the right ventricular wall. The thickness of the left ventricle is needed for the strength to pump the blood into the systemic circulation.[1]

Blood Flow Through Heart

Fig. 35.1 shows the blood flow through the heart.

Heart valves. The 4 valves of the heart keep blood flowing in a forward direction. The cusps of the mitral and tricuspid valves are attached to thin strands of fibrous tissue called *chordae tendineae* (Fig. 35.2). Chordae are anchored in the papillary muscles of the ventricles. This support prevents the eversion of the valve leaflets into the atria during ventricular contraction. The pulmonic and aortic valves (also known as *semilunar valves*) prevent blood from regurgitating back into the ventricles at the end of each ventricular contraction.

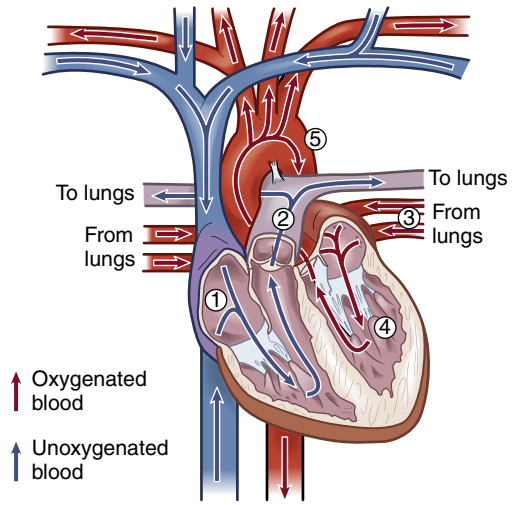

Fig. 35.1 Diagram of blood flow through the heart. *Arrows* show direction of flow. *1,* The right atrium receives venous blood from the inferior and superior venae cava and the coronary sinus. The blood then passes through the tricuspid valve into the right ventricle. *2,* With each contraction, the right ventricle pumps blood through the pulmonic valve into the pulmonary artery and to the lungs. *3,* Oxygenated blood flows from the lungs to the left atrium by way of the pulmonary veins. *4,* It then passes through the mitral valve and into the left ventricle. *5,* As the heart contracts, blood is ejected through the aortic valve into the aorta and enters the systemic circulation.

Blood Supply to Myocardium

The myocardium has its own blood supply, the *coronary circulation* (Fig. 35.3). Blood flow into the 2 major coronary arteries occurs primarily during **diastole** (relaxation of the myocardium). The left coronary artery arises from the aorta and divides into 2 main branches: the left anterior descending artery and left circumflex artery. These arteries supply the left atrium, left ventricle, interventricular septum, and part of the right ventricle. The right coronary artery also arises from the aorta, and its branches supply the right atrium, right ventricle, and part of the posterior wall of the left ventricle. In 90% of people, the atrioventricular (AV) node and the bundle of His receive blood supply from the right coronary artery. For this reason, blockage of this artery often causes serious defects in cardiac conduction.

The divisions of coronary veins parallel the coronary arteries. Most of the blood from the coronary system drains into the coronary sinus (a large channel). It empties into the right atrium, near the entrance of the inferior vena cava.[1]

Conduction System

The conduction system consists of specialized tissue that creates and transports the electrical impulse, or **action potential**. This impulse starts depolarization of the heart cells, leading to heart muscle contraction (Fig. 35.4A). The electrical impulse normally begins in the sinoatrial (SA) node (pacemaker of the heart). Impulses from the SA node travel through interatrial pathways to depolarize the atria, resulting in a contraction.

The electrical impulse travels from the atria to the AV node through internodal pathways. The signal then moves through the bundle of His and the left and right bundle branches. The left bundle branch has 2 divisions: anterior and posterior. The

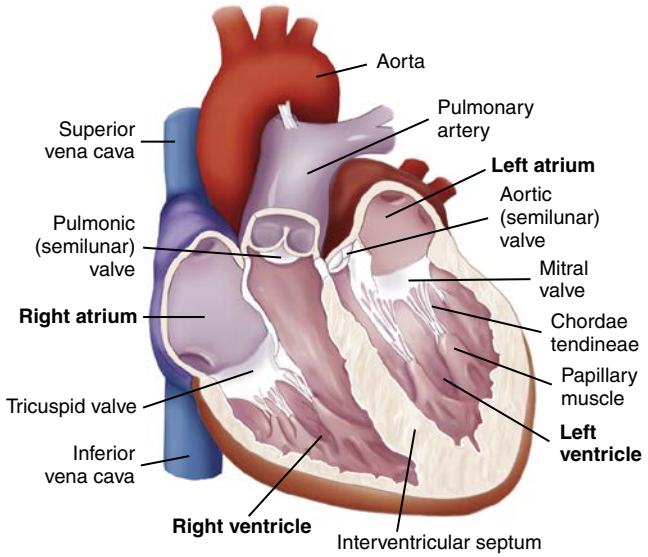

Fig. 35.2 Anatomic structures of the heart and heart valves.

action potential moves through the walls of both ventricles via *Purkinje fibers*. The ventricular conduction system delivers the impulse within 0.12 second. This triggers a synchronized right and left ventricular contraction and ejection of blood into the pulmonary and systemic circulations.

Last, repolarization occurs when the contractile and conduction pathway cells regain their resting polarized condition. Heart muscle cells have a compensatory mechanism that makes them unresponsive or *refractory* to restimulation during the action potential. During ventricular contraction, there is an *absolute refractory period* when heart muscle does not respond to any new stimuli. After this period, heart muscle gradually recovers its excitability, and a *relative refractory period* occurs by early diastole.[2]

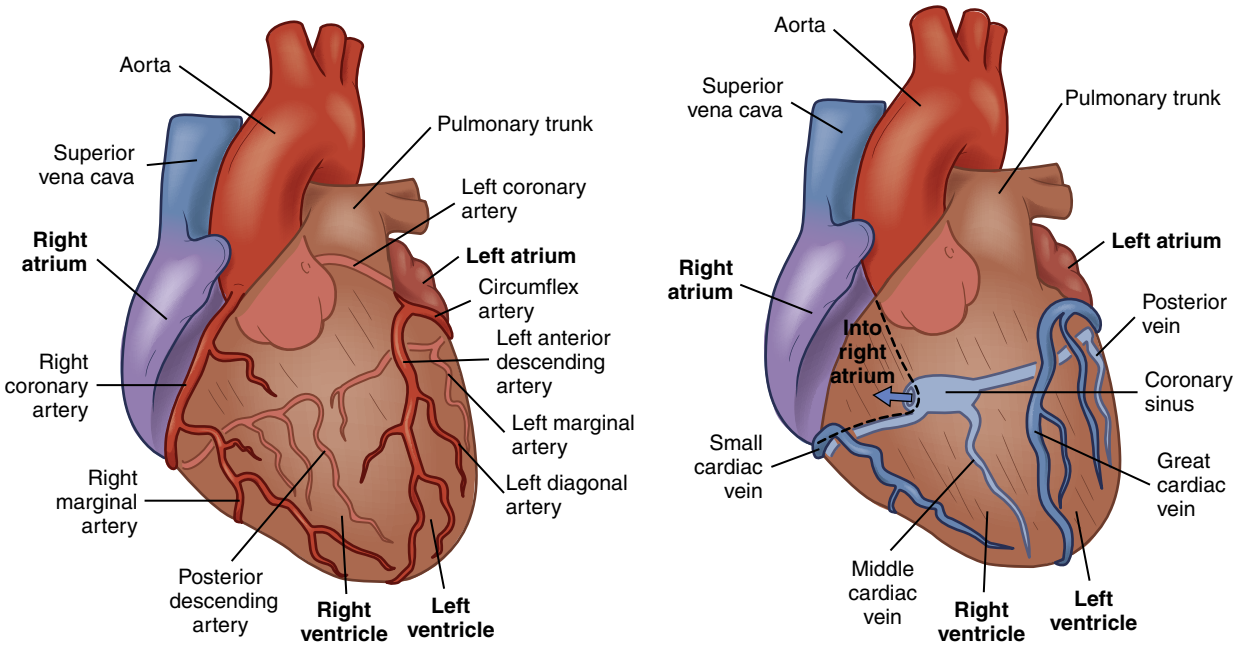

Fig. 35.3 Coronary arteries and veins.

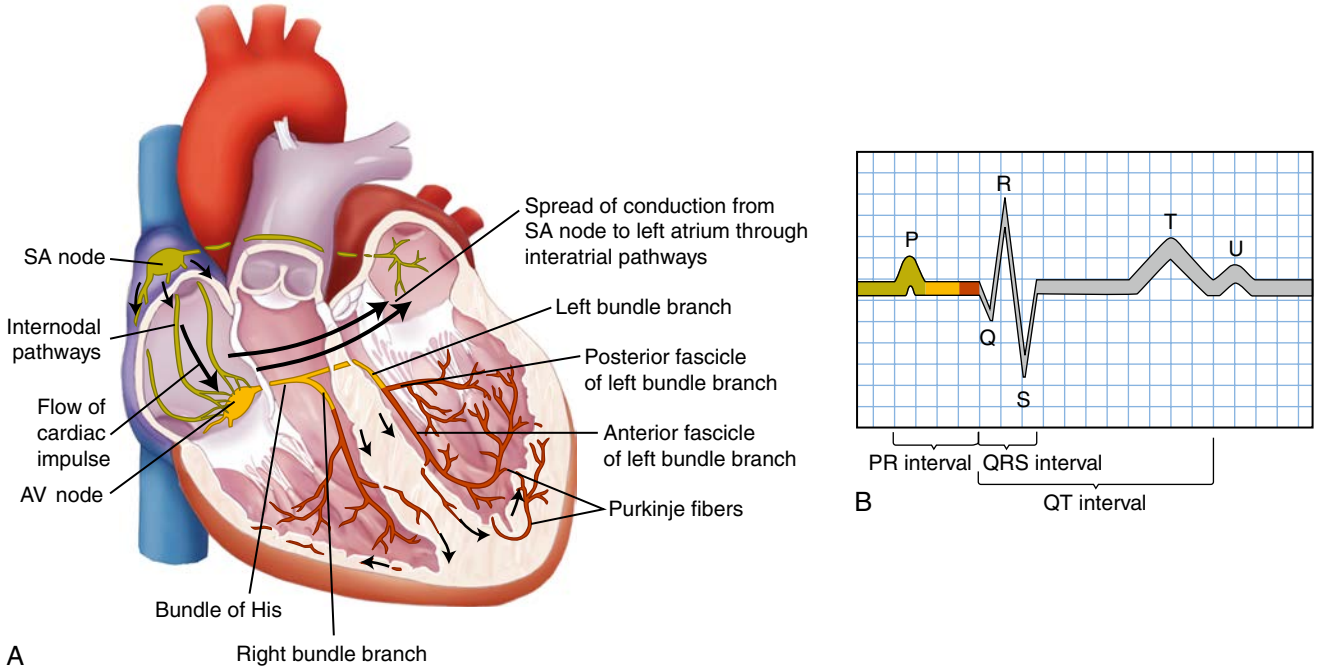

Fig. 35.4 (A) Conduction system of the heart. *AV,* Atrioventricular; *SA,* sinoatrial. (B) The normal ECG pattern. The *P* wave represents depolarization of the atria. The *QRS* complex indicates depolarization of the ventricles. The *T* wave represents repolarization of the ventricles. The *U* wave, if present, may represent repolarization of the Purkinje fibers or be associated with hypokalemia. The PR, QRS, and QT intervals reflect the time it takes for the impulse to travel from one area of the heart to another.

Electrocardiogram. The electrical activity of the heart can be detected using electrodes and recorded on an electrocardiogram (ECG). We use the letters *P, QRS, T,* and *U* to name the separate waveforms (Fig. 35.4B). The first waveform, the P wave, begins with the firing of the SA node. It represents depolarization of the atria. The QRS complex represents depolarization from the AV node throughout the ventricles. A delay of impulse transmission through the AV node accounts for the time between the beginning of the P wave and the beginning of the QRS wave. The T wave represents repolarization of the ventricles. The U wave, if seen, may represent repolarization of the Purkinje fibers. A large U wave may occur with hypokalemia.

Intervals between these waves (PR, QRS, and QT intervals) reflect the time it takes for the signal to travel from 1 area of the heart to another. Changes in the timing often indicates a pathologic condition.[3] See Chapter 39 for a complete discussion of ECG monitoring.

Mechanical System

Depolarization triggers mechanical activity. **Systole**, contraction of the heart muscle, results in ejection of blood from the ventricles. Relaxation of the heart muscle, *diastole*, allows for filling of the ventricles. **Cardiac output (CO)** is the amount of blood pumped by each ventricle in 1 minute. Calculate CO by multiplying the amount of blood ejected from the ventricle with each heartbeat: *stroke volume* (SV) times heart rate (HR) per minute:

$$CO = SV \times HR$$

For the normal adult at rest, CO is maintained in the range of 4 to 8 L/min.

Factors affecting cardiac output. Many factors can affect either the HR or SV and thus the CO. HR is controlled primarily by the autonomic nervous system. It can reach as high as 180 beats/min for short periods without harmful effects. With rapid HRs, there is less time for diastolic filling and perfusion of the coronary arteries. The factors affecting the SV are preload, contractility, and afterload. Increasing preload, contractility, and afterload increases the workload of the heart muscle, resulting in increased O_2 demand.

The Frank-Starling law states that, to a point, the more the myocardial fibers are stretched, the greater their force of contraction. The volume of blood stretching the ventricles at the end of diastole, before the next contraction, is called **preload**. Preload can be increased by conditions such as hypertension, aortic valve disease, and hypervolemia. Preload is decreased when a rapid HR or hypovolemia reduces ventricular filling during diastole. Contractility can be increased by epinephrine and norepinephrine released by the sympathetic nervous system. Increasing contractility raises the SV by increasing ventricular emptying.[1]

Afterload is the peripheral resistance against which the left ventricle must pump. Afterload depends on the size of the ventricle, wall tension, and arterial BP. If the arterial BP is elevated, the ventricles meet increased resistance to ejection of blood, increasing the work demand. Eventually this results in *ventricular hypertrophy,* an enlargement of the heart muscle without an increase in CO or the size of chambers. Both right and left ventricles work against resistance. The right ventricle pumps against the afterload of pulmonary arterial resistance.[2]

Cardiac Reserve

The cardiovascular system must respond to many situations in health and illness (e.g., exercise, stress, hypovolemia). The ability to respond to these demands by maintaining or increasing CO is the **cardiac reserve**.

Vascular System

Blood Vessels

The 3 major types of blood vessels are the arteries, veins, and capillaries. Arteries, except for the pulmonary artery (PA), carry oxygenated blood away from the heart. Veins, except for the pulmonary veins, carry deoxygenated blood toward the heart. Small branches of arteries and veins are arterioles and venules, respectively. Blood circulates from the left side of the heart into arteries, arterioles, capillaries, venules, and veins and then back to the right side of the heart.

Arteries and arterioles. The arterial system differs from the venous system by the amount and type of tissue that make up arterial walls (Fig. 35.5). The large arteries have thick walls composed mainly of elastic tissue. This elastic property cushions the impact of the pressure from ventricular contraction and provides recoil that propels blood forward into the circulation. Large arteries contain some smooth muscle. Examples of large arteries are the aorta and PA.

Arterioles have more smooth muscle and little elastic tissue. Arterioles control arterial BP and distribution of blood flow. They respond readily to local conditions such as low O_2 and increasing levels of carbon dioxide (CO_2) by dilating or constricting.

The innermost lining of the arteries is the endothelium. The endothelium maintains hemostasis, promotes blood flow, and, under normal conditions, inhibits blood coagulation. When the endothelial surface is disrupted (e.g., rupture of an

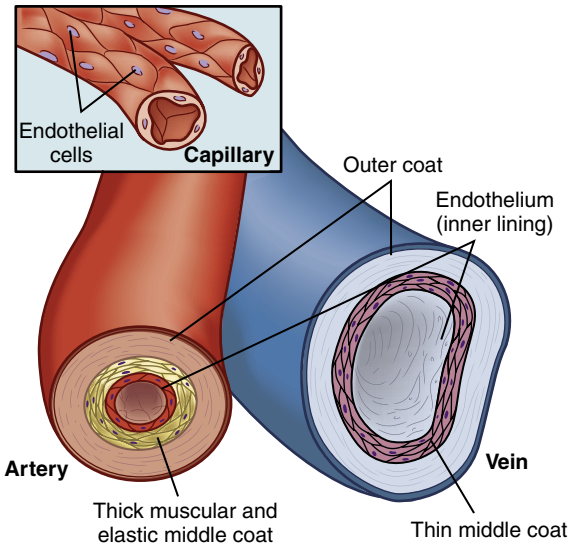

Fig. 35.5 Comparative thickness of layers of the artery, vein, and capillary.

atherosclerotic plaque), the coagulation cascade results in the formation of a fibrin clot.

Capillaries. The thin capillary wall made up of endothelial cells has no elastic or muscle tissue (Fig. 35.5). Exchange of cellular nutrients and metabolic end products takes place through these thin-walled vessels. Capillaries connect the arterioles and venules.

Veins and venules. Venules are small vessels with a minor amount of muscle and connective tissue. Venules collect blood from the capillary beds and channel it to the larger veins.

Veins are large-diameter, thin-walled vessels that return blood to the right atrium (Fig. 35.5). The venous system is a low-pressure, high-volume system. The larger veins have semilunar valves at intervals to maintain the blood flow toward the heart and to prevent backward flow. Several factors affect the amount of blood in the venous system. These include arterial flow, compression of veins by skeletal muscles, changes in thoracic and abdominal pressures, and right atrial pressure.

The largest veins are the *superior vena cava,* which returns blood to the heart from the head, neck, and arms, and the *inferior vena cava.* It returns blood to the heart from the lower part of the body. Pressure in the right side of the heart affects these large vessels. Elevated right atrial pressure can cause distended neck veins or liver engorgement because of resistance to blood flow.[1]

Regulation of Cardiovascular System

Autonomic Nervous System

The autonomic nervous system consists of the sympathetic nervous system and parasympathetic nervous system (see Chapter 60).

Effect on heart. Stimulation of the sympathetic nervous system increases the HR, speed of impulse conduction through the AV node, and force of atrial and ventricular contractions. This effect is mediated by specific sites in the heart called *beta (β)-adrenergic receptors*. They are receptors for norepinephrine and epinephrine.

In contrast, stimulation of the parasympathetic system (mediated by the vagus nerve) slows the HR by decreasing the impulses from the SA node and conduction through the AV node.

Effect on blood vessels. The source of neural control of blood vessels is the sympathetic nervous system. Alpha$_1$ (α_1)-adrenergic receptors are found in vascular smooth muscles. Stimulation of α_1-adrenergic receptors results in vasoconstriction. Decreased stimulation to α_1-adrenergic receptors causes vasodilation. Sympathetic nervous system receptors that influence BP are described in Table 36.1.

Baroreceptors

Baroreceptors in the aortic arch and carotid sinus (at the origin of the internal carotid artery) are sensitive to stretch or pressure within the arterial system. Stimulation of these receptors (e.g., volume overload) sends information to the vasomotor center in the brainstem. This results in temporary inhibition of the sympathetic nervous system and enhancement of the parasympathetic influence. The result is a decreased HR and peripheral vasodilation. Decreased arterial pressure has the opposite effect.

Chemoreceptors

Chemoreceptors are found in the aortic and carotid bodies and the medulla. They can cause changes in respiratory rate and BP in response to increased arterial CO_2 pressure (hypercapnia) and, to less degree, decreased plasma pH (acidosis) and arterial O_2 pressure (hypoxia). Chemoreceptors in the medulla stimulate the vasomotor center to increase BP.[2]

Blood Pressure

The **arterial blood pressure** is a measure of the force exerted by blood against the walls of the arterial system. The **systolic blood pressure (SBP)** is the peak pressure exerted against the arteries when the heart contracts. The **diastolic blood pressure (DBP)** is the residual pressure in the arterial system during ventricular relaxation (or filling).

The main factors influencing BP are CO and *systemic vascular resistance* (SVR):

$$BP = CO \times SVR$$

SVR is the force opposing the movement of blood. This force is created primarily in small arteries and arterioles. Normal BP is SBP less than 120 mm Hg and DBP less than 80 mm Hg (see Chapter 36).[4]

Measurement of Arterial Blood Pressure

We can measure BP with invasive or noninvasive techniques. The invasive technique consists of catheter insertion into an artery. The catheter is attached to a transducer, and the pressure is measured directly. Invasive arterial BP monitoring is discussed later in this chapter.

Noninvasive, indirect measurement of BP is done with a sphygmomanometer and stethoscope. The sphygmomanometer consists of an inflatable cuff and a pressure gauge. We measure BP by auscultating for sounds of turbulent blood flow through a compressed artery (termed **Korotkoff sounds**). The brachial artery is the recommended site for taking a BP.

After placing the right sized cuff on the upper arm, inflate the cuff to a pressure 20 to 30 mm Hg above the patient's usual SBP. This stops blood flow in the artery. If the SBP is not known, estimate the pressure by palpating the brachial pulse and inflating the cuff until the pulse ceases. The pressure noted at this time is the estimated SBP. Inflate the BP cuff 20 to 30 mm Hg above this number.

As you lower the pressure in the cuff, listen over the brachial artery for Korotkoff sounds. There are 5 phases of Korotkoff sounds. The first phase is a tapping sound caused by the spurt of blood into the constricted artery as the pressure in the cuff is gradually deflated. This sound is the SBP. The fifth phase occurs when the sound disappears, which is the DBP.

BP is recorded as the ratio of SBP to DBP (e.g., 120/80 mm Hg). Sometimes, an *auscultatory gap* occurs, which is a loss of

sound between the SBP and DBP. Proper BP technique, such as using the correct cuff and positioning arm at heart level, is essential for correct readings (see Table 36.11).

Another noninvasive way to measure BP indirectly is with an automated device that uses oscillometric measurements to assess BP. Although this method does not involve auscultation, attention to proper technique is essential for accuracy.

We can assess SBP and pulse using a Doppler ultrasonic flowmeter. The hand-held transducer is positioned over the artery (identified by audible, pulsatile sounds). The cuff is applied above the artery, inflated until the sounds disappear, and then inflated another 20 to 30 mm Hg beyond that point. The cuff is then slowly deflated. The point where sounds return is the SBP.[4]

Pulse Pressure and Mean Arterial Pressure

Pulse pressure is the difference between the SBP and DBP. It is normally about one-third of the SBP. If the BP is 120/80 mm Hg, the pulse pressure is 40 mm Hg. An increased pulse pressure and SBP may occur when a person exercises or has atherosclerosis of the larger arteries. A decreased pulse pressure may occur with heart failure (HF) or hypovolemia.

Another measurement related to BP is **mean arterial pressure (MAP)**. The MAP refers to the average pressure within the arterial system. It is not the average of the DBP and SBP, because the length of diastole is about twice that of systole at normal HRs. MAP is calculated as follows:

$$MAP = (SBP + 2\ DBP) \div 3$$

A person with a BP of 120/60 mm Hg has an estimated MAP of 80 mm Hg. The MAP must be greater than 60 mm Hg to perfuse the vital organs under most conditions. When the MAP is low for a period of time, vital organs become ischemic.

Gerontologic Considerations: Effects of Aging on the Cardiovascular System

One of the greatest risk factors for cardiovascular disease (CVD) is age. CVD is the leading cause of death in adults older than age 65. The most common problem is coronary artery disease (CAD) due to atherosclerosis. Many of the changes in the cardiovascular system of older adults are a result of the combined effects of the aging process, disease, environmental factors, and lifetime health behaviors.

Age-related changes in the cardiovascular system and differences in assessment findings are found in Table 35.1. With increased age, collagen in the heart increases and elastin decreases. These changes affect the heart muscle's ability to stretch and contract. The older adult has a decreased cardiovascular response to physical and emotional stress and is less sensitive to β-adrenergic agonist drugs. Exercise results in a much smaller increase in CO for older adults than for younger adults.[5]

Heart valves thicken and stiffen from lipid accumulation, collagen degeneration, and fibrosis. The aortic and mitral valves are most often affected. These changes result in either regurgitation of blood when the valve should be closed or narrowing of the orifice of the valve *(stenosis)* when the valve should be open. Turbulent blood flow across the affected valve is heard as a whooshing sound or **murmur** between heartbeats.

The number of pacemaker cells in the SA node and conduction cells in the internodal tracts, bundle of His, and bundle branches decreases with age. The decrease contributes to the development of sinus and atrial dysrhythmias and heart blocks. Many older adults have an abnormal resting ECG that shows increases in the PR and/or QT intervals.[6] The number and function of β-adrenergic receptors in the heart decrease with age.[7]

With age, arteries and veins thicken and become less elastic. Arteries become more sensitive to vasopressin (antidiuretic hormone). Both changes increase SBP and pulse pressure with a decreased or unchanged DBP. Valves in the large leg veins return the blood to the heart less effectively, often resulting in dependent edema.

When an older adult changes position (e.g., sits upright), the sympathetic nerve pathway produces a blunted (reduced) HR response, which may lead to a drop in BP and sense of lightheadedness on arising (orthostatic hypotension). *Postprandial hypotension* (decrease in BP of at least 20 mm Hg that occurs within 75 minutes after eating) may occur in otherwise healthy older adults. Both orthostatic and postprandial hypotension may increase fall risk in older adults.

TABLE 35.1 GERONTOLOGIC ASSESSMENT DIFFERENCES

Cardiovascular System

Changes	Differences in Assessment Findings
Chest Wall	
Kyphosis	Altered chest landmarks for palpation, percussion, and auscultation. Distant heart sounds
Heart	
Myocardial hypertrophy, ↑ collagen and scarring, ↓ elastin	↓ Cardiac reserve, HF. S_4 may be present
Downward displacement	Difficulty in isolating apical pulse.
↓ CO, HR, SV in response to exercise or stress	↓ Response to exercise and stress. Slowed recovery from activity
Cellular aging and fibrosis of conduction system	↓ Amplitude of QRS complex and slight lengthening of PR, QRS, and QT intervals. Irregular rhythms, ↓ maximal HR, ↓ HR variability
Valvular rigidity from calcification, sclerosis, or fibrosis, impeding complete closure of valves	Systolic murmur (aortic or mitral) possible without a sign of cardiovascular disease
Blood Vessels	
Arterial stiffening caused by loss of elastin in arterial walls, thickening of intima of arteries, and progressive fibrosis of media	↑ In SBP and possible ↑ or ↓ in DBP. Possible widened pulse pressure. ↓ Pedal pulses. Intermittent claudication
↑ Venous tortuosity	Inflamed, painful, or cord-like varicosities. Dependent edema

Case Study

Patient Introduction

(©Jupiterimages/Banana-Stock/Thinkstock.)

L.P., a 63-year-old man, is brought to the hospital by ambulance at 0600 after reporting chest tightness, shortness of breath (SOB), and "heart pounding" (palpitations). The paramedics started an IV and O_2 at 2 L/min via nasal cannula. They obtained a 12-lead ECG and gave him 4 low-dose ASA and a nitroglycerin tablet. L.P. is pain free on arrival to the emergency department but still has palpitations.

Discussion Questions

1. What are the possible causes of L.P.'s symptoms?
2. Is L.P.'s condition stable or unstable?

You will learn more about L.P. and his condition as you read this assessment chapter.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

ASSESSMENT OF CARDIOVASCULAR SYSTEM

Subjective Data

A careful health history and physical assessment will help you distinguish symptoms of a cardiovascular problem from problems of other body systems. Explore and record all cues that alert you to the possibility of underlying CVD.

Important Health Information

History of present illness. Ask the patient what problem has led to seeking health care. Fully explore all symptoms the patient reports.

Health history. Many illnesses affect the cardiovascular system directly or indirectly. Ask the patient about a history of angina, diabetes, alcohol and tobacco use, anemia, rheumatic fever, streptococcal throat infections, congenital heart disease, stroke, hypertension, thrombophlebitis, dysrhythmias, and varicosities. Fully explore any symptoms the patient reports. Ask about dyspnea, fatigue, dizziness with position changes, syncope, edema, intermittent claudication, and palpitations.

Assess for allergies to drugs, food, or the environment. Determine whether the patient has ever had a drug reaction or an allergic or anaphylactic reaction. Ask specifically about any allergic reaction to contrast media.

Medications. Assess the patient's current and past use of medications. Record the dose and time last taken for each. Include over-the-counter (OTC) and prescription drugs and herbal supplements. For example, aspirin prolongs the blood clotting time. It is found in some drugs used to treat cold symptoms. Assess for use of noncardiac drugs that can adversely affect the cardiovascular system (Table 35.2).

Surgery or other treatments. Ask the patient about specific treatments, surgeries, or hospital admissions related to cardiovascular problems. Explore any admissions or procedures performed for cardiovascular symptoms. Note whether the patient has had an ECG or a chest x-ray done.

Functional Health Patterns

The strong correlation between lifestyle and cardiovascular health supports the need to review each functional health pattern. Key questions to ask a person with a cardiovascular problem are listed in Table 35.3.

Health perception–health management pattern. Ask the patient about the presence of major cardiovascular risk factors. These include abnormal serum lipids, hypertension, sedentary lifestyle, diabetes, obesity, and tobacco use. Estimate the number of pack-years of tobacco use (number of packs smoked per day multiplied by the number of years the patient has smoked). Note the patient's attitude about tobacco use and attempts and methods used to stop. Record the type of alcohol used, amount, and frequency. Note any use of habit-forming or recreational substances.

Confirmed illnesses of blood relatives can highlight any genetic or familial tendencies toward CAD, hypertension, varicosities, bleeding, diabetes, atherosclerosis, and stroke (Box 35.1). Note any family members who had heart disease at an early age (<50 years of age for men; <55 years of age for women). Last, assess for family health history of noncardiac problems that affect the cardiovascular system such as obesity and lung, kidney, or liver disease.

Nutritional-metabolic pattern. Being underweight or overweight may indicate potential cardiovascular problems. Assess the patient's weight history (e.g., over the past year) in relation to height. Determine the amount of salt and saturated fats in the patient's typical diet. In addition to food habits, which are influenced by culture, explore the patient's attitudes and plans about diet and weight management.

Elimination pattern. The patient taking diuretics may report increased voiding and/or nocturia. Ask about incontinence or constipation, including use of prescribed and OTC drugs for constipation. Teach patients with heart problems to avoid straining *(Valsalva maneuver)* during a bowel movement. Ask patients if they have swelling of the lower extremities and if it resolves when their feet are elevated.

TABLE 35.2 Potential Cardiovascular Effects of Select Noncardiac Drugs

Drug Classification	Examples	Cardiovascular Effects
Anticancer agents	daunorubicin doxorubicin	Dysrhythmias, cardiomyopathy
Antipsychotics	chlorpromazine haloperidol	Dysrhythmias, orthostatic hypotension
Antirheumatics	hydroxychloroquine	Dysrhythmias, cardiomyopathy, heart block, prolonged QT interval,
Corticosteroids	cortisone prednisone	Hypotension, edema, potassium depletion
Hormone therapy, oral contraceptives	estrogen + progestin (Prempro)	MI, thromboembolism, stroke, hypertension
Nonsteroidal antiinflammatory drugs (NSAIDs)	celecoxib (Celebrex) diclofenac ibuprofen	MI, stroke, hypertension, HF
Psychostimulants	amphetamines cocaine	Tachycardia, angina, MI, hypertension, dysrhythmias
Tricyclic antidepressants	amitriptyline doxepin (Silenor)	Dysrhythmias, orthostatic hypotension

TABLE 35.3 HEALTH HISTORY

Cardiovascular System

Health Perception–Health Management
- Do you practice any measures to decrease risk factors for heart disease?[a]
- Have you noticed an increase in heart symptoms such as chest pain or dyspnea?[a]
- Does your heart problem cause you to be less able to care for yourself?[a]
- Do you foresee any potential self-care problems because of your heart problem?[a]
- Have you ever used tobacco? If yes, in what form, how much, and for how long? Have you tried to quit? If yes, what methods have you tried? Are you interested in learning about quitting?
- How often and how much alcohol do you drink?

Nutritional-Metabolic
- Describe your usual daily diet, including salt, fat, and liquid intake.
- What is your present weight? What was your weight 1 year ago? If different, explain.
- Does eating cause fatigue or shortness of breath?[a]

Elimination
- Do your feet or ankles ever swell?[a] If yes, how far up your legs? Does it go away after sleeping all night?
- Have you ever taken drugs to help you get rid of excess fluid or to relieve constipation?[a]
- Are you having any problems related to urination?[a]
- Do you ever strain to have a bowel movement?

Activity-Exercise
- Are your daily activities or exercise limited because of your heart problem?[a]
- When were you last able to comfortably perform your usual activities or exercise?
- Do you have any discomfort or symptoms because of exercise or any activity?[a]
- Can you comfortably walk and talk at the same time?
- How often do you attend activities outside your home?
- What was your most strenuous activity in the past few weeks compared with 6 months ago?

Sleep-Rest
- How many pillows do you sleep on at night? Has this changed recently?[a]
- Do you ever wake up suddenly and feel as if you cannot catch your breath?[a]
- Do you have a history of sleep apnea?[a]
- Do you ever sleep in a chair at night? Is yes, how often?
- How many times a night do you awaken to urinate?

Cognitive-Perceptual
- Do you ever have dizziness or fainting?[a]
- Do you ever find it hard to express yourself or to remember things?[a]
- Do you have any pain (e.g., chest pain, leg pain with activity) because of your heart problem?[a]

Self-Perception–Self-Concept
- Have your perceptions of yourself changed since you were diagnosed with heart disease?[a]
- How has your heart disease affected the quality of your life?

Role-Relationship
- Has this illness affected any of the roles that you play in your daily life?[a]
- How has your heart disease affected your significant others?

Sexuality-Reproductive
- Has your heart disease caused a change in your sexual activity?[a]
- Do you have any heart-related symptoms during sexual activity?[a]
- Do any of your drugs affect your ability to take part in sexual activities?[a]
- *Females:* Are you currently taking oral contraceptives, hormonal therapy, or drug therapy for breast cancer?
- *Males:* Are you taking any drugs to treat erectile dysfunction?

Coping–Stress Tolerance
- Describe your normal coping mechanisms during times of stress or anxiety.
- To whom or where would you turn during a time of stress? Are these people or services helping you now?[a]
- Do you practice any stress reduction techniques?[a]
- Do you have a history of depression?[a]
- Do you feel capable of handling your present health situation?
- Do you have any heart symptoms (e.g., chest pain, palpitations) during times of stress or anger?[a]

Values-Beliefs
- What influence have your values or beliefs had during your illness?
- Do you feel any conflicts between your values or beliefs and the plan of care?[a]
- Describe any cultural or spiritual beliefs that may influence managing your heart problem.

[a]If yes, describe.

Activity-exercise pattern. The benefit of exercise for cardiovascular health is clear, with aerobic exercise being most beneficial. Record the types, duration, intensity, and frequency of exercise. Ask about symptoms during exercise (e.g., chest pain, dyspnea, claudication) that may indicate a cardiovascular problem.

Sleep-rest pattern. Cardiovascular problems often disrupt sleep. *Paroxysmal nocturnal dyspnea* (attacks of shortness of breath, especially at night that awaken the patient) and *Cheyne-Stokes respiration* (periods of very shallow breaths to alternating periods of apnea and deep, rapid breathing) are associated with HF. Note the number of pillows needed to sleep or the need to sleep upright in a chair *(orthopnea)*.

Sleep apnea is associated with an increased risk for life-threatening dysrhythmias, especially in patients with HF. Nocturia, a common finding in CVD, interrupts normal sleep patterns.

Cognitive-perceptual pattern. Ask both the patient and caregiver about cognitive-perceptual problems. Cardiovascular problems such as dysrhythmias, hypertension, and stroke may cause difficulties with syncope, language, and memory. Report pain associated with the cardiovascular system (e.g., chest pain, claudication).

Self-perception–self-concept pattern. Acute cardiovascular events may affect the patient's self-perception. Invasive diagnostic procedures often lead to body image concerns. The patient with chronic CVD may describe an inability to "keep up" previous levels of activity, affecting quality of life.

Role-relationship pattern. Gender, race, and age are related to cardiovascular health. The patient's marital status, role in the household, employment status, number of children and their ages, living environment, and caregivers help you to identify

BOX 35.1 GENETIC RISK ALERT

Coronary Artery Disease (CAD)

- More than 50 genetic links, especially related to lipoprotein genes, have been found in some families with CAD.[5]
- The clustering of CAD in families is strong if early age of onset affected several relatives.

