

I wanna do a Database for a franchise with different located shops. It should have at least a table for the productID, the price, the location, the type/version of the product, and the expiration Date. I would also like to connect my Database Design final project with the programming final project. The programming part of the project should make the I/O of the database more user-friendly and more efficient.

In general, it should be able to tell the vendors the price of a product, the vendors and customers where to find a specific product, and it tells the shops which products they have to throw away due to their expiration date.