Cardiomyopathy

- Autosomal dominant mutations can cause hypertrophic cardiomyopathy.
- X-linked and autosomal dominant mutations can cause dilated cardiomyopathy.

Hypertension

- Hypertension results from a complex interplay of genetic and environmental factors.
- Lifestyle choices (e.g., smoking, lack of exercise) may trigger genetic tendencies to hypertension.

strengths and support systems in the patient's life. Assess the patient's satisfaction with life roles.

Sexuality-reproductive pattern. Ask the patient about the effect of the cardiovascular problem on sexual activity. Because some patients fear sudden death during sexual intercourse, they may change their sexual behavior. Fatigue, chest pain, or dyspnea may limit activity. Erectile dysfunction (ED) may be a symptom of peripheral vascular disease (PVD) and/or a side effect of some drugs used to treat CVD (e.g., β-blockers, diuretics). Ask male patients about the use of drugs such as phosphodiesterase inhibitors for ED. These drugs are contraindicated if the patient is taking a nitrate because the combination can cause significant hypotension.[6]

Ask female patients if they use oral contraceptives, hormone therapy (HT) for symptoms of menopause, or drug therapy for breast cancer. Women who smoke tobacco and use oral contraceptives are at increased risk for blood clots (e.g., venous thromboembolism). Similarly, there is an increased risk for CVD with the use of HT and selective estrogen-receptor modulators (e.g., tamoxifen).[6]

Coping–stress tolerance pattern. Ask the patient to identify sources of stress and the usual methods of coping with stress. Potentially stressful areas include health concerns, marital relationships, family and friends, occupation, and finances.

Work-related stress, depression, and inadequate social support are risk factors for CVD and heart events. Ask the patient about these factors. Information about the patient's support systems such as family, extended family and friends, counselors, or religious groups is useful in planning care.

Values-belief pattern. Individual values and beliefs, which are greatly affected by culture, may play a key role in the real or potential conflict that a patient faces when dealing with CVD. Some patients may attribute their illness to punishment; others may think that a "higher power" can help them. Information about a patient's values and beliefs will help you to provide support during periods of crisis.

Objective Data

Physical Assessment

Vital signs. Observe the patient's general appearance and obtain vital signs. Measure BP bilaterally. Readings can vary from 5 to 15 mm Hg between arms. Use the arm with the highest BP for later measurements. Obtain an orthostatic (postural) BP and HR while the patient is supine, sitting with legs dangling, and standing. SBP should not decrease more than 20 mm Hg from the supine to the standing position. HR should not increase more than 20 beats/min from the supine to the standing position.

Case Study

Subjective Data

(@ Jupiterimages/ Banana-Stock/ Thinkstock.)

A focused subjective assessment of L.P. revealed the following:

- ***Medical History:*** History of hypertension, mitral valve prolapse with mild regurgitation, HF, and type 2 diabetes.
- ***Oral Medications:*** Lisinopril (Prinivil) 10 mg/day, metoprolol (Lopressor) 50 mg twice daily, aspirin 81 mg/day, furosemide 40 mg/day, and glipizide 5 mg/day.
- ***Health Perception–Health Management:*** L.P. denies any history of chest pain or coronary artery disease. He reports feeling fine until this morning when he awoke and developed shortness of breath (SOB), chest tightness, and palpitations while walking to the bathroom. He thought he was having a heart attack, so his wife called 911. Denies smoking or alcohol intake. SOB and chest tightness are now gone, but he continues to feel palpitations.
- ***Elimination:*** Denies edema or nocturia. States he takes furosemide in the morning and typically "passes urine until lunchtime."

Discussion Questions

1. Which subjective assessment findings most concern you?
2. How will you conduct a patient-centered assessment?
3. Is this a good time to teach him about how to use nitroglycerin tablets?
4. What should you include in the physical assessment? What cues would you be looking for?

You will learn more about the physical assessment of the cardiovascular system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

Peripheral vascular system

Inspection. Inspect the skin for color, hair distribution, and venous pattern. Check the extremities for edema, dependent rubor, clubbing of the nail beds, varicosities, and lesions such as stasis ulcers. Edema in the legs can be caused by gravity, varicosities, or right-sided HF.

Inspect the large neck veins (internal and external jugular) while gradually moving the patient from a supine position to an upright (30 to 45 degrees) position. Right-sided HF can cause distention and prominent pulsations of the neck veins referred to as *jugular venous distention* (JVD).

Palpation. Palpate the upper and lower extremities for temperature, moisture, pulses, and edema bilaterally to assess for symmetry. Look for edema by depressing the skin over the tibia or medial malleolus for 5 seconds. Normally, there is no depression after you release pressure. If pitting edema is present, grade it from 1+ (mild pitting, slight brief indentation) to 4+ (very deep pitting, indentation that lasts a long time).

Palpate the pulses in the neck and extremities for rhythm and force of arterial blood flow. Palpate each carotid pulse separately to avoid vagal stimulation and dysrhythmias. Compare

the characteristics of the arteries in the right and left extremities simultaneously to determine symmetry.

When palpating the arteries identified in Fig. 35.6, rate the force of the pulse using the following scale:

0 = Absent
1+ = Weak
2+ = Normal
3+ = Increased, full, bounding

Note the rigidity (hardness) of the artery. The normal pulse feels like a tap, but a narrowed or bulging vessel wall vibrates. The term for a palpable vibration is *thrill*.

We use *capillary refill* to assess arterial flow to the extremities. Position the patient's hands near the level of the heart and squeeze a nail bed briefly to produce blanching. Color should return to the nail bed in less than 2 seconds after release.

Auscultation. An artery that is narrowed or has a bulging wall may create turbulent blood flow. This abnormal flow can cause a buzzing or humming termed a *bruit*. We can hear it with the bell of the stethoscope over the vessel. Auscultate the carotid arteries, abdominal aorta, and femoral arteries as part of the initial cardiovascular assessment. Abnormalities of the cardiovascular system are described in Table 35.4.

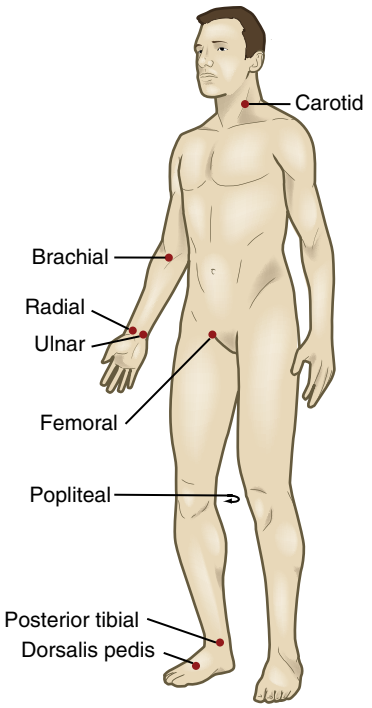

Fig. 35.6 Common sites for palpating arteries.

TABLE 35.4 ASSESSMENT ABNORMALITIES

Cardiovascular System

Finding[a]	Description	Possible Etiology[a] and Significance
Inspection		
Central cyanosis	Bluish or purplish tinge in tongue, conjunctivae, inner surface of lips	Inadequate O_2 saturation of arterial blood because of pulmonary or cardiac disorders
Clubbing of nail beds	Loss of normal angle between base of nail and skin	Endocarditis, congenital defects, prolonged O_2 deficiency
Color changes in extremities with postural change	Pallor, cyanosis, mottling of skin after limb elevation. Dependent rubor (reddish blue discoloration). Glossy skin	Chronic decreased arterial perfusion
Jugular venous distention (JVD)	Distended neck (jugular) veins with patient sitting at 30- to 45-degree angle	↑ Right atrial pressure, right-sided HF
Peripheral cyanosis	Bluish or purplish tinge in extremities or in nose and ears	↓ Blood flow from HF, vasoconstriction, cold environment
Splinter hemorrhages	Small red to black streaks under fingernails	Infective endocarditis
Ulcers	*Venous:* Necrotic crater-like lesion, usually at medial malleolus. Slowly healing wound.	Poor venous return, varicose veins, incompetent venous valves
	Arterial: Pale ischemic base, well-defined edges usually found on toes, heels, lateral malleoli	Arteriosclerosis, diabetes
Varicose veins	Visible dilated, discolored, tortuous vessels in legs	Incompetent valves in vein
Palpation		
Pulse		
<60 beats/min	Bradycardia	Rest, sleep, athletic conditioning, SA or AV node damage, side effect of drugs (e.g., β-blockers), hypothyroidism
>100 beats/min	Tachycardia	Exercise, anxiety, hypovolemia, shock, need for increased CO, hyperthyroidism
Absent	Lack of pulse	Local atherosclerosis, trauma, embolus
Bounding	Sharp, brisk, pounding pulse	Hyperkinetic states (e.g., anxiety, fever), anemia, hyperthyroidism
Displaced point of maximal impulse (apical pulse)	Palpate (or auscultate) the point of maximal impulse below the 5th ICS and to the left of the MCL	Cardiac enlargement because of coronary artery disease, HF, cardiomyopathy
Irregular	Regularly irregular or irregularly irregular. Skipped beats	Dysrhythmias
Pulsus alternans	Regular rhythm, but strength of pulse varies with each beat	HF, cardiac tamponade
Rigidity	Stiffness or inflexibility of vessel wall	Atherosclerosis
Thready	Weak, slowly rising pulse easily obliterated by pressure	Blood loss, ↓ CO, aortic valve disease, peripheral arterial disease
Thrill	Vibration of vessel or chest wall	Aneurysm, aortic regurgitation, arteriovenous fistula

TABLE 35.4 ASSESSMENT ABNORMALITIES—cont'd

Cardiovascular System

Finding[a]	Description	Possible Etiology[a] and Significance
Extremities		
Asymmetry in limb circumference	Measurable swelling of involved limb	Venous thromboembolism, varicose veins, lymphedema
Cold extremities	Hands and/or feet cold to touch. External covering needed for comfort	Peripheral arterial disease, ↓ CO, severe anemia
Delayed capillary refill	Blanching of nail bed for ≥2 sec after release of pressure	↓ Perfusion, anemia
Pitting edema of lower extremities or sacral area	Visible finger indentation after firm pressure, weight gain, tightening of clothing (including shoes), marks or indentations from constricting garments	Interruption of venous return to heart, right-sided HF
Unusually warm extremities	Hands and feet warmer than normal	Thyrotoxicosis
Auscultation		
3rd heart sound (S_3)	Extra heart sound, low pitched, heard in early diastole. Similar to sound of a gallop	Left ventricular failure. Volume overload. Mitral, aortic, or tricuspid regurgitation. Hypertension
4th heart sound (S4)	Extra heart sound, low pitched, heard in late diastole. Similar to sound of a gallop	Forceful atrial contraction from resistance to ventricular filling (e.g., in left ventricular hypertrophy, aortic stenosis, hypertension, coronary artery disease)
Arterial bruit	Turbulent flow sound in peripheral artery	Arterial obstruction or aneurysm
Heart murmurs	Turbulent sounds between normal heart sounds. Note loudness, pitch, shape, quality, duration, timing	Heart valve disorder, abnormal blood flow patterns
Pericardial friction rub	High-pitched, scratchy sound during S_1 and/or S_2 at the apex. Heard best with patient sitting and leaning forward while holding breath at end expiration	Pericarditis
Pulse deficit	Apical HR exceeding peripheral pulse rate	Dysrhythmias, most often atrial fibrillation/flutter or premature ventricular contractions

[a]Limited to common abnormal assessment findings and etiologic factors. (Further discussion of conditions listed is found in Chapters 36 to 42).

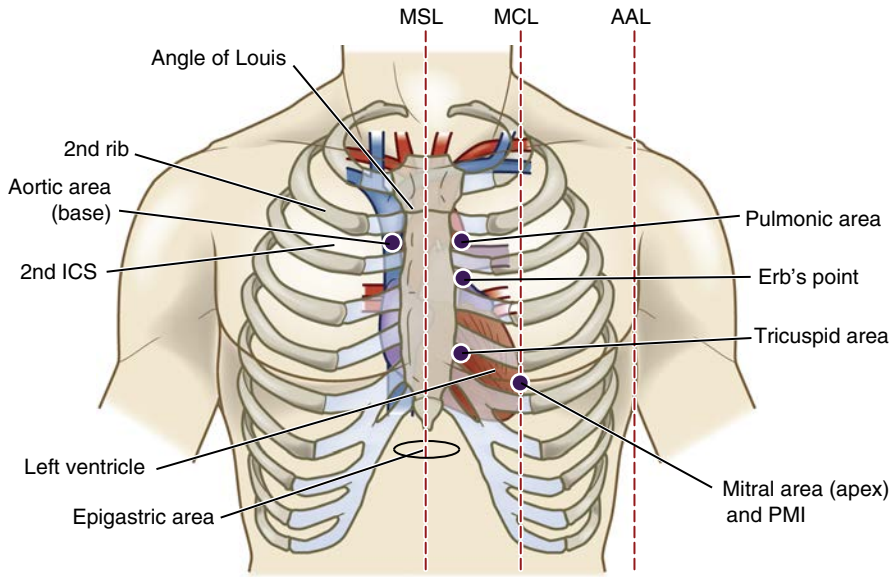

Fig. 35.7 Orientation of the heart within the thorax and cardiac auscultatory areas. *Red lines* indicate the midsternal line *(MSL),* midclavicular line *(MCL),* and anterior axillary line *(AAL). ICS,* Intercostal space; *PMI,* point of maximal impulse.

Thorax

Inspection and palpation. Begin examining the thorax with a general inspection and palpation. Next, inspect and palpate the areas where the heart valves project their sounds by finding the intercostal spaces (ICSs). The raised notch, the *angle of Louis,* is where the manubrium and body of the sternum join at the level of the 2nd rib. It is palpable in the midline of the sternum. Palpate for the 2nd ICS, then count each ICSs to find specific auscultatory areas (Fig. 35.7).

Locate the following auscultatory areas: aortic area in the 2nd ICS to the right of the sternum, pulmonic area in the 2nd ICS to the left of the sternum, tricuspid area in the 5th left ICS close

to the sternum, and mitral area in the left midclavicular line at the 5th ICS. A 5th auscultatory area is the *Erb point,* located at the 3rd left ICS near the sternum. Normally, we cannot feel pulsations in these areas unless the patient has a thin chest wall. A heart valve disorder may be present if you feel abnormal pulsations or thrills.

Next, inspect and palpate the epigastric area on either side of the midline just below the xiphoid process. In a thin person, you may see abdominal aortic pulsations. Normally, you can palpate the aorta here. Next, inspect the precordium, which is over the heart, for heaves. **Heaves** are sustained lifts of the chest wall in the precordial area that you can see or palpate. They may be caused by left ventricular hypertrophy.

When the patient is supine, palpate the mitral valve area for the **point of maximal impulse (PMI)** (also called the *apical pulse*). This reflects the pulsation of the apex of the heart. The PMI lies medial to the midclavicular line in the 4th or 5th ICS. If you can palpate the PMI, record its position in relation to the midclavicular line and ICSs. If the PMI is below the 5th ICS and left of the midclavicular line, the heart may be enlarged.

Auscultation. Normal heart sounds are made by the movement of blood through the heart valves. We can hear these sounds through a stethoscope placed on the chest wall. The first heart sound (S_1) represents closure of the tricuspid and mitral valves. It has a soft lubb sound. The second heart sound (S_2) represents closure of the aortic and pulmonic valves. It has a sharp dupp sound. S_1 signals the beginning of systole. S_2 signals the beginning of diastole (Fig. 35.8). Listen to the auscultatory areas in sequence (Fig. 35.7).

S_1 and S_2 are heard best with the diaphragm of the stethoscope because they are high pitched. Extra heart sounds (S_3 or S_4), if present, are heard best with the bell of the stethoscope because they are low pitched. Have the patient lean forward while sitting to enhance the sounds from the 2nd ICSs (aortic and pulmonic areas). Place the patient in a left side-lying position to enhance the sounds at the mitral area.

When auscultating the apical area, simultaneously palpate the radial pulse. Determine whether the rhythm is regular or irregular while listening and feeling. If the apical and radial pulses are not equivalent, count the apical pulse while a 2nd person simultaneously counts the radial pulse for 1 full minute. A difference between the 2 numbers, called a *pulse deficit,* can indicate dysrhythmias.

Normally no sound is heard between S_1 and S_2. An exception to this is a normal splitting of S_2, which is best heard at the pulmonic area during inspiration. Splitting of S_2 can be abnormal if it is heard during expiration or if it is constant (fixed) during the respiratory cycle. Describe any sounds heard in addition to S_1 and S_2.

The S_3 heart sound is a low-intensity vibration of the ventricular walls usually from decreased compliance of the ventricles during filling. An S_3 heart sound may be normal (physiologic) in young adults. It is pathologic in patients with left-sided HF or mitral valve regurgitation. S_3 is heard closely after S_2. It is known as a ventricular gallop.

The S_4 heart sound is a low-frequency vibration caused by atrial contraction. It precedes S_1 of the next cycle and is known as an atrial gallop. An S_4 heart sound may be normal in older adults with no evidence of heart disease. It is pathologic in patients with CAD, cardiomyopathy, left ventricular hypertrophy, or aortic stenosis.

Murmurs, if heard, are graded on a 6-point Roman numeral scale based on loudness and recorded as a ratio. I/VI means a murmur that is barely audible with the stethoscope, heard only in a quiet room and then not easily. VI/VI means a murmur that you can hear with the stethoscope lifted just off the chest wall.

Pericardial friction rubs are sounds that occur when inflamed surfaces of the pericardium (pericarditis) move against each other. They are high-pitched, scratchy sounds that may be intermittent and may last several hours to days. Friction rubs are heard best at the apex with patients upright, leaning forward, and holding their breath after expiration.[5]

Record the characteristics of any abnormal sounds. This includes the timing (during systole or diastole), location (the anatomic site on the chest where it is heard the loudest), and position (heard best when the patient is supine, sitting and leaning forward, or in the left side-lying position).[5] Note any other findings (irregular apical pulse, palpable chest wall heaves) associated with the sound.

Abnormal assessment findings are described in Table 35.4. A method of recording data from the cardiovascular assessment is shown in Table 35.5. A focused assessment is used to evaluate the status of previously identified cardiovascular problems and to monitor for signs of new problems. A focused assessment of the cardiovascular system is outlined in Box 35.2.

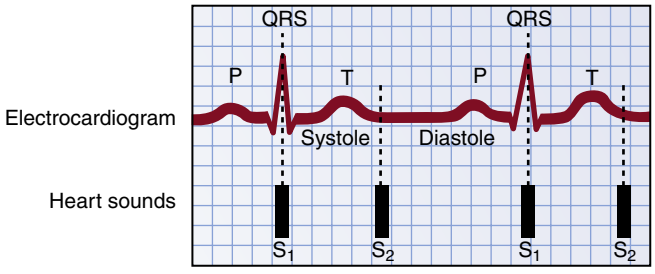

Fig. 35.8 Relationship of ECG, cardiac cycle, and heart sounds.

TABLE 35.5 Normal Physical Assessment of Cardiovascular System

Inspection	No pallor or cyanosis. PMI not visible. No JVD with patient at 45-degree angle
Palpation	Skin warm. Capillary refill <2 sec. PMI palpable in 4th ICS at left MCL. No thrills or heaves. Slight palpable pulsations of abdominal aorta in epigastric area. Carotid and extremity pulses 2+ and equal bilaterally. No pedal or sacral edema
Auscultation	S_1 and S_2 heard. Apical-radial pulse rate equal, 72, and regular. No murmurs or extra heart sounds

MCL, Midclavicular line; *PMI,* point of maximal impulse.

Case Study

Objective Data: Physical Assessment

(© Jupiterimages/ Banana-Stock/ Thinkstock.)

Physical assessment findings of L.P. are as follows:

- BP 100/54, apical pulse rate 154 and irregular, respiratory rate 20, temperature 98.2°F (36.8°C), O_2 saturation 94% on room air
- Awake, alert, and oriented ×3
- Lungs clear on auscultation; systolic murmur present
- Heart monitor shows atrial fibrillation with a rapid ventricular response
- +1 pedal pulses bilaterally
- No peripheral edema, JVD, or heaves noted

Discussion Questions

1. Which physical assessment findings most concern you?
2. Based on the results of the subjective and physical assessment findings, what diagnostic studies do you think will be ordered for L.P.?

You will learn more about diagnostic studies related to the cardiovascular system in the next section.

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

HEMODYNAMIC MONITORING

Hemodynamic monitoring is the measurement of pressure, flow, and oxygenation within the cardiovascular system. The purpose of hemodynamic monitoring is to assess heart function, fluid balance, and the effects of fluids and drugs on CO. Both invasive (internally placed) and noninvasive (externally placed) devices measure hemodynamic parameters (values). These include systemic and pulmonary arterial pressures, central venous pressure (CVP), pulmonary artery wedge pressure (PAWP) (also called pulmonary artery occlusive pressure [PAOP]), CO/cardiac index (CI), SV/SV index (SVI), O_2 saturation of the hemoglobin of arterial blood (SaO_2), and mixed venous O_2 saturation (SvO_2).

From these measurements, you can calculate other values. These include the resistance of the systemic and pulmonary arterial vasculature and O_2 content, delivery, and consumption. The combined data provide a picture of the patient's hemodynamic status and the effects of therapy over time (trends). Pay attention to accuracy of measurement to help guide effective treatment.

BOX 35.2 FOCUSED ASSESSMENT

Cardiovascular System

Use this checklist to remind you of the key assessment steps.

Subjective

Ask the patient about the following and note responses.

Chest pain, discomfort	Y	N
Palpitations	Y	N
Shortness of breath (especially when lying down or at rest)	Y	N
Edema in legs or any part of body	Y	N
Leg pain during exercise	Y	N
Excess urination at night	Y	N

Objective: Diagnostic

Check the following for critical values or changes.

Cardiac biomarkers	✓
Hematocrit, hemoglobin, platelets	✓
Glucose, electrolytes, BUN, creatinine	✓
ECG	✓
Chest x-ray	✓

Objective: Physical Assessment

Inspect and Palpate

Anterior chest wall for pulsations and heaves	✓
Pulses for symmetry, quality, and rhythm	✓

Auscultate

Bilateral BP	✓
Heart for rate, rhythm, and sounds	✓

Hemodynamic Measurements

Cardiac Output and Cardiac Index

CO is the volume of blood in liters pumped by the heart in 1 minute. **Cardiac index** (CI) is the measurement of CO adjusted for body surface area (BSA). CI reflects the relative CO for the body size. The normal CI is 2.8 to 4.2 L per minute per meter squared ($L/min/m^2$).[13] The volume ejected with each heartbeat is the SV. Like CI, *stroke volume index* (SVI) is the measurement of SV adjusted for BSA.

CO and the forces opposing blood flow determine BP. SVR (opposition encountered by the left ventricle) or *pulmonary vascular resistance* (PVR) (opposition encountered by the right ventricle) is the resistance to blood flow by the vessels. Preload, afterload, and contractility determine SV and thus CO. Table 35.6 presents the formulas and values for common hemodynamic parameters.

Preload

Preload is the volume in the ventricle at the end of diastole. Chamber volume measurements are hard to obtain so we use pressure measurements to estimate the volume. Left ventricular preload is the *left ventricular end-diastolic pressure*. PAWP reflects left ventricular end-diastolic pressure under normal conditions (i.e., when there is no mitral valve dysfunction, intracardiac defect, or dysrhythmia). CVP is measured in the right atrium or in the vena cava close to the heart. It is the right ventricular preload or right ventricular end-diastolic pressure when there is no tricuspid valve dysfunction, intracardiac defect, or dysrhythmia.

The clinical measurement of preload is not a direct measurement of the muscle stretch. The measurement is of the pressure at the time of the peak stretch (end diastole). This pressure indirectly indicates the amount of stretch and the volume. Diuresis and vasodilation decrease preload. Fluid administration increases preload.

Afterload

Afterload refers to the forces opposing ventricular ejection of blood. These forces include systemic arterial pressure, aortic valve resistance, and the blood volume and density. SVR and arterial

TABLE 35.6 Resting Hemodynamic Parameters

Indicators	Normal Range
Preload	
Pulmonary artery diastolic pressure (PADP)	4–12 mm Hg
Pulmonary artery wedge pressure (PAWP) or left atrial pressure (LAP)	6–12 mm Hg
Right atrial pressure (RAP) or central venous pressure (CVP)	2–8 mm Hg
Right ventricular end-diastolic volume (RVEDV) = $\frac{\text{Stroke volume (SV)}}{\text{Right ventricular ejection fraction (RVEF)}}$	100–160 mL
Afterload	
MAP = $\frac{\text{Systolic blood pressure} + 2\,(\text{Diastolic blood pressure})}{3^a}$	70–105 mm Hg
PAMP = $\frac{\text{Pulmonary artery systolic pressure (PASP)} + 2\text{PADP}}{3^a}$	10–20 mm Hg
Pulmonary vascular resistance (PVR) = $\frac{(\text{Pulmonary artery pressure [PAMP]} - \text{PAWP}) \times 80}{\text{Cardiac output (CO)}}$	<250 dynes/sec/cm^{-5}
Pulmonary vascular resistance index (PVRI) = $\frac{[\text{PAMP} - \text{PAWP}] \times 80}{\text{Cardiac index (CI)}}$	160–380 dynes/sec/cm^{-5}/m^2
Systemic vascular resistance (SVR) = $\frac{(\text{Mean arterial pressure [MAP]} - \text{CVP}) \times 80}{\text{CO}}$	800–1200 dynes/sec/cm^{-5}
Systemic vascular resistance index (SVRI) = $\frac{(\text{MAP} - \text{CVP}) \times 80}{\text{CI}}$	1970–2390 dynes/sec/cm^{-5}/m^2
Other	
CI = $\frac{\text{CO}}{\text{Body surface area (BSA)}}$	2.2–4 L/min/m^2
CO = SV × HR	4–8 L/min
Heart rate	60–100 beats/min
RVEF = $\frac{\text{SV}}{\text{RVEDV} \times \text{V100}}$	40%–60%
Stoke volume = $\frac{\text{CO}}{\text{Heart rate}}$	60–150 mL/beat
Stoke volume index (SVI) = $\frac{\text{CI}}{\text{Heart rate}}$	30–65 mL/beat/m^2
Stoke volume variation (SVV) = $\frac{\text{SV}_{max} - \text{SV}_{min}}{\text{SV}_{mean}}$	<13%
Oxygenation	
Arterial hemoglobin O_2 saturation	95%–100%
Mixed venous hemoglobin O_2 saturation	60%–80%
Venous hemoglobin O_2 saturation	70%

[a]This formula is an approximation because it does not take the heart rate into consideration. The monitor measures the area under the pressure curve and HR to calculate MAP and PAMP.

pressure are indices of left ventricular afterload, but they do not include all the components of afterload. SVR is the resistance of the systemic vascular bed. Similarly, PVR and pulmonary arterial pressure are indices of right ventricular afterload. PVR is the resistance of the pulmonary vascular bed (Table 35.6).

Increased afterload often results in a decreased CO and increased O_2 demand. CO can be improved and myocardial O_2 needs reduced by decreasing afterload (i.e., decreasing forces opposing contraction). For example, vasodilator drug therapy (e.g., milrinone) can reduce afterload.

Contractility

Contractility describes the strength of contraction. Epinephrine, norepinephrine, isoproterenol (Isuprel), dopamine, dobutamine, digitalis-like drugs, calcium, and milrinone increase or improve contractility. We call these drugs *positive inotropes.* Increased contractility results in increased SV and increased myocardial O_2 needs. *Negative inotropes* reduce contractility. These include certain drugs (e.g., calcium channel blockers, β-adrenergic blockers) and clinical conditions (e.g., acidosis).

There are no direct clinical measures of cardiac contractility. Measuring the patient's preload (PAWP) and CO and graphing the results indirectly indicate contractility. If preload, HR, and afterload remain constant and CO changes, then contractility changed. Contractility is reduced in the failing heart and with cardiac ischemia.[7]

Noninvasive Hemodynamic Monitoring

Methods to estimate CO noninvasively include pulse wave analysis, thoracic electrical bioimpedance or bioreactance, and pulse wave transit time. Noninvasive finger cuff devices or a sensor over the radial artery provides a method of continuous monitoring through pulse wave analysis. CO and BP are calculated from pulsation and pressure waveform analysis in the digital arteries. Bioimpedance methods use electrodes to sense changes in electrical conductivity of the blood and estimate SV. Pulse wave transit time is the time the pulse wave needs to travel from the heart to the peripheral arteries. It can be measured with a device that includes electrodes and pulse oximetry.[8]

CO also can be measured noninvasively and reliably using ultrasound (US) technology. Both transesophageal echocardiography (TEE) and ultrasonic CO monitoring have provided consistent values similar to the standard method of thermodilution CO. Noninvasive CO measurement is less reliable when the patient has structural changes in the heart anatomy.[9]

Major uses of noninvasive hemodynamic monitoring include (1) detecting early signs and symptoms of pulmonary or cardiac problems, (2) determining cardiac or pulmonary cause of dyspnea, (3) evaluating the cause and managing hypotension, (4) monitoring after removing a PA catheter or justifying insertion of a PA catheter, (5) evaluating drug therapy, and (6) diagnosing rejection after heart transplantation. Some noninvasive methods of measuring hemodynamic parameters are less accurate than invasive methods. However, noninvasive methods decrease the patient's risks (i.e., sepsis) from invasive methods.[10]

Principles of Invasive Pressure Monitoring

Invasive lines are used in the ICU to measure systemic and pulmonary BPs. Fig. 35.9 shows the parts of a typical invasive arterial BP monitoring system. The catheter, pressure tubing, flush system, and transducer are disposable.

Pressure monitoring equipment is referenced and zero-balanced to the environment, and dynamic response characteristics are optimized for accuracy. *Referencing* means placing the transducer so that the zero-reference point is at the level of the atria of the heart. The stopcock nearest the transducer is used for the zero reference. To place this level with the atria, use an external landmark, the phlebostatic axis. To find the *phlebostatic axis,* draw 2 imaginary lines with the patient supine (Fig. 35.10A). Draw a horizontal line from the axilla, midway between the anterior and posterior chest walls. Draw a vertical line laterally through the 4th ICS along the chest wall. The phlebostatic axis is the intersection of the 2 imaginary lines. Mark this location on the patient's chest with a permanent marker. Position the port of the stopcock nearest the transducer level at the phlebostatic axis. Tape the transducer to the patient's chest at the phlebostatic axis, or ideally mount it on a bedside pole (Fig. 35.10B).

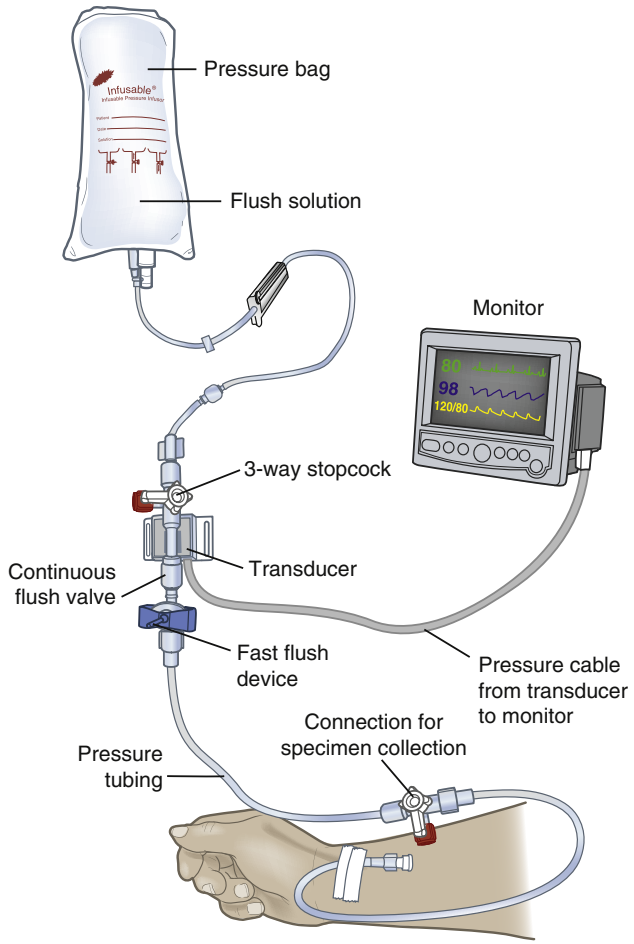

Fig. 35.9 Parts of a pressure monitoring system. The cannula, shown entering the radial artery, is connected via pressure (nondistensible) tubing to the transducer. The transducer converts the pressure wave into an electronic signal. The transducer is wired to the electronic monitoring system, which amplifies, conditions, displays, and records the signal. Stopcocks allow for specimen withdrawal and referencing and zero-balancing procedures. A flush system, consisting of a pressurized bag of IV fluid, tubing, and a flush device, is connected to the system. The flush system provides continuous slow (~3 mL/hr) flushing and a mechanism for fast flushing of lines.

Zeroing confirms that when pressure within the system is zero, the monitor reads 0. To do this, open the reference stopcock to room air (off to the patient) and observe the monitor for a reading of 0. This allows the monitor to use the atmospheric pressure as a reference for 0. Zero the transducer during the initial setup, immediately after insertion of the arterial line, when the transducer has been disconnected from the pressure cable or the pressure cable has been disconnected from the monitor and when the accuracy of the measurements is questioned. Always follow the manufacturer's guidelines.

Optimizing dynamic response characteristics involves checking that the equipment reproduces, without distortion, a signal that changes rapidly. Perform a *dynamic response test (square wave test)* every 8 to 12 hours, when the system is opened to air, or when you question the accuracy of the measurements. It involves activating the fast flush and checking that the equipment reproduces a distortion-free signal (Fig. 35.11).[7]

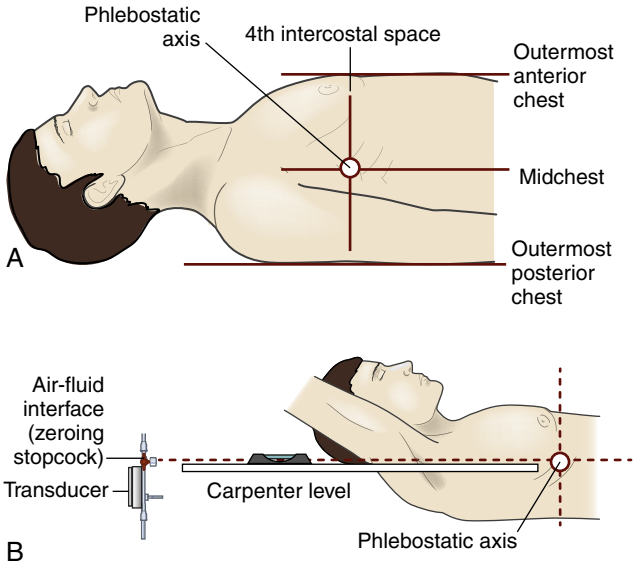

Fig. 35.10 Identification of the phlebostatic axis. (A) Phlebostatic axis is an external landmark used to identify the level of the atria in the supine patient. It is defined as the intersection of 2 imaginary lines: 1 drawn horizontally from the axilla, midway between the anterior and posterior chest walls, and the other drawn vertically through the 4th ICS along the lateral chest wall. (B) Air-fluid interface (zeroing the stopcock) is level with the phlebostatic axis using a carpenter's or laser level.

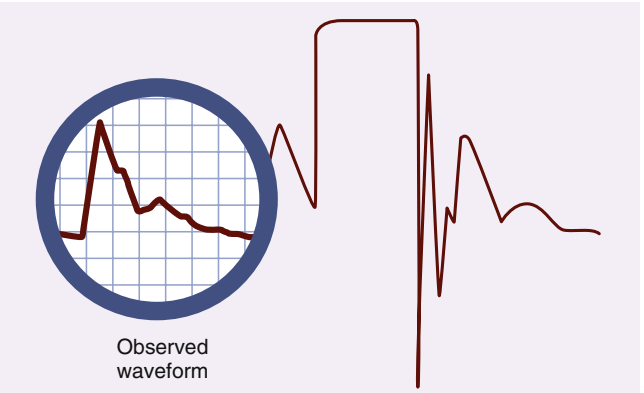

When the fast flush of the continuous flush system is activated and quickly released, a sharp upstroke terminates in a flat line at the maximal indicator on the monitor and hard copy. This is then followed by an immediate rapid downstroke extending below baseline with just 1 or 2 oscillations within 0.12 second (minimal ringing) and a quick return to a baseline. The patient's pressure waveform is also clearly defined with all components of the waveform, such as the dicrotic notch on an arterial waveform, clearly visible.

Fig. 35.11 Optimally damped system. Dynamic response test using the fast flush system: normal response. No adjustment in the monitoring system is needed. (From Darovic GO, Vanriper S, Vanriper J: Fluid-filled monitoring systems. In Darovic GO, editor: *Hemodynamic monitoring,* ed 2, Philadelphia, 1995, Saunders.)

! SAFETY ALERT

Positioning the Zero Reference Stopcock

- Mark the location of the phlebostatic axis on the patient's chest with a permanent marker.
- Recheck the leveling of the zero-reference stopcock to the phlebostatic axis with any change in the patient's position.
- Transducers higher than the phlebostatic axis will produce falsely low BP readings.
- Transducers lower than the phlebostatic axis will produce falsely high BP readings.

Types of Invasive Pressure Monitoring

Arterial BP

Continuous arterial BP monitoring is indicated for patients in many situations. These include acute hypotension and hypertension, respiratory failure, shock, neurologic injury, coronary interventional procedures, continuous infusion of vasoactive drugs (e.g., norepinephrine), and frequent arterial blood gas (ABG) sampling. A nontapered Teflon catheter is typically used to cannulate an artery (e.g., radial, femoral) using a percutaneous approach. After insertion, the HCP usually sutures the catheter in place. Immobilize the insertion site to prevent dislodging or kinking the catheter line.

Measurements. Use the arterial line to obtain systolic, diastolic, and mean arterial pressure (MAP) (Fig. 35.12). Table 35.7 outlines the steps in obtaining BP measurements with an invasive line. Values with the head of the bed elevated up to 45 degrees are generally equal to measurements with the patient supine unless the patient's BP is extremely sensitive to orthostatic changes. It is important to keep the zero-reference stopcock level with the phlebostatic axis to ensure accurate continuous measurements.

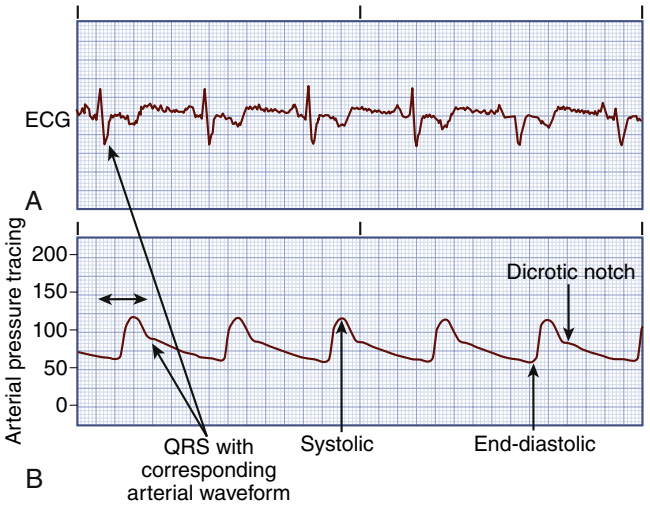

Fig. 35.12 (A) Simultaneously recorded ECG tracing. (B) Systemic arterial pressure tracing. Systolic pressure is the peak pressure. The *dicrotic notch* indicates aortic valve closure. Diastolic pressure is the lowest value before contraction. Mean pressure is the average pressure over time calculated by the monitoring equipment. (Modified from Urden LD, Stacy KM, Lough ME: *Critical care nursing: diagnosis and management,* ed 6, St Louis, 2010, Mosby.)

Set the high- and low-pressure alarms based on the patient's status. Various patient conditions will change the pressure tracings. In HF, the systolic upstroke may be slower. In volume depletion, systolic pressure varies with mechanical ventilation, decreasing during inspiration. Tracings of the arterial wave may be documented in the health record. Observe simultaneous ECG and pressure tracings with dysrhythmias. Urgently address dysrhythmias that significantly decrease arterial BP.

TABLE 35.7 Invasive Arterial Blood Pressure Measurement

1. Explain the procedure to the patient.
2. Position the patient supine and flat or, if appropriate, with the head of the bed less than 45 degrees or prone.
3. Confirm that the zero reference (port of the stopcock nearest the transducer) is at the level of the phlebostatic axis (Fig. 35.10). If the reference stopcock is not taped to the patient's chest, use a leveling device to position the stopcock on a bedside pole at the point level with the phlebostatic axis.
4. Observe the monitor tracing, and assess the quality of the tracing. Perform a dynamic response test (Fig. 35.11).
5. Obtain an analog printout (if available), and measure the systolic and diastolic pressures at end expiration (Fig. 35.12). If no printout is available, freeze the tracing on the oscilloscope screen. Use the cursor to measure the pressures at end expiration.
6. Record the pressure measurements promptly. Include (if available) the printout marked to identify the points read.

Complications. Arterial lines carry the risk for hemorrhage, infection, thrombus formation, neurovascular impairment, and loss of limb. Hemorrhage is most likely to occur if the catheter dislodges or the line disconnects. To avoid this complication, use Luer-Lok connections, monitor the arterial waveform, and activate alarms. If the pressure in the line falls (e.g., when the line is disconnected), the low-pressure alarm sounds immediately, notifying you to promptly correct the problem.

To limit the risk for catheter-related infection, inspect the insertion site for local signs of inflammation. Monitor the patient for signs of systemic infection. Change the pressure tubing, flush bag, and transducer every 96 hours or according to agency policy. If you suspect infection, notify the HCP, remove the catheter, and replace the equipment.

Circulatory impairment can result from formation of a thrombus around the catheter, release of an embolus, spasm, or occlusion of the circulation by the catheter. Before inserting a line into the radial artery, perform an *Allen test* to confirm that ulnar circulation to the hand is adequate. Apply pressure to the radial and ulnar arteries simultaneously. If the patient is able, ask the patient to open and close the hand repeatedly. The hand should blanch. Release the pressure on the ulnar artery while maintaining pressure on the radial artery. If pinkness does not return within 6 seconds, the ulnar artery is not adequate. You should not use the radial artery on that limb for line insertion.

Once the catheter is inserted, assess the neurovascular status distal to the arterial insertion site hourly. The limb with compromised arterial flow will be cool and pale, with capillary refill time longer than 3 seconds. The patient may have symptoms of neurovascular impairment (e.g., paresthesia, pain, paralysis). This is an emergency and must be reported to the HCP at once to avoid the loss of a limb.

To maintain line patency and limit thrombus formation, assess the flush system every 1 to 4 hours to determine that the (1) pressure bag is inflated to 300 mm Hg, (2) flush bag contains fluid, and (3) system is delivering a continuous slow (1 to 3 mL/hr) flush. Follow agency policy for adding heparin to the flush solution.[7]

Fig. 35.13 FloTrac sensor and Vigileo monitor. (Courtesy Edwards Lifesciences, Irvine, CA.)

Arterial Pressure-Based Cardiac Output

Arterial pressure–based cardiac output (APCO) measurement is a minimally invasive technique to determine *continuous CO* (CCO)/*continuous CI* (CCI). This technology uses a sensor attached to a standard invasive arterial pressure line and a monitor (Fig. 35.13).

APCO can assess a patient's ability to increase SV in response to fluids *(preload responsiveness)* (Table 35.6). This is determined by using stroke volume variation (SVV) or measuring the percent increase in SV after a fluid bolus. SVV is the variation of the arterial pulsation caused by the heart-lung interaction. It is a sensitive indicator of preload responsiveness in some patients. SVV helps predict if a patient would benefit from additional IV fluid boluses.[11]

Measurements. *Arterial pressure* is the force generated by the ejection of blood from the left ventricle into the arterial circulation. The heart's contractions (systole) produce pulsatile pressure waves. The sensor measures the arterial pulse pressure, which is proportional to SV. APCO monitoring uses the arterial waveform characteristics, along with demographic data (e.g., gender, age, height, weight) to calculate SV, and HR to calculate CCO/CCI and SV/SVI every 20 seconds. CO is calculated by multiplying the HR and calculated SV. It is displayed on a continuous basis. APCO monitoring is often used with a central venous oximetry catheter. Together, these allow for continuous monitoring of central venous O_2 saturation ($ScvO_2$) and SVR that is derived from the CVP.

Pulmonary Artery Flow-Directed Catheter

PA pressure monitoring guides the management of patients with select complicated heart and lung problems (Table 35.8). Pulmonary artery diastolic pressure (PADP) and PAWP are sensitive indicators of heart function and fluid volume status. PADP and PAWP increase in HF and fluid volume overload. They decrease with volume depletion. PA pressures can guide fluid therapy while limiting overcorrection or undercorrection.

A PA flow-directed catheter (e.g., Swan-Ganz) is used to measure PA pressures, including PAWP. The standard PA

catheter has multiple lumens (Fig. 35.14). When properly positioned, the distal lumen port (catheter tip) is within the PA. We use this port to monitor PA pressures and sample mixed venous blood (e.g., to monitor O_2 saturation).

A balloon connected to an external valve surrounds the distal lumen port. Balloon inflation has 2 purposes: (1) to allow blood to "float" the catheter forward and (2) to allow PAWP measurement. There are 1 or 2 proximal lumens, with exit ports in the right atrium or right atrium and right ventricle (if 2). The right atrium port is used for CVP measurement, injecting fluid for CO measurement, and withdrawing blood specimens. The 2nd proximal port (if available) is for infusing fluids and drugs or for blood sampling. A sensor near the distal tip monitors core temperature and is used for the thermodilution method of measuring CO.

An advanced technology PA catheter can continuously monitor the patient's SvO_2. CCO and right ventricular ejection fraction (RVEF) can be measured using advanced thermodilution technology. RVEF gives information about right ventricular function and helps to assess right heart contractility. Right ventricular end-diastolic volume, a key indicator of preload, is assessed by dividing SV by RVEF (Table 35.6).

The use of PA pressure monitoring has decreased dramatically. This is due, in part, to risks associated with this invasive technology (e.g., dysrhythmias, infection) and the development of less invasive techniques.[11]

The HCP often inserts a PA catheter at the bedside. Preparation includes arranging the monitor, cables, and infusion and pressurized flush solutions. The system is leveled and zero-referenced to the phlebostatic axis. Note the patient's electrolyte, acid-base, oxygenation, and coagulation status. Imbalances such as hypokalemia, hypomagnesemia, hypoxemia, or acidosis can make the heart more irritable. This can increase the risk for ventricular dysrhythmia during catheter insertion. Coagulopathy increases the risk for hemorrhage.

During insertion, a key nursing role is to observe the characteristic waveforms on the monitor as the HCP moves the catheter through the heart to the PA Fig. 35.15. Monitor the ECG continuously because of the risk for dysrhythmias, especially when the catheter reaches the right ventricle. After insertion and before using the PA catheter, obtain a chest x-ray to confirm catheter placement. Note and record the measurement at the exit point. Apply an occlusive sterile dressing and change it according to agency policy.[7]

TABLE 35.8 Common Indications and Contraindications for Pulmonary Artery Catheterization

Indications

- Assessment of response to therapy in mixed types of shock
- Cardiogenic shock
- Differential diagnosis and response to therapy in pulmonary hypertension
- MI with complications (e.g., HF, cardiogenic shock)
- Potentially reversible systolic HF
- Severe chronic HF requiring vasoactive drug therapy
- Transplantation workup

Contraindications

- Coagulopathy
- Endocardial pacemaker
- Endocarditis
- Mechanical tricuspid or pulmonic valve
- Right heart mass (e.g., thrombus, tumor)

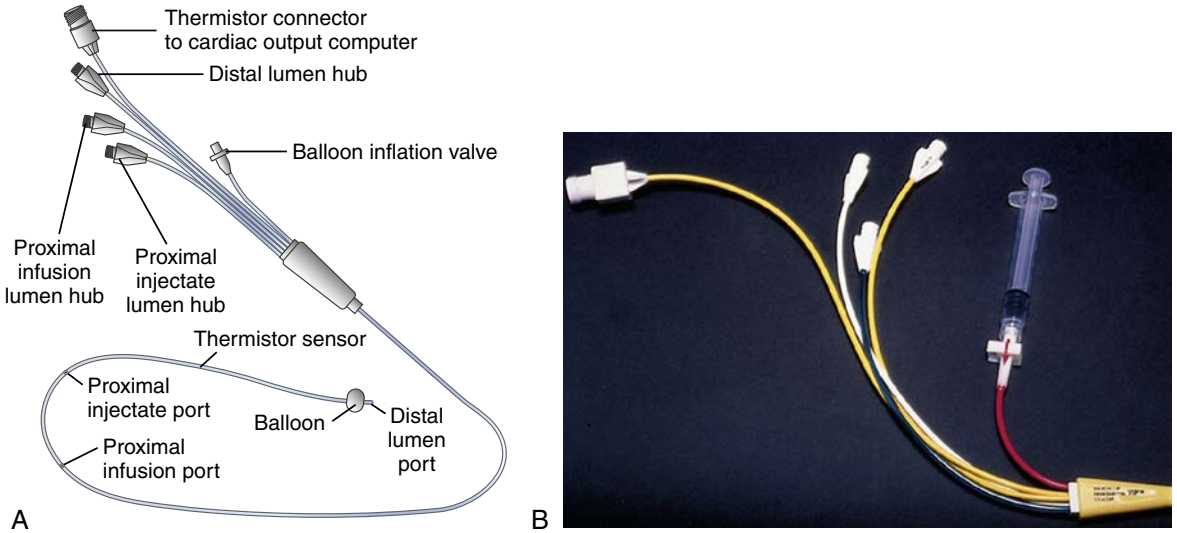

Fig. 35.14 Pulmonary artery (PA) catheter. (A) Catheter with 5 lumens. When properly positioned, the distal lumen exit port is in the PA and the proximal lumen ports are in the right atrium and right ventricle. The distal and 1 of the proximal ports are used to measure PA and CVP, respectively. A balloon surrounds the catheter near the distal end. The balloon inflation valve is used to inflate the balloon with air to allow reading of the PAWP. A thermistor near the distal tip senses PA temperature and measures thermodilution cardiac output when solution cooler than body temperature is injected into a proximal port. (B) Photo of an actual catheter. (B, Courtesy Edwards Critical Care Division, Baxter Healthcare Corporation, Santa Ana, CA.)

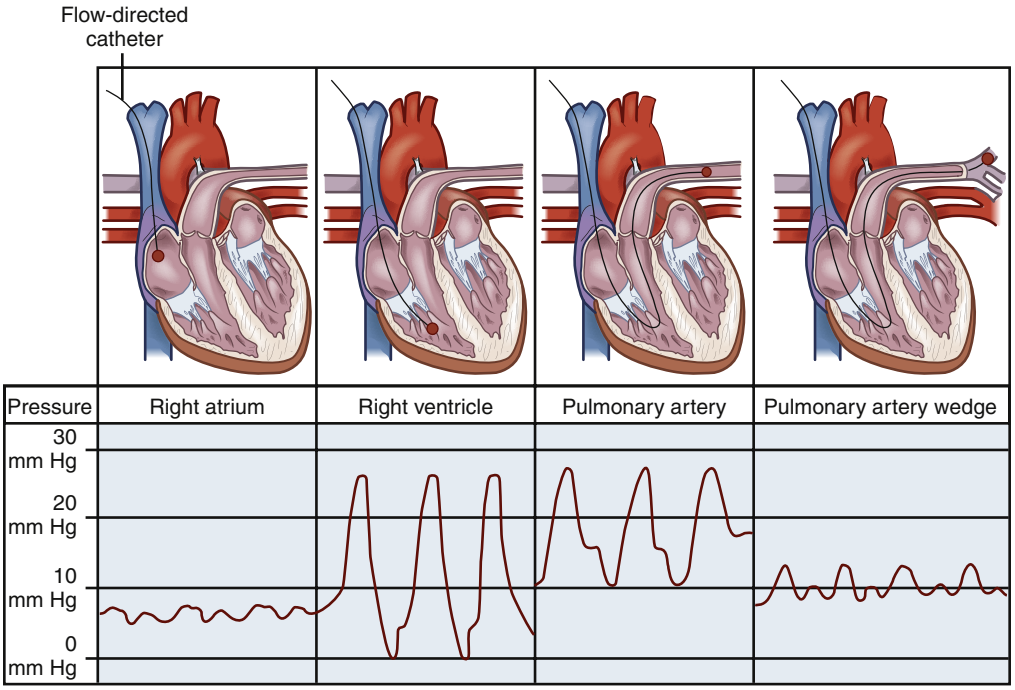

Fig. 35.15 Position of the pulmonary artery flow-directed catheter during progressive stages of insertion with corresponding pressure waveforms. (Modified from Urden LD, Stacy KM, Lough ME: *Critical care nursing: diagnosis and management,* ed 6, St Louis, 2010, Mosby.)

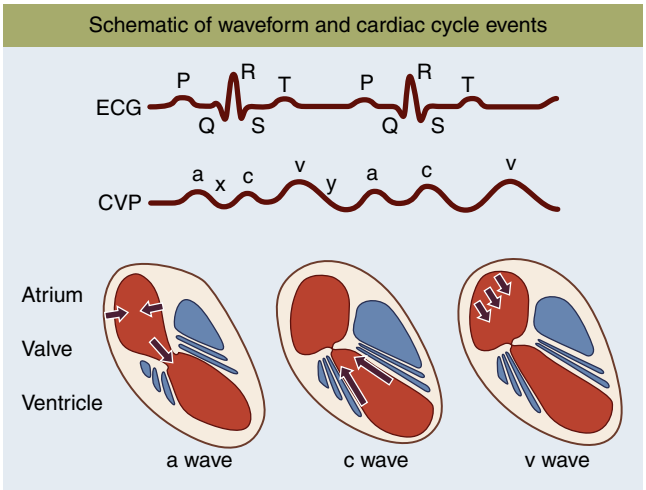

Fig. 35.16 Cardiac events that produce the CVP waveform with *a, c,* and *v* waves. The *a* wave represents atrial contraction. The *x* descent represents atrial relaxation. The *c* wave represents the bulging of the closed tricuspid valve into the right atrium during ventricular systole. The *v* wave represents atrial filling. The *y* descent represents opening of the tricuspid valve and filling of the ventricle. (Modified from Urden LD, Stacy KM, Lough ME: *Critical care nursing: diagnosis and management,* ed 6, St Louis, 2010, Mosby.)

Central Venous or Right Atrial Pressure Measurement

CVP is a measurement of right ventricular preload and reflects fluid volume status. We most often measure it with a central venous catheter placed in the internal jugular or subclavian vein. It can be measured with a PA catheter using the proximal lumen in the right atrium. CVP waveforms (Fig. 35.16) are similar to PAWP waveforms. CVP is measured as a mean pressure at the end of expiration. A high CVP indicates right ventricular failure or volume overload. A low CVP indicates hypovolemia.[11]

❖ NURSING MANAGEMENT: HEMODYNAMIC MONITORING

Assessment of hemodynamic status requires integrating data from many sources and trending data over time. Comprehensive nursing observations give important clues about the patient's hemodynamic status.

Begin by obtaining baseline data about the patient's general appearance, level of consciousness, skin color and temperature, vital signs, peripheral pulses, capillary refill, and urine output. Does the patient appear tired, weak, or exhausted? There may be too little cardiac reserve to sustain even minimum activity. Pallor, cool skin, and decreased pulses may indicate decreased CO. Changes in mental status may reflect problems with cerebral perfusion or oxygenation. Monitor urine output to determine the adequacy of perfusion to the kidneys. The patient with decreased perfusion to the GI tract may develop hypoactive or absent bowel sounds. If the patient is bleeding and developing shock, the BP may be stable at first. The patient may become increasingly pale and cool from peripheral vasoconstriction. Conversely, the patient with septic shock may be warm and pink yet have tachycardia and BP instability. Increased HRs are common in stressed, compromised, critically ill patients. However, sustained tachycardia increases myocardial O_2 demand and can result in decreased CO.

Always correlate your observations of the patient with data obtained from technology (e.g., ECG, arterial and PA pressures, $ScvO_2$, SvO_2). Single hemodynamic values are rarely helpful.

Monitor trends in the values over time and evaluate the clinical picture. The goal is to recognize early clues and intervene before the patient's status declines.[7]

DIAGNOSTIC STUDIES OF CARDIOVASCULAR SYSTEM

Numerous diagnostic tests are available to assess the cardiovascular system. Select studies are discussed in detail in this section. Table 35.9 describes common serology studies.

Blood Studies

Many blood studies provide information about the cardiovascular system. For example, some reflect the O_2-carrying capacity (red blood cell count, hemoglobin) and coagulation properties (clotting times) of the blood. See Chapter 33 about hematology studies.

Cardiac Biomarkers

When cells are injured, they release contents including enzymes and other proteins into the circulation. These *biomarkers* are

TABLE 35.9 Serology Studies

Cardiovascular System

Study	Reference Interval[a]	Description and Purpose
Biomarkers		
b-Type natriuretic peptide (BNP)	<100 pg/mL (100 pmol/L)	Peptide that causes natriuresis. ↑ in HF. Levels ↑ after nesiritide (Natrecor) infusion and for 1 month after cardiac surgery.
CK-MB	Concentrations <4%–6% of total creatine kinase (CK)	Tests for myocardial cell injury. ↑ Levels highly indicative of MI. Serum levels ↑ within 3–6 hr after MI, peak after 12–24 hours, normalize within 48 hours.
Copeptin	<10 pmol/L	Reflects arginine vasopressin (AVP) concentration. ↑ Levels highly indicative of MI. Higher in men, after exercise, and with stress. Influenced by fasting and water load.
C-reactive protein (CRP)	High-sensitivity CRP assay. *Lowest risk:* <1 mg/dL *Moderate risk:* 1–3 mg/dL *High risk:* >3 mg/dL	Marker of inflammation. May help predict risk for cardiac disease and cardiac events such as an acute MI. ↑ in bacterial infections and inflammatory disorders.
Homocysteine	4–14 μmol/L Levels may ↑ with age	Amino acid made during protein catabolism. Risk factor for cardiovascular disease. Associated with vitamin B_{12} and folate deficiencies.
N-terminal (NT)-Pro-BNP	≤*74 years:* 124 pg/mL >*75 years:* 449 pg/mL	Helps to assess severity of HF. Levels are higher in women and patients with renal insufficiency.
Troponin (cardiac)	*Troponin T (cTnT)* <0.1 ng/mL (<0.1 mcg/L) *High sensitivity Troponin T (hsTnT):* <14 ng/L for women <22 ng/L for men *Troponin I (cTnI)* *Negative:* <0.03 ng/mL (<0.03 mcg/L)	Preferred test for cardiac injury/ischemia: hsTnT assays detect troponins at lower concentrations as early as 90 min, speeding triage in possible MI. After the initial blood sample, blood is collected at 12 hr, then daily for 3–5 days.
Lipids		
Cholesterol	<200 mg/dL (<5.2 mmol/L) (varies with age and gender)	A blood lipid associated with arteriosclerosis. ↑ Level is a risk factor for cardiovascular heart disease. Nonfasting or fasting.
Lipoprotein (a) (Lp[a])	<30 mg/dL (<0.3 g/L)	↑ Level indicates an increased risk for atherosclerosis, MI, and stroke. Nonfasting or fasting.
Lipoprotein-associated phospholipase A_2 (Lp-PLA_2)	*Low risk:* ≤151 ng/mL *Moderate risk:* 152–194 ng/mL *High risk:* ≥195 ng/mL	Indicates inflammation and increased risk for CAD. Nonfasting or fasting.
Lipoproteins (HDL, LDL)	HDL Recommended *Male:* >45 mg/dL *Female:* >55 mg/dL *Low risk for CAD:* ≥60 mg/dL *High risk for CAD:* <40 mg/dL LDL <130 mg/dL *Moderate risk for CAD:* 130–159 mg/dL *High risk for CAD:* >160 mg/dL	There are marked day-to-day fluctuations, so more than 1 level is needed for accurate diagnosis. Nonfasting or fasting. Assess risk for heart disease by dividing the total cholesterol level by the HDL level and obtaining a ratio. *Low risk:* Ratio <3 *Average risk:* Ratio 3–5 *Increased risk:* Ratio >5
Triglycerides	*Male:* 40–160 mg/dL *Female:* 35–135 mg/dL	Mixtures of fatty acids. Elevations are associated with cardiovascular disease and diabetes. Avoid alcohol for 24 hr before testing. Nonfasting or fasting.

[a]Reference ranges for the laboratory tests vary by agency because of differences in equipment and reagents used.

useful in diagnosing acute coronary syndrome (ACS) (Table 35.9). Interpreting biomarker level results requires you to consider the time elapsed from the onset of symptoms. Other data (patient symptoms, history, and ECG changes) complete the diagnostic picture for the patient with suspected ACS.

Cardiac-specific troponin is a heart muscle protein released into circulation after injury or infarction. Two subtypes, cardiac-specific troponin T (cTnT) and cardiac-specific troponin I (cTnI), are specific to heart muscle. Normally the troponin level in the blood is very low. A rise in level is diagnostic of myocardial infarction (MI) or injury. cTnT and cTnI are detectable within hours (on average 4 to 6 hours) of MI or injury, peak at 10 to 24 hours, and can be detected for up to 10 to 14 days. Troponin is the biomarker of choice in diagnosing ACS. High-sensitivity troponin (hs-cTnT, hs-cTnI) assays provide even earlier detection of a heart event, within 1 to 3 hours.[12]

Copeptin, a substitute marker for arginine vasopressin (AVP), can be detected in patients with an acute MI, ischemic stroke, or HF. Considering both troponin and copeptin levels together may provide increased sensitivity for rapidly diagnosing acute MI. High copeptin levels are associated with increased mortality in patients with acute MI.[13]

Creatine kinase (CK) enzymes are found in a variety of organs and tissues and occur as 3 isoenzymes. These isoenzymes are specific to skeletal muscle (CK-MM), brain and nervous tissue (CK-BB), and the heart (CK-MB). CK-MB rise is specific for MI or cardiac injury. Levels begin to increase 3 to 6 hours after symptom onset, peak in 12 to 24 hours, and return to baseline within 12 to 48 hours after MI. CK is rarely used for diagnosis of acute MI.

C-Reactive Protein

C-reactive protein (CRP) is made by the liver during periods of acute inflammation. Increased CRP levels are linked with atherosclerosis and the first occurrence of a heart event. The CRP level may predict the risk for future heart events in patients with MI.

Homocysteine

Homocysteine (Hcy) is an amino acid made during protein catabolism. High Hcy levels can be either hereditary or from diet deficiencies of vitamin B_6, vitamin B_{12}, or folate. They are linked to a higher risk for CVD, PVD, and stroke. Hcy testing is recommended for patients with a family history of early CVD or a history of CVD in the absence of common risk factors.

Cardiac Natriuretic Peptide Markers

There are 3 natriuretic peptides: (1) atrial natriuretic peptide (ANP) from the atrium, (2) b-type natriuretic peptide (BNP) from the ventricles, and (3) c-type natriuretic peptide from endothelial and renal epithelial cells. BNP is the marker of choice for distinguishing between a cardiac or respiratory cause of dyspnea. N-terminal pro-brain natriuretic peptide (NT-pro-BNP) is secreted in the ventricles and is more sensitive but less specific than BNP as a diagnostic marker of HF. When DBP increases (e.g., HF), BNP and NT-pro-BNP are released and increase natriuresis (excretion of sodium in the urine). ANP and BNP are discussed in Chapter 36 and Chapter 38.

Serum Lipids

Serum lipids consist of triglycerides, cholesterol, and phospholipids (Table 35.9). These *lipoproteins* circulate in the blood bound to protein. A lipid panel usually measures cholesterol, triglyceride, low-density lipoprotein (LDL), and high-density lipoprotein (HDL).

Triglycerides, the main storage form of lipids, make up about 95% of fatty tissue. Cholesterol, a structural part of cell membranes and plasma lipoproteins, is a precursor of corticosteroids, sex hormones, and bile salts. It is absorbed from food in the gastrointestinal tract and synthesized in the liver. Phospholipids contain glycerol, fatty acids, phosphates, and a nitrogenous compound. Although formed in most cells, phospholipids usually enter the circulation as lipoproteins synthesized by the liver. Apoproteins are water-soluble proteins that combine with most lipids to form lipoproteins.

Different classes of lipoproteins contain varying amounts of the naturally occurring lipids. These include:

1. *Chylomicrons:* primarily exogenous triglycerides from fat intake
2. *Low-density lipoproteins (LDLs):* mostly cholesterol with moderate amounts of phospholipids
3. *High-density lipoproteins (HDLs):* about 50% protein and 50% phospholipids and cholesterol
4. *Very-low-density lipoproteins (VLDLs):* primarily endogenous triglycerides with moderate amounts of phospholipids and cholesterol

Increases in triglycerides and LDL are strongly associated with CAD. An increased HDL level is associated with a decreased risk of CAD. HDLs serve a protective role by mobilizing cholesterol from tissues.

Although a relationship exists between high serum cholesterol levels and CAD, a measure of total cholesterol alone is not enough for an assessment of CAD. A risk assessment is calculated by comparing the total cholesterol to HDL ratio over time. An increase in the ratio means increased risk.

Plasma levels of apolipoprotein A-I (apo A-I) (the major HDL protein) and the ratio of apo A-I to apolipoprotein B (apo B) (the major LDL protein) are stronger predictors of CAD than the HDL cholesterol level alone. Measurements of these lipoproteins can be useful in identifying patients at risk for CAD.

Lipoprotein (a), or Lp(a), has been studied for its role as a risk factor for CAD. Increased levels of Lp(a), especially with increased levels of lactate dehydrogenase (LDH), have been linked with atherosclerosis, especially in women.

Lipoprotein-associated phospholipase A_2 (Lp-PLA_2) is an inflammatory enzyme expressed in atherosclerotic plaques. High levels of Lp-PLA_2 are related to an increased risk for CAD.[14]

Diagnostic Studies

A number of tests provide information about the structure and function of the heart and cardiovascular system (Table 35.10).

TABLE 35.10 Diagnostic Studies

Cardiovascular System

Study	Description and Purpose	Nursing Responsibility
Electrocardiography (ECG)		
12-Lead ECG	Electrodes on the chest and extremities record cardiac electrical activity from 12 different views. A resting 12-lead ECG can identify conduction problems, dysrhythmias, position of heart, cardiac hypertrophy, pericarditis, myocardial ischemia or infarction, pacemaker activity, and effectiveness of drug therapy at 1 point in time.	*Before:* Prepare skin. Apply electrodes and leads. Place patient supine (or with head of bed elevated, if short of breath). Tell patient that no discomfort is involved and to lie still to decrease motion artifact. *During*: Ensure the patient lies still to decrease motion artifact.
ECG Event monitor or loop recorder	Records rhythm changes that are not frequent enough to be recorded in 1 24-hr period. Can aid in diagnosing the cause of chest pain, palpitations, dyspnea, and syncope. It allows more freedom than a regular Holter monitor. Some units have electrodes that attach to the chest and have a loop of memory that captures the onset and end of an event. Other types are placed directly on patient's wrist, chest, or fingers and record the patient's ECG in real time. Recordings may be transmitted over the phone to a receiving unit.	*Before:* Teach how to use equipment for recording and transmitting events. Teach patient about skin preparation for lead placement or steady skin contact to ensure quality tracings. Tell patient to start recording when symptoms begin or as soon after as possible.
ECG Holter monitoring	Recording of ECG rhythm for 24–48 hr to correlate with symptoms and activities recorded in diary. Encourage normal patient activity to simulate conditions that produce symptoms. Electrodes are placed on chest. A recorder stores information until it is recalled, printed, and analyzed for any rhythm changes.	*Before:* Prepare skin. Apply electrodes and leads. Explain importance of keeping an accurate diary of activities and symptoms. Tell patient there is no bathing and showering during monitoring. Skin irritation may develop from electrodes. If device has an event marker, teach patient to push that button when having symptoms.
Signal-averaged ECG (SAECG)	A high-resolution ECG that can identify electrical activity called late potentials. Their presence indicates a patient is at risk for developing ventricular dysrhythmias (e.g., ventricular tachycardia).	Same as for 12-lead ECG.
Functional		
6-Minute walk test	Distance patient can walk on a flat surface in 6 min. Measures response to treatments and determines functional capacity for activities of daily living. Useful in those who are debilitated or unable to perform treadmill or exercise bike testing. May be a better measure of fitness for older adults than exercise testing.	*Before:* Tell patient to wear comfortable shoes. Inform patient to carry or pull O_2 if used routinely. *During:* Encourage patient to walk as quickly as possible.
Exercise or stress testing	Provides information on cardiac function and exercise tolerance. A common protocol uses 3-min stages at set speeds and elevation of treadmill belt. The patient can exercise to either predicted peak HR (calculated by subtracting the person's age from 220) or peak exercise tolerance, at which time the test is ended. The test is end ed for chest discomfort, significant changes in vital signs from baseline, or significant ECG changes (e.g., ischemia, dysrhythmias). The ECG is monitored after exercise for ischemia and rhythm changes or, if ECG changes occurred with exercise, for return to baseline. Important diagnosing CAD. An exercise bike may be used if the patient is unable to walk on the treadmill.	*Before:* Tell patient to wear comfortable clothes and shoes fit for walking or running. Tell patient to report any symptoms. β-Blockers may be held 24 hr before the test because they blunt the HR and limit the patient's ability to achieve maximal HR. Caffeine is held for 24 hr. Patients must refrain from smoking and strenuous exercise for 3 hr before test. Obtain baseline vital signs and 12-lead-ECG. *During:* Monitor vital signs and ECG during each stage of exercise and after until all vital signs and ECG changes have returned to normal or baseline. Monitor patient's response throughout procedure for any signs of distress (e.g., angina, dyspnea).
Noninvasive hemodynamic monitoring	Obtained using a continuous finger cuff or by thoracic bioreactance/ bioimpedance methods. Possible to obtain repeated measurements of SV, CO, and systemic BP.	Minimal to no risk. Patients who need hemodynamic monitoring are likely to be in perioperative settings, critical care units, and emergency departments.
Imaging		
Chest x-ray	Patient is placed in lateral and posteroanterior (PA) positions to examine lung fields and heart size (Fig. 35.17). Helps diagnosis HF and pulmonary edema and visualize heart size and contour.	*Before:* Ask about frequency of recent x-rays and chance of pregnancy. Provide lead shielding to areas not being viewed. Remove jewelry or metal objects that may obstruct the view of heart and lungs.
Cardiac computed tomography (CT); electron beam CT (EBCT)	Heart-specific imaging technology with or without IV contrast medium. Used to evaluate heart anatomy, coronary circulation, and blood vessels. EBCT, or ultrafast CT, uses a scanning electron beam to quantify calcification in coronary arteries and heart valves (Fig. 35.19). IV contrast may be used if calcium scoring is below threshold level. Primarily used for risk assessment in asymptomatic patients and to assess for heart disease in patients with atypical symptoms potentially related to cardiac causes.	*Before:* Assess for contrast allergy. Explain that patient may feel a warm sensation, salty taste after IV contrast injection, nausea. *During*: Patient must lie still during test.

TABLE 35.10 Diagnostic Studies—cont'd

Cardiovascular System

Study	Description and Purpose	Nursing Responsibility
Cardiovascular magnetic resonance imaging (CMRI)	Noninvasive imaging technique obtains information about heart tissue, EF, aneurysms, CO, and patency of proximal coronary arteries. Measures regurgitant fraction that may determine valve repair or replacement. It does not involve ionizing radiation. Is a very safe procedure. Provides images in multiple planes with uniformly good resolution.	*Before:* Check for pregnancy, allergies, and renal function before test. Have patient remove all metal objects. Remove metallic foil patches. Patient may need to be fasting. Assess for claustrophobia and need for antianxiety medication Contraindicated for persons with implanted metallic devices or other metal fragments unless noted to be MRI safe. Ask about the presence of staples, plates, dental bridges, or other metal appliances. *During*: Patient must lie completely still during test.
Coronary CT angiography (CTA)	Use of CT with injected IV contrast medium to obtain images of coronary vessels and diagnose CAD. Used to evaluate chest pain and monitor the progression of coronary vascular disease.	*Before:* Assess for contrast allergy. Obtain IV access. Remove metal objects before test. The patient may need to fast for several hours prior. A β-blocker may be given before the test to control HR. *During:* Patients must have a regular heart rhythm for accurate testing.
Echocardiogram • Contrast • M-mode • 2-dimensional • Color-flow imaging (duplex) • Real-time 3-dimensional • Pharmacologic echocardiogram	Ultrasound transducer is placed in 4 positions on the chest to record sound waves bounced off the heart. Records direction and flow of blood through the heart and transforms it to audio and graphic data. Measures valve abnormalities, congenital heart defects, wall motion, EF, and heart function. IV contrast agent may be used to enhance images (Fig. 35.18). Pharmacologic echocardiogram is a substitute for the exercise stress test in persons unable to exercise. IV adenosine, dobutamine, or dipyridamole is given over several minutes or regadenoson (Lexiscan) is given as a single bolus over 10 sec while echocardiogram is performed to detect wall motion abnormalities.	*Before:* Place patient in a left side-lying position. Tell patient about procedure and sensations (pressure and mechanical movement from head of transducer). May be difficult to obtain in patients with COPD due to large amount of air between heart and chest cavity. Pharmacologic echocardiogram: *Before*: Obtain baseline vital signs and IV access for injection of drugs. *During*: Monitor vital signs until baseline achieved. Monitor patient for signs and symptoms of distress or side effects (e.g., dyspnea, dizziness, nausea). Aminophylline may be given to prevent or reverse side effects of dipyridamole.
Exercise (stress) nuclear imaging	Identifies cardiac symptoms and rhythm changes and simulate in a safe environment. Nuclear imaging images are taken at rest. Injection is given at maximum HR (usually 85% of age-predicted maximum) on bicycle or treadmill. Patient then continues exercise for 1 min to circulate the radioactive isotope. Scanning is done 15–60 min after exercise. A resting scan is done 60–90 min after initial infusion or 24 hr later.	*Before:* Tell patient to eat only a light meal between scans. Some drugs may need to be held for 1–2 days before the scan. Patients should not have caffeine 12 hr prior. Obtain IV access. *During:* If targeted maximum HR is not achieved with exercise, test may be changed to pharmacologic imaging.
Magnetic resonance angiography (MRA)	Used for imaging vascular occlusive disease and abdominal aortic aneurysms. Same as MRI but with use of gadolinium as IV contrast medium.	*Before:* Contraindications include allergies to contrast medium and implanted metallic devices or other metal fragments unless noted to be MRA safe. Discuss any implants before scan. Obtain IV access.
Multigated acquisition (MUGA) (cardiac blood pool) scan	Small amount of the patient's blood is removed, mixed with a radioactive isotope (e.g., Technetium-99m [^{99m}Tc sestamibi]), and reinjected IV. With the ECG used for timing, images are obtained during the cardiac cycle. Indicated for patients with MI, HF, or valve disease. Can evaluate the effect of various cardiac or cardiotoxic drugs on the heart and the cardiac EF.	*Before:* Explain procedure to patient. Obtain IV access for removal of blood sample and reinjection of isotope. Start ECG monitoring.
Nuclear imaging	Study involves IV injection of radioactive isotopes (^{99m}Tc sestamibi [Cardiolite]). Radioactive uptake is counted over the heart by scintillation camera. Gives information about heart contractility, myocardial perfusion, and acute injury.	*Before:* Remove bra to decrease artifact. Obtain IV access for injection of isotopes. Explain that radioactive isotope used is a small, diagnostic amount and will lose most of its radioactivity in a few hours. Tell patient that they will be lying still on back with arms extended overhead for 20 min. *During*: Repeat scans are done within a few minutes to hours after the injection.
Pharmacologic nuclear imaging	Regadenoson, dipyridamole, or adenosine are given to produce vasodilation for patients unable to tolerate exercise. Vasodilation increases blood flow to well-perfused coronary arteries. Scanning procedure is same. Aminophylline may be given to prevent or reverse side effects of dipyridamole (e.g., dyspnea, dizziness, nausea). Dobutamine is used if vasodilators are contraindicated.	*Before*: Tell patient to avoid caffeine products and theophylline (for regadenoson or dipyridamole testing) for 12 hr before procedure. Hold calcium channel blockers and β-blockers for 24 hr before the test. *During*: Observe patient for any side effects (dyspnea, dizziness, nausea).

Continued

TABLE 35.10 Diagnostic Studies—cont'd

Cardiovascular System

Study	Description and Purpose	Nursing Responsibility
Positron emission tomography (PET)	Highly sensitive in distinguishing viable and nonviable heart tissue. Uses 2 radionuclides. Nitrogen-13-ammonia is injected IV first and scanned to evaluate myocardial perfusion. A second radioactive isotope, fluoro-18-deoxyglucose, is then injected and scanned to show myocardial metabolic function. In the normal heart, both scans match, but in an ischemic or damaged heart, they differ. The patient may or may not be stressed. A baseline resting scan is usually done for comparison.	*Before:* Obtain IV access to inject the tracer substance. Patients should be NPO, except for water and medications, for at least 4 hr prior. If exercise is part of testing, patient needs to fast and refrain from tobacco and caffeine for 24 hr before test. Hold glucose-containing IV solutions and change to normal saline. Check blood glucose levels. The glucose level must be between 60 and 140 mg/dL (3.3–7.8 μmol/L) for accurate glucose metabolic activity. *During:* Patient must lie completely still during scan. *After:* Encourage fluids to excrete radioactive substance.
Single-photon emission computed tomography (SPECT)	Used to determine size or risk for infarction and to determine infarction size. Small amounts of a radioactive isotope (e.g., ^{99m}Tc tetrofosmin [Myoview], thallium-201) are injected IV, and recordings are made of the radioactivity emitted over a specific area of the body. Circulation of the isotope can detect coronary artery blood flow, intracardiac shunts, motion of ventricles, EF, and size of the heart chambers.	*Before:* Short fasting period may be needed. Obtain IV access for injection of isotope. Remove all jewelry from chest wall. Start ECG monitoring. *During:* Patient must lie completely still during scan. *After:* Encourage fluids to excrete radioactive substance.
Stress echocardiogram	Combination of exercise test and echocardiogram. Evaluates differences in left ventricular wall motion and thickening before and after exercise with ultrasound. Postexercise images taken within 1 min of stopping exercise.	*Before:* Prepare patient for treadmill or exercise bicycle. Tell patient of importance of timely return to examination table for imaging after exercise.
Transesophageal echocardiogram (TEE)	A probe with an ultrasound transducer at the tip is swallowed while the HCP controls angle and depth. As it passes down the esophagus, it sends back clear images of heart size, wall motion, valve abnormalities, endocarditis vegetation, and possible source of thrombi without interference from lungs or chest ribs. A contrast medium may be injected IV for evaluating direction of blood flow if an atrial or ventricular septal defect is suspected. Doppler ultrasound and color flow imaging can be used concurrently.	*Before:* Tell patient to fast for at least 6 hr before test. Remove dentures. *During:* IV sedation is given and throat locally anesthetized. A bite block is placed in the mouth. Monitor vital signs, specifically O_2 saturation and BP. Perform suctioning as needed during procedure. *After:* Patient may not eat or drink until gag reflex returns. Monitor patient until sedation resolves. Sore throat is temporary. A designated driver is needed if test is done in the outpatient department.

Electrocardiography

Electrocardiogram

The basic P, QRS, and T waveforms (Fig. 35.4B) are used to assess heart activity. Deviations from the normal sinus rhythm can indicate problems in heart function. There are many types of ECG monitoring, including a resting 12-lead ECG, ambulatory ECG monitoring, and exercise or stress testing (Table 35.10). Continuous ambulatory ECG (Holter monitoring) provides diagnostic information over a period of time. See Chapter 39 for a complete discussion of ECG monitoring.

Event Monitor

An event monitor is used to record less-frequent ECG events. An event monitor is a portable unit that uses electrodes to store and/or send ECG data. There are 2 types, external and implantable. External event recorders are worn for 2 to 4 weeks. They require electrodes continuously attached to the skin. The patient pushes a button to activate a notation when symptoms occur. The electrocardiographic activity can be sent in real time to an HCP or analyzed at the end of the wearing period. These devices also can perform a routine pacemaker check over the phone.

An implantable loop recorder is used for patients who may have serious yet infrequent dysrhythmias. This small recorder is implanted through a small incision into the chest wall to continuously monitor heart activity.

ECG applications are available for use from a smartphone. By touching special sensors or applying a smartphone watch, patients can see and record their cardiac rhythms for routine monitoring or for later discussion with the HCP.

Functional Studies

Exercise or Stress Testing

Heart symptoms often occur only with activity because of the demand on the coronary arteries to supply more O_2 to the heart muscle. Exercise testing can evaluate the heart's response to physical stress. This helps to assess CVD and set limits for exercise programs. Exercise testing is used for persons who can walk unassisted or use a bicycle. It is also helpful for those with ECGs that limit diagnostic interpretation (e.g., pacemakers) (Table 35.10). ECG and BP are monitored throughout the exercise period for signs of cardiac stress.

6-Minute walk test. A general test of cardiac fitness, often used with older adults, is measuring the distance the patient can walk on a flat surface in 6 minutes. The test can provide a baseline for determining response to treatment and physical therapy.

Imaging

Chest X-Ray

A radiographic picture of the chest can show heart shape and size and anatomic changes in individual chambers (Fig. 35.17). A chest x-ray records any displacement or enlargement of the

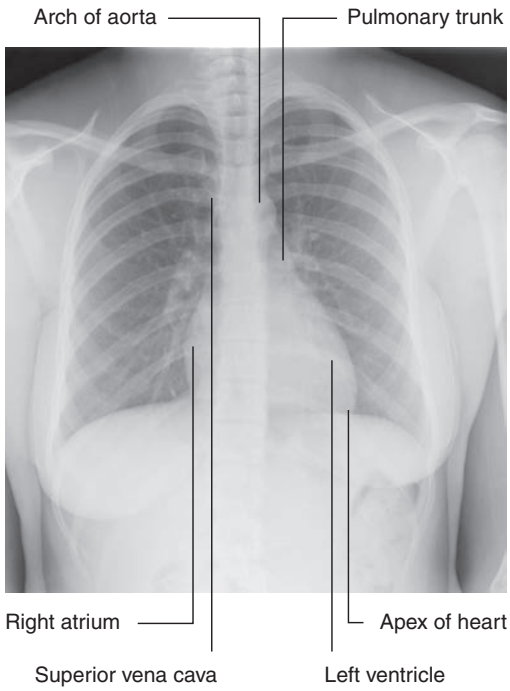

Fig. 35.17 Chest x-ray: standard posterior-anterior view. (From Drake RL, Vogl AW, Mitchell AWM: *Gray's anatomy for students,* ed 2, Philadelphia, 2010, Churchill Livingstone.)

heart, extra fluid around the heart (pericardial effusion), and pulmonary congestion (Table 35.10).

Echocardiography

The echocardiogram uses US waves to record the movement of the structures of the heart. In the normal heart, US waves directed at the heart are reflected back in typical patterns. *Contrast echocardiography* involves the addition of an IV contrast agent (e.g., agitated saline) to help define the images, especially in patients with increased body mass.

The echocardiogram provides information about abnormalities of (1) valvular structures and motion, (2) heart chamber size and contents, (3) ventricular and septal motion and thickness, (4) pericardial sac, and (5) ascending aorta. The **ejection fraction (EF),** or the percentage of end-diastolic blood volume that is ejected during systole, can be measured. The EF provides information about the function of the left ventricle during systole.

Two common types of echocardiograms are the *motion-mode (M-mode) echocardiogram* and the *2-dimensional (2D) echocardiogram.* In the M-mode, a single US beam is directed toward the heart, recording the motion of the intracardiac structures and detecting wall thickness and chamber size. The 2D echocardiogram sweeps the US beam through an arc, producing a cross-sectional view. This shows correct spatial relationships among the structures.

Doppler technology allows for sound evaluation of the flow or motion of the scanned object (heart valves, ventricular walls, blood flow). *Color-flow imaging (duplex)* is the combination of 2D echocardiography and Doppler technology (Fig. 35.18). It uses color changes to show the speed and direction of blood flow. This helps to diagnose pathologic conditions, such as valvular leaks and congenital defects, more effectively.

Real-time 3D ultrasound is a technology that uses multiple 2D echo images with computer technology to provide a reconstruction of the heart. This technique gives information about the structures of the heart and how these structures change during the cardiac cycle.

Stress echocardiography combines the information from a stress test with the information from an echocardiogram. A digital computer compares images before and after exercise, showing wall motion and function. For those persons unable to exercise, IV drugs are used. These include dobutamine, which produces pharmacologic stress on the heart and dipyridamole, which vasodilates healthy arteries. Unhealthy arteries do not respond as well, which is seen on the echocardiogram.

A *bubble study* is a type of contrast echocardiography used to check for a defect in the wall between the 2 upper chambers of the heart, such as a patent foramen ovale (PFO). Tiny bubbles in sterile solution are injected into a vein while an echocardiogram scans to detect any passage of the bubbles from the right to left heart. The bubbles are very small, and the bubble solution is absorbed into the bloodstream without endangering the patient.

TEE provides more precise echocardiography of the heart than surface 2D echocardiography. It removes interference from the chest wall and lungs (Table 35.10). The TEE uses a flexible endoscope with a US transducer in the tip to image the heart and great vessels. The scope is passed into the esophagus to the level of the heart. M-mode, 2D, Doppler, and color flow imaging can be obtained.

TEE is used often in an outpatient setting for evaluation of mitral valve disease and for identification of endocarditis vegetation, thrombus before cardioversion, or the source of heart emboli. In addition, TEE is used in the operating room to assess intraoperative heart function and in the emergency department to detect suspected aortic dissection.

The risks of TEE are low. However, complications include perforation or tearing of the esophagus, hemorrhage, dysrhythmias, vasovagal reactions, and transient hypoxemia. TEE is contraindicated if the patient has a history of esophageal disorders, dysphagia, or radiation therapy to the chest wall. Patients need sedation during a TEE.

Cardiac Computed Tomography (CT)

Cardiac CT is a heart-imaging test that uses CT technology with or without IV contrast (dye) to see the heart anatomy, coronary circulation, and great blood vessels (e.g., aorta, pulmonary veins, artery). This technology may be called *multidetector CT (MDCT) scanning.* Types of CT scans used to diagnose heart disease include coronary CT angiography (CTA) and calcium-scoring CT scan (Table 35.10).

Coronary CTA is a noninvasive test. It is faster, is less risky, and requires less radiation exposure than a cardiac catheterization. Patients must have a normal sinus rhythm for this test. Although the use of coronary CTA is increasing, cardiac catheterization is the gold standard to diagnose CAD. During a cardiac catheterization, procedures (e.g., angioplasty, stent placement) can be done if coronary blockages are found.

The calcium-scoring CT scan is used to find calcium deposits in plaque in the coronary arteries. The most common method used is the electron beam CT (EBCT) (Fig. 35.19). It can detect early coronary calcification before symptoms develop and confirm suspected CAD. The amount of coronary calcium predicts the risk of future cardiac events.

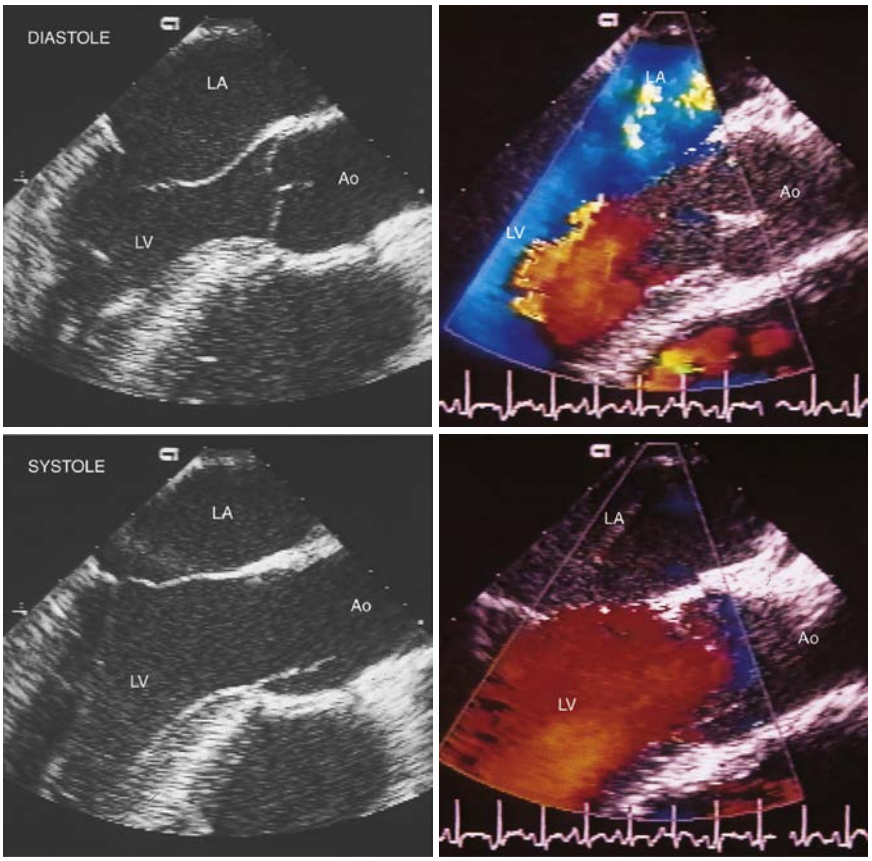

Fig. 35.18 Long-axis images of the aortic and mitral valve with the depth adjusted to optimize evaluation of valve anatomy and motion. The 2-D images *(left)* in diastole *(top)* and systole *(bottom)* show normal aortic and mitral opening and closure. The color flow images *(right)* show normal left ventricular inflow with no aortic regurgitation in diastole *(top)* and normal antegrade flow in the left ventricular outflow tract and no mitral regurgitation in systole *(bottom). Ao,* Aorta; *LA,* left atrium; *LV,* left ventricular. (From Otto C: *Textbook of clinical echocardiography,* ed 3, St Louis, 2004, Saunders.)

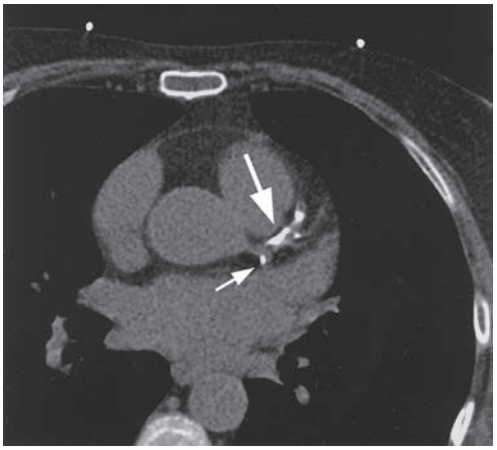

Fig. 35.19 Examples of coronary calcification of the left anterior descending coronary artery *(large arrow)* and left circumflex artery *(small arrow)* as seen on electron beam computed tomography. (From Libby P, Bonow R, Zipes D, et al.: *Braunwald's heart disease: a textbook of cardiovascular medicine,* ed 8, St Louis, 2008, Saunders.)

Cardiovascular Magnetic Resonance Imaging

Cardiovascular magnetic resonance imaging (CMRI) can detect and find areas of MI in a 3D view. It is sensitive enough to find even small MIs that are not apparent with single-photon emission computed tomography (SPECT). CMRI aids in the final diagnosis of MI and the assessment of EF. It plays a role in predicting recovery from MI and diagnosing congenital heart and aortic disorders and CAD. One major advantage of CMRI is that it does not require any radiation to the patient.

Patients with coronary stents can undergo CMRI 6 weeks after stent placement. CMRI is discouraged in those with older model pacemakers and implantable cardioverter defibrillator (ICDs) because the magnets can change the function of the devices. However, when there is a strong clinical need and the benefits outweigh the risks, CMRI can be done at centers experienced in this procedure. Many newer models of pacemakers and ICDs are approved for use with MRI.

Nuclear Cardiology

One of the most common nuclear imaging tests is the multigated acquisition (MUGA) or cardiac blood pool scan. This test provides information on wall motion during systole and diastole, heart valves, and EF (Table 35.10).

Perfusion imaging is used with exercise testing to determine whether the coronary blood flow changes with increased activity. Stress perfusion imaging may show an abnormality even when a resting image is normal. This procedure is used to diagnose CAD, make a prognosis in existing CAD, distinguish viable heart muscle from scar tissue, and determine the potential

for success of various interventions (e.g., coronary artery bypass surgery, percutaneous coronary intervention) (see Chapter 37).

Exercise stress perfusion imaging is an option if a patient cannot exercise. IV regadenoson, dipyridamole, or adenosine can be given to dilate the coronary arteries and simulate the effect of exercise. After the drug takes effect, the isotope is injected, and the imaging is done.

SPECT uses technetium, thallium, or sestamibi as an imaging agent (isotope). Patients who are obese or have large breasts may have false-positive results. Patients with severe multivessel coronary disease or blockages in their left main coronary artery may have false-negative results.

Positron emission tomography (PET) stress testing is increasingly being used due to its high sensitivity for revealing myocardial ischemia and viability. This type of myocardial perfusion imaging is often done using rubidium-82.

Interventional Studies

Cardiac Catheterization

Cardiac catheterization provides information about CAD, coronary spasm, congenital and valvular heart disease, and ventricular function. Cardiac catheterization is used to measure intracardiac pressures and O_2 levels, as well as CO and EF (Fig. 35.20). With injection of contrast media and fluoroscopy, the coronary arteries can be seen, chambers of the heart can be outlined, and wall motion assessed (Table 35.11).

Cardiac catheterization is done by inserting a radiopaque catheter into the right and/or left side of the heart. For the right

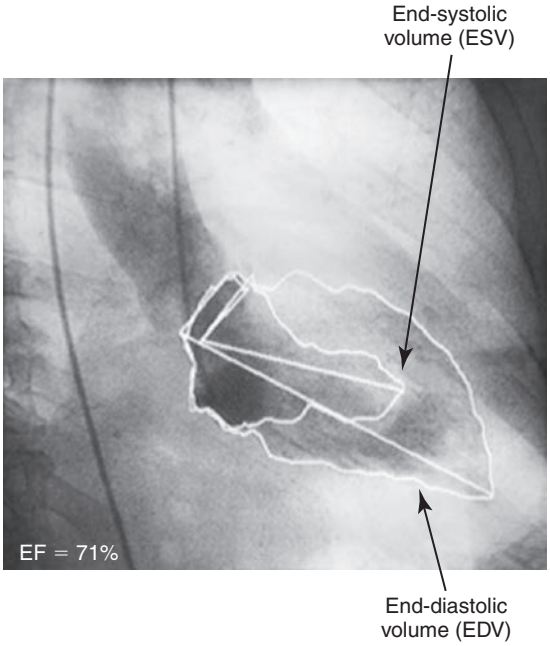

Fig. 35.20 Cardiac catheterization. End-diastolic volume and end-systolic volume used to determine ejection fraction *(EF)*. (From Lough M: *Hemodynamic monitoring: evolving technologies and clinical practice*. St Louis, 2016, Elsevier.)

TABLE 35.11 Interventional Studies

Cardiovascular System

Study	Description and Purpose	Nursing Responsibility
Cardiac catheterization; coronary angiography	Involves insertion of catheter into heart via a vein (for right side of heart) and/or an artery (for left side of heart). Procedure is done to evaluate chest pain and obtain information about the heart and major vessels. Measures pressures within the heart chambers. Contrast medium is injected to help see structures and motion of heart. With coronary angiography, contrast medium is injected directly into coronary arteries to evaluate patency and collateral circulation.	See Table 35.12.
Electrophysiology study (EPS)	Invasive study to record intracardiac electrical activity using catheters (with multiple electrodes) inserted via the femoral or jugular veins into right side of heart. Catheter electrodes record the electrical activity in different heart structures. Can induce and stop dysrhythmias. Insertion of a pacemaker or implantable cardioverter defibrillator (ICD) or ablation of a dysrhythmia pathway may be done during or right after the EPS. See Chapter 34 for more details.	*Before:* Antidysrhythmic drugs may be stopped several days before study. Keep patient NPO 6–8 hr before test. Give premedication to promote relaxation if ordered. Obtain IV access. IV sedation often used during procedure. *After:* Assess vital signs often. Monitor ECG continuously per agency protocol. Patient will be on bedrest for 6–8 hr after procedure.
Fractional flow reserve (FFR)	During cardiac catheterization, a specialized wire is inserted into coronary arteries to measure pressure and flow. Information is used to determine need for angioplasty or stenting on nonsignificant blockages.	Same as for cardiac catheterization.
Intravascular ultrasound (IVUS)	During cardiac catheterization a small ultrasound probe is introduced into coronary arteries. Used to assess blood vessel patency, size and consistency of plaque, arterial walls, and effectiveness of intracoronary artery treatment.	Same as for cardiac catheterization.
Peripheral arteriography and venography	Peripheral vessel blood flow is assessed by injecting contrast media into appropriate arteries or veins (arteriography and venography). Serial x-ray studies done to detect atherosclerotic plaques, occlusion, aneurysms, venous abnormalities, or traumatic injury. See Table 41.9 for more peripheral vascular diagnostic studies.	*Before:* Assess for contrast allergy. Explain that patient may feel a warm sensation, salty taste after contrast injection. Patient may have nausea. Give mild sedative, if ordered. *During:* Observe patient for allergic reaction to contrast media. *After:* Inspect insertion site for bleeding or swelling. Check extremity with puncture site for pulsation, warmth, color, and motion. Encourage fluids to excrete radioactive substance.

TABLE 35.12 NURSING MANAGEMENT

Care of the Patient Undergoing Cardiac Catheterization

Preprocedure

- Assess for allergies, especially to contrast dye.
- Perform baseline assessment, including vital signs, pulse oximetry, heart and breath sounds, neurovascular assessment of extremities (e.g., distal pulses, skin temperature, skin color, sensation).
- Withhold food and fluids for 6 hours before the procedure.
- Assess baseline laboratory values (e.g., cardiac biomarkers, creatinine).
- Teach patient and caregiver about procedure and postprocedure care. Explain the use of local anesthesia at insertion site. Describe the flushed feeling when dye is injected and possible fluttering sensation of heart as catheter is passed.
- Give sedative and other drugs, as ordered.

Postprocedure

- Perform assessment and compare to baseline: vital signs, pulse oximetry, and heart and breath sounds. Note hypotension or hypertension and signs of pulmonary emboli (e.g., respiratory difficulty).
- Assess neurovascular status, including peripheral pulses, color, and sensation, of extremity per agency protocol.
- Place compression device over arterial site to achieve hemostasis, if indicated.
- Observe insertion site for hematoma and bleeding every 15 min for the first hour, then according to agency policy.
- Monitor ECG for dysrhythmias or other changes (e.g., ST segment elevation).
- Monitor patient for chest pain and other sources of pain or discomfort.
- Maintain bedrest as prescribed after femoral access, depending on hemostasis method.
- Maintain IV and/or oral fluid intake and monitor urine output.
- Teach patient and caregiver about discharge care, including signs and symptoms to report to HCP (e.g., site complications, return of chest pain), and any activity restrictions.

side of the heart, the HCP inserts a catheter into the femoral, internal jugular, subclavian, or antecubital vein. Pressures are recorded as the catheter is moved into the vena cava, right atrium, right ventricle, and PA. The catheter is then moved until it is wedged or lodged in position. This blocks the blood flow and pressure from the right side of the heart and detects pressure through the pulmonary capillary bed to the left side of the heart (PAWP).

Left-sided heart catheterization is done by inserting a catheter into a radial, femoral, or brachial artery. The catheter is passed in a retrograde manner up to the aorta, across the aortic valve, and into the left ventricle.

Coronary angiography is done with a left-sided heart catheterization. The catheter is positioned at the origin of the coronary arteries (Fig. 35.3), and contrast medium is injected into the arteries. Patients often feel a temporary flushed sensation with dye injection. The images show the location and severity of any coronary blockages (see Figs. 35.21 and 37.15).

Fig. 35.21 Angiogram showing a normal left coronary and circumflex artery. (From Drake RL, Vogl AW, Mitchell AWM: *Gray's anatomy for students,* ed 2, Philadelphia, 2010, Churchill Livingstone.)

Complications of cardiac catheterization include bleeding or hematoma at the puncture site; allergic reactions to the contrast media; looping or kinking of the catheter; infection; thrombus formation; aortic dissection; dysrhythmias; MI; stroke; and puncture of the ventricles, septum, or lung tissue.[11,15]

Intravascular Ultrasound

Intravascular ultrasound (IVUS), or intracoronary ultrasound (ICUS), is an invasive procedure done in the catheterization laboratory with coronary angiography. The 2D or 3D US images provide a cross-sectional view of the arterial walls of the coronary arteries. In IVUS, a miniature transducer attached to a small catheter is moved to the artery to be studied. Once it is in the artery, US images are obtained. The health of the arterial layers is assessed, including the composition, location, and thickness of any plaque. IVUS can evaluate vessel response to treatments such as stent placement and atherectomy.[15] Patients often have IVUS in addition to angiography or a coronary intervention. Nursing care after IVUS is similar to that of patient after a cardiac catheterization.

Electrophysiology Study

The electrophysiology study (EPS) records and manipulates the heart's electrical activity using electrodes placed inside the heart chambers. It provides information on SA node, AV node, and ventricular conduction. It is particularly helpful in determining the source and treatment of dysrhythmias. Patients with symptomatic tachydysrhythmias are at risk for sudden cardiac death. Information from an EPS helps to make a correct diagnosis and guides treatment decisions (Table 35.11). In EPS, catheters are inserted like a right-sided heart catheterization. Nursing care after EPS is similar to that of a patient after a cardiac catheterization.[15]

Case Study

Objective Data: Diagnostic Studies

(©Jupiterimages/ Banana-Stock/ Thinkstock.)

The HCP orders the following initial diagnostic studies for L.P.:

- 12-lead ECG
- CBC, basic metabolic panel (glucose, electrolytes, BUN, creatinine)
- PTT, PT, INR
- Pro-BNP
- Troponin, CK-MB
- TSH, free T_4
- Chest x-ray

The ECG shows atrial fibrillation with a rapid ventricular response. L.P.'s initial troponin and CK-MB levels are within normal limits. Chest x-ray, CBC, and coagulation studies are all within normal limits. The potassium level is 3.1 mEq/L and pro-BNP is high (1204 pg/mL). The HCP orders 250 mL NSS IV bolus; an oral dose of potassium, a loading dose of IV diltiazem followed by a continuous infusion, and weight-based heparin to be started in the emergency department. L.P. will be admitted to the progressive care unit and have a consult with a cardiologist.

Discussion Questions

1. Are these the diagnostic studies that you expected to be ordered?
2. Which diagnostic study results are abnormal?
3. Which diagnostic study results most concern you?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Where is the blood flow altered when a patient has a tricuspid valve problem?
   - **a.** Vena cava and right atrium
   - **b.** Left atrium and left ventricle
   - **c.** Right atrium and right ventricle
   - **d.** Right ventricle and pulmonary artery
2. A patient has a severe blockage in his right coronary artery. Which heart structures would the nurse expect to be affected by this blockage? (*select all that apply)*
   - **a.** AV node
   - **b.** Left ventricle
   - **c.** Coronary sinus
   - **d.** Right ventricle
   - **e.** Pulmonic valve
3. Which part of the vascular system provides hemostasis?
   - **a.** Thin capillary vessels
   - **b.** Endothelial layer of the arteries
   - **c.** Elastic middle layer of the veins
   - **d.** Smooth muscle of the arterial wall
4. Which homeostatic mechanism is stimulated to compensate for a rise in blood pressure?
   - **a.** Baroreceptors that inhibit the sympathetic nervous system, causing vasodilation
   - **b.** Chemoreceptors that inhibit the sympathetic nervous system, causing vasodilation
   - **c.** Baroreceptors that inhibit the parasympathetic nervous system, causing vasodilation
   - **d.** Chemoreceptors that stimulate the sympathetic nervous system, causing an increased heart rate
5. Which action does the P wave on an ECG represent?
   - **a.** Firing of the SA node and repolarizing the atria
   - **b.** Firing of the SA node and depolarizing the atria
   - **c.** Conduction through the AV node and depolarizing the atria
   - **d.** Conduction through the AV node and spreading to the bundle of His
6. Which subjective data related to the cardiovascular system would the nurse plan to obtain? *(select all that apply)*
   - **a.** Annual income
   - **b.** Smoking history
   - **c.** Spiritual preferences
   - **d.** Number of pillows used to sleep
   - **e.** Blood for basic laboratory studies
7. Which heart valve sound is heard best at the left midclavicular line at the level of the 5th ICS?
   - **a.** Aortic
   - **b.** Mitral
   - **c.** Tricuspid
   - **d.** Pulmonic
8. Which condition is likely to cause a pulse deficit of 23 beats?
   - **a.** Dysrhythmia
   - **b.** Heart murmur
   - **c.** Gallop rhythm
   - **d.** Pericardial friction rub
9. Which finding is expected in the assessment of an 81-year-old patient?
   - **a.** Narrowed pulse pressure
   - **b.** Diminished carotid artery pulses
   - **c.** Difficulty isolating the apical pulse
   - **d.** Increased heart rate in response to stress
10. Which item would the nurse zero to establish accurate hemodynamic monitoring for a patient?
    - **a.** Pressure monitoring system to phlebostatic axis
    - **b.** Pressure monitoring system to the level of the midclavicular line
    - **c.** Cardiac output monitoring system to the level of the left ventricle
    - **d.** Pressure monitoring system to the level of the catheter tip in the patient
11. Which nursing responsibilities are priorities when caring for a patient returning from a cardiac catheterization? *(select all that apply)*
    - **a.** Monitoring vital signs and ECG

b. Checking the catheter insertion site and distal pulses
c. Helping the patient to ambulate to the bathroom to void
d. Telling the patient that he will be sleepy from the general anesthesia
e. Teaching the patient about the risks of the radioactive isotope injection

1. c; 2. a, b, d; 3. b; 4. a; 5. b; 6. b, c, d; 7. b; 8. a; 9. c; 10. a; 11. a, b.

CONCEPTUAL FOCUS

Adherence
Fluids and Electrolytes
Perfusion
Self-Management

LEARNING OUTCOMES

1. Relate the pathophysiology of primary hypertension to the clinical manifestations and complications.
2. Choose appropriate strategies for the prevention of primary hypertension.
3. Describe the interprofessional care for primary hypertension.
4. Explain the interprofessional care of the older adult with primary hypertension.
5. Prioritize the nursing management of the patient with primary hypertension.
6. Describe the nursing and interprofessional care of a patient with a hypertensive crisis.

KEY TERMS

blood pressure (BP)
elevated blood pressure, Table 36.2
hypertension
hypertensive crisis
orthostatic hypotension
primary hypertension
secondary hypertension
systemic vascular resistance (SVR)

Hypertension, or high blood pressure (BP), is one of the most important modifiable risk factors for the development of cardiovascular disease (CVD). As BP increases, so does the risk for myocardial infarction (MI), heart failure (HF), stroke, renal disease, and vision loss. This chapter discusses the nursing and interprofessional care of patients with or at risk for hypertension. Providing comprehensive care will require you to collaborate with many members of the health care team. Patient education is key to hypertension management. Proper nutrition and exercise are important health promotion behaviors.

Current guidelines reveal that around 45% of adults in the United States meet the criteria for the diagnosis of hypertension. Heart disease, often directly related to hypertension, accounts for 23.7% of all deaths each year in the United States.[1,2]

Most people with high BP need a combination of medication and lifestyle modifications.[3] Of the 108 million US adults with hypertension, 71% do not have their BP in control. Of those with uncontrolled BP, 49% are untreated.

The American College of Cardiology Foundation and the American Heart Association (AHA) provides performance measures for hypertension management. Target goals are based on the evidence-based Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults: A Report of the American College of Cardiology/AHA Task Force on Clinical Practice Guidelines and the Systolic Blood Pressure Intervention Trial (SPRINT). Target goals take age and comorbidities into consideration when recommending treatment options.[4,5]

National guidelines are designed to apply to all racial and ethnic groups. However, specific groups have higher incidences of risk factors (Boxes 36.1 and 36.2). BP control is strongly impacted by social determinants of health. These include lack of access to health care, poverty, and chronic stress.[6] Emerging research highlights the need to include underrepresented populations in clinical and genetic studies.[6,7]

NORMAL REGULATION OF BLOOD PRESSURE

Blood pressure (BP) is the force exerted by the blood against the walls of the blood vessel. It must be adequate to maintain tissue perfusion during activity and rest. Maintaining normal BP and tissue perfusion requires the integration of both systemic factors and local peripheral vascular effects. BP is mainly a function of cardiac output (CO) and systemic vascular resistance (Fig. 36.1).

CO is the total blood flow through the systemic or pulmonary circulation per minute. It is determined by the stroke volume (SV) or the amount of blood pumped out of the left ventricle per beat (about 70 mL) multiplied by the heart rate (HR).

Systemic vascular resistance (SVR) is the force opposing the movement of blood within the blood vessels. The radius of the small arteries and arterioles is the principal factor determining SVR. As arteries narrow, resistance to blood flow increases. As arteries dilate, resistance to blood flow decreases. A small change in the radius of the arterioles creates a significant change in the SVR. If SVR is increased and CO stays constant or increases, arterial BP will increase.

The mechanisms that regulate BP can affect either CO or SVR or both. Regulation of BP is a complex process involving both short-term (seconds to hours) and long-term (days to weeks) mechanisms. Short-term mechanisms, including the sympathetic nervous system (SNS) and vascular endothelium, are active within a few seconds. Long-term mechanisms include renal and hormonal processes that regulate arteriolar resistance and blood volume. In a healthy person, these regulatory mechanisms work in response to the body's demands.

BOX 36.1 PROMOTING HEALTH EQUITY

Hypertension

Blacks
- Have the highest prevalence of hypertension in the world
- Are more likely to have resistant hypertension
- Develop hypertension at a younger age than other ethnicities with higher average BP
- Have a higher incidence of hypertension among women than among men
- Have more nocturnal nondipping BP than Whites, which increases risk for CVD
- Hypertension is more aggressive and results in more severe end-organ damage
- Have the highest death rate from hypertension

Hispanics
- Are less likely to receive treatment for hypertension than Whites and non-Hispanic Blacks
- Have lowest rates of BP control
- Have lowest levels of awareness of hypertension and its treatment

BOX 36.2 BIOLOGIC SEX CONSIDERATIONS

Hypertension

Men
- Before early middle age, hypertension is more common in men

Women
- Hypertension is 2 to 3 times more common in women who take oral contraceptives
- A history of preeclampsia may be an early sign of risk for CVD
- After age 64, hypertension is more common in women. This is due in part to menopause-related factors, such as estrogen withdrawal, overproduction of pituitary hormones, and weight gain
- Harder to control hypertension in older women (ages 70–79) than in women ages 50–69, despite similar treatment

Sympathetic Nervous System

The nervous system, which reacts within seconds after a drop in BP, increases BP by activating the SNS. Increased SNS activity increases HR and cardiac contractility. It causes widespread vasoconstriction in the peripheral arterioles and promotes the release of renin from the kidneys. The net effect of SNS activation is to increase BP by increasing both CO and SVR.

Specialized nerve cells called *baroreceptors* are found in the carotid arteries and arch of the aorta. These cells sense changes in BP and send this information to the vasomotor centers in the brainstem. The brainstem sends this information through complex networks of neurons that excite or inhibit efferent nerves. SNS efferent nerves innervate cardiac and vascular smooth muscle cells. Under normal conditions, a low level of continuous SNS activity maintains vascular tone. BP may be reduced by the withdrawal of SNS activity or by stimulation of the parasympathetic nervous system (PNS). The PNS decreases the HR (via the vagus nerve) and thereby decreases CO.

The neurotransmitter norepinephrine (NE) is released from SNS nerve endings. NE activates receptors in the sinoatrial node, myocardium, and vascular smooth muscle. The response to NE depends on the type of receptors present. SNS receptors are classified as α_1, α_2, β_1, and β_2 (Table 36.1). The smooth muscle of the blood vessels has α-adrenergic and β_2-adrenergic receptors. α-Adrenergic receptors found in the peripheral vasculature cause vasoconstriction when stimulated by NE.

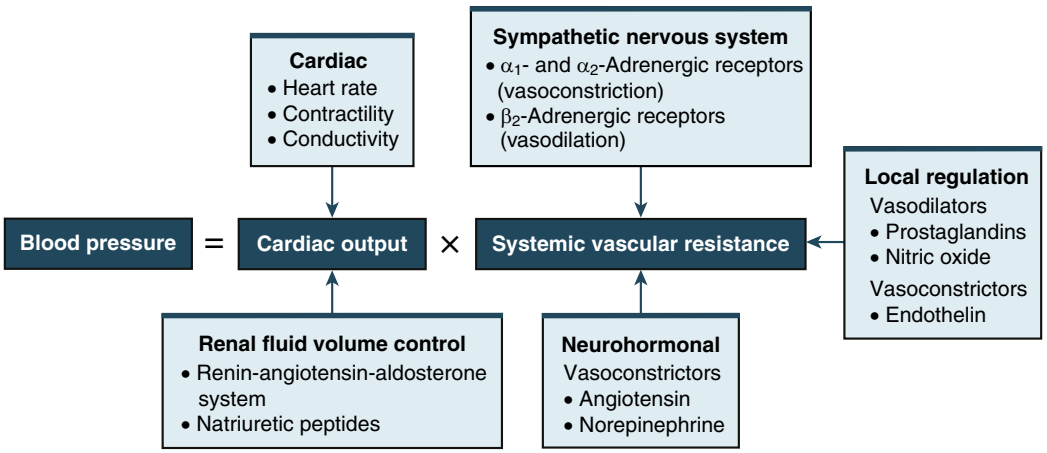

Fig. 36.1 Factors influencing BP. Hypertension develops when one or more of the BP-regulating mechanisms are defective.

TABLE 36.1 Sympathetic Nervous System Receptors Affecting BP

Receptor	Location	Response When Activated
α_1	Vascular smooth muscle	Vasoconstriction
	Heart	↑ Contractility (positive inotropic effect)
α_2	Presynaptic nerve terminals	Inhibition of norepinephrine release
	Vascular smooth muscle	Vasoconstriction
β_1	Heart	↑ Contractility (positive inotropic effect) ↑ Heart rate (positive chronotropic effect) ↑ Conduction (positive dromotropic effect)
	Juxtaglomerular cells of the kidney	↑ Renin secretion
β_2	Smooth muscle of blood vessels in heart (e.g., coronary arteries), lungs (e.g., bronchi), and skeletal muscle	Vasodilation
Dopamine receptors	Primarily renal blood vessels	Vasodilation

β_1-Adrenergic receptors in the heart respond to NE and epinephrine with increased HR (chronotropic), increased force of contraction (inotropic), and increased speed of conduction (dromotropic). β_2-Adrenergic receptors are activated mainly by epinephrine released from the adrenal medulla. They cause vasodilation (see Fig. 36.1).

The sympathetic vasomotor center interacts with many areas of the brain to maintain normal BP under various conditions. It is activated during times of pain, stress, and exercise. The SNS response causes an appropriate increase in CO and BP to adjust to the body's increased O_2 demands. During the postural change from lying to standing, there is a transient decrease in BP. The vasomotor center is stimulated. The SNS response causes peripheral vasoconstriction and increased venous return to the heart. If this reaction did not occur, blood flow to the brain would be inadequate, resulting in dizziness or syncope.

Baroreceptors

Baroreceptors have a vital role in maintaining BP stability during normal activities. They are sensitive to stretching. When stimulated by an increase in BP, they send inhibitory impulses to the sympathetic vasomotor center. SNS inhibition results in decreased HR, decreased force of contraction, and vasodilation in peripheral arterioles.

When baroreceptors sense a fall in BP, the SNS is activated. The result is constriction of the peripheral arterioles, increased HR, and increased contractility of the heart. In long-standing hypertension, the baroreceptors become adjusted to increased BP levels and recognize this level as their new "normal."

Vascular Endothelium

The vascular endothelium is a single-cell layer that lines the blood vessels. The endothelium is responsible for several critical functions. These include platelet adhesion, coagulation regulation, immune function, and regulating fluid control within the vessel and extravascular space. The endothelium can cause adhesion and aggregation of neutrophils and stimulate smooth muscle growth.

The endothelium is essential to the regulation and maintenance of vasodilating and vasoconstricting substances. Endothelium-derived vasoactive substances include *nitric oxide* (NO) and *prostacyclin*. Both are vasodilators. Another product of the endothelium is *endothelin* (ET). It is a potent vasoconstrictor (Fig. 36.1). Cardiovascular risk factors, such as smoking and diabetes, can reduce functional endothelial cells. This can cause arterial tone changes (excessive constriction or dilation), which are early warning signals of CVD.

Renal System

The kidneys contribute to BP regulation by controlling sodium excretion and extracellular fluid (ECF) volume (see Chapter 49). Sodium retention results in water retention, which increases ECF volume. This action increases venous return to the heart and SV. Together, these increase CO and BP.

The renin-angiotensin-aldosterone system (RAAS) plays an essential role in BP regulation (Fig. 36.1). The juxtaglomerular apparatus in the kidney secretes renin in response to SNS stimulation, decreased blood flow through the kidneys, or decreased serum sodium concentration. Renin is an enzyme that converts angiotensinogen to angiotensin I. Angiotensin I is then converted to angiotensin II (A-II) by angiotensin-converting enzyme (ACE). A-II increases BP by 2 different mechanisms (see Fig. 49.4). First, A-II is a potent vasoconstrictor and increases SVR. This results in an immediate increase in BP. Second, over a period of hours or days, A-II increases BP indirectly by stimulating the adrenal cortex to secrete aldosterone.

A-II acts at a local level within the heart and blood vessels. These effects include vasoconstriction and tissue growth that result in remodeling of the vessel walls. These changes are linked to the development of primary hypertension and the long-term effects of hypertension (e.g., atherosclerosis, renal disease, cardiac hypertrophy).

Prostaglandins (PGE_2 and PGI_2) secreted by the renal medulla have a vasodilator effect on the systemic circulation. This results in decreased SVR and lower BP. Heart cells secrete the natriuretic peptides (atrial natriuretic peptide [ANP] and b-type natriuretic peptide [BNP]). They oppose the effects of antidiuretic hormone (ADH) and aldosterone. This results in *natriuresis* (excretion of sodium in urine) and diuresis, resulting in reduced blood volume and BP.

Endocrine System

SNS stimulation results in the release of epinephrine along with a small fraction of NE by the adrenal medulla. Epinephrine increases CO by increasing HR and myocardial contractility. Epinephrine activates β_2-adrenergic receptors in peripheral arterioles of skeletal muscle, causing vasodilation. In peripheral arterioles with only α_1-adrenergic receptors (skin and kidneys), epinephrine causes vasoconstriction.

TABLE 36.2 Diagnostic Criteria

Classification of Hypertension

Category	Systolic BP (mm Hg)		Diastolic BP (mm Hg)
Normal	<120	and	<80
Elevated	120–129	and	<80
Hypertension, stage 1	130–139	or	80–89
Hypertension, stage 2	≥140	or	≥90

Source: Whelton PK, Carey RM, Aronow WS, et al.: 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA guideline for the prevention, detection, evaluation, and management of high blood pressure in adults: a report of the American College of Cardiology/AHA Task Force on Clinical Practice Guidelines, *J Am Coll Cardiol* 71:e127, 2018.

TABLE 36.3 Common Causes of Secondary Hypertension

- Cirrhosis
- Coarctation or congenital narrowing of the aorta
- Drug-related: estrogen replacement therapy, oral contraceptives, corticosteroids, nonsteroidal antiinflammatory drugs (e.g., COX-2 inhibitors), sympathetic nervous system stimulants (e.g., cocaine, monoamine oxidase)
- Endocrine problems (e.g., pheochromocytoma, Cushing syndrome, thyroid disease)
- Neurologic problems (e.g., brain tumors, stroke, traumatic brain injury)
- Pregnancy-induced hypertension
- Renal disease (e.g., renal artery stenosis, glomerulonephritis)
- Sleep apnea

A-II stimulates the adrenal cortex to release aldosterone. Aldosterone stimulates the kidneys to retain sodium and water, which increases blood volume and CO (see Fig. 49.4).

Increased blood sodium and osmolarity levels stimulates the release of ADH from the posterior pituitary gland. ADH increases the ECF volume by promoting water reabsorption in the distal and collecting tubules of the kidneys. The resulting increase in blood volume causes an increase in CO and BP.

HYPERTENSION

Classification of Hypertension

Table 36.2 shows the BP classifications for people 18 years of age and older.[5] If either the systolic BP (SBP) or diastolic BP (DBP) is outside of a range, the higher measurement determines the classification. For example, 115/86 would be classified as hypertension stage 1 even though the SBP is within normal limits. SBP increases with age. DBP rises until around 55 years old and then declines. BP classification is based on 2 or more readings, accurately performed on both arms, on 2 separate occasions.

Etiology

Hypertension can result from either primary or secondary causes.

Primary Hypertension

Primary hypertension *(essential* or *idiopathic)* is elevated BP without an identified cause. It accounts for 90% to 95% of all cases of hypertension. Although we do not know the exact cause for primary hypertension, there are many contributing factors. These include changes in endothelial function related to either vasoconstricting or vasodilating agents, increased SNS activity, overproduction of sodium-retaining hormones, increased sodium intake, greater than ideal body weight, age, family history, ethnicity, diabetes, tobacco use, and excess alcohol use.

Secondary Hypertension

Secondary hypertension is elevated BP with a specific cause that often can be identified and corrected (Table 36.3). It accounts for 5% to 10% of hypertension in adults. Secondary hypertension should be suspected in people who suddenly develop high BP, especially if it is severe. Findings that suggest secondary hypertension relate to the underlying cause. For example, an abdominal bruit heard over the renal arteries may indicate renal disease. It is often present in patients with obstructive sleep apnea. Treatment is aimed at removing or treating the underlying cause. Secondary hypertension is a contributing factor to hypertensive crisis.

Pathophysiology of Primary Hypertension

BP rises with any increase in CO or SVR. As hypertension progresses from elevated to stage 1, increases in both blood volume and CO are often present, leading to an increase in SVR. As hypertension progresses, SVR rises, and CO returns to normal. The hemodynamic hallmark of hypertension is a persistently increased SVR. This persistent increase in SVR may occur in several ways. Table 36.4 shows factors that relate to the development of primary hypertension or contribute to its consequences. Abnormalities of any of the mechanisms involved in maintaining normal BP can result in hypertension (Fig. 36.1).

Genetic Link

Genetic variations are associated with the development of hypertension. For example, genetic abnormalities can cause a rare form of hypertension characterized by excess potassium levels. Several genetic variants of substances on the endothelium affect BP and the development of hypertension by influencing the body's sensitivity to salt. When endothelial surface proteins are activated, proinflammatory properties are stimulated. This impairs the endothelial cells' ability to activate vasodilatory effects, leading to hypertension.

Research is currently ongoing to understand the complicated role that endothelial dysfunction and genetics play in the formation and progression of hypertension. We recommend screening children and siblings of persons with hypertension and advising them to adopt healthy lifestyles to minimize their risk for developing hypertension.

Water and Sodium Retention

Excess sodium intake is linked to the development of hypertension. Although most people consume a high-sodium diet, only 1 in 3 will develop hypertension. When sodium is restricted in people with hypertension, their BP usually falls. This suggests that some degree of sodium sensitivity may exist for high sodium intake to trigger the development of hypertension. A high sodium intake may activate a number of systemic mechanisms.

TABLE 36.4 Risk Factors for Primary Hypertension

Risk Factor	Description
Age	• Systolic BP rises progressively with age • After age 50, SBP >140 mm Hg is a more important cardiovascular risk factor than diastolic BP
Alcohol	• Excess alcohol use is associated with hypertension • Moderate alcohol use has cardioprotective properties; males should limit their daily intake of alcohol to 2 drinks per day, and 1 drink per day for females
Diabetes	• Hypertension is more common in patients with diabetes • When hypertension and diabetes coexist, complications (e.g., target organ disease) are more severe
Ethnicity	• Incidence of hypertension is higher in Blacks (Box 36.1)

Excess sodium intake	• High sodium intake can
	  • Contribute to hypertension in salt-sensitive patients
	  • ↓ Effectiveness of certain antihypertensive drugs

Family history	• History of a close blood relative (e.g., parents, sibling) with hypertension ↑risk for developing hypertension
Gender	• More prevalent in men in young adulthood and early middle age • After age 64, hypertension is more prevalent in women (Box 36.2)
Increased serum lipids	• ↑ Cholesterol and triglyceride levels are primary risk factors for atherosclerosis • Hyperlipidemia is more common in people with hypertension
Obesity	• Weight gain ↑ frequency of hypertension • Risk increases with central abdominal obesity
Sedentary lifestyle	• Regular physical activity can help control weight and reduce cardiovascular risk • Physical activity may ↓ BP
Socioeconomic status	• More prevalent in lower socioeconomic groups and among the less educated
Stress	• People exposed to repeated stress may develop hypertension more often • People who develop hypertension may respond differently to stress than those who do not develop hypertension
Tobacco use	• Smoking tobacco greatly↑ risk for CVD • People with hypertension who smoke tobacco are at even greater risk for CVD

Fig. 36.2 shows the relationships among salt intake, BP, and changes in heart structure.

In clinical practice, there is not an easy or straightforward test to identify people whose BP will rise with even a small increase in salt intake *(salt sensitive)* versus those who can ingest large amounts of sodium without much change in BP *(salt resistant)*. The effect of sodium on BP has a strong genetic component. The effect of sodium is more significant in Blacks and middle-aged and older adults. This can increase the risk of renal problems, endothelial dysfunction, and HF in these persons.[7,8]

Altered Renin-Angiotensin-Aldosterone Mechanism

High plasma renin activity (PRA) increases the conversion of angiotensinogen to angiotensin I (see Fig. 49.4). This change in the RAAS may contribute to the development of hypertension. Any rise in BP inhibits the release of renin from the renal juxtaglomerular cells. Based on this feedback loop, we would expect low levels of PRA in patients with primary hypertension. However, only about 30% have low PRA, 50% have normal levels, and 20% have high PRA. These normal or high PRA levels may be related to excess renin secretion from ischemic nephrons.

Stress and Increased Sympathetic Nervous System Activity

Factors such as anger, fear, and pain influence BP. Physiologic responses to stress, which are typically protective, may persist to a pathologic degree, resulting in a prolonged increase in SNS activity. Increased SNS stimulation causes increased vasoconstriction, increased HR, and increased renin release. Increased renin activates the RAAS, leading to elevated BP. People with high levels of repeated psychological stress develop hypertension more than those who have less stress.

Insulin Resistance and Hyperinsulinemia

Defects in glucose, insulin, and lipoprotein metabolism are common in primary hypertension. These defects are not present in secondary hypertension and do not improve when primary hypertension is treated. Insulin resistance is a risk factor in the development of hypertension and CVD. High insulin levels stimulate SNS activity, impair nitrous oxide-mediated vasodilation, promote vascular hypertrophy, and increase renal sodium reabsorption.

Endothelial Dysfunction

Hypertension can manifest as a prolonged vasoconstriction response or as a reduced vasodilator response. High levels of ET may cause prolonged vasoconstriction. Vasodilation effects can be altered by oxygen free radicals, which impair the bioavailability of NO. This leads to cellular dysfunction and an imbalance of the vasodilation and vasoconstriction mechanisms in the endothelium.

Clinical Manifestations

Hypertension is called the "silent killer" because it is often asymptomatic until it becomes severe and target organ disease occurs. A patient with severe hypertension may have a variety of symptoms from the effects on blood vessels in the various organs and tissues or to the increased workload of the heart. These secondary symptoms include fatigue, dizziness, palpitations, angina, and dyspnea.

In the past, we thought headaches and nosebleeds were symptoms of hypertension. They are no more frequent in people with hypertension than in the general population. However, patients with hypertensive crisis may have severe headaches, dyspnea, and nosebleeds.[9]

Complications

The most common complications of hypertension are *target organ diseases* occurring in the heart (hypertensive heart disease), brain (cerebrovascular disease), peripheral vessels (peripheral vascular disease [PVD]), kidneys (nephrosclerosis), and eyes (retinal damage) (Fig. 36.3).

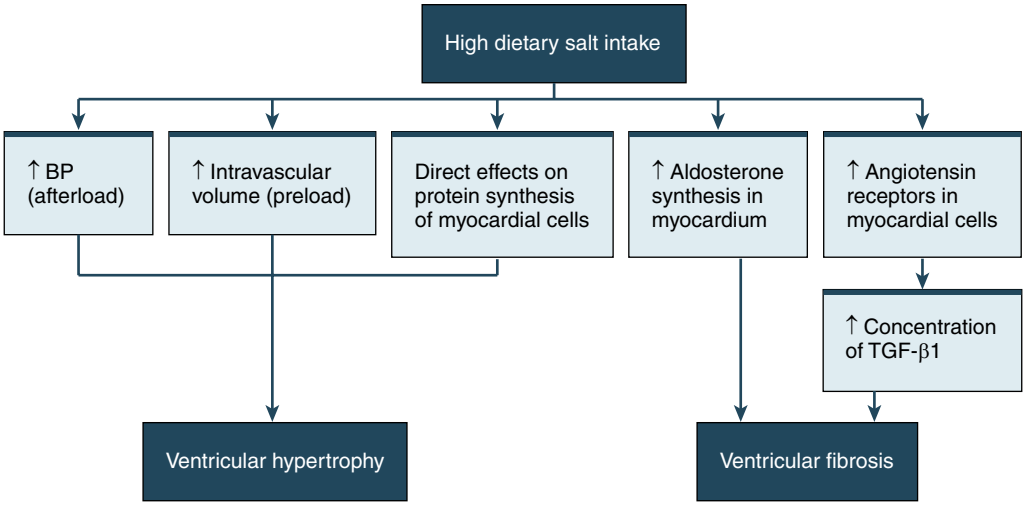

Fig. 36.2 Proposed link among salt intake, BP, and changes in the heart. High diet salt intake exerts hypertrophic effects on the left (and potentially the right) ventricle. Ventricular fibrosis can also result from the high salt intake through mechanisms mediated by the renin-angiotensin-aldosterone system (RAAS). Transforming growth factor-β1 *(TGF-β1)* is a multifunctional cytokine with fibrogenic properties. Overproduction of TGF-β1 (in part mediated by angiotensin II) results in fibrosis and ventricular dysfunction. (Modified from Frisoli TM, Schmieder RE, Grodzicki T, et al.: Salt and hypertension: is salt dietary reduction worth the effort? *Am J Med* 125:433, 2012.)

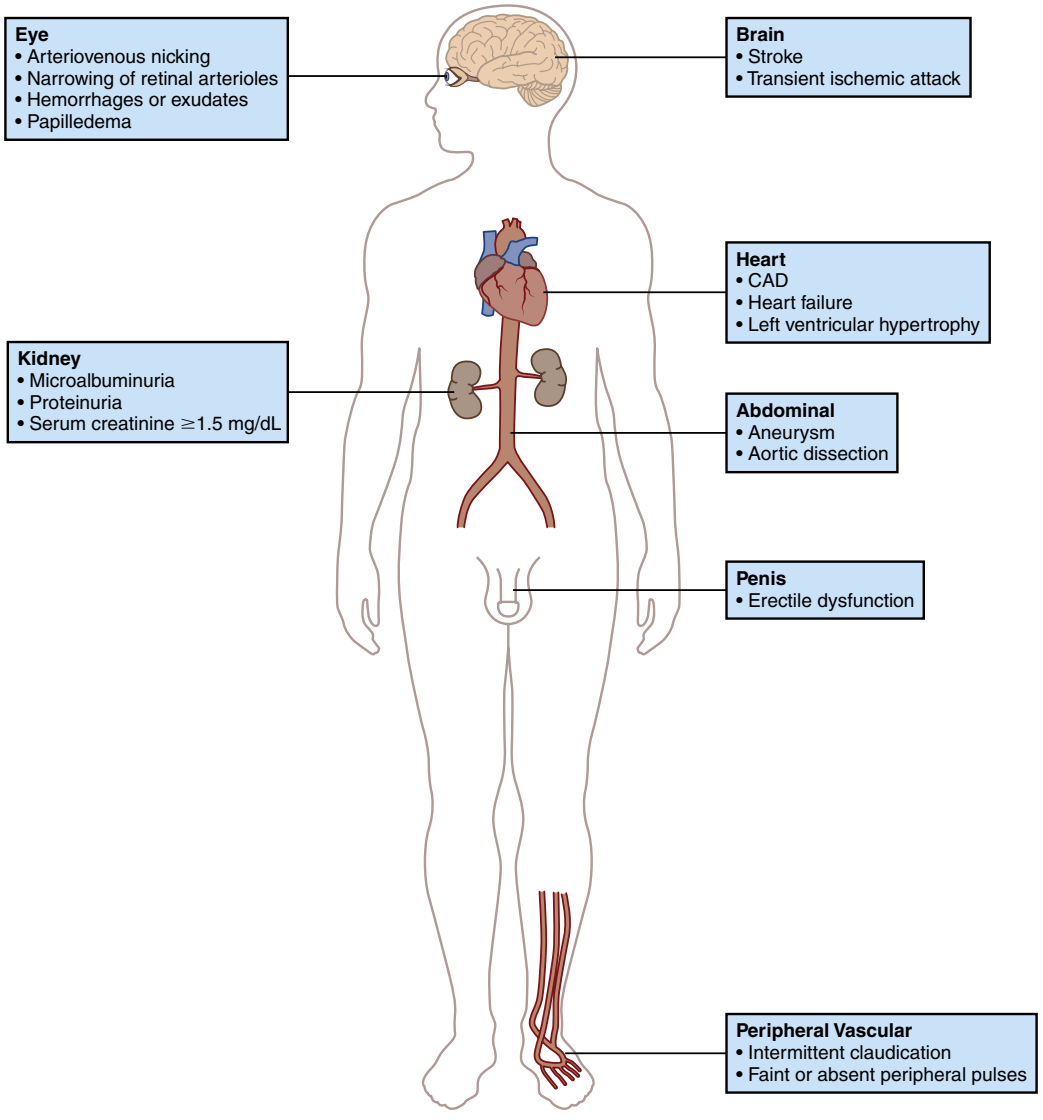

Fig. 36.3 Common complications of hypertension.

Hypertensive Heart Disease

Coronary artery disease. Hypertension is a significant risk factor for coronary artery disease (CAD). The "response-to-injury" theory of atherogenesis suggests that hypertension disrupts the coronary artery endothelium (see Fig. 37.1). This results in a rigid arterial wall with a narrowed lumen and may account for the high rate of CAD, angina, and MI.

Left ventricular hypertrophy. Sustained high BP increases the cardiac workload and causes left ventricular hypertrophy (LVH) (Fig. 36.4). Initially, LVH is a compensatory mechanism that strengthens cardiac contraction and increases CO. However, increased contractility increases myocardial work and O_2 demand. Progressive LVH, especially in the presence of CAD, can cause HF.

Heart failure. HF occurs when the heart's compensatory mechanisms are overwhelmed, and the heart can no longer pump enough blood to meet the body's demands (see Chapter 38). Contractility is depressed. SV and CO are decreased. The patient may have shortness of breath on exertion, paroxysmal nocturnal dyspnea, and fatigue.

Cerebrovascular Disease

Atherosclerosis is the most common cause of cerebrovascular disease. Hypertension is a significant risk factor for cerebral atherosclerosis and stroke. Even in mildly hypertensive people, the risk for stroke is 4 times higher than in normotensive people. Adequate BP control decreases the risk for stroke.

Atherosclerotic plaques are often found at the bifurcation of the common carotid artery and in the internal and external carotid arteries. Portions of the atherosclerotic plaque or the blood clot that forms with disruption of the plaque may break off and travel to cerebral vessels, producing thromboembolism. The patient may have transient ischemic attacks or a stroke. These conditions are discussed in Chapter 62.

Hypertensive encephalopathy may occur after a marked rise in BP if autoregulation does not decrease the cerebral blood flow. *Autoregulation* is a physiologic process that keeps cerebral blood flow constant despite fluctuations in BP. Typically, as pressure in the cerebral blood vessels rises, the vessels constrict to maintain constant flow. When BP exceeds the body's ability to autoregulate, the cerebral vessels suddenly dilate, capillary permeability increases, and cerebral edema develops. This causes a rise in intracranial pressure. If left untreated, patients can die quickly from brain damage. Chapter 60 reviews cerebral blood flow and autoregulation.

Peripheral Vascular Disease

Hypertension speeds up the process of atherosclerosis in the peripheral blood vessels. This leads to PVD, aortic aneurysm, and aortic dissection (see Chapter 41). *Intermittent claudication* (ischemic leg pain precipitated by activity and relieved by rest) is a classic symptom of PVD.

Nephrosclerosis

Hypertension is one of the leading causes of chronic kidney disease (CKD). Some degree of renal disease is usually present even with mild hypertension. Renal disease results from ischemia caused by the narrowing of the renal blood vessels. This leads to atrophy of the tubules, destruction of the glomeruli, and eventual death of nephrons. The remaining intact nephrons can compensate, but changes may eventually lead to renal failure. Laboratory signs of renal disease are albuminuria, proteinuria, microscopic hematuria, and high serum creatinine and blood urea nitrogen (BUN) levels. Nocturia is an early symptom of renal disease (see Chapter 50).

Retinal Damage

Damage to the retinal vessels seen with an ophthalmoscope indicates similar vessel damage in the heart, brain, and kidneys. Manifestations of severe retinal damage include blurred vision, retinal hemorrhage, and vision loss.

Diagnostic Studies

Measurement of BP is essential in assessing and monitoring hypertension. Chapter 35 and the Nursing Management section later in this chapter discuss BP measurement.

Table 36.5 lists diagnostic studies performed in a person with hypertension. Basic laboratory studies may be done to (1) identify or rule out causes of secondary hypertension, (2) evaluate target organ disease, (3) determine overall cardiovascular risk, or (4) establish baseline levels before starting therapy. Routine urinalysis, BUN, and serum creatinine levels are used to screen for renal involvement and provide baseline information about kidney function. Creatinine clearance reflects the glomerular filtration rate. Decreases in creatinine clearance indicate renal insufficiency. Chapter 49 discusses serum creatinine and creatinine clearance.

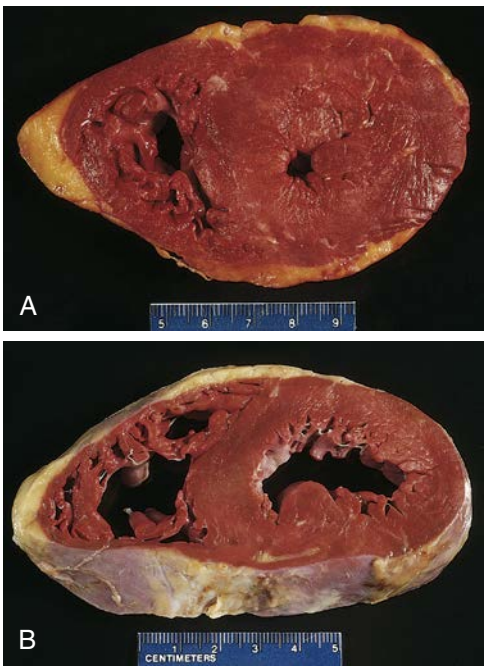

Fig. 36.4 (A) Massively enlarged heart caused by hypertrophy of the muscle in the left ventricle. (B) Compare with the thickness of the normal left ventricle. The patient had severe hypertension. (From Kumar V, Cotran RS, Robbins SL: *Robbins basic pathology,* ed 8, Philadelphia, 2007, Saunders.)

TABLE 36.5 Interprofessional Care

Hypertension

Diagnostic Assessment

- History and physical assessment, including an ophthalmic examination
- Fasting blood glucose
- Routine urinalysis
- Basic metabolic panel with estimated glomerular filtration rate (eGFR)
- Complete blood count
- Serum lipid profile (total lipids, triglycerides, HDL and LDL cholesterol, total-to-HDL cholesterol ratio)
- Serum uric acid, calcium, and magnesium
- 12-Lead ECG

Optional

- 24-hour urinary creatinine clearance
- Echocardiography
- Liver function studies
- Serum thyroid-stimulating hormone (TSH)

Management

- Periodic BP monitoring
  - Home BP monitoring
  - Ambulatory BP monitoring
  - Every 3–6 months by an HCP once goal BP is achieved and stabilized
- Nutrition therapy
  - Restrict salt and sodium
  - Restrict cholesterol and saturated fats
  - Maintain adequate potassium and calcium intake
  - Weight management
- Regular, moderate physical activity
- Tobacco cessation (see Tables 11.3 through 11.5)
- Moderate alcohol use
- Stress management techniques (see Chapter 7)
- Antihypertensive drugs (see Tables 36.7–36.9)
- Patient and caregiver teaching

Measurement of serum electrolytes, especially potassium, is essential to detect hyperaldosteronism, a cause of secondary hypertension. Blood glucose levels aid in the diagnosis of diabetes. A lipid profile gives information about risk factors related to atherosclerosis and CVD. Uric acid levels establish a baseline since the levels often rise with diuretic therapy. An ECG can identify the presence of LVH, cardiac ischemia, or previous MI. If LVH is suspected, echocardiography is often done. If the patient's age, history, physical assessment, or severity of hypertension points to a secondary cause, further diagnostic testing is needed.

Ambulatory Blood Pressure Monitoring

Some patients have high BP readings in a clinical setting and normal readings when BP is measured elsewhere. This phenomenon is referred to as *"white coat"* hypertension. Ambulatory BP monitoring (ABPM) is one method for diagnosing white coat hypertension. It is a noninvasive, fully automated system that measures BP at preset intervals over a 12- to 24-hour period. The equipment is worn continuously for 24 hours, and results are reviewed by the provider. The monitoring equipment includes a BP cuff and a microprocessing unit that fits into a pouch worn on a shoulder strap or belt. Tell patients to hold their arm still by their side when the device is taking a reading. Have them keep a diary of activities that may affect BP. Other applications for ABPM include suspected antihypertensive drug resistance, hypotensive symptoms with antihypertensive therapy, episodic hypertension, or SNS dysfunction.

BP has diurnal variability expressed as sleep-wakefulness difference. For day-active people, BP is highest in the early morning, decreases during the day, and is lowest at night. BP at night (during sleep) usually drops by 10% or more from daytime (awake) BP.[5] ABPM verifies the presence of diurnal variability.

Some patients with hypertension do not show a typical nocturnal dip in BP. They are referred to as "nondippers." Patients at highest risk for CVD are "reverse dippers." They have an increase in nighttime SBP. Current research is focused on using drugs to optimize cardioprotective effects and convert nondippers and reverse dippers to dippers.

Interprofessional Care

The 2019 ACC/AHA guidelines recommend team-based care for the control of risk factors for atherosclerotic cardiovascular disease (ASCVD).[7] Table 36.5 summarizes the interprofessional care for a patient with hypertension. Goals include achieving and maintaining goal BP and reducing cardiovascular risk and target organ disease. Lifestyle modifications are a part of therapy for all patients with elevated BP and hypertension.

Lifestyle Modifications

Lifestyle modifications are directed toward reducing the patient's BP and overall cardiovascular risk. The AHA's "Life's Simple 7" steps support ways to modify and improve health. These are (1) manage BP, (2) control cholesterol, (3) reduce glucose, (4) get active, (5) eat better, (6) lose weight, and (7) stop smoking. Other modifications by the taskforce on hypertension address sodium restrictions and alcohol use. Assess social determinants of health as part of lifestyle modifications (see Chapter 2).[7]

Weight loss. Persons who are overweight have an increased incidence of hypertension and increased risk for CVD. Weight loss can have a significant effect on lowering BP. The effect is seen with even moderate weight loss. A rule of thumb is for every 1 kg of weight lost, BP will decrease by 1 mm Hg. When a person decreases caloric intake, sodium and fat intake are usually also reduced. Although reducing diet fat content has not shown any sustained benefits in BP control, it may slow the progress of atherosclerosis and reduce overall CVD risk (see Chapter 37). Weight loss through a combination of calorie restriction and moderate physical activity is recommended for overweight patients with hypertension.

Nutrition and diet. Plant-based and Mediterranean diets with increased fruit, nut, vegetable, legumes, and lean proteins from fish and vegetables decreases BP and mortality rates from CVD.[7,10] The Dietary Approaches to Stop Hypertension (DASH) eating plan has also been shown to significantly decrease BP.[11]

Sodium reduction. The average adult sodium intake is around 4200 mg/day in men and 3300 mg/day in women. Healthy adults should restrict sodium intake to 2300 mg/day or

less.[8] Adults who consume less than 1500 mg of sodium lower their BP even further.[7]

The patient and caregiver, especially the person who prepares the meals, need to learn about low-sodium diets. Review the patient's typical diet to identify foods high in sodium. The AHA calls 6 food groups that are the highest sodium sources in the United States the "Salty Six." They recommend not adding salt and reducing intake of foods in these groups: bread products, lunch meat and cured meats, pizza, soup, sandwiches, and poultry (see Table 38.8). Teaching should include reading labels of over-the-counter (OTC) drugs, prepared and packaged foods, and health products (e.g., toothpaste containing baking soda) to identify hidden sources of sodium.

Sodium restriction may be enough to control BP or allow for lower drug dosages in some patients. Further, moderate sodium restriction lessens the risk for hypokalemia from diuretic therapy. However, the response differs between patients who are salt sensitive or salt resistant.

The significance of other diet elements for the control of hypertension is not certain. Increased diet intake potassium and calcium are associated with lower BP. People with hypertension should receive adequate intake of these from food sources. Calcium supplements are not recommended to lower BP.

Moderate alcohol use. Excess alcohol use is strongly associated with hypertension. Drinking 3 or more alcoholic drinks a day is a risk factor for CVD and stroke. Men should limit their intake of alcohol to no more than 2 drinks per day and women and lighter-weight men to no more than 1 drink per day; 1 drink is defined as 12 oz of regular beer, 5 oz of wine (12% alcohol), or 1.5 oz of 80-proof distilled spirits. Excess alcohol use that results in cirrhosis is a frequent cause of secondary hypertension.

Physical activity. A physically active lifestyle is essential to promote good health. Adults should perform a minimum of 150 minutes of moderate exercise or 75 minutes of vigorous exercise per week. For those unable to do the minimum recommendation, even some exercise improves BP.[7,12,13]

Physical activity guidelines are different for adults age 18 to 65 years, adults over 65 years, and adults age 50 to 64 years with functional limitations. The differences relate to the definition of moderate and vigorous aerobic activity. For adults ages 18 to 65, walking briskly at a pace that noticeably increases the pulse defines moderate-intensity aerobic activity. Jogging at a pace that substantially increases the pulse and causes rapid breathing is an example of vigorous activity for this age group. For all other adults, individual fitness levels guide aerobic intensity.[12]

All adults should perform muscle-strengthening activities using the major muscles of the body at least twice a week. This helps to maintain or increase muscle strength and endurance. Flexibility and balance exercises are recommended at least twice a week for older adults, especially for those at risk for falls.[13] Moderate-intensity activities can lower BP, promote relaxation, and decrease or control body weight. Regular activity of this type can reduce SBP by 4 to 9 mm Hg.[5,7]

Physical activity is more likely to become a habit if it is safe and enjoyable, fits easily into one's daily schedule, and is inexpensive. Many shopping malls open early in the morning, offering a warm, safe, flat area for walking. Some health clubs offer special "off-peak" rates to encourage physical activity among older adults. Some health insurance carriers offer health club discounts as a benefit to encourage member fitness. Cardiac rehabilitation programs offer supervised exercise and education about reducing cardiovascular risk factors.

Help people with hypertension to increase their physical activity by explaining the need for physical activity, describing the types of physical activities, and aiding in starting an exercise plan. Tell sedentary people to increase activity levels gradually. Those with CVD or other serious health problems need a thorough examination and possibly a stress test before beginning an exercise program.

Avoiding tobacco products. Nicotine contained in tobacco causes vasoconstriction and increases BP, especially in people with hypertension. Smoking tobacco is a major risk factor for CVD. Strongly encourage everyone, especially patients with hypertension, to avoid tobacco use. We see the cardiovascular benefits of stopping tobacco use within a year. Teach those who continue to use tobacco products to monitor their BP regularly. Chapter 11 discusses tobacco use and smoking cessation.

Other risk factors. Risk factors can be related to social determinants of health and psychosocial risk factors. These factors can contribute to the risk for developing CVD and to a poorer prognosis and clinical course in those with CVD. Social determinants of health are the conditions in which people are born, grow, live, work, and age and the wider set of forces and systems shaping the conditions of daily life.[14] These factors include socioeconomic status, resources to meet daily needs, support systems, stress at work and in family life, education, health care access, safe housing, and exposure to violence. These risk factors have direct effects on the cardiovascular system by activating the SNS and stress hormones. They can contribute to CVD indirectly by their impact on lifestyle behaviors and choices.

Screening is essential so appropriate referrals can be given to help the patient and family. Referrals might include counseling, behavioral interventions such as community or religious support systems, social work assistance for finding resources such as fresh fruits and vegetables, or information on housing assistance. Once basic needs are met, beneficial options might include relaxation training, stress management, support groups, and exercise training.[6,15]

Drug Therapy

These are the current recommendations for antihypertensive drug therapy[5]:

- In patients 65 years or older with an average SBP of more than 130 mm Hg who are ambulatory and living in a community setting, rather than living in a skilled agency, treatment goals should be to obtain an SBP less than 130 mm Hg.
- In patients 65 years or older with an average SBP of more than 130 mm Hg who live in a skilled agency, and/or have multiple comorbidities or limited life expectancy, treatment should be based on patient preference, clinical experiences, and team input.

TABLE 36.6 Drug Therapy

Antihypertensive Agents

Drug	Mechanism of Action	Nursing Considerations
Adrenergic Inhibitors		
Central-Acting α-Adrenergic Agonists		
clonidine (Catapres) clonidine patch (Catapres-TTS)	↓ Sympathetic outflow from central nervous system ↓ Peripheral sympathetic tone, produces vasodilation, ↓ SVR and BP	Sudden discontinuation may cause withdrawal syndrome, including rebound hypertension, tachycardia, headache, tremors, apprehension, sweating Chewing gum or hard candy may relieve dry mouth Alcohol and sedatives ↑ sedation Transdermal patch may be related to fewer side effects and better adherence
guanfacine	Same as clonidine	Same as clonidine, but not available in the transdermal formulation
methyldopa	Same as clonidine	Teach patient about daytime sedation and avoiding hazardous activities Taking a single daily dose at bedtime minimizes the sedative effect
α_1-Adrenergic Blockers		
doxazosin (Cardura) prazosin (Minipress) terazosin	Block α_1-adrenergic effects, producing peripheral vasodilation (↓ SVR and BP) Beneficial effects on lipid profile	↓ Resistance to the outflow of urine in benign prostatic hyperplasia Take at bedtime to reduce risk associated with orthostatic hypotension
phentolamine	Blocks α_1-adrenergic receptors, resulting in peripheral vasodilation (↓ SVR and BP)	Used in the short-term management of pheochromocytoma Used locally to prevent necrosis of skin and subcutaneous tissue after extravasation of adrenergic drug No oral formulation
β-Adrenergic Blockers		
Cardioselective Blockers		
acebutolol atenolol (Tenormin) betaxolol bisoprolol esmolol (Brevibloc) metoprolol (Lopressor)	Block β_1-adrenergic receptors (Table 36.1) ↓ BP by blocking β-adrenergic effects ↓ CO and sympathetic vasoconstrictor tone ↓ Renin secretion by kidneys	Monitor pulse and BP regularly Use with caution in patients with diabetes because may depress the tachycardia associated with hypoglycemia and adversely affect glucose metabolism Drug of choice for patients with a history of an MI or HF Less effective BP reduction in black patients Esmolol is for IV use only Lose cardioselectivity at higher doses
Non-Cardioselective Blockers		
nadolol (Corgard) pindolol propranolol (Inderal)	Block β_1- and β_2-adrenergic receptors (Table 36.1) ↓ BP by blocking β_1- and β_2-adrenergic effects	Same as cardioselective, except may cause bronchospasm, especially in patients with a history of asthma
Mixed α- and β-Blockers		
carvedilol (Coreg) labetalol	α_1-, β_1-, and β_2-adrenergic blocking properties producing peripheral vasodilation and ↓ heart rate (Table 36.1) ↓ CO, SVR, and BP	Same as β-blockers IV form is available for hypertensive crisis in hospitalized patients Keep patient supine during IV administration Assess patient tolerance of upright position (severe orthostatic hypotension) before allowing upright activities (e.g., commode)
Angiotensin Inhibitors		
Angiotensin-Converting Enzyme (ACE) Inhibitors		
benazepril (Lotensin) captopril enalapril (Vasotec) fosinopril lisinopril (Zestril) moexipril perindopril quinapril (Accupril) ramipril (Altace) trandolapril	Inhibit ACE, ↓ conversion of angiotensin I to angiotensin II (A-II) Inhibit A-II–mediated vasoconstriction	Aspirin and NSAIDs may ↓ effectiveness Adding a diuretic enhances effect, but should not be used with potassium-sparing diuretics Can ↑ serum creatinine Inhibit breakdown of bradykinin, which may cause a dry, hacking cough that can occur at any point during treatment, even years later Captopril may be given orally for hypertensive crisis

TABLE 36.6 Drug Therapy—cont'd

Antihypertensive Agents

Drug	Mechanism of Action	Nursing Considerations
Angiotensin II Receptor Blockers (ARBs)		
azilsartan (Edarbi) candesartan (Atacand) irbesartan (Avapro) losartan (Cozaar) olmesartan (Benicar) telmisartan (Micardis) valsartan (Diovan)	Prevent action of A-II Produce vasodilation ↑ Na^+ and water excretion	Full effect on BP may not be seen for 3–6 weeks Do not affect bradykinin levels, therefore an acceptable alternative to ACE inhibitors in people who develop a dry cough In patients with kidney disease, ACE inhibitors and ARBs should not be used together due to adverse renal effects
Calcium Channel Blockers (CCB)		
Non-Dihydropyridines		
diltiazem extended release (Cardizem LA) verapamil intermediate release (Calan SR) verapamil timed-release (Verelan PM)	Inhibit movement of Ca^{++} across cell membrane, resulting in vasodilation Cardioselective resulting in a ↓ in heart rate and slowing of AV conduction	Use with caution in patients with HF Grapefruit juice may ↑ serum concentrations and toxicity of certain CCBs; avoid concurrent use Used for supraventricular tachydysrhythmias Avoid in patients with second- or third-degree AV block or left ventricular systolic dysfunction
Dihydropyridines		
amlodipine (Norvasc) clevidipine (Cleviprex) felodipine isradipine nicardipine sustained release nifedipine long acting (Procardia XL) nisoldipine (Sular)	Cause vascular smooth muscle relaxation resulting in ↓ SVR and arterial BP	More potent peripheral vasodilators Clevidipine is for IV use only; solution must be changed every 12 hr Use of sublingual short-acting nifedipine in hypertensive emergencies is unsafe and not effective Serious adverse events (e.g., stroke, acute MI) have occurred IV nicardipine is available for hypertensive crisis in hospitalized patients; change peripheral IV infusion sites every 12 hr
Direct Vasodilators		
fenoldopam (Corlopam)	Activates dopamine receptors, resulting in systemic and renal vasodilation	IV use only for hypertensive crisis in hospitalized patients Use cautiously in patients with glaucoma Patient should remain flat for 1 hr after administration
hydralazine	↓ SVR and BP by direct arterial vasodilation	IV use for hypertensive crisis in hospitalized patients Twice-daily oral dosage Not used as monotherapy because of side effects Contraindicated in patients with CAD
minoxidil	↓ SVR and BP by direct arterial vasodilation	Reserved for treatment of severe hypertension associated with renal failure and resistant to other therapy Once- or twice-daily dosage
nitroglycerin	Relaxes arterial and venous smooth muscle, reducing preload and SVR At a low dose, venous dilation predominates; at a higher dose, arterial dilation is present	IV use for hypertensive crisis in hospitalized patients with myocardial ischemia Given by continuous IV infusion with pump or control device
sodium nitroprusside	Direct arterial vasodilation ↓ SVR and BP	IV use for hypertensive crisis in hospitalized patients Given by continuous IV infusion with pump or control device Arterial BP monitoring BP recommended Wrap IV solutions with an opaque material to protect from light Stable for 24 hr then metabolized to cyanide, then thiocyanate Monitor thiocyanate levels with prolonged use (>3 days) or doses ≥4 mcg/kg/min

- In patients over 18 years old with hypertension, known CVD or other risk factors, a BP of 130/80 mm Hg is the goal of treatment.
- In all other patients without CVD or other risk factors, a BP of less than 130/80 mm Hg may be reasonable.

Drugs currently available for treating hypertension have 2 primary actions: (1) decrease the volume of circulating blood and (2) reduce SVR (Tables 36.6, 36.7, and 36.8).[5] Fig. 36.5 shows the various sites and methods of action of antihypertensive agents. Drugs used in the treatment of hypertension include:

- *Adrenergic-inhibiting agents* act by decreasing SNS effects centrally on the vasomotor center and peripherally to inhibit

TABLE 36.7 Drug Therapy

Diuretic Agents

Drug	Mechanism of Action	Nursing Considerations
Aldosterone Receptor Blockers		
eplerenone (Inspra) spironolactone (Aldactone)	Inhibit the Na^+-retaining and K^+-excreting effects of aldosterone in the distal and collecting tubules	Monitor for orthostatic hypotension and hyperkalemia Do not combine with potassium-sparing diuretics or potassium supplements Use with caution in patients on ACE inhibitors or angiotensin II blockers Classified as potassium-sparing diuretics
Loop Diuretics		
bumetanide (Bumex) furosemide (Lasix) torsemide	Inhibit NaCl reabsorption in the ascending limb of the loop of Henle ↑ Excretion of Na^+ and Cl^- More potent diuretic effect than thiazides, but shorter duration of action	Monitor for orthostatic hypotension and electrolyte abnormalities Remain effective despite renal insufficiency ↑ Diuretic effect at higher doses Less effective for hypertension
Potassium-Sparing Diuretics		
amiloride (Midamor) triamterene (Dyrenium)	↓ K^+ and Na^+ exchange in the distal and collecting tubules ↓ Excretion of K^+, H^+, Ca^{++}, and Mg^{++}	Monitor for orthostatic hypotension and hyperkalemia Contraindicated in patients with renal failure Use with caution in patients on ACE inhibitors or angiotensin II blockers Avoid potassium supplements
Renin Inhibitors		
Aliskiren hemifumarate (Tekturna)	Directly inhibits renin, thus reducing the conversion of angiotensinogen to angiotensin I	May cause angioedema of the face, extremities, lips, tongue, glottis, and/or larynx Not to be used in pregnancy
Thiazide and Related Diuretics		
chlorothiazide chlorthalidone hydrochlorothiazide indapamide metolazone (Zaroxolyn)	Inhibit NaCl reabsorption in the distal convoluted tubule ↑ Excretion of Na^+ and Cl^- Initial ↓ in ECF Sustained ↓ in SVR Lower BP moderately in 2–4 weeks	Monitor for orthostatic hypotension, hypokalemia, and alkalosis May potentiate cardiotoxicity of digoxin by producing hypokalemia Sodium restriction ↓ the risk for hypokalemia NSAIDs can ↓ diuretic and antihypertensive effect and potentially cause renal problems Teach patient to supplement with potassium-rich foods

NE release or to block the adrenergic receptors on blood vessels.

- *ACE inhibitors* prevent the conversion of angiotensin I to angiotensin II and reduce angiotensin II (A-II)–mediated vasoconstriction and sodium and water retention.
- *A-II receptor blockers (ARBs)* prevent angiotensin II from binding to its receptors in the walls of the blood vessels.
- *Calcium channel blockers* (*CCB*) increase sodium excretion and cause arteriolar vasodilation by preventing the movement of calcium into cells.
- *Direct vasodilators* decrease the BP by relaxing the vascular smooth muscle and reducing SVR.
- *Diuretics* promote sodium and water excretion, reduce plasma volume, and reduce the vascular response to catecholamines.

The preferred first-line therapy for patients with stage 1 hypertension includes nonpharmacologic treatment and one first-line drug. The preferred first-line drug classes are a thiazide diuretic, a CCB, and an ACE inhibitor or ARB. For most patients, a diuretic should be the first drug ordered.[5,7] Patients with stage 2 hypertension receive nonpharmacologic treatment and 2 antihypertensive agents from different classifications. If a drug is not tolerated or is contraindicated, then a drug from another class is used.

DRUG ALERT

Doxazosin (Cardura)

- Use caution when giving the first dose. It is best to give the first dose at bedtime to reduce the first dose BP drop.
- Syncope occasionally occurs 30–90 min after the first dose, a too-rapid increase in dose, or addition of another antihypertensive agent to therapy.
- Severe hypotension can occur with patients taking phosphodiesterase inhibitors, such as sildenafil (Viagra) or tadalafil (Cialis).

Once antihypertensive therapy begins, patients should return for follow-up and dosage adjustments monthly until the goal BP is reached. More frequent visits are needed for patients with stage 2 hypertension or with comorbidities. After BP is at goal and stable, follow-up visits can usually be at 3- to 6-month intervals. Comorbidities (e.g., HF), associated diseases (e.g., diabetes), and the need for ongoing monitoring (e.g., laboratory testing) influence the frequency of visits.

TABLE 36.8 Drug Therapy

Combination Therapy for Hypertension

Combinations	Trade Names
ACE Inhibitors and Diuretics	
benazepril/hydrochlorothiazide	Lotensin HCT
enalapril/hydrochlorothiazide	Vaseretic
lisinopril/hydrochlorothiazide	Zestoretic
Angiotensin II Receptor Blockers and CCBs	
olmesartan/amlodipine	Azor
telmisartan/amlodipine	Twynsta
valsartan/amlodipine	Exforge
Angiotensin II Receptor Blockers and Diuretics	
candesartan/hydrochlorothiazide	Atacand HCT
losartan/hydrochlorothiazide	Hyzaar
olmesartan medoxomil/hydrochlorothiazide	Benicar HCT
valsartan/hydrochlorothiazide	Diovan HCT
Angiotensin II Receptor Blocker, Diuretic, and CCB	
amlodipine/hydrochlorothiazide/valsartan	Exforge HCT
β-Blockers and Diuretics	
metoprolol/hydrochlorothiazide	Lopressor HCT
nadolol/bendroflumethiazide	Corzide
olmesartan medoxomil/amlodipine/hydrochlorothiazide	Tribenzor
CCB and ACE Inhibitor	
amlodipine/benazepril	Lotrel
Diuretics and Diuretics	
spironolactone/hydrochlorothiazide	Aldactazide
triamterene/hydrochlorothiazide	Dyazide, Maxzide

Resistant hypertension. Carefully explore all reasons why a patient may not be at goal BP (Table 36.9). *Resistant hypertension* is the failure to reach goal BP in patients who are taking full doses of an appropriate 3-drug therapy regimen that includes a diuretic. Resistant hypertension carries a 2- to 6-fold increase in complications including MI and stroke over other hypertensive patients. Treatments focus on identifying risk factors that could contribute to hypertension, assessing adherence, and evaluating alternative drug therapies. Overactive renal nerves can be a cause of resistant hypertension. Percutaneous catheter-based radiofrequency ablation of the renal nerves (known as *renal denervation*) may be used to help lower BP and SNS activity in patients with resistant hypertension.

❖ NURSING MANAGEMENT: PRIMARY HYPERTENSION

◆ Assessment

Table 36.10 presents subjective and objective data to obtain from a patient with hypertension.

◆ Clinical Problems

Clinical problems for the patient with hypertension include:

- Altered blood pressure
- Body weight problem
- Difficulty coping
- Health maintenance alteration
- Impaired cardiac function
- Impaired sexual function
- Inadequate tissue perfusion
- Nutritionally compromised

◆ Planning

Nursing care focuses on the priority problems of maintaining BP at a level that decreases complications and supporting the patient to manage what may be a complicated drug regimen with many side effects. The overall goals for the patient with hypertension are that the patient will (1) achieve and maintain the goal BP; (2) have minimal side effects of therapy; and (3) manage and cope with this condition.

◆ Implementation

◆ Health Promotion

Primary prevention of hypertension is a cost-effective approach. Current recommendations for primary prevention include lifestyle modifications that avoid or delay the rise in BP in at-risk people. Following the Mediterranean or DASH diet and reducing sodium can lower BP. Changes by the food industry, such as reducing the amount of salt in processed foods, may be useful.

The National Heart, Lung, and Blood Institute provides Web-based educational materials in several languages for HCPs, patients, and the public to raise awareness about the dangers of high BP. Search available publications at https://catalog.nhlbi.nih.gov/.

Patient evaluation. Hypertension is usually discovered through routine screening for insurance, employment, and military physical examinations. You are in an ideal position to assess for the presence of hypertension, identify the risk factors for hypertension and CAD, and teach patients about these conditions. In addition to BP measurement, a health assessment should include such factors as age; gender; diet history (including salt and alcohol intake); weight patterns; tobacco use; and family history of CVD, stroke, renal disease, and diabetes. Note all drugs taken, prescribed, OTC, and recreational. Ask the patient about a history of high BP and the results of any treatment.

Blood pressure measurement. Proper size and correct placement of the BP cuff are critical for accurate measurement (Table 36.11). Place the cuff snugly around the patient's bare upper arm with the midline of the bladder of the cuff (usually marked on the cuff by the manufacturer) placed in line with the brachial artery. Place the patient's arm at the level of the heart during BP measurement. For BP measurements taken in the sitting position, raise and support the arm at the level of the heart. For measurements taken in a supine position, raise and support (e.g., with a small pillow) the arm at heart level. If the arm is resting on the bed, it will be below heart level.

BP can be measured using the auscultatory (oscillatory) method.[16] Note any differences in measurements between each

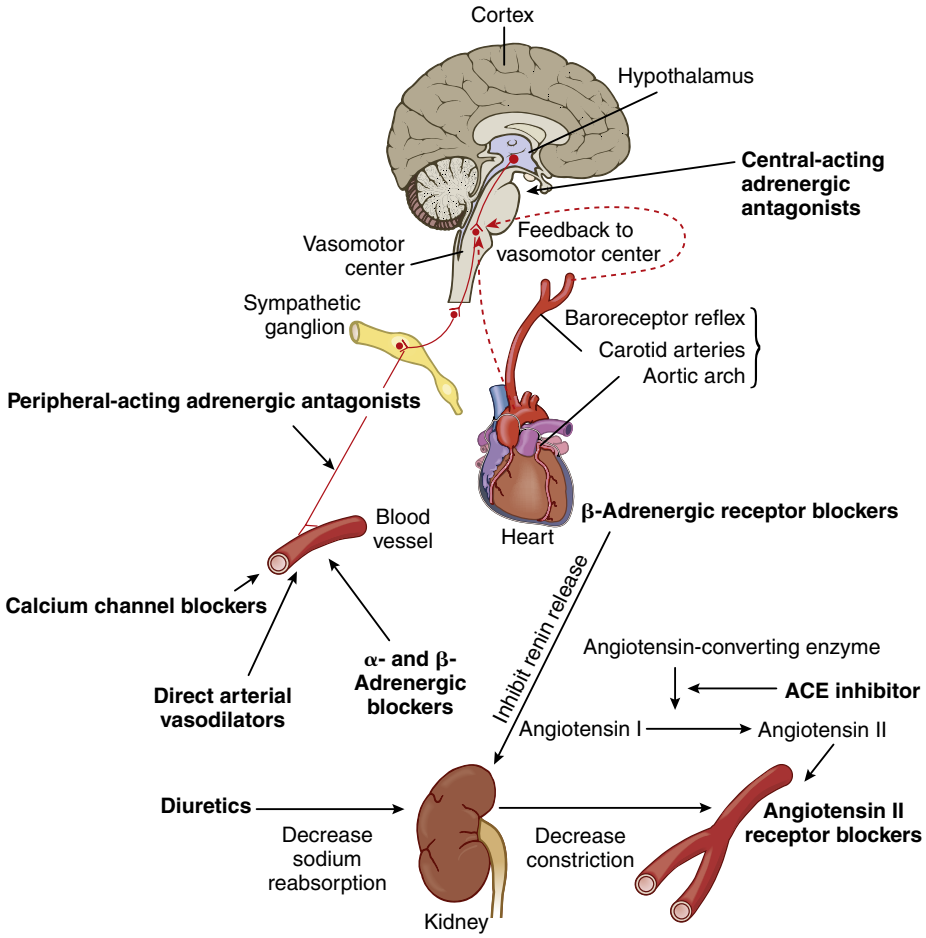

Fig. 36.5 Site and method of action of various antihypertensive drugs *(bold type)*. (From US Department of Health and Human Services: *Seventh report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure* [JNC 7], Washington, DC, 2003, National Institutes of Health.)

arm. Atherosclerosis in the subclavian artery can cause a falsely low reading on the side where the narrowing occurs.

If neither upper arm can be used to measure the BP (e.g., the presence of IV lines, fistula), or if a maximum size BP cuff does not fit the upper arm, use the forearm. In this case, position the proper size cuff midway between the elbow and the wrist. Auscultate Korotkoff sounds over the radial artery or use a Doppler device to note SBP. Use of an oscillometric device on the forearm is acceptable. Forearm and upper arm BPs are not interchangeable.

! SAFETY ALERT

BP Measurement

- If using the forearm rather than the upper arm for BP measurement, document the site.
- BP cuffs that are too small or too large will result in readings that are falsely high or low, respectively.
- If bilateral BP measurements are not equal, record this finding and use the arm with the highest BP for all future measurements.

Assess for orthostatic (or postural) changes in BP and HR in older adults, people taking antihypertensive drugs, and patients who report symptoms consistent with reduced BP on standing (e.g., lightheadedness, dizziness, syncope). Start by having the person rest in the supine position for 3 minutes. Take baseline readings for BP and pulse. Have the patient sit and repeat the BP and pulse. Then have the patient stand and assess BP and pulse. After the patient has been standing for 3 minutes, measure BP and pulse again. Usually, the SBP decreases slightly (less than 10 mm Hg) on standing, while the DBP and pulse increase slightly.[17]

Orthostatic hypotension occurs when a patient moves from a supine to standing position, and there is a decrease of 20 mm Hg or more in SBP, a decrease of 10 mm Hg or more in DBP, and/or an increase in the HR of 20 beats/min. Note any lightheadedness or dizziness during the procedure, which is considered an abnormal finding. Common causes include dehydration and inadequate vasoconstrictor mechanisms related to disease or drug therapy.

Some people have a wide gap between the first Korotkoff sound and subsequent beats. This is called the *auscultatory gap*. Failure to inflate the cuff high enough may result in an inaccurate SBP, a reading lower than the patient's actual BP.

Trends in BP are more important than a single value. In acute care settings, BP measurement is usually done to assess volume status and effects of drugs rather than diagnose hypertension. Inform the HCP of any patient with a persistent elevated BP. They should be evaluated for hypertension.[5]

TABLE 36.9 Causes of Resistant Hypertension

Causes of Pseudoresistant Hypertension
- Improper BP measurements (i.e., inappropriate BP cuff size)
- Inadequate drug doses
- Inappropriate drug therapy
- Poor adherence to drug regimen (e.g., due to side effects, finances)
- White coat syndrome

Volume Overload
- Drug-induced
- Corticosteroids
- Cyclosporine and tacrolimus (Prograf)
- Erythropoietin
- Nonsteroidal antiinflammatory drugs
- Oral contraceptives
- Sympathomimetics (e.g., decongestants, diet pills)
- Excess salt intake
- Herbal supplements (e.g., ma huang, bitter orange)
- Inadequate diuretic therapy
- Illegal drugs (e.g., cocaine, amphetamines)
- Licorice
- Volume retention from kidney disease

Associated Conditions
- Excess alcohol use
- Increasing obesity
- Obstructive sleep apnea

Source: Brandani L: Resistant hypertension: a therapeutic challenge, *J Clin Hypertens* 20:76, 2018.

Verifying how BP is obtained at home is important when assessing for potential hypertension. Ensure that the home machine has been validated for accuracy and the patient records measurements at the same time of day for consistency. Confirming office BP readings with BP readings obtained at home can help determine average BP.

Screening programs. Screening programs in the community are widely used to identify persons who have a high BP. At the time of the BP measurement, give each person a written, numeric value of the reading. Explain why further evaluation is needed.

Ambulatory Care

Your primary role in the long-term management of hypertension is to assist the patient to reach the goal BP and adhere to the treatment plan (Table 36.12). Your actions include evaluating therapeutic effectiveness, detecting and reporting any adverse treatment effects, assessing and enhancing adherence, and teaching patients and caregivers.

Cardiovascular risk factor modification. Teaching about CVD risk factors is appropriate for all persons. Modifiable CVD risk factors include hypertension, obesity, diabetes, tobacco use, and physical inactivity. Discuss lifestyle modifications based on identified risk factors. Table 36.13 contains general information and health-promoting behaviors for patients with hypertension.

Teaching related to drug therapy. Side effects of antihypertensive therapy are common. They may be so severe or undesirable that the patient does not adhere to the therapy.[5,7]

TABLE 36.10 NURSING ASSESSMENT

Hypertension

Subjective Data

Important Health Information
- *Health history:* Known duration and past workup of high BP; cardiovascular, cerebrovascular, renal, or thyroid disease; diabetes; pituitary disorders; obesity; dyslipidemia; menopause or hormone replacement status
- *Medications:* Use of any prescription, OTC, recreational, or herbal products; use of antihypertensive drug therapy

Functional Health Patterns
- *Health perception–health management:* Family history of hypertension or CVD; tobacco use, alcohol use; sedentary lifestyle; health literacy; readiness for change
- *Nutritional-metabolic:* Usual salt and fat intake; weight gain or loss
- *Elimination:* Nocturia
- *Activity-exercise:* Fatigue; dyspnea on exertion, palpitations, exertional chest pain; intermittent claudication, muscle cramps; usual pattern and type of exercise
- *Cognitive-perceptual:* Dizziness; blurred vision; paresthesias
- *Sexual-reproductive:* Erectile dysfunction, decreased libido
- *Coping–stress tolerance:* Stressful life events

Objective Data

Cardiovascular
- SBP consistently >130 mm Hg or DBP >80 mm Hg; orthostatic changes in BP and HR; bilateral BPs significantly different; abnormal heart sounds; laterally displaced apical pulse; decreased or absent peripheral pulses; carotid, renal, or femoral bruits; peripheral edema

Gastrointestinal
- Obesity (BMI ≥30 kg/m^2); abnormal waist-hip ratio

Neurologic
- Mental status changes

Possible Diagnostic Findings
- Abnormal serum electrolytes (especially potassium); ↑ BUN, creatinine, glucose, cholesterol, and triglyceride levels; proteinuria, albuminuria, microscopic hematuria; evidence of ischemic heart disease and left ventricular hypertrophy on ECG; evidence of structural heart disease and left ventricular hypertrophy on echocardiogram; evidence of arteriovenous nicking, retinal hemorrhages, and papilledema on funduscopic examination

Telling the patient about side effects that may reduce with time may help the person to continue with therapy. The number or severity of side effects may relate to the dose. It may be necessary to change the drug or decrease the dose. Teach the patient to report all side effects to the HCP.

A common side effect of several of the antihypertensive drugs is orthostatic hypotension. It results from a change in the autonomic nervous system's mechanisms for regulating BP during position changes. Consequently, the patient may feel dizzy and faint when assuming an upright position after sitting or lying down. Table 36.13 presents specific measures to teach the patient to control or decrease orthostatic hypotension.

Sexual problems may occur with many antihypertensive drugs. This can be a significant reason that patients do not adhere to the treatment plan. Problems can range from reduced

TABLE 36.11 Blood Pressure Measurement

The patient should not have smoked, exercised, or ingested caffeine within 30 min before measurement.

1. Seat patient with legs uncrossed, feet on the floor, and back supported. Bare the patient's arm and support it at heart level.
2. Begin measurement after the patient has rested quietly for 5 min. Ask the patient to relax as much as possible and not to talk during the measurement.
3. Use the right cuff size. Follow instructions for fit and placement according to manufacturer's recommendations.
4. Measure and record BP in both arms initially and note any differences. There are conditions when an extremity should not be used to measure BP. These exclusions include deep venous thrombosis, arteriovenous fistula or graft, peripherally inserted central line (PICC), lymphedema, and limb ischemia. Use the arm with the highest BP and verify the reference point is at the heart.
5. BP should preferably be taken with an oscillometric device, rather than manually. The accuracy of oscillometric devices may be limited if patients are hypertensive, hypotensive, or have heart dysrhythmias (e.g., atrial fibrillation).
6. Patients with atrial fibrillation may have HR variations causing variations in BP, so it is recommended to take 3 different measurements over several minutes to confirm the BP.
7. For auscultatory measurement, estimate SBP by palpating the radial pulse and inflating the cuff until the pulse disappears. Inflate the cuff 20–30 mm Hg above this level.
8. Deflate the cuff at a rate of 2–3 mm Hg/sec.
9. Record the SBP and DBP. Note the SBP when the first of 2 or more Korotkoff sounds are heard and the DBP when sound disappears.
10. Provide the patient (verbally and in writing) with the BP reading, BP goal, and recommendations for follow-up.
11. Clean BP cuffs between patients according to the agency's policy for reusable medical equipment cleaning.

Source: Whelton PK, Carey RM, Aronow WS, et al: 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA guideline for the prevention, detection, evaluation, and management of high blood pressure in adults: A report of the American College of Cardiology/AHA Task Force on Clinical Practice Guidelines, *J Am Coll Cardiol* 71:e127, 2018.

libido to erectile dysfunction. Rather than discussing a sexual problem with an HCP, the patient may decide to stop therapy. Approach the patient on this sensitive subject and encourage discussion. The sexual problems may be easier for the patient to discuss once you explain that the drug may be the source of the problem.

Changing to another antihypertensive drug can decrease or relieve these side effects. Encourage the patient to discuss sexual issues with the HCP. If the patient is reluctant to do so, offer to alert the HCP to the side effects that the patient has. There are many options for treating hypertension. A plan that is acceptable to the patient should be the goal.

Some unpleasant side effects result from a drug's therapeutic effect, but these can be decreased. For example, diuretics cause dry mouth and frequent voiding. Sugarless gum or hard candy may help ease the dry mouth. Taking diuretics earlier in the day may limit frequent voiding during the night and preserve sleep.

Home blood pressure monitoring. Most patients with known or suspected hypertension should monitor their BP at home. The readings are often lower than those taken in the office setting and are a better predictor of CVD risk. Home BP readings may help achieve patient adherence by reinforcing the need for therapy. However, some patients become overly concerned with the BP readings. Provide information that will help patients understand what their goal or target BP is and why.

CHECK YOUR PRACTICE

You are making a home visit for a 78-year-old woman who is recovering from a hip replacement after she fractured her femur. She currently takes a combination of lisinopril/hydrochlorothiazide. The patient's daughter (her caregiver) tells you that her BP that morning was 150/88. She took it 2 more times, and it was the same. They are both worried and anxious that something is wrong because they heard that a BP over 120/80 is very bad.

- What should you do? What teaching would you provide?

Patient teaching is critical to ensure accuracy. Tell patients to buy an oscillometric BP monitor that uses a cuff for the upper arm or wrist. The patient should bring the BP monitor to the office to verify proper cuff size, the accuracy of the device, and the patient's technique.

Teach the patient to obtain a BP according to the steps in Table 36.11. Tell the patient to measure BP in the nondominant arm, or arm with the higher BP if there is a known difference between arms. Tell the patient to measure BP first thing in the morning (if possible, before taking any drugs) and at night before going to bed. Have the patient record all BP measurements and bring the record to office visits.

For clinical decision making (e.g., changes in dosage, starting a new drug), tell patients to take BP readings as described for 1 week. Stable, normotensive patients should measure morning and evening BP for at least 1 week every 3 months. Devices that have memory or printouts of the readings are convenient for reporting.[5]

Patient adherence. A significant problem in the long-term management of the patient with hypertension is poor adherence to the treatment plan (Box 36.3). The reasons for nonadherence are complicated. They can include inadequate patient teaching, low health literacy, unpleasant drug side effects, the BP returning to normal range with the therapy, the high cost of drugs, and lack of insurance.

It is important to determine the reasons why a patient is not adhering to treatment. Assess the patient's diet, activity level, and lifestyle as other indicators of adherence. Develop a plan with the patient and caregiver to improve adherence. The plan should be compatible with the patient's habits, cultural beliefs, and lifestyle. Active patient participation increases the chance of adherence to the plan. Measures include involving the patient in choosing drugs that are affordable and involving caregivers to help increase patient adherence.

Substituting combination drugs for multiple drugs once the BP is stable may promote adherence. Combination drugs are shown in Table 36.8. They reduce the number of pills that the patient must take each day and may reduce costs.

It is important to help the patient and caregiver understand that primary hypertension is a chronic illness that cannot be cured. Stress that it can be controlled with drug therapy, diet changes, physical activity, periodic follow-up, and other relevant lifestyle modifications.

TABLE 36.12 NURSING MANAGEMENT

Caring for the Patient With Hypertension

You will need to collaborate with many health care team members to deliver, delegate, and coordinate care based on the patient's status.

- Develop and conduct hypertension screening programs.
- Assess patients for hypertension risk factors and develop risk modification plans.
- Teach patients about lifestyle management and drug therapy.
- Monitor for adverse effects of antihypertensive drugs.
- Evaluate the effectiveness of lifestyle management and drug therapy in decreasing BP to acceptable levels.
- Teach about home BP monitoring, including the correct use of automatic BP monitors. Check that the device chosen by the patient meets the Association for the Advancement of Medical Instrumentation Standards (www.dableducational.org/sphygmomanometers/devices_1_clinical.html#ClinTable).
- Make appropriate referrals to other HCPs, such as dietitians or stress management programs.
- Monitor for complications of hypertension, such as CAD, HF, cerebrovascular disease, PVD, and renal disease.
- Assess the patient with a hypertensive crisis for evidence of target organ disease (e.g., encephalopathy, renal insufficiency, cardiac decompensation).
- Manage the patient with hypertensive urgency or emergency, including giving drugs and evaluating for resolution of the crisis.
- Supervise AP in measuring BP.
  - Obtain accurate BP readings in outpatient and inpatient settings.
  - Report high or low BP readings at once to RN.
  - Check postural BPs as directed.

Collaborate With Other Team Members

Dietitian

- Obtain a diet history from the patient.
- Teach the components of the DASH diet.
- Provide instructions for any diet changes needed.

Physical Therapist

- Assess current fitness level.
- Develop an exercise plan with the patient.

DASH, Dietary Approaches to Stop Hypertension.

TABLE 36.13 PATIENT & CAREGIVER TEACHING

Hypertension

When teaching the patient and/or caregiver about hypertension, include the following:

General Instructions

- Give the patient the BP reading and explain what it means (e.g., high, low, goal, borderline).
- Encourage the patient to monitor BP at home and teach the patient to call the HCP if BP exceeds high or low limits set by HCP.
- Hypertension is usually asymptomatic, and symptoms (e.g., nosebleeds) do not reliably indicate BP levels.
- Long-term therapy and follow-up care are necessary to treat hypertension. Therapy involves lifestyle changes (e.g., weight management, sodium reduction, smoking cessation, regular physical activity) and, in most cases, drugs to regulate the BP.
- Therapy will not cure but should control, hypertension.
- Controlled hypertension usually results in an excellent prognosis.
- Explain the potential dangers of uncontrolled hypertension (e.g., stroke, heart attack).

Instructions Related to Medication Therapy

- Be specific about the names, actions, dosages, and side effects of prescribed drugs.
- Help the patient plan regular and convenient times for taking medications and measuring BP.
- Do not stop drugs abruptly since withdrawal may cause a severe hypertensive reaction.
- Do not double up on a dose when a dose is missed.
- If BP increases or decreases, do not change the dose of the drug without consulting the HCP.
- Do not take any drugs belonging to someone else.
- Supplement diet with foods high in potassium (e.g., citrus fruits, green leafy vegetables) if taking potassium-wasting diuretics.
- Avoid hot baths, excess amounts of alcohol, and strenuous exercise within 3 hr of taking drugs that promote vasodilation.
- Many drugs cause orthostatic hypotension. Reduce the effects of orthostatic hypotension by rising slowly from the bed, sitting on the side of the bed for a few minutes, standing slowly, and beginning to move if no symptoms develop (e.g., dizziness, lightheadedness).
- Do not stand still for prolonged periods, do leg exercises to increase venous return, or sleep with the head of the bed raised. Do lie or sit down when dizziness occurs.
- Some drugs cause sexual problems (e.g., erectile dysfunction, decreased libido). Consult with the HCP about changing drugs or dosages if sexual problems develop.
- Some side effects may decrease with time (e.g., fatigue, diarrhea).
- Be careful about taking potentially high-risk OTC drugs, such as high-sodium antacids, NSAIDs, appetite suppressants, and cold and sinus medications. Read warning labels and consult with a pharmacist.

◆ Evaluation

The overall expected outcomes are that the patient with hypertension will

- Achieve and maintain goal BP as defined for the person
- Understand, accept, and implement the treatment plan
- Report minimal side effects of drug therapy

Gerontologic Considerations: Hypertension

The prevalence of hypertension increases with age. The lifetime risk for developing hypertension is around 90% for normotensive men and women over age 55. Older adults are more likely to have white coat hypertension.[5]

The pathophysiology of hypertension in the older adult involves several age-related physical changes: (1) loss of elasticity in large arteries from atherosclerosis, (2) increased collagen content and stiffness of the myocardium, (3) increased peripheral vascular resistance, (4) decreased adrenergic receptor sensitivity, (5) blunting of baroreceptor reflexes, (6) decreased renal function, and (7) decreased renin response to sodium and water depletion.

In the older adult who is taking antihypertensive drugs, absorption of some agents may be altered because of decreased blood flow to the gut. Metabolism and excretion may be prolonged. Care should be taken to assess for orthostatic

BOX 36.3 EVIDENCE-BASED PRACTICE

Medication Adherence in Hypertension

T.B. is a 67-year-old male admitted to the surgery unit after a partial bowel resection for diverticulitis. The health record shows he has a history of stage 2 hypertension. The cardiologist has noted T.B. has repeated nonadherence to the antihypertensive medication plan. T.B.'s BP on arrival to the unit is 160/84 mm/Hg. The current prescribed daily oral medications include hydrochlorothiazide and lisinopril. He is tolerating clear liquids. The HCP prescribed liquid forms of antihypertensive agents. T.B. is refusing to take them.

Making Clinical Decisions

Synthesis of Best Available Evidence

Medication adherence is based on multiple factors. Identifying and understanding those factors represents the first step in developing interventions to improve adherence and facilitate hypertension management.

Clinician Expertise

Several hours later, you realize T.B. has had no visitors since his arrival. You ask him if he is expecting family or friends to come to visit that evening after work, and he responds abruptly, "No one's coming." During the next scheduled postoperative assessment, you ask gently T. B. about his discharge plan and if someone will be available to assist him at home. He said, "I don't know any of the neighbors. We moved to a new community just a month before my wife died late last year. Our 2 kids live up north and couldn't get away from work for this surgery."

The gastroenterology nurse practitioner visits T.B. on rounds. The NP expresses concern about T.B.'s BP, which has consistently remained high. Recognizing the importance of social support, you tell the NP that the patient's wife died late last year, and the adult children live far away. You discuss with the NP about this possible influence on his medication adherence.

Patient Preferences and Values

T.B. tells you, "I used to take my meds like clockwork with my wife over breakfast. After she died, and the diverticulitis got worse, I didn't want to bother most of the time."

Implications for Nursing Practice

1. What other elements of social support could you explore?
2. Besides social support, what other factors could influence his nonadherence to the medication plan?
3. How would you confirm T.B.'s understanding of his medication plan?

Reference for Evidence

Thuy LT, Monkong S, Pookboonmees R, et al.: Factors explaining medication adherence of older adults with hypertension: a cross-sectional study, *PRIJNR* 24:306–320, 2020.

hypotension and acute kidney injury in patients over 65 years old. Older adults who have multiple comorbidities and do not live independently (i.e., skilled agency) should have gradual dosage changes to minimize complications.[5]

Orthostatic hypotension often occurs in older adults because of impaired baroreceptor reflexes. Orthostatic hypotension in this age group is often related to volume depletion or chronic disease states, such as decreased renal and liver function or electrolyte imbalance.

Older adults may have drops in BP after meals. The most significant decrease occurs about 1 hour after eating. BP returns to preprandial levels 3 to 4 hours after eating. Drugs should be started at low doses and increased slowly to reduce the chance of orthostatic hypotension. Measure BP and HR in the supine, sitting, and standing positions at every visit.

After CVD, arthritis is the second most prevalent disease in older adults. Older adults often take prescription and OTC nonsteroidal antiinflammatory drugs (NSAIDs). Nonselective NSAIDs (e.g., ibuprofen) and selective NSAIDs (e.g., celecoxib) can cause loss of BP control and HF. There is the risk for adverse renal effects and/or hyperkalemia when NSAIDs are used with ACE inhibitors, ARBs, or aldosterone antagonists.

HYPERTENSIVE CRISIS

Hypertensive crisis is a term that indicates either a hypertensive urgency or emergency. A hypertensive crisis occurs at systolic BP greater than 180 mm Hg and/or DBP greater than 120 mm Hg. BPs often can be greater than 220/140 mm Hg. The differences between hypertensive urgency and emergency are the presence of target organ damage and the type of treatment the patient will receive.

Hypertensive emergencies have evidence of target organ disease. They most often require hospitalization for immediate, controlled BP reduction. Without prompt treatment, complications include encephalopathy, intracranial or subarachnoid hemorrhage, HF, MI, renal failure, dissecting aortic aneurysm, and retinopathy.[18] Untreated hypertensive emergencies have a 1-year mortality rate of more than 79%. Prompt recognition and treatment are essential to decrease the threat to organ function and life.

Hypertensive urgency is more common. There is no clinical evidence of target organ disease. Hospitalization may not be needed. It may be associated with chronic, stable complications such as stable angina, chronic HF, or prior MI or cerebrovascular accident with no threat of an acute event.

A hypertensive crisis occurs more often in patients with a history of hypertension who have not adhered to their medication regimens or who have been undermedicated. Rapidly increasing BP can cause shearing of the endothelial surface due to turbulent blood flow within the vessels leading to further vascular damage and the release of more vasoconstricting substances. A vicious cycle of increased BP follows, leading to life-threatening damage to target organs.

Hypertensive crisis related to cocaine or crack use is a frequent problem. Other drugs, such as amphetamines, phencyclidine (PCP), and lysergic acid diethylamide (LSD), can cause a hypertensive crisis that may be complicated by drug-induced seizures, stroke, MI, or encephalopathy. Table 36.14 lists common causes of hypertensive crisis.

Clinical Manifestations

A hypertensive emergency often presents as *hypertensive encephalopathy*. This is a syndrome in which a sudden rise in BP is associated with a severe headache, nausea, vomiting, seizures, confusion, and coma (Table 36.14). The manifestations of encephalopathy are the result of increased cerebral capillary permeability, which can lead to cerebral edema and disruption in cerebral function. Retinal examination shows exudates, hemorrhages, and/or papilledema (Fig. 36.6).

Renal insufficiency ranging from minor injury to complete renal failure can occur. Rapid cardiac decompensation ranges from unstable angina to MI and pulmonary edema. Patients can have chest pain and dyspnea. Aortic dissection can cause

TABLE 36.14 EMERGENCY MANAGEMENT

Hypertensive Crisis

Etiology	Assessment Findings	Interventions
• Acute aortic dissection • Drug use (cocaine, amphetamines) • Exacerbation of chronic hypertension • Head injury • Monoamine oxidase inhibitors are taken with tyramine-containing foods • Pheochromocytoma • Preeclampsia, eclampsia • Rebound hypertension (from abrupt withdrawal of some antihypertensive drugs, such as clonidine or β-blockers)	• Systolic BP greater than 180 mm Hg and/or diastolic BP greater than 120 mm Hg • Blurred vision • Chest pain • Confusion • Dyspnea • Headache • Nausea and vomiting • Nosebleeds • Seizures	• Obtain baseline vital signs, including O_2 saturation. • Start continuous BP and ECG monitoring. • Auscultate heart and breath sounds. • Insert IV. • Administer IV antihypertensive medications as ordered (e.g., sodium nitroprusside). • Obtain baseline blood work. • Give O_2 per agency protocol. **Ongoing Monitoring** • Monitor vital signs, level of consciousness, heart and breath sounds, neurologic function, heart rhythm, and O_2 saturation. • Titrate the drug according to MAP or SBP as ordered. • Assess and record response to drugs (e.g., decrease in chest pain). • Measure urine output hourly. • Maintain the patient on bed rest. • Provide reassurance and emotional support to patient and caregiver. • Explain all interventions to patient and caregiver.

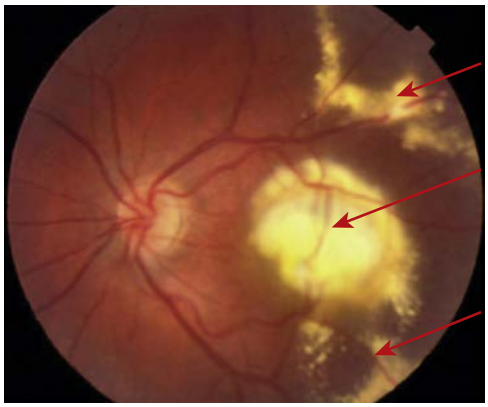

Fig. 36.6 Massive retinal exudates (indicated by *arrows*) from hypertensive retinopathy. To see what a normal retina looks like on ophthalmoscopic examination, see Fig. 22.7. (From Kliegman RM, Behrman RE, Jenson HB, et al.: *Nelson textbook of pediatrics,* ed 18, Philadelphia, 2011, Saunders.)

sudden, severe chest and back pain with reduced or absent pulses in the extremities.

Interprofessional and Nursing Management

Hypertensive emergencies require hospitalization, IV administration of antihypertensive drugs, and intensive monitoring. BP level alone is not the major factor in deciding treatment. The link between elevated BP and signs of new or progressive target organ disease determines the seriousness of the situation.

When treating hypertensive emergencies, we often use the mean arterial pressure (MAP) instead of BP readings to guide and evaluate therapy. Calculate the MAP as follows:

$$MAP = (SBP + 2DBP) \div 3$$

The initial goal is to decrease MAP by no more than 20% to 25% or to decrease MAP to 110 to 115 mm Hg. If the patient is clinically stable, drugs can be titrated to gradually lower BP over the next 24 hours. Lowering the BP too quickly or too much may decrease cerebral, coronary, or renal perfusion. A rapid decrease could cause a stroke, MI, or renal failure.

CHECK YOUR PRACTICE

A 68-year-old male patient presents to the emergency department with a BP 210/118. He reports a severe headache and vomiting. You know that his BP is dangerously high and must be lowered.

- Calculate his MAP.
- What treatments would you expect to be ordered for this patient?

Patients with aortic dissection require special consideration. They should have their SBP lowered to less than 100 to 120 mm Hg as soon as possible (if tolerated). Another exception is the patient with acute ischemic stroke whose BP is lowered to allow the use of thrombolytic agents. Last, an elevated BP in the immediate poststroke period may be a compensatory response to improve cerebral perfusion to ischemic brain tissue. There is no evidence supporting the use of antihypertensive drugs in these patients (see Chapter 62).[5]

IV agents used for hypertensive emergencies include vasodilators (e.g., sodium nitroprusside, fenoldopam, nicardipine), adrenergic inhibitors (e.g., phentolamine, labetalol, esmolol), and the CCB clevidipine (Cleviprex). Sodium nitroprusside is the most effective IV drug to treat hypertensive emergencies. Oral agents may be given along with IV drugs to help make an earlier transition to long-term therapy.

Antihypertensive drugs given IV have a rapid (within seconds to minutes) onset of action. Assess the patient's BP and HR every 2 to 3 minutes during their initial administration. Use an arterial line (see Chapter 35) or an automated, noninvasive BP

DRUG ALERT

Labetalol

- Teach the patient not to stop the drug abruptly.
- Abrupt cessation may precipitate angina or HF.

machine to monitor the BP. Titrate the drug according to MAP or SBP as ordered. Monitor the ECG for dysrhythmias and signs of ischemia or MI. Use extreme caution in treating the patient with CAD or cerebrovascular disease. Measure urine output hourly to assess renal perfusion. Patients receiving IV agents may be kept on bed rest. Getting up (e.g., to use the commode) may cause severe cerebral ischemia and fainting.

Ongoing assessment is essential to evaluate the effectiveness of and the patient's response to therapy. Monitor cardiac, lung, and renal systems for decompensation caused by the severe increase in BP (e.g., angina, pulmonary edema, renal failure).

Frequent neurologic checks, including the level of consciousness, pupillary size and reaction, and movement of extremities, help detect any changes in the patient's condition. The neurologic changes of a hypertensive crisis are often like those of a stroke but without the focal or lateralizing signs often seen with a stroke. In a stroke, impairments affect a specific region or side of the body.

Hypertensive urgencies usually can be managed with oral agents and outpatient follow-up care within 24 hours. The initial decision for oral antihypertensive agents should be made based on the underlying cause of the hypertensive urgency, the patient characteristics, and comorbidities. A disadvantage of oral drugs is the inability to regulate the dosage moment to moment, as can be done with IV therapy. Some of the most commonly used oral drugs are captopril, labetalol, clonidine (Catapres), and amlodipine (Norvasc) (Table 36.6).[18]

Once the hypertensive crisis is resolved, it is essential to determine the cause. The patient will need appropriate management and teaching to avoid future crises.

DRUG ALERT

Clonidine (Catapres)

- Teach the patient to change positions slowly to limit orthostatic hypotension.
- Avoid hazardous activities since the drug may cause drowsiness.
- Do not stop abruptly as this may cause a rebound increase in BP.

Not every patient with an elevated BP will need emergent drug therapy or hospitalization. Allowing the patient to sit for 20 or 30 minutes in a quiet environment may significantly reduce BP. Oral drugs may be started or adjusted. Other interventions include encouraging the patient to share any concerns or fears, answering questions about hypertension, and reducing any adverse stimuli (e.g., excess noise) in the environment.

Case Study

Primary Hypertension

(© Ridofranz/iStock.com)

Patient Profile

R.L. is a 45-years-old Black man with no history of hypertension. At a screening clinic 2 months ago, his BP was 150/95 mm Hg. His HCP has followed him for the past month. During this time, he has been taking hydrochlorothiazide 12.5 mg/day. He is here today for a follow-up visit.

Subjective Data

- Father died of a stroke at age 60
- Mother is alive but has hypertension and a history of MI
- States that he feels fine
- Smokes 1 pack of cigarettes daily for the past 28 years
- Drinks 5–6 beers on most Friday and Saturday nights with work colleagues.
- Has heard that BP drugs "make you impotent"

Objective Data

Physical Assessment

- Mild retinopathy (retinal arteriolar narrowing on ophthalmoscopic examination)
- BP: 166/108 mm Hg (highest of 2 readings, 2 min apart)
- Sustained apical impulse palpable in the 4th intercostal space just lateral to the midclavicular line
- Heart rate is regular with a pulse of 84

Diagnostic Studies

- ECG: mild left ventricular hypertrophy
- Urinalysis: protein 30 mg/dL (0.3 g/L)
- Serum creatinine level: 1.6 mg/dL (141 mmol/L)

Interprofessional Care

- Low-sodium, DASH diet
- Hydrochlorothiazide 25 mg/day oral (dose increase)
- Lisinopril 5 mg once daily (second drug added)

Discussion Questions

1. ***Recognize***: What risk factors does R.L. have for hypertension?
2. ***Recognize***: What stage of hypertension does R.L. have?
3. ***Analyze***: What are the abnormal findings in the objective data?
4. ***Analyze***: Based on the assessment, what target organ disease may be present?
5. ***Analyze***: What additional assessment would be done for this patient?
6. ***Plan***: What medications would you expect to see ordered for this patient?
7. ***Plan***: What referrals may be indicated for R.L.?
8. ***Prioritize***: Based on your assessment, which teaching points about hypertension are the most important?
9. ***Prioritize***: What is the most important problem to manage for R.L. right now?
10. ***Act***: What would you teach this patient about the medications he is prescribed?
11. ***Act***: What other teaching is needed for this patient?
12. ***Evaluate***: What follow-up is needed for this patient to assess his response to your plan?

Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A defect in which BP-regulating mechanisms can result in the development of hypertension? *(select all that apply)*
   - **a.** Release of norepinephrine
   - **b.** Secretion of prostaglandins
   - **c.** Stimulation of the sympathetic nervous system
   - **d.** Stimulation of the parasympathetic nervous system
   - **e.** Activation of the renin-angiotensin-aldosterone system
2. Which item in a patient history would the nurse recognize as a modifiable risk factor for the development of hypertension?
   - **a.** Low-calcium diet
   - **b.** Excess alcohol use
   - **c.** Family history of hypertension
   - **d.** Consumption of a high-protein diet
3. Which information would the nurse apply to a teaching plan for a patient with hypertension?
   - **a.** All patients with elevated BP need drug therapy
   - **b.** Obese persons must achieve a normal weight to lower BP.
   - **c.** It is not necessary to limit salt in the diet if taking a diuretic.
   - **d.** Lifestyle modifications are needed for persons with elevated BP.
4. Which consideration would the nurse include in the management of the older adult with hypertension?
   - **a.** Preventing primary hypertension from converting to secondary hypertension
   - **b.** Recognizing that the older adult is less likely to adhere to the drug therapy regimen than a younger adult
   - **c.** Ensuring that the patient receives larger initial doses of antihypertensive drugs because of impaired absorption
   - **d.** Using a precise technique in assessing the BP of the patient because of the possible presence of orthostatic hypertension
5. A patient with newly discovered high BP has an average reading of 158/98 mm Hg after 3 months of exercise and diet modifications. Which management strategy would the nurse expect?
   - **a.** Drug therapy will be needed because the BP has not reached the goal.
   - **b.** BP monitoring should continue for 3 months to confirm a diagnosis of hypertension.
   - **c.** Lifestyle changes are less important since they were not effective, and drugs will be started.
   - **d.** More changes in the patient's lifestyle are needed for a longer time before starting drug therapy.
6. A patient is admitted to the hospital in a hypertensive emergency (BP 244/142 mm Hg). Sodium nitroprusside is started to treat the elevated BP. Which management strategies would the nurse anticipate? *(select all that apply)*
   - **a.** Measuring hourly urine output
   - **b.** Continuous BP monitoring with an arterial line
   - **c.** Decreasing the MAP by 50% within the first hour
   - **d.** Maintaining bed rest and giving tranquilizers to lower the BP
   - **e.** Assessing the patient for signs of heart failure and changes in mental status

LEARNING OUTCOMES

1. Relate the etiology and pathophysiology of coronary artery disease (CAD), chronic stable angina, and acute coronary syndrome (ACS) to the clinical manifestations of each disorder.
2. Describe the nursing role in promoting therapeutic lifestyle changes in patients at risk for CAD.
3. Distinguish the precipitating factors, clinical manifestations, and interprofessional and nursing care of the patient with CAD and chronic stable angina.
4. Explain the clinical manifestations, diagnostic studies, complications, and interprofessional and nursing care of the patient with ACS.
5. Outline drug therapy used to treat patients with CAD, chronic stable angina, and ACS.
6. Prioritize key components to include in the rehabilitation of patients recovering from ACS and coronary revascularization procedures.
7. Distinguish the precipitating factors, manifestations, and interprofessional and nursing care of patients who are at risk for or have had sudden cardiac death.

KEY TERMS

acute coronary syndrome (ACS)
angina
atherosclerosis
chronic stable angina
collateral circulation
coronary artery disease (CAD)
coronary revascularization
metabolic equivalent (MET)
myocardial infarction (MI)
percutaneous coronary intervention (PCI)
Prinzmetal's angina
stent
sudden cardiac death (SCD)
unstable angina (UA)

Cardiovascular disease (CVD) is the leading cause of death worldwide. It is expected to account for more than 22.2 million deaths by 2030.[1] CVD encompasses several disorders of the heart and blood vessels, including coronary artery disease (CAD), cerebrovascular disease, and peripheral artery disease.[2] CAD is the most common type of CVD and the leading cause of death in the United States.[1] Patients with CAD may be asymptomatic or develop chronic stable angina (chest pain). CAD may evolve to more serious conditions of unstable angina (UA) and myocardial infarction (MI), which we refer to as acute coronary syndrome (ACS).

The process of perfusion depends on the heart's ability to generate enough cardiac output (CO) to distribute blood to all body tissues. Significant CAD negatively affects heart function, resulting in impaired CO and decreased perfusion. This chapter discusses the care of patients with CAD, chronic stable angina, and ACS along with measures to promote optimal perfusion.

CORONARY ARTERY DISEASE

Coronary artery disease (CAD) is a type of blood vessel disorder in the general category of atherosclerosis. The term

atherosclerosis comes from 2 Greek words: *athere,* meaning "gruel or fatty mush," and *skleros,* meaning "hard."[3] Atherosclerosis begins as soft deposits of fat that harden with age, often referred to as "hardening of the arteries." Atherosclerosis can occur in any artery in the body. When the *atheromas* (fatty deposits) form in the coronary arteries, the disease is called CAD. *Arteriosclerotic heart disease (ASHD), cardiovascular heart disease (CVHD), ischemic heart disease (IHD), coronary heart disease (CHD)* are other terms used to describe CAD.

Etiology and Pathophysiology

Atherosclerosis is characterized by lipid deposits within the intima, the innermost layer of the arterial wall. A layer of endothelial cells lines the intima to provide a barrier between blood and the arterial wall. The endothelium is normally nonreactive to platelets and leukocytes, as well as coagulation, fibrinolytic, and complement factors. Endothelial injury and inflammation play a key role in developing atherosclerosis. Damage to the endothelial lining can result from tobacco use, hyperlipidemia, hypertension, toxins, diabetes, inflammation, and infection (Fig. 37.1A).[3]

C-reactive protein (CRP) is a nonspecific marker of inflammation made by the liver. CRP levels rise when there is systemic inflammation, such as rheumatoid arthritis or inflammatory bowel disease. It may also be increased in CAD. Lipoprotein(a) is a type of low-density lipoprotein (LDL) attached to a protein called apo(a). Homocysteine is made by the breakdown of the essential amino acid methionine, found in diet protein. High lipoprotein(a) and homocysteine levels may contribute to atherosclerosis by (1) damaging the inner lining of blood vessels, (2) promoting plaque buildup, and (3) changing the clotting mechanism to make clots more likely to occur. Although elevation of any of these levels may increase the risk for development of CAD, they are not part of a routine risk assessment for CAD. They can be used in patients with an intermediate or high-risk suspicion of CAD.[4]

Developmental Stages

CAD is a progressive disease that develops in stages over many years. By the time the patient becomes symptomatic, the disease process usually is well advanced. The stages of development in atherosclerosis are (1) fatty streak, (2) fibrous plaque, and (3) complicated lesion.

Fatty streak. *Fatty streaks,* the earliest lesions of atherosclerosis, are lipid-filled smooth muscle cells. As streaks of fat develop within the smooth muscle cells, a yellow tinge appears. Fatty streaks appear in the coronary arteries by age 20. They involve more surface area as one ages. Treatment that lowers LDL cholesterol may slow this process (Fig. 37.1B).

Fibrous plaque. The *fibrous plaque* stage is the beginning of progressive changes in the endothelium of the arterial wall. These changes can appear in the coronary arteries by age 30 and increase with age.

Normally, the endothelium repairs itself immediately. This does not occur in the person with CAD. LDLs and growth factors from platelets stimulate smooth muscle proliferation and thickening of the arterial wall. Once endothelial injury has taken place, lipoproteins (carrier proteins within the bloodstream) transport cholesterol and other lipids into the arterial intima. Collagen covers the fatty streak and forms a fibrous plaque with a grayish or whitish appearance. These plaques can form on one side of the artery or in a circular fashion involving the entire lumen. The borders can be smooth or irregular with rough, jagged edges. The result is a narrowing of the vessel lumen and reduced blood flow to the distal tissue (Fig. 37.1C).

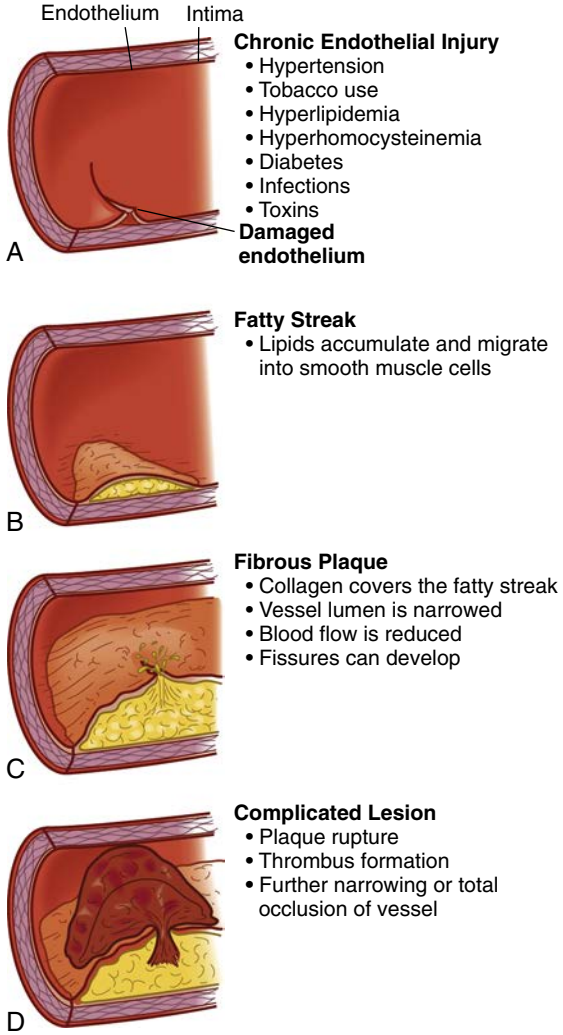

Fig. 37.1 Pathogenesis of atherosclerosis. (A) Damaged endothelium. (B) Fatty streak and lipid core formation. (C) Fibrous plaque covers the lipid core. (D) Complicated lesion: Plaque rupture with thrombus formation.

Complicated lesion. The last stage in the development of the atherosclerotic lesion is the most dangerous. As the fibrous plaque grows, continued inflammation can result in plaque instability, ulceration, and rupture. Once the integrity of the artery's inner wall is compromised (plaque rupture), platelets accumulate in large numbers, leading to a thrombus (platelet aggregation and adhesion is the body's attempt to "heal" the ruptured area). The thrombus may adhere to the wall of the artery, leading to further narrowing or total occlusion of the artery. Activation of the exposed platelets causes expression of glycoprotein IIb/IIIa (GP IIb/IIIa) receptors that bind fibrinogen. This, in turn, leads to more platelet aggregation and

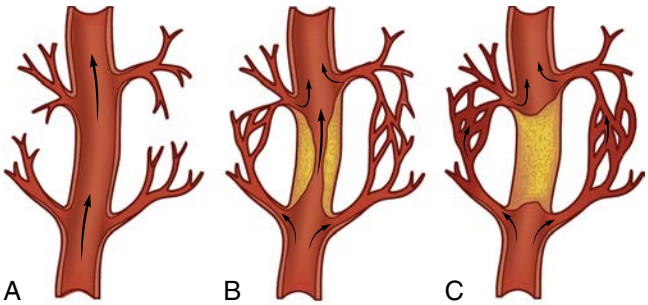

Fig. 37.2 Vessel occlusion with collateral circulation. (A) Open, functioning coronary artery. (B) Partial coronary artery closure with collateral circulation being established. (C) Total coronary artery occlusion with collateral circulation bypassing the occlusion to supply blood to the myocardium.

adhesion, further enlarging the thrombus. At this stage, the plaque is termed a *complicated lesion* (Fig. 37.1D).

Collateral Circulation

Normally, some arterial anastomoses or connections, called **collateral circulation**, exist within the coronary circulation. Two factors contribute to the growth and extent of collateral circulation: (1) inherited predisposition to develop new blood vessels *(angiogenesis)* and (2) presence of chronic ischemia (poor blood flow). When plaque blocks the normal flow of blood through a coronary artery and the resulting *ischemia* is chronic, collateral circulation may develop (Fig. 37.2). When blockages in coronary arteries occur slowly over a long time, collateral circulation has a greater chance to develop, so the heart muscle may still receive an adequate amount of blood and oxygen (O_2) except during increased workload on the heart, such as exercise.

However, with acute coronary occlusion or acute severe coronary spasm, collateral circulation does not have enough time to develop. When this happens, reduced blood flow results in more severe ischemia or infarction.

Risk Factors for Coronary Artery Disease

Nonmodifiable and modifiable risk factors are associated with CAD (Table 37.1). *Nonmodifiable risk factors* include age, gender, ethnicity, family history, and genetics. The *modifiable risk factors* are high serum lipids, high blood pressure (BP), tobacco use, physical inactivity, obesity, diabetes, and metabolic syndrome. *Contributing modifiable risk factors* include psychological states, substance use, and increased levels of CRP, lipoprotein(a), and homocysteine.

Nonmodifiable Risk Factors

Age, gender, ethnicity, and genetics. The incidence of CAD is highest among middle-aged men (Box 37.1). However, the risk for CAD increases for men over age 45 and women over age 55.[4] Heart disease often is diagnosed about 10 years later in women than men (Box 37.2). One possible reason may be the cardioprotective effects of estrogen. Interestingly, hormone replacement therapy does not protect women after menopause and may be harmful.[4] Because women are older at the time of CAD diagnosis, they are more likely to have co-morbidities (e.g., hypertension, diabetes). Women are more likely than men to die after their first MI. CAD is present in Black women at rates higher than White or Hispanic women.[4]

Most women do not consider CAD their greatest health risk.[4] Despite efforts to increase awareness that more women die from heart disease than from breast cancer (e.g., the American Heart Association's [AHA] Go Red for Women campaign), heart disease kills almost 10 times more women than breast cancer. It is the leading cause of death in women. When women present to the HCP, their symptoms may be unrecognized as heart-related because the symptoms are often atypical. These symptoms include fatigue, shortness of breath, upper back pain, indigestion, memory problems, palpitations, and anxiety.[4] These atypical symptoms can relate to many different diseases and syndromes. This lack of recognition of symptoms as a heart

TABLE 37.1 Risk Factors for Coronary Artery Disease

Nonmodifiable Risk Factors	Modifiable Risk Factors

• Increasing age
• Ethnicity (Box 37.1)
• Gender (Box 37.2)
• Genetic predisposition and family history of heart disease (Box 37.3)
	Major
	• BP >120/80 mm Hg
	• Diabetes
	• Lipid levels:
	  • Total cholesterol >200 mg/dL
	  • Triglycerides ≥150 mg/dL
	  • LDL cholesterol >130 mg/dL
	  • HDL cholesterol <40 mg/dL in men or <50 mg/dL in women
	• Metabolic syndrome
	• Obesity (see Chapter 45)
	Physical inactivity
	Tobacco use
	Contributing Risk Factors
	• ↑ Homocysteine, CRP, lipoprotein (a) levels
	• Psychosocial risk factors (e.g., depression, hostility)
	• Substance use

BOX 37.1 PROMOTING HEALTH EQUITY

Coronary Artery Disease

Whites
- White males have the highest incidence of CAD
- Have the highest mortality from CAD

Blacks
- Males have a higher incidence of CAD compared to Hispanic and Asian males

Hispanics
- Have slightly lower rates of CAD than either non-Hispanic Whites or Blacks
- Have lower death rates from CAD than non-Hispanic Whites and Blacks

Native Americans
- Die from heart disease earlier than expected
- Mortality rates for those under age 65 are twice as high as those of other Americans

BOX 37.2 BIOLOGIC SEX CONSIDERATIONS

Coronary Artery Disease and Acute Coronary Syndrome

Men	Women
• First heart event is more often MI than angina • Report more typical signs and symptoms of angina and MI • Receive more evidence-based therapies (e.g., diagnostic catheterization, PCI) when acutely ill from CAD (e.g., MI) • Mortality rates from CAD have decreased more rapidly for men than women • Have larger diameter coronary arteries. Vessel diameter is inversely related to risk for restenosis after interventions • After age 55, the incidence of MI in men and women equalizes • Develop more collateral circulation • Standard screening for risk for sudden cardiac death is more predictive in men	• First heart event is more often UA than MI • Fewer women have the "classic" signs and symptoms of angina or MI • Fatigue is often the first symptom of ACS • Experience the onset of heart disease about 10 years later than men • More often have non-obstructive CAD causing angina • Before menopause, have higher HDL cholesterol levels and lower LDL cholesterol levels. After menopause LDL levels and risk for MI increase • Report more disability after a heart event • Seek medical care later in the CAD process, most likely because of lack of recognition of atypical symptoms • Have more "silent" MIs • Those who have an MI are more likely to have a fatal heart event within 5 years than men • Women who have coronary artery bypass graft surgery have a higher mortality rate and more complications after surgery • Are undertreated with guideline-based recommendations, leading to worse outcomes and increased rates of readmission, reinfarction, and death in the first year after MI

BOX 37.3 GENETICS IN CLINICAL PRACTICE

Familial Hypercholesterolemia

Genetic Basis
- Autosomal dominant disorder
- Heterozygous (most common) and homozygous forms
- Mutation in low-density lipoprotein receptor (LDLR) gene
- Gene codes for low-density lipoprotein (LDL) receptor that binds to LDLs
- High cholesterol levels are a result of defective function of the LDL receptors
- Person has high serum LDLs throughout life

Incidence
- Heterozygotes: 1 in 500
- Homozygotes: rare

Genetic Testing
- DNA testing is available

Clinical Implications
- Develop severe atherosclerosis in early to middle years
- A baseline serum lipid profile that measures total cholesterol, triglycerides, LDLs, and high-density lipoproteins (HDLs) should be done early if there is a history of familial hypercholesterolemia
- Homozygous familial hypercholesterolemia is much more severe. Cholesterol levels may exceed 600 mg/dL
- Develop xanthomas (fatty growths on the skin [e.g., around eyes, over joints])
- Treatment includes low-fat diet, exercise, and lipid-lowering drugs (e.g., PCSK9 inhibitors)

problem leads to delays in women seeking treatment and HCPs recognizing the symptoms.

Genetic Link

Genetic predisposition is a key factor in the occurrence of CAD (Box 37.3). Family history is a risk factor for CAD and MI. Often patients with angina or MI can name a parent or sibling who has CAD or died from CAD. A family history of premature CAD (under age 55) puts the patient at even greater risk for developing CAD.[1]

The genetic basis of CAD/MI is complex and poorly understood. We estimate that the genetic contribution to CAD is as high as 40% to 60%. This proportion relates mainly to genes that control known risk factors (e.g., lipid metabolism). Work is being conducted using genetic risk stratification to determine one's risk for CAD.[5]

Major Modifiable Risk Factors

High serum lipids. High serum lipid levels are a major risk factor for CAD (see Table 35.9). The increased risk for CAD is associated with a total serum cholesterol level greater than 200 mg/dL (5.2 mmol/L), an LDL greater than 130 mg/dL (3.4 mmol/L), a high-density lipoprotein (HDL) level less than 40 mg/dL (1.0 mmol/L) in men and less than 50 mg/dL (1.3 mmol/L) in women, and/or a fasting triglyceride level greater than 150 mg/dL (1.7 mmol/L). Most refer to HDL as the "good cholesterol" and LDL as the "bad cholesterol." Studies in the United States reveal that adults with a total cholesterol in the range of 150 mg/dL, which corresponds to an LDL level of about 100 mg/dL, have low rates of CAD.[6] Drugs used to treat high serum lipids focus mostly on lowering LDL cholesterol.

For the body to be able to use and transport lipids, they must become soluble in blood by combining with proteins. Lipids combine with proteins to form lipoproteins. Lipoproteins are vehicles for fat mobilization and transport. They vary in composition. The 3 main lipoproteins are HDLs, LDLs, and very-low-density lipoproteins (VLDLs).

HDLs contain more protein by weight and fewer lipids than any other lipoprotein. HDLs carry lipids away from arteries to the liver for metabolism through a process called reverse

cholesterol transport. This process of HDL transport helps prevent lipid accumulation within the arterial walls.[3] This is why high serum HDL levels are desirable and lower the risk for CAD. Although there are a few medications that help raise HDL (e.g., niacin), research has shown that taking niacin does not reduce the risk of CAD and MI.

Premenopausal women usually have higher HDL levels than men. This may be related to the protective effects of natural estrogen. After menopause, women's HDL levels decrease to levels near those of men. In general, HDL levels are higher in women, decrease with age, and are low in those with CAD. Physical activity, eating more healthy fats, losing excess weight, moderate alcohol use, and quitting smoking help increase HDL levels.

LDLs contain more cholesterol than any of the lipoproteins and have an attraction for arterial walls. High LDL levels correlate closely with an increased incidence of atherosclerosis and CAD. This is why low serum LDL levels are desirable. We cannot routinely calculate LDL if the triglycerides are higher than 400 mg/dL (>4.35 mmol/L). Remember, drugs used to treat high lipid levels focus mostly on lowering LDL. VLDLs have a higher concentration of triglycerides and can deposit cholesterol directly on the walls of arteries.

Triglycerides are the most common type of fat in the blood. High triglyceride levels increase the risk for CAD. Certain diseases (e.g., type 2 diabetes, chronic kidney disease [CKD]), drugs (e.g., corticosteroids, hormone therapy), and genetic disorders are associated with high triglyceride levels. Lifestyle factors that can contribute to high levels include high alcohol intake, high intake of refined carbohydrates and simple sugars, and physical inactivity. When a high triglyceride level is combined with a high LDL level, a smaller, denser LDL particle is formed, which favors deposition on arterial walls. People with insulin resistance often have this pattern.

Guidelines for treating high LDL levels are based on known risk factors and a person's 10-year risk for having heart disease or stroke. The 10-year risk calculator is used for people between the ages of 40 to 79 who have not been diagnosed with CAD, MI, or stroke. The following data generate a risk score: (1) age, (2) gender, (3) race, (4) use of tobacco, (5) diabetes, (6) systolic BP, (7) diastolic BP, (8) use of BP drugs, (9) total cholesterol level, and (10) HDL cholesterol level. A score of less than 5% puts you at a low risk for developing CAD. A 10-year risk calculator is available at www.cvriskcalculator.com.

Hypertension. Hypertension increases the risk for CAD, stroke, peripheral vascular disease, heart failure (HF), and death. In postmenopausal women, hypertension is associated with a higher incidence of CAD than in men and premenopausal women.

According to the most recent published hypertension guidelines, a normal BP is defined as less than 120/80 mm Hg. BP is classified as elevated (BP 120 to 129 mm Hg/<80 mm Hg); stage 1 hypertension (BP 130 to 139/80 to 89 mm Hg); or stage 2 hypertension (BP ≥140/90 mm Hg).[7]

Elevated BP and hypertension are controlled with lifestyle changes and medications. Those with stage 1 or 2 hypertension often need more than 1 drug to reach therapeutic goals (see Tables 36.6, 36.7, and 36.8).[7] Teach patients the importance of achieving and maintaining target BP goals.

The shearing stress of an elevated BP causes endothelial injury that increases the rate of atherosclerosis. Atherosclerosis, in turn, causes narrowed, thickened arterial walls, and decreases the distensibility and elasticity of vessels. More force is needed to pump blood through diseased arteries. This increased force is reflected in a higher BP. This added workload can result in left ventricular (LV) hypertrophy and decreased stroke volume with each contraction. See Chapter 36 for a complete discussion of hypertension.

Tobacco use. Tobacco use is a major CAD risk factor. The risk for developing CAD is much higher in those who smoke tobacco or use smokeless tobacco than in those who do not. Further, tobacco smoking decreases estrogen levels, placing premenopausal women who smoke at greater risk for CAD.

Nicotine in tobacco smoke causes catecholamine (i.e., epinephrine, norepinephrine) release. These neurohormones cause an increased heart rate (HR), peripheral vasoconstriction, and increased BP. These changes increase the heart's workload. Tobacco smoke is related to an increase in LDL levels, a decrease in HDL levels, and release of toxic O_2 radicals. All of these add to vessel inflammation and thrombosis.

Carbon monoxide, found in tobacco smoke, reduces the numbers of hemoglobin sites available for O_2 transport. Thus, the effects of an increased cardiac workload and the O_2-depleting effect of carbon monoxide significantly decrease the O_2 available to the heart muscle. In addition, carbon monoxide is a toxin that injures the endothelium.

At any age, the benefits of smoking cessation are dramatic. CAD risk and mortality rates drop within weeks to months after quitting. The risk goes down even further the longer the time goes by without smoking.[1] However, nicotine is highly addictive. People usually need intensive intervention to quit. Individual and group counseling, nicotine replacement therapy, and smoking cessation drugs (e.g., bupropion, varenicline) are examples of smoking cessation strategies. See Chapter 11, Tables 11.3, 11.4, and 11.5 for information on smoking cessation.

Although the rate of cigarette smoking has decreased in the United States, the rate of using new tobacco products such as electronic cigarettes has increased. Using any tobacco product (e.g., electronic cigarettes, cigars, pipes, smokeless tobacco) carries a potential cardiovascular risk. We need more long-term studies to determine the impact of electronic cigarettes on CAD.[8]

Nonsmokers exposed to secondhand tobacco smoke increase their risk for CAD by 25% to 30%.[1] People who live in the same house as the person who smokes should encourage that person to quit or smoke outside to decrease others' exposure to environmental smoke.

Diabetes. Diabetes is a major modifiable risk factor for CAD. The incidence of CAD is 2 to 4 times greater among people who have diabetes, even with well-controlled glucose levels. Both male and female patients with diabetes manifest CAD at an earlier age than those without diabetes.

Undiagnosed diabetes is often discovered when a person has an MI. An increased tendency toward endothelial

dysfunction may cause the development of fatty streaks in the arteries. Patients with diabetes also have changes in lipid metabolism and tend to have high cholesterol and triglyceride levels. Management of diabetes should include lifestyle changes and drug therapy to achieve a glycosylated hemoglobin (A1C or Hb A1C) level of less than 7%.[9]

Metabolic syndrome. *Metabolic syndrome* refers to a cluster of risk factors for CAD whose underlying pathophysiology may be related to insulin resistance. These risk factors include central obesity, hypertension, abnormal serum lipids, and a high fasting glucose level (see Table 45.11). Chapter 45 discusses metabolic syndrome.

Physical inactivity. Physical inactivity increases risk for CAD. Physical inactivity implies a lack of adequate physical exercise on a regular basis. Exercise training for those who are physically inactive reduces the risk for CAD through more efficient lipid metabolism, increased HDL production, a decreased risk of thrombus formation, and more efficient O_2 extraction by the muscles. This decreases the heart's workload. For people with CAD, regular physical activity may reduce symptoms, improve functional capacity, and improve other risk factors, such as insulin resistance, glucose intolerance, and obesity.

Obesity. The death rate from CAD is higher in obese persons. *Obesity* is defined as a body mass index (BMI) of greater than 30 kg/m^2 and a waist circumference more than 40 inches for men and more than 35 inches for women. We calculate BMI by dividing a person's weight (in kilograms) by the square of the height in meters (see Fig. 45.7).

The degree of obesity affects the risk for CAD. Obese persons may have increased levels of LDLs and triglycerides, which are strongly related to atherosclerosis. Obesity is often linked with hypertension and insulin resistance. People who tend to store fat in the abdomen (an "apple" figure) rather than in the hips and buttocks (a "pear" figure) have a higher incidence of CAD (see Table 45.5).

Contributing Modifiable Risk Factors

Psychologic states. Certain behaviors and lifestyles may contribute to the development of CAD. One type of behavior, referred to as type A, includes perfectionism and a hardworking, driven personality. The person with a type A personality often suppresses anger and hostility, has a sense of time urgency, is impatient, and creates stress and tension. This person may be more prone to MIs than one with a type B personality. Type Bs are more easygoing, take upsets in stride, know personal limitations, take time to relax, and are not an overachievers. However, the relationship between behaviors and the risk for CAD/MI is controversial and complex.

Psychologic risk factors include depression, acute and chronic stress (e.g., poverty, serving as a caregiver), anxiety, hostility and anger, and lack of social support. Stressful states contribute to the development and progression of CAD through sympathetic nervous system (SNS) stimulation. An increased release of catecholamines (i.e., epinephrine, norepinephrine) with SNS stimulation increases BP and may contribute to endothelial injury, inflammation, and platelet activation. SNS stimulation increases HR and the force of myocardial contraction, which increases myocardial O_2 demand. Stress-induced mechanisms can cause increased lipid and glucose levels and changes in blood coagulation, which contribute to atherosclerosis.

Substance use. The use of illegal drugs such as cocaine and methamphetamine can produce coronary artery spasm resulting in myocardial ischemia and chest pain. Initially, we cannot distinguish drug-induced chest pain from CAD. Patients often have sinus tachycardia, high BP, and chest pain. Chest pain occurs because of increased myocardial O_2 demand from the increased HR and contractility and coronary vasoconstriction.[10] An MI can occur because of coronary spasm. Serum cardiac biomarkers and an electrocardiogram (ECG) help determine if the patient is experiencing ACS. A drug screen may be helpful to identify if illegal drugs precipitated the cardiac event.

CRP, lipoprotein(a), homocysteine, levels. Increased levels of CRP, lipoprotein(a), and homocysteine increase the risk of CAD. Folic acid deficiency can cause high homocysteine levels, but lowering homocysteine levels through folic acid supplements does not lower the risk of CAD.[11]

❖ INTERPROFESSIONAL AND NURSING MANAGEMENT: CORONARY ARTERY DISEASE

◆ Health Promotion

Management of CAD risk factors may prevent, modify, or slow disease progression. In the United States, CAD-related deaths have gradually declined. This decline relates to our efforts to become healthier and research advances in the treatment of CAD. Prevention and early treatment of heart disease involves a multifaceted approach throughout the life span. In fact, healthy lifestyle behaviors should begin in childhood.

◆ Identifying High-Risk Persons

Clinical signs of CAD are not apparent in the early stages of the disease. Therefore, it is critical to identify people at risk for CAD. Risk screening involves obtaining a thorough health history. Ask the patient about a family history of heart disease in parents and siblings, especially a premature history of CAD (under age 55).[1] Note the presence of any cardiovascular symptoms. Assess environmental factors, such as eating habits, type of diet, and level of exercise, to elicit lifestyle patterns. Include a psychosocial history to determine tobacco use, alcohol intake, recent stressful events (e.g., loss of a spouse), and psychologic state (e.g., anxiety, depression, anger). The place and type of employment provide vital information on the kind of activity performed, exposure to pollutants or toxins, and degree of stress associated with work.

Assess the patient's attitudes and beliefs about health and illness. The patient's attitude gives insight to how disease and lifestyle changes may affect the patient. It can reveal misconceptions about heart disease. Knowing the patient's educational background and health literacy helps determine teaching needs. If the patient has prescribed drugs, you need to assess their knowledge of their medications and adherence to their drug regimen. If the patient is unable to tell you, you can get the information from the patient's HCP or pharmacy.

TABLE 37.2 PATIENT & CAREGIVER TEACHING

Reducing Risk Factors for Coronary Artery Disease

Include the following instructions when teaching risk reduction for coronary artery disease:

Risk Factor	Health-Promoting Behaviors
Hypertension	• Monitor home-based BP and obtain regular check-ups. • Take prescribed drugs for BP control. • Reduce salt intake. • Stop tobacco use. Avoid exposure to environmental tobacco (secondhand) smoke. • Control or reduce weight. • Perform physical activity daily.
High serum lipids	• Reduce total fat intake. • Reduce saturated fat intake. • Take prescribed drugs for lipid reduction. • Adjust total caloric intake to achieve and maintain ideal body weight. • Engage in daily physical activity. • Increase amount of complex carbohydrates, fiber, and vegetable proteins in diet. • Follow-up with HCP for regular lipid panel assessments.
Tobacco use (see Chapter 11)	• Begin a tobacco cessation program. • Change daily routines associated with tobacco use to reduce desire to smoke. • Substitute other activities for smoking. • Ask caregivers to support efforts to stop smoking. • Avoid exposure to environmental tobacco smoke.
Physical inactivity	• Develop and maintain at least 30 min of moderate physical activity daily (minimum 5 days a week). • Increase activities to a fitness level.
Psychologic state	• Increase awareness of behaviors that are harmful to health. • Change patterns that add to stress (e.g., get up 30 min earlier so that breakfast is not eaten on way to work). • Set realistic goals for self. • Reassess priorities considering identified risk factors. • Learn effective stress management strategies (see Chapter 7). • Seek professional help if feeling depressed, angry, or anxious. • Plan time for adequate rest and sleep (see Chapter 8).
Obesity (see Chapter 45)	• Change eating patterns and habits. • Reduce caloric intake to achieve body mass index of 18.5–24.9 kg/m^2. • Increase physical activity to increase caloric expenditure. • Avoid fad and crash diets, which are not effective over time. • Avoid large, heavy meals. Consider smaller, more frequent meals.
Diabetes (see Chapter 53)	• Follow the recommended diet. • Control or reduce weight. • Take prescribed drugs for diabetes. • Monitor glucose levels regularly and follow up with HCP regularly.

◆ Managing High-Risk Persons

Recommend preventive measures for all persons at risk for CAD. The person with non-modifiable risk factors (e.g., age, gender, ethnicity) can still reduce the risk for CAD by controlling other modifiable risk factors. For example, a young person with a family history of premature heart disease can decrease the risk for CAD by maintaining an ideal body weight, getting adequate physical exercise, reducing intake of saturated fats, and avoiding tobacco and illicit drug use.

Encourage people who have modifiable risk factors to make lifestyle changes to reduce their risk for CAD. You play a key role in teaching health-promoting behaviors (Table 37.2). For highly motivated persons, just knowing how to reduce their risk may be all the information they need to start.

For people who are less motivated to take charge of their health, the idea of reducing risk factors may be so remote that they are unable to perceive a threat of CAD. Few people want to make lifestyle changes, especially in the absence of symptoms. First, help them to clarify their personal values. Then, discuss risk factors and have them identify their individual risks. Help them set realistic goals and choose which risk factor(s) to change first. Trying to change too many things at once can be a set-up for failure, so recommend working on one risk factor at a time. Some people are reluctant to change until they have symptoms or have an MI. Others, having had an MI, may find the idea of changing lifelong habits still unacceptable. Help them review options and respect their decisions.

◆ Physical Activity

A regular physical activity program should be designed and implemented following the FITT formula (Table 37.3): Frequency (how often), Intensity (how hard), Type (isotonic), and Time (how long). Everyone should aim for at least 150 minutes (30 minutes at least 5 days per week) of moderate aerobic activity per week. Examples of moderate physical activity include brisk walking, biking, and recreational swimming. Another option is to do 75 minutes of vigorous aerobic activity each week such as jogging, singles tennis, or swimming laps.[12]

The AHA encourages increasing daily physical activity and lowering the chance of developing heart disease simply by walking. Adding weight training to an exercise program 2 days a week can help treat metabolic syndrome and improve muscle strength. Regular physical activity helps with weight reduction, reduces systolic BP, and can help increase HDL cholesterol.

TABLE 37.3 PATIENT & CAREGIVER TEACHING

FITT Activity Guidelines for CAD, Chronic Stable Angina, and ACS

Include the following information in the teaching plan for the patient with chronic stable angina and acute coronary syndrome and the caregiver:

Warm-Up/Cool-Down

Perform mild stretching for 3–5 min before the physical activity and 5 min after the activity. Do not start or stop activity abruptly.

Frequency

Perform physical activity on most days of the week.

Intensity

The patient's HR determines the activity intensity. If an exercise stress test has not been done, the HR of the patient recovering from an MI should not exceed 20 beats/min over the resting HR. Patients taking β-blockers may not be able to achieve the same HR with exercise as those not taking β-blockers. They should discuss specific HR targets with their HCP.

Type of Physical Activity

Select physical activity that is regular, rhythmic, and repetitive, using large muscles to build up endurance (e.g., walking, cycling, swimming, rowing).

Time

Physical activity sessions should be at least 30 min long. Begin slowly at personal tolerance (perhaps only 5–10 min) and build up to 30 min.

TABLE 37.4 NUTRITION THERAPY

Therapeutic Lifestyle Changes to Diet

Diet Recommendations	Recommended Daily Intake

Combined total fat calories from:
• *Saturated fats:* Limit fats that are usually solid at room and refrigerator temperature (e.g., lard, butter, whole-milk products, fatty cuts of meat, bacon)
• *Trans fats:* Mainly in foods made with hydrogenated vegetable oils, such as many hard margarines and shortenings
• *Unsaturated fats*: In oils that are usually liquid at room and refrigerator temperature (e.g., olive, corn, sunflower, soybean). There are 2 types of unsaturated fats:
  • *Monounsaturated fats:* In greatest amounts in foods from plants, including olives, avocadoes, and canola, sunflower, and peanut oils.
  • *Polyunsaturated fats:* Found mostly in nuts, seeds, fish, seed oils, and oysters. Omega-3 fatty acid is a type of polyunsaturated fat that may help reduce the risk of CAD.
	25%–35% of total daily calories (including <7% from saturated fat)

Cholesterol	<200 mg
Plant stanols or sterols (e.g., margarines, nuts, seeds, legumes, vegetable oils)[a]	2 g
Diet soluble fiber[a]	10–25 g of soluble fiber
Total calories	Only enough calories to reach or maintain a healthy weight

[a]Diet options for additional lowering of low-density lipoprotein (LDL).

Nutrition Therapy

Diet recommendations focus on lowering LDL cholesterol through a decreasing saturated fat and cholesterol intake and increasing complex carbohydrates (e.g., whole grains, fruit, vegetables) and fiber (Tables 37.4 and 37.5). Fat intake should be about 25% to 35% of total calories, with most coming from monounsaturated and polyunsaturated fats. Red meat, egg yolks, and whole milk products are major sources of saturated fat and cholesterol. They should be reduced or eliminated from diets. Foods high in unsaturated fat include unsalted nuts (e.g., walnuts, peanuts, almonds) and avocado. Examples of oils low in saturated fat include canola, olive, and avocado. The patient with a high serum triglyceride level should reduce or eliminate alcohol and simple sugars.

Omega-3 fatty acids reduce triglyceride levels and can slow the progression of CAD. They do not affect LDL levels. The AHA recommends eating fatty fish twice a week because it is high in omega-3 fatty acids. Examples of fatty fish include salmon, albacore tuna, and mackerel. Omega-3 fatty acids can be hard to get by diet alone. The HCP may recommend medication supplements to assist in lowering triglycerides. The AHA has a website entitled "4 Ways to Get Good Fats" at https://www.heart.org/en/healthy-living/healthy-eating/eat-smart/fats/4-ways-to-get-good-fats-infographic.

Lipid-Lowering Drug Therapy

The prevalence of total cholesterol levels of 240 mg/dL (6.2 mmol/L) has decreased. This decrease is likely due to increased use of statins rather than to diet changes.[1] The treatment of high cholesterol focuses mostly on lowering LDL cholesterol. A complete lipid profile should be done every 5 years beginning at age 20.[13] Middle-aged adults should be screened every 1 to 2 years. If multiple risk factors are present, more frequent testing is recommended.[13]

The 2019 AHA/ACC cholesterol guideline recommends patients with the following receive statin therapy:

- Known CAD
- At very high risk for CAD with an LDL greater than 70 mg/dL
- Primary elevations of LDL cholesterol levels of ≥190 mg/dL (e.g., familial hypercholesterolemia)
- 40 to 75 years of age with diabetes and LDL cholesterol levels greater than 70 mg/dL
- 40 to 75 years of age without diabetes, with LDL cholesterol levels ≥70 mg/dL plus a 10-year risk for CAD of 7.5% or greater

Guideline details include (1) treating patients with known CAD but no clinical events with a high-dose statin (e.g., atorvastatin 80 mg) to reduce the LDL by 50%, (2) treating very high-risk patients (patients with a history of 1 or more major events and multiple high-risk conditions) with a high dose statin to

TABLE 37.5 NUTRITION THERAPY

Tips to Make Diet and Lifestyle Changes

General Tips

1. Know your calorie needs to achieve and maintain a healthy weight.
2. Know the calorie content of the foods and beverages you eat.
3. Track your weight, physical activity, and calorie intake.
4. Prepare and eat smaller, more frequent meals.
5. Track your activities and, whenever possible, decrease sedentary activities (e.g., watching television, computer time).
6. Incorporate physical movement into daily activities (e.g., take stairs and extra steps whenever possible).
7. Do not smoke or use tobacco products.
8. If you drink alcohol, do so in moderation (i.e., no more than 1 drink for women or 2 drinks for men a day).

Tips Related to Food Choices and Preparation

1. Use the Nutrition Facts panel on food labels and ingredients list when choosing foods to buy.
2. Use fresh or frozen vegetables and fruits in place of canned vegetables and fruits.
3. Replace high-calorie foods with fresh fruits and vegetables.
4. Increase fiber intake by eating beans (legumes), whole-grain products, fruits, and vegetables.
5. Use liquid vegetable oils in place of solid fats.
6. Limit beverages and foods high in added sugars (e.g., sucrose, glucose, fructose, maltose, dextrose, corn syrups, concentrated fruit juice, honey).
7. Choose foods made with whole grains (e.g., whole wheat, oats, rye, barley, brown rice, wild rice, buckwheat).
8. Avoid pastries and high-calorie bakery products (e.g., muffins, doughnuts).
9. Select milk and dairy products that are either fat free or low fat.
10. Reduce salt intake by
    - Comparing the sodium content of similar products (e.g., different brands of tomato sauce) and choosing products with less sodium.
    - Choosing versions of processed foods with reduced salt, including cereals, canned products, and baked goods.
    - Limiting condiments (e.g., soy sauce, ketchup).
11. Use lean cuts of meat and remove skin from poultry before cooking or eating.
12. Avoid processed meats that are high in saturated fat and sodium (e.g., deli meats).
13. Grill, bake, or broil fish, meat, and poultry.
14. Incorporate plant-based meat substitutes into recipes (e.g., soy, tofu, quinoa).
15. Consume whole vegetables and fruits in place of juices.

lower the LDL to less than 70 mg/dL. For primary prevention (people without known CAD) in adults 40 to 75 years of age, the guideline recommends having a discussion with the HCP to determine their 10-year risk before starting a statin. In contrast, the 2017 American Association of Clinical Endocrinologists (AACE) guideline is more specific because it endorses treating LDL to specific target goals. The AACE guideline states that the LDL goal is less than 130 mg/dL for those with no cardiac risk factors considered at low risk for the development of CAD.[13] Those with 2 or fewer risk factors and a 10-year risk of less than 10% (moderate risk) should be treated to an LDL target of less than 100 mg/dL. Those at high risk (>2 risk factors and a 10-year risk of 10% to 20%; or diabetes or CKD stage 3 to 4 with no other risk factors) should be treated to an LDL of less than 100 mg/dL. Those at very high risk for developing CAD (recent hospitalization for ACS, established CAD, carotid disease, or peripheral vascular disease; diabetes, CKD stage 3 to 4 with 1 or more risk factors) should be treated to an LDL target of less than 70 mg/dL.

Drug therapy continues for a lifetime. If the patient becomes intolerant, we may change the drug. Intolerance to one statin does not mean intolerance to all statins. The patient must fully understand the rationale and goals of treatment, as well as the safety and side effects of lipid-lowering drugs.

Concurrent diet change reduces the need for drug therapy. Treatment also includes weight loss, if overweight, and increased physical activity. Serum lipid levels should be reassessed after 4 to 12 weeks of therapy.[6] If levels are still high, drug therapy may be changed.

Drugs That Restrict Lipoprotein Production

HMG-CoA reductase inhibitors (statins). The statin drugs are the most widely used lipid-lowering drugs (Table 37.6). They inhibit the synthesis of cholesterol in the liver and increase the numbers of hepatic LDL receptors, removing more LDL from the blood. Statins also cause a minor increase in HDL. Rosuvastatin (Crestor) is the most potent statin currently available. Serious adverse effects are rare. They include liver damage and myalgia (muscle ache or weakness without breakdown of skeletal muscle) that can progress to rhabdomyolysis (breakdown of skeletal muscle).

DRUG ALERT

Simvastatin (Zocor)

- Increased risk for rhabdomyolysis when used with fibric acid derivatives (e.g., gemfibrozil), niacin, or erythromycin.
- Prothrombin times may increase in patients taking warfarin (Coumadin).
- Dose should not exceed 40 mg daily.
- Use with caution in patients on amiodarone because it can increase the risk of myopathy.

Niacin. Niacin, a water-soluble B vitamin, is effective in lowering triglyceride levels and mildly lowering LDL levels (Table 37.6). At high doses, niacin increases HDL levels, but it does not correlate to a decreased risk of CAD or MI. Unfortunately, common side effects include severe flushing, itching, gastrointestinal (GI) symptoms, and orthostatic hypotension.

DRUG ALERT

Niacin

- Teach the patient that flushing (especially of face and neck) may occur within 20 min after taking drug and last for 30–60 min.
- Premedicate with aspirin 30 min before taking to reduce flushing.
- Use of extended-release niacin may decrease side effects.

TABLE 37.6 Drug Therapy

Hyperlipidemia

Drug	Mechanism of Action	Side Effects	Nursing Considerations
Restrict Lipoprotein Production			
ATP-Citrate Lyase Inhibitor			
bempedoic acid (Nexletol)	↓ Hepatic synthesis of cholesterol ↓ LDL	Diarrhea Fatigue Muscle pain Upper respiratory tract infection	Monitor uric acid levels due to increased risk of gout. Use in caution with patients who have had a previous tendon rupture.
Fibric Acid Derivatives			
fenofibrate (Tricor) gemfibrozil (Lopid)	↓ Hepatic synthesis and secretion of VLDL ↓ VLDL ↓ Triglycerides ↓ LDL ↑ HDL	Rashes GI problems (e.g., nausea, diarrhea) ↑ Liver enzymes	May ↑ effects of warfarin (Coumadin) and some antihyperglycemic drugs. When used in combination with statins, may increase adverse effects of statins, especially myopathy.
HMG-CoA Reductase Inhibitors (Statins)			
atorvastatin (Lipitor) fluvastatin (Lescol XL) lovastatin pitavastatin (Livalo) pravastatin (Pravachol) rosuvastatin (Crestor) simvastatin (Zocor)	Block synthesis of cholesterol and increase LDL receptors in liver ↓ LDL ↓ Triglycerides ↑ HDL (small amount)	Rash GI problems ↑ Liver enzymes Myopathy, rhabdomyolysis	Well tolerated with few side effects. Monitor liver enzymes and recheck them after any increase in dosage. Assess CK-MM if symptoms of myopathy (e.g., muscle aches, weakness) occur.
Niacin			
niacin (Niaspan)	Inhibits synthesis and secretion of VLDL and LDL ↓ LDL ↓ Triglycerides ↑ HDL	Flushing and itching in upper torso and face GI problems (e.g., nausea, vomiting, dyspepsia, diarrhea) Orthostatic hypotension	Most side effects subside with time. Taking aspirin or ibuprofen 30 min before drug may reduce flushing. Take drug with food. Decreased liver function may occur with high doses.
Omega-3 Fatty Acid			
icosapent ethyl (Vascepa) (eicosapentaenoic acid [EPA])	Inhibits synthesis and/or secretion of triglycerides	Arthralgia	Used for patients with severe hypertriglyceridemia (levels ≥ 500 mg/dL). Used with statin therapy for patients with CAD who have high triglyceride levels. High incidence of bleeding when taken with drugs that increase the risk of bleeding, such as aspirin or warfarin.
omega-3 acid ethyl esters (Lovaza) (eicosapentaenoic acid [EPA] and docosahexaenoic acid [DHA])	↓ Triglycerides ↑ HDL	Anaphylaxis Rash Taste changes GI problems (e.g., constipation, vomiting)	Used for patients with high triglycerides. Give with meals and do not open or dissolve capsules.
Increase Lipoprotein Removal			
Bile-Acid Sequestrants			
colesevelam (Welchol) colestipol (Colestid) cholestyramine (Prevalite)	Binds with bile acids in intestine, forming insoluble complex and excreted in feces Binding results in removal of LDL and cholesterol ↓ LDL	Unpleasant quality to taste GI problems (e.g., indigestion, constipation, bloating)	Effective and safe for long-term use. Side effects lessen with time. Interferes with absorption of many drugs (e.g., digoxin, thiazide diuretics, warfarin, some antibiotics [e.g., penicillin]). Teach patient to take other drugs 1 hour before or 3–4 hr after bile-acid sequestrants.
Proprotein Convertase Subtilisin/Kexin 9 (PCSK9) Inhibitors			
alirocumab (Praluent) evolocumab (Repatha)	Inactivate PCSK9 protein ↓ LDL	Injection-site reactions Muscle pain, limb pain, and fatigue	Used with diet and maximum statin therapy to treat familial hypercholesterolemia, those who need further LDL lowering, or are statin intolerant. Given by injection every 2 wk or every 4 wk at a higher dose.

TABLE 37.6 Drug Therapy—cont'd

Hyperlipidemia

Drug	Mechanism of Action	Side Effects	Nursing Considerations
Decrease Cholesterol Absorption			
Cholesterol Absorption Inhibitor			
ezetimibe (Zetia)	Inhibits the intestinal absorption of cholesterol ↓ LDL ↑ HDL	Infrequent, but may include headache and mild GI distress	When used with a statin, further reduces LDL. Avoid use by patients with liver problems.

Fibric acid derivatives. *Fibric acid derivatives* (Table 37.6) increase HDL levels. They lower triglyceride levels by reducing the liver's production of VLDL and speeding up the removal of triglycerides from the blood. They indirectly lower LDL through their effect on HDL and triglycerides Although most patients tolerate the drugs well, GI irritability is common. They should be used with caution when combined with statins due to increased risk for myopathy.

DRUG ALERT

Gemfibrozil (Lopid)

- May increase the risk for bleeding in patients taking warfarin (Coumadin).
- Use cautiously in patients taking statins due to an increased risk of myopathy.

ATP-citrate lyase inhibitor. Bempedoic acid (Nexletol) helps lower LDL in patients with heterozygous familial hypercholesterolemia or patients with CAD who do not have adequate LDL lowering. We should monitor uric acid levels as the drug increases the risk of gout. Tendon rupture may occur, so use in caution with patients who have had a previous tendon rupture.[14]

Drugs That Increase Lipoprotein Removal

Bile acid sequestrants. Bile-acid sequestrants increase conversion of cholesterol to bile acids in the liver (Table 37.6). The primary effect is a decrease in total cholesterol and LDL levels. Bile-acid sequestrants decrease absorption of many other drugs (e.g., warfarin, thiazides, thyroid hormones, β-adrenergic blockers). Tell patients to take those drugs 1 hour before or 3 to 4 hours after bile-acid sequestrants to decrease this adverse effect.[3]

Proprotein convertase subtilisin/kexin 9 (PCSK9) inhibitors. PCSK9 inhibitors reduce the number of receptors in the liver that remove LDL cholesterol from the blood (Table 37.6). By blocking PCSK9's ability to work, more receptors are available and can get rid of LDL. This decreases circulating LDL levels. Evolocumab (Repatha) and alirocumab (Praluent) are PCSK9 inhibitors. They are not a first-line therapy. They are used with diet and maximum statin therapy for adults with familial hypercholesterolemia, those intolerant of statin drugs, or those with CAD who have an inadequate response to statins.[6] Patients receive subcutaneous injections every 2 weeks or every 4 weeks at a higher dose, depending on patient preference.

Drugs That Decrease Cholesterol Absorption

Ezetimibe (Zetia) selectively inhibits the absorption of diet and biliary cholesterol across the intestinal wall (Table 37.6). When combined with a statin as a combination drug (e.g., ezetimibe and simvastatin [Vytorin]) or as 2 separate drugs (ezetimibe and a statin), even greater reductions in LDLs occur.

Antiplatelet Therapy

We recommended low-dose aspirin (81 mg) to prevent CAD for years. However, its use in primary prevention (people without known CAD) is controversial due to the potential risk for bleeding. Low-dose aspirin may be used for primary prevention in adults age 40 to 59 years who are higher risk of CAD but do not have an increased risk for bleeding. Low-dose aspirin should not be started as primary prevention in adults over age 60.[10] Recommend taking coated aspirin to help with GI protection.

Gerontologic Considerations: Coronary Artery Disease

Heart disease is the leading cause of death in older persons. In the older adult, CAD is often a result of the complex interaction of nonmodifiable risk factors (e.g., age) and lifelong modifiable risk behaviors (e.g., inactivity, tobacco use).

Strategies to reduce CAD risk and treat CAD are effective in this age group. Aggressive treatment of hypertension and hyperlipidemia helps stabilize plaques in the coronary arteries. Tobacco cessation helps to decrease the risk for CAD at any age. Physical activity improves activity performance, endurance, and ability to tolerate stress. It can increase self-esteem, enhance emotional well-being, and improve body image. For the older adult who is obese, making modest diet changes and slowly increasing physical activity (e.g., walking) results in more positive benefits than aiming for a significant weight loss.
